Ward Mountain will have minimal commercial stock activities with occasional use as a pass-through. Light use will be approved to Ward Mountain Lake within this analysis unit. Trails will be maintained consistent to the Recreation Category 1 desired conditions, with low density of primitive trails.

Sallie Keyes unit will continue to have a high level of stock use and the potential for continued overlap of services. There will be overlap of spot and dunnage services between three operators and additional operators passing through this popular region on traveling trips. The draw of Sequoia/Kings Canyon National Park where use restrictions may continue to allow for additional use may draw packers who can rely on grazing resources in the Park and laxer restrictions that accommodate some growth in services.

Along the JMT/PCT stock use will be moderate to high. Designated stock camps at Sallie Keyes will concentrate impacts associated with stock camping to areas that are more durable. One camp south of the lake along the old trail corridor (“trail meadow”) that is being used under the No

Action alternative will be closed and this will reduce impacts occurring in the meadow. Allowances for campfires for commercial packers, at designated stock camps, may lead to non-compliance by the public due to the confusion of seeing the smoke from campfires. This area is mostly well forested with wood resources, which may add to the confusion. The use trail to Senger Creek will be rarely used and mostly in association with hunting. Use beyond the campsite along Senger Creek will be prohibited, which will help protect opportunities for solitude and pristine conditions in this area.

Seldon Pass will continue to have moderate to high stock use and overlap between two operators providing spot and dunnage services to the same locations. Public use in this area is very high and pack stock support helps facilitate thru hikers as well as organized groups into the Bear Lakes and the Italy Pass regions. Access to Rose Lake will continue on the system trail. With no direct controls to this destination, there could be some change in use patterns over time that may lead a higher use in this area than is currently occurring. Camping opportunities are limited and the setting is remote and can be easily disturbed with more than one party camped here. The trail is also primitive and is not expected to sustain additional use without degradation or additional maintenance needs. Lou Beverly will be available to commercial packers and overlap between two operators is likely here. A designated stock camp will concentrate use and stock related impacts. Very low public use occurs here and conflicts between uses would be minimal. Use above Lou Beverly would be authorized on the system trail to Sandpiper Lake but not beyond to Three Island Lake. Without direct controls on the amount of use that can be on this section of trail it is possible that the trail may need more maintenance and/or reconstruction needs to support any additional use. This may change the character of there if the trail were to be more highly developed and may facilitate access.

Hooper unit will continue to have one operator with very low use. Commercial pack stock would be infrequently encountered in this area and most likely only during the hunting season. A use trail would be approved during the hunting season only, thereby maintaining most of the area as trail-less with high opportunities for solitude, wilderness character, and low stock numbers.

Apollo will remain a low use area with very low commercial stock use. Less than 25 stock a year would be authorized and encounters with pack stock would be infrequent or rare. Use in this area would however take place off the main system trail. At such low levels it is expected there would be no effect to the character of the trail-less areas. One stock camp is designated at Cirque and two stock camps at Marcella. With allowances for campfires in stock camps, with full service trips, this area could be an area of non-compliance with campfire restrictions for the public and cause some confusion over the campfire restrictions. If low use levels were to occur annually over a short time (3-4 years) there could be an increase in noticeable impacts and disturbance and some loss of opportunities for solitude.

Use in the Bear Lakes unit primarily consists of pass-through on the PCT on the western edge of the unit. Occasional use may occur along the Seven Gables trail. This will protect opportunities for solitude in the upper Bear Lakes region and reduce impacts associated with stock on this trail that is not designed or sustainable to stock use.

Use into the Italy unit will also be limited to the first 2 miles of Hilgard Branch. Designated stock camps at the Hilgard Meadow marks will concentrate impacts associated with stock. Use in this area by the public will continue to be high during the peak of the summer season. By designating the trail beyond these camps as not suitable for commercial stock the trail will be

able to remain primitive and suitable for hardy hikers only. This helps protect the character of the area, reducing trail maintenance and trail development needs. Opportunities for solitude will remain moderate at Italy Lake and evidence of humans, primitive campsite impacts will remain.

Cumulative Impacts

Muir Trail Ranch and Lost Valley are private inholdings within the interior of the wilderness boundaries. Muir Trail Ranch operates a guest ranch on the property that opened in 1940. There is four-wheel drive access to the private property, which has been under a Special Use Permit since 1948. The presence of the road has both experiential and environmental effects. Multiple trailing has occurred due to confusion, desire for direct access to eastbound destinations and historical grazing by the pack stock associated with the permits issued in the area. This causes some confusion and a high density of trails in a small corridor. Both the presence of the road, including any encounters with motorized uses and the confusion and resource impacts of multiple trailing can diminish the wilderness experience for users. Both the private inholdings and their associated four-wheel drive access trail affect the wilderness character.

Florence/Bear – Alternative 4

Analysis

The primary access in this area is Florence and Dutch trailheads. Multiple operators will still overlap services in this area and compete for the daily trailhead quota as in Alternative 1 – No Action. The quota remains the same for both these trailheads. Overall use levels being reduced by the 20 percent cut to service day allocations will be the primary difference between this alternative and the No Action in this geographic region. The number of locations where pack stock can drop clients will be limited to 13 areas. Although in the No Action there are numerous possibilities for dropping clients, most use is currently spot and dunnage to these same primary locations. There will be no flexibility that exists in the other alternatives.

Seven of 22 system trails would be designated Not Suitable for Commercial Stock, three more than in Alternatives 2 and 3. This provides few additional limits on access to destinations compared to Alternatives 2 and 3. Use trails would be limited more than system trails in this alternative. 20 or 24 use trails would be prohibited from commercial pack stock use compared to 8 trails in Alternative 3 and 9 in Alternative 2. Many of these trails not approved are used in hunting season and only occasionally.

Areas where commercial pack stock would be excluded include Orchid Lake, Three Island Lake, Senger Creek toward Turret Lake, Seven Gables, Lake Italy, and Gordon. These locations are relatively remote with few impacts. By excluding pack stock it would eliminate the chance that pack stock use could increase and/or contribute to impacts that may be associated with even light levels of stock use.

Use would still occur at relatively remote locations in this region such as Apollo, Lou Beverly Rose Lake, and Cirque Lake. There would be more opportunity for dispersed pack stock use in this region than in other regions. These destinations will be vulnerable to impacts if use levels were to increase. Without direct controls on these destinations, conditions could change over time. Incremental increases in pack stock use can change the character of a place like Cirque and Apollo Lakes if stock use displaced from other locations were to disperse to Cirque. Lou Beverly has the potential to withstand some increase in use, with a well-established stock camp and

evidence of higher use in the past; it is expected that it can absorb more tock use without affecting the resource or other visitors.

Cumulative Impacts

There may be a cumulative effect of uses converging and possibly increasing in the adjacent Sequoia Kings Canyon National Park. With a 20 percent decrease in service days and direct access from Florence Lake, where the trailhead quota remains the same as in Alternative 1, there could be a cumulative effect, specifically in the Evolution Valley area. This could occur because of the possibility that stock numbers may increase because of only regulating people numbers in this alternative. In addition, the desire to maximize stock numbers could result in accessing the National Park where service days or any limits are not currently in place.

Florence/Bear – Alternative 5

Analysis and Cumulative Impacts

No overnight packer use has been recorded in Bolsillo, Dutch/Boulder, Ward Mountain, and East Florence. Any packer use in these areas is traveling through but not dropping clients or camping with clients. Eliminating this use would have some but little effect. Trail conditions may improve but the level of use is so low there would be no noticeable change in resource or social conditions.

Most of the use in this geographic unit is in Sallie Keyes, Italy, and Seldon, with low use in Hooper, Apollo, and Bear Lakes. Trail use is primarily on the JMT/PCT, which is high priority for maintenance and has some sections that are substantially developed. Overall use on this trail is very high with a high level of encounters, especially in July, August, and early September. The level of stock use by packers is over 600 per season but is dispersed significantly across this geographic area. By comparison, over 700 stock are in one drainage in the Ansel Adams East – Rush Creek. The dispersal of stock in this region has a moderate effect on resource impacts and social conditions. The effect of eliminating the use would be noticeable on the trail from Bear Ridge junction to Piute trail. Encounters would be noticeably less. Campsite in the Sallie Keyes area would improve with the absence of stock and stock holding on a regular basis in August.

John Muir Southeast – Alternative 1

Analysis

The North Fork of Big Pine will have a high level of commercial pack stock use. The use would be concentrated at the lake destinations. Sites that have been used and impacted for years would continue to be used. Since the canyon has limited camping opportunities different that what is currently being serviced by pack stock, there is very little potential for new sites to develop or significant new impacts to occur. Destinations are well established. The trail to Sam Mack meadow could be improved up to a Trail Class 2, which could facilitate stock use that is currently not occurring. Little opportunities for camping at Sam Mack would make this somewhat self-limiting and it is expected the existing packer would not pursue any growth in services to this location.

Commercial pack stock use is currently not occurring in South Fork Big Pine. An agreement between the packer and the Forest Service has led to this non-use. No regulation prohibits pack stock use.

Taboose, Sawmill, and Shepherd are all single quota trails that commercial pack stock competes with the public for. They are low quotas, yet do allow for growth in services. In this alternative any packer willing to truck stock to these trailheads could access these areas. Access is attractive as it is a pass-through trail on the National Forest and accesses Sequoia-Kings Canyon National park where fewer limitations are currently in place. Increased commercial pack stock use on these trails would have minimal affect on the Forest. Trails would be subject to higher maintenance needs that would be consistent with both Sawmill and Taboose that are managed as trail class 3 trails. The character of these areas, which are low use and rough trails, could therefore change in this alternative, especially Taboose and Sawmill.

Kearsarge Pass would have a high potential for commercial pack stock. Use would primarily be accessing Sequoia-Kings Canyon National Park. Some destinations would receive low to moderate commercial pack stock use, Bench, Gilbert, Matlock, and Pothole Lakes. It is likely that commercial use to these destinations would not have any impact, even if use were to increase a substantial amount as the trails and sites are well established and already heavily impacted from over 50 years of high use.

The Cottonwood Lakes area will have light to moderate commercial pack stock use. Use can disperse to multiple locations in the basin in this alternative, including Hidden Lake, Muir Lake, Cirque Lake and 5th and 6th Lakes. Although it is possible for use to disperse it is likely that use will continue to concentrate at third lake and impacts will be minimal and restricted to trails.

No commercial pack stock use will be allowed on the Mt. Whitney trail. Use can, however, be facilitated by pack stock that enters the Golden Trout Wilderness over Cottonwood Pass and drops parties at Crabtree in Sequoia-Kings Canyon National Park. The party then travels over Trail Crest, which is managed by the Forests' only exit quota. Some quotas are reserved for this type of use, and will continue to draw use over the crest. Use can also exit Trail Crest this way from any trail on the Inyo National Forest, such as Shepherd, Taboose, and Kearsarge and subject to the Trail Crest quota. The party is not under commercial service or support once they have been dropped off at Crabtree or vicinity. This will continue to have some effect on crowding and campsite affects at Crabtree and Guitar Lakes in the National Park. Additional regulations may be put into effect to control the use on the Park side of Trail Crest.

Cumulative Impacts

Past and present high use and management occurs in the North Fork of Big Pine. This area receives a high volume of commercial pack stock use, private and commercial mountaineering and backpacking use, and high day use. Management over the years has contained some impacts. Packers were asked not to travel to Sam Mack meadow or South Fork of Big Pine, and have complied with that request. Commercial mountaineers have been requested not to camp at Sam Mack meadow. A reasonably foreseeable action is that Sam Mack meadow may be closed to all camping because of meadow compaction and hydrologic function concerns due to high concentration of use, most all of which is non-stock use. The commercial pack stock does facilitate use into the drainage through dunnage trips. Campfire closures have been in effect for over twenty years and some improvements to the area are noticeable. A resort facility in

existence at the time of the Wilderness Act at Fourth Lake has been removed, greatly enhancing the wilderness character of the area.

Visitor use in the southern portion of the John Muir (Taboose to Whitney) directly access Sequoia –Kings Canyon National Park. Most visitors travel through the Forest to the Park and very little impacts occur east of the passes. This use does however have effects in the Park. Trailhead limits regulate the amount of use to a great degree but destinations west of the pass receive use and impacts as a result of this east side use. Some of these trailhead quotas were lowered in the 2001 Wilderness Plan and commercial packers using these trails must compete with the public for that quota. Without additional direct restrictions on the use from the Park, commercial pack stock use will be attracted to these areas since the Forest control (service days) does not apply once they cross the boundary. With limited service days to use, the park and these access points have become more popular for the commercial pack stock.

Cottonwood Lakes is an area where the State Department of Fish and Game (DFG) have a fish rearing operation. There is early season activity associated with this operation, some of which uses the commercial pack station. A cabin used by DFG is also located in the basin and is a noticeable human imprint. An equestrian campground at the trailhead of Cottonwood Lakes does contribute to additional stock use into the basin, most of which is day riding and remains on system trails.

John Muir Southeast – Alternative 2 – Modified

Analysis

In this region 12 discrete destinations or zones will be used by commercial pack stock. The southern part of this region is characterized by the access it provides to Sequoia- Kings Canyon National Park. One operator, that has historically used this region, will be managed through the existing trailhead quotas system where they will still need to compete with the public for access via the daily quota on people. Two operators will be managed through the destination quota concept. The trend the past few years has been an increase in use of these trailheads. This action will likely curb that trend.

There will continue to be a slight overlap of operations in Taboose, Sawmill, Kearsarge, and Shepherd Analysis Units. The past few years saw an increase in use by other operators either entering or exiting via these trails. This trend was a reaction to the limits placed on the Forest use and the ability to increase use in the Park. More operators accessed Sequoia-Kings National Park on traveling trips. It is expected that most of that trend will be curbed; however, until the Park establishes limits on Park use this will continue to some degree.

In Taboose, Sawmill, and Shepherd, the packer use is passing through to the Park and rarely, if ever, does any use occur off the system trail. This alternative allows camping at Anvil camp (Shepherd) but maintains the grazing closure. Annually it is most likely that there will be only the occasional packer use of the camping at Anvil. Impacts on the trails and opportunities for solitude in these pass-through areas will remain moderate to high and the character and conditions of these areas will not change. If Park management allows for more use to pass-through, there may be a change in character.

Kearsarge Analysis Unit is primarily a pass-through to Sequoia-Kings National Park, but does receive some use on the Forest. Opportunities for solitude would remain low to moderate in this

drainage with little effect by the packer operation. It is a Recreation Category 3 area and with up to 16 trips allowed for by packers for spot and dunnage their use is a very small percentage of the total use. One use-trail accessing Bench Lake would be approved and would not see any change.

North Fork of Big Pine would be managed as a zone for packer use, with Black Lake being the only separate destination managed. Packer use would be prohibited up to Sam Mack meadow and beyond, and although not currently prohibited, the trail is such that the packer chooses not to go there now. Use trails would be allowed to the snow survey sites, Heidi Cabin for hunting season, and to campsites at Fifth Lake. The predominant use would be on the system trail. Day rides would be minimal here. Currently the packer conducts day rides as a part of his spot and dunnage trips and this pattern would continue.

In this alternative there are two trips identified for South Fork of Big Pine to Willow Lake with the trail designated not suitable for commercial stock above Willow Lake. With very low, occasional use (one party a year round trip) opportunities for solitude would remain moderate to high and for most of the days a year, there would be no encounters with stock. This level of stock use on the trail would not affect the condition of the trail.

Cottonwood Basin will continue to receive light packer use relative to non-commercial use. This basin is a Recreation Category 3 area and receives very high public use. Like Kearsarge, the packer use is a very small percentage of the overall use. Up to 50 trips to the basin, with specific destinations undefined will probably not change the area. Opportunities for solitude will be low to moderate with or without this use. If the packers use the system trail and the use trail for the early season fish-hatchery support projects on a limited basis, the area will see little continued impacts. South Fork Creek trail will be designated not suitable for commercial stock above South Fork Meadow and the effect of this will be to minor beneficial effects to natural conditions as the trail can be maintained at a primitive level.

A quota is identified to Trail Crest for two pack station operators. Although stock is not allowed on the Whitney trail, packers will be able to service parties to within five miles of the sierra crest in the National Park and the clients can exit Trail Crest through the Main Mt. Whitney Zone. Although this use is limited to ten trips a year, there may be an affect on National Park wilderness, which in the future may need further management by the Park. Mt. Whitney is an area of extremely high use and an additional ten parties a year will not be noticeable. This will help facilitate parties that may not otherwise be capable of ascending Mt. Whitney. The type of client will not be managed and may be just be a first come first serve with no difference to capability.

Cumulative Impacts

Past and present high use occurs in the North Fork of Big Pine Creek, including commercial pack stock use, private and commercial mountaineering and backpacking use, and high day use. Past management over the years has contained some impacts (see Alternative 1). These actions have and continue to maintain a high level of the wilderness character of the area despite the high use. The actions in this alternative should maintain these conditions. In one case it will open areas up to packer use that has not occurred in the recent past, which may lead to additional resource and experiential impacts such as at South Fork of Big Pine.

Visitor use in the southern portion of the John Muir Wilderness (Taboose to Whitney) directly access Sequoia –Kings Canyon National Park. Visitors will continue to travel through the Forest

to the Park and very little impacts would occur east of the passes with these actions. There will probably be minor to moderate effects of the use in the Park, but given that it is consistent with current use, there should not be any additional adverse effects. Commercial pack stock use that facilitates the use of Crabtree and Guitar Lakes in the Park may have some minor adverse effects to crowding and physical impacts in the area from camping. Park management will be undertaking their own wilderness management plan within the next five years and can provide further limits here and elsewhere if needed. Nothing in this alternative will preclude the Park from further limitations.

Cottonwood Lakes is an area where the California Department of Fish and Game has a fish rearing operation. There is early season activity associated with this operation, some of which uses the commercial pack station. No changes to this use would occur with this alternative. A cabin used by the Department of Fish and Game is also located in the basin and is a noticeable human imprint. An equestrian campground at the trailhead of Cottonwood Lakes does contribute to additional stock use into the basin, most of which is day riding and remains on system trails. The additional effects of this alternative are minor relative to these effects as the use is comparatively small.

Horseshoe equestrian campground is located at the trailhead and will continue to facilitate stock use into this area. The effects of commercial use activities in this alternative will have minor adverse effects to the areas where these uses will overlap, primarily Cottonwood Lakes Basin and the Golden Trout Wilderness (GTW). These actions, combined with the activities in the surrounding Golden Trout Wilderness have no adverse effects to wilderness character in either the John Muir or Golden Trout Wildernesses. A reasonable foreseeable action is to provide limits on commercial pack stock use in the Golden Trout to prevent dispersal of use into the GTW or into the Park via Cottonwood Pass.

John Muir Southeast – Alternative 2

Analysis

In this region 12 discrete destinations or zones will be used by commercial pack stock. The southern part of this region is characterized by the access it provides to Sequoia- Kings Canyon National Park. Two operators that have historically used this region will be managed through the existing trailhead quotas system where they will still need to compete with the public for access via the daily quota on people. The other operator will be managed through the destination quota concept with allowances for very little growth. The trend the past few years has been an increase in use of these trailheads. This action will curb that trend. Park management will be addressing the appropriate level of use in the Park and Forest controls should be consistent with NPS regulations. If this happens in the next 5-10 years there may be future actions that increase or decrease this use.

There will continue to be a slight overlap of operations in Taboose, Sawmill, Kearsarge, and Shepherd Analysis Units. The past few years saw an increase in use by other operators either entering or exiting on these trails. This trend was a reaction to the limits placed on the Forest use and the ability to increase use in the Park. More operators accessed SEKI through traveling trips. It is expected that most of that trend will be curbed; however, until the Park establishes limits this will continue to some degree.

In Taboose, Sawmill, and Shepherd, the packer is passing through and rarely, if ever, gets off the system trail or uses campsites. On Shepherd, there have been exceptions made to the closure at Anvil Camp to allow packers to spend the night. This action would open that up to camping but maintain the grazing closure. Annually it is most likely that there will be only the occasional packer use of the camping at Anvil. Impacts on the trails and opportunities for solitude in these pass-through areas will remain high and the character and conditions of these areas will not likely change. If Park management allows for more use to pass-through, there may be a change in character.

Kearsarge Analysis Unit is primarily a pass-through to SEKI but does have some use on the Forest side. It is a Recreation Category 3 area and with up to 16 trips allowed for by packers for spot and dunnage it is a very small percentage of the use. One trail accessing Bench Lake would be approved for use and would likely not see any change. Opportunities for solitude would remain low to moderate in this drainage with little effect by the packer operation.

North Fork of Big Pine would be managed as a zone for packer use, with Black Lake being the only separate destination managed. Packer use would be prohibited up to Sam Mack meadow and beyond, and although not currently prohibited, the trail is such that the packer chooses not to go there now. Use trails would be allowed to the snow survey sites, Heidi Cabin for hunting season, and to campsites at Fifth Lake. The predominant use would be on the system trail. Day rides would be minimal here, up to 250 a year. Currently the packer conducts day rides as a part of his spot and dunnage trips and this pattern would continue.

In this alternative, there is no trip quotas identified for South Fork of Big Pine (SFBP); however, the trail is not designated as “Not Recommended for Stock.” In the past the packer rarely, if ever, went up this trail but this action would not preclude this use. The packer could use their five unassigned trips to access SFBP. If this were to happen the character of the area may change. If use remained occasional opportunities for solitude would remain moderate to high, but facilitating use via pack stock could change this. Improvements to the system trail could facilitate stock use to Willow Lake but not beyond as it is proposed as a TC1 beyond Willow Lake.

Cottonwood Basin will continue to receive relatively light packer use. This basin is Recreation Category 3 area and receives very high public use. Like Kearsarge, the packer use is a very small percentage of the overall use. Up to 50 trips to the basin, with specific destination undefined will probably not change the area. Opportunities for solitude will be low to moderate with or without this use and if the packers use the system trail with very limited use of the use trail for the early season fish hatchery support projects, the area will see little continued impacts. Southfork Creek trail will not be recommended for stock and, while commercial stock are not authorized, it may receive some private stock. Horseshoe equestrian campground is located at the trailhead and will continue to facilitate stock use into this area.

A quota is identified to Trail Crest for packers. Although stock is not allowed on the Whitney trail, packers will be able to take parties to within 5 miles of the crest in the National Park and the clients can exit Mt. Whitney, having their trip facilitated by pack stock. Although this use is limited to 10 trips a year, there may be an affect on the Park side, which in the future may need further management by the Park. Mt. Whitney is an area of extremely high use and an additional ten parties a year will not be noticeable. This will help facilitated parties that may not otherwise

be capable of ascending Mt. Whitney. However, the type of client will not be managed and maybe just be a first come first serve with no difference to capability.

Cumulative Impacts

Past and present high use occurs in the North Fork of Big Pine including commercial pack stock use, private and commercial mountaineering and backpacking use, and high day use. Past management over the years has contained some impacts (see Alternative 1). These actions have and continue to maintain a high level of the wilderness character of the area despite the high use. The actions in this alternative should maintain these conditions. In some case it will open areas up to packer use that have been closed in the past, which may lead to additional resource and experiential impacts such as at Sam Mack Meadow and South Fork of Big Pine. Allowing campfires may negate past actions to close the area to campfires.

Visitor use in the southern portion of the John Muir (Taboose to Whitney) directly access Sequoia –Kings Canyon National Park. Visitors will continue to travel through the Forest to the Park and very little impacts would occur east of the passes with these actions. Trips by commercial pack stations will be limited more than Alternative 1 unless the park directs changes to these use levels. Past trends towards more pack stations using these trailheads and accessing the park will be eliminated with this alternative with the establishment of Primary Operating areas, unless or until the Park establishes more direct controls on the commercial pack stock use.

Cottonwood Lakes is an area where the State Department of Fish and Game have a fish rearing operation. There is early season activity associated with this operation, some of which uses the commercial pack station. No changes to this use would occur with this alternative. A cabin used by DFG is also located in the basin and is a noticeable human imprint. An equestrian campground at the trailhead of Cottonwood Lakes does contribute to additional stock use into the basin, most of which is day riding and remains on system trails.

John Muir Southeast – Alternative 3

Analysis

Coyote Analysis Unit will continue to have no overnight pack stock use. There will be day rides into this area but such activities would be infrequent and visitors would not encounter pack stock on very many days during the season.

North Fork of Big Pine will continue to be an area of high commercial stock use. There will continue to be only one operator. Use will be concentrated at Third Lake, Fourth Lake, and along the trail corridor with some use at Fifth Lake. Pack stock use will not be authorized from the junction of the NFBP trail to Sam Mack meadow or beyond. This will provide a hiker only experience in this area and insure that trail damage by pack stock does not occur in the future. Opportunities for solitude will be low to moderate in this drainage. This area is a very popular location for many user types including day hiking, climbing, fishing, and backpacking. Encounters with pack stock will continue to be high, as it will remain to be about 12 percent of overall use in the drainage. The wilderness character of this area is dominated by the very high scenic qualities of the Palisades and will not change. Pack stock use facilitates will continue to facilitate access to the Palisades.

South Fork of Big Pine will be an area of potential growth for the pack operator at Big Pine. Currently no use occurs. Pack stock use expanding into this area again (use has occurred here in the past, just not the recent past) will increase potential conflicts between stock and hikers, since the area is now considered and expected to be a location where there is no packer use. This change in expectations may lead to conflicts between user groups. Trail conditions would likely deteriorate if use were to be more than occasional.

Birch unit will be used as a location for occasional hunting use. Hunting use is determined by State game permits and changing patterns of deer populations. Therefore the use will not occur every year and will continue to be very light when it does.

Red unit will have no commercial stock use.

Taboose will continue to be an area of light to moderate commercial stock use. Use will be pass-through use to Sequoia/Kings Canyon National Park. Use will be controlled with a single quota where the packer must compete with the public for quota space. Use will be limited to 50 stock a year, a slight increase from recent years. Use will be limited to two operators. In the No Action, use is not limited to a number of operators, and any packer willing to truck stock down to the trailhead could access with quota space.

Sawmill will continue to be an area of low commercial stock use. 15 head of stock or less will be in this drainage in a given season. If current use patterns continue, and they will, there will be many years when there is no use. There will be two operators that can potentially use the area. Both will compete with the public for quota space of 10 persons per day. Sawmill will likely remain an area of very low use all around, with high opportunities for solitude.

Baxter Pass will have no commercial stock use allocation. The system trail will be designated as “not suitable for commercial stock” and no use would occur on the trail in the future. The No Action alternative allows for occasional (case-by-case decisions) commercial use, but none has occurred in a number of years. This alternative would help maintain high opportunities for solitude. Maintaining a primitive trail would keep the sense of a high wilderness character.

Kearsarge would continue to be an area of low commercial stock use. Most of the commercial stock use would travel through the drainage into Sequoia/Kings Canyon National Park. Some use would be spot and dunnage to destinations on the east side such as Matlock, Bench, and Flower. Some minimal use of use trails to access camps would be needed and authorized at Bench Lake. Most use would be accessing the Park, and the effects of this are consistent with current Park policy that regulates use by stock nights in the Park. There may be an increase on use exiting this area. In Alternative 1 (No Action) as much use exits via Kearsarge as enters, only by other operators. This overlap may be increased if traveling trips increase under this alternative, which is possible. Overall use in the drainage is very high, with pack stock use being a relatively small proportion of the use. It is expected that commercial stock use will be less than 5 percent of total use into the future.

Shepherd unit would continue to have moderate levels of commercial stock use. This use would be pass-through use to Sequoia-Kings Canyon National Park. Some use would be allowed at a designated stock camp at Anvil Camp. Under the No Action, use is not allowed to stay overnight east of the Pass: however, exceptions have been made for safety reasons (generally no more than once a year). It is expected that there would be only occasional overnight use at Anvil. Exits on the trail occur as often as entry, and this will continue if not increase. Exits may increase if

further restrictions on use are not put into effect by the Park, which currently manages commercial pack stock by grazing nights. Two operators would overlap providing services entering Shepherd, and this overlap may increase if traveling trips increase.

There will be no commercial pack stock use in the North Fork Lone Pine, Whitney, Meysan, or Langley units. However, there may be some hiker use that has been facilitated by commercial pack stock that exits these areas. It is a popular activity to get pack stock support into the Park from an east side trailhead and hike the rest of the trip self supported. The party is no longer associated with the packer services, but the pack support does make the trip easier and more accessible to a larger group of people. A popular trip is to be dropped by a packer on the east side of Mt Whitney, at Crabtree. In this alternative the Trail Crest quota will be made available to packers for allowing parties to continue the trip over Trail Crest. This is a departure from the No Action alternative, which limits this trail to case-by-case.

Cottonwood will continue to be an area of one operator with relatively low commercial pack stock use. Commercial pack stock use will continue to be less than 3 percent of the overall use in this area. Some day rides will be permitted in this alternative, up to 200 in the season. This would be an increase from the No Action, where current use and allocation is 41 service days. Early season pack stock use would continue to provide support to the State fish-rearing project. Besides impacts to the trail system, this use is rarely observed or in conflict with other users. The opportunities for solitude are low in this drainage and commercial stock use has little or no effect on this condition.

Cumulative Impacts

There may be some effects to Sequoia-Kings Canyon National Park with this alternative, including increased crowding at Crabtree and Guitar Lakes. Park policy may dictate differently in the future.

Trails in the southern portion of the John Muir directly access Sequoia-Kings Canyon National Park. Most visitors travel through the Forest to the Park and very little impacts occur east of the passes. Trailhead limits regulate the amount of use to a great degree but destinations west of the pass receive use and impacts as a result of this east side use. In particular use allowances at roughly current levels over Kearsarge, Taboose, Sawmill, and Shepherd Pass may have some effects on destinations in the Park. A reasonably foreseeable action may be that the Park will have to provide additional regulation other than relying on the access regulation on the Forest to control this use.

Cottonwood Lakes is an area where the State Department of Fish and Game have a fish rearing operation. There is early season activity associated with this operation, some of which uses the commercial pack station. A cabin used by DFG is also located in the basin and is a noticeable human imprint. An equestrian campground at the trailhead of Cottonwood Lakes does contribute to additional stock use into the basin, most of which is day riding and remains on system trails.

John Muir Southeast – Alternative 4

Analysis

North Fork of Big Pine will have little change from the Alternative 1. The 20 percent reduction in service days will effect an overall reduction in people serviced. Stock number may continue to

increase, with up to 700 stock in this canyon. Use will be prohibited to Sam Mack meadow, which will insure that the trail is not subjected to the potential for more rapid deterioration that may occur with stock use as is allowed in Alternative 1 and 2. Currently, the operator has chosen not to use this trail due to the deteriorated condition, but the use is not prohibited. Commercial stock use will continue to be concentrated at Third and Fourth Lakes with less use at Black and Fifth Lakes with a consistent, steady use of the trail from mid July through August.

Opportunities for solitude along the trail and at these destinations will be very low and commercial stock use will remain at about 12 percent of total use overnight use. Impacted areas will continue to be used with no new areas that will become subjected to new impacts. Limited cross-country travel will continue to Heidi Cabin and snow survey sites, but cross-country travel to Coyote Ridge will be eliminated. This will have no effect as the current approval has led to infrequent use that has no sign of impact.

The canyons south of North Fork Big Pine will mostly be designated Not Suitable for Commercial Stock (NSCS). Only Kearsarge trail will be available for commercial stock use. This will likely have the effect of increasing commercial stock use on this trail. The number of days the commercial quota fills will be much higher, with possibly up to 40 days being filled compared to 2004 when on no days was the commercial quota filled.

Cottonwood Lake will continue to have low to moderate stock use, with up to 300 stock a year in the basin. Access to Hidden Lake would be prohibited which would concentrate use at other destinations in the basin. Little use occurred at Hidden so the effect of use dispersal would be minimal. Most commercial stock use would occur at Lake 3, as it does currently, and the effects of this would not likely be different from in other alternatives, including Alternative 5.

Cumulative Impacts

North Fork of Big Pine will continue to see high levels of private day hiking, mountaineering and outfitter-guide use. All these uses combine to create low opportunities for solitude in most locations in this basin. Some improvement to Wilderness character has occurred with past actions removing structures (old resort facilities) since 1964.

Commercial pack stock use will be greatly reduced into Sequoia-Kings Canyon National Park. An overall reduction of impacts west of the passes may occur because of this action, unless Park management authorizes or allows use to increase from other points of entry.

John Muir Southeast – Alternative 5

Analysis and Cumulative Impacts

This region has a few areas of moderate to high use, including North Fork Big Pine, Cottonwood, Shepherd, Whitney, and Kearsarge. The remainder of the region is more typically low use. Most visitors in these areas access Sequoia-Kings Canyon National Park. Overall up to 1500 commercial pack stock use this region. With Alternative 5, no stock would be servicing visitors.

North Fork of Big Pine with access to the Palisades would see a reduction of use by about 12 percent. There would still be a high level of day hiking, climbing, and backpacking that would occur. In the months of July and August, there would be a noticeable difference in encounters with pack stock. Typically, however, the packer here takes one run up and down the trail a day.

This pattern helps to reduce encounters. With no encounters with stock there would still be a high level of visitors and opportunities for solitude would still be low to moderate. Camping encounters would be slightly less than hiking encounters but this use would remain high.

Taboose Pass receives moderate packer use, less than 15 trips and 75 stock a season. All this use passes through to Sequoia-Kings National Park and little impacts exist from this use other than to the trail system, which is rough and difficult to maintain. It would remain difficult to maintain but may not require the present level of maintenance.

Shepherd Pass receives moderate stock use, 22 trips and just over 100 head of stock. The trail is, like Taboose, rough and difficult to maintain. There has been no camping allowed except by exception on the east side of this pass so no change would occur east of Shepherd Pass. On the west side, in SEKI, there may be a noticeable change in stock numbers accessing the Park. This is a popular loop trip through the park either starting or ending at Shepherd. In August, it is common to encounter stock that have accessed from the east side on these loops. Opportunities for solitude would not be affected, as these areas will remain popular for visitors that do not travel with commercial stock.

Kearsarge has a moderate level of commercial pack stock use with over 130 stock a year. Most of this use is through to SEKI to Charlotte or the JMT/PCT. There is occasional use to destinations east of Kearsarge Pass, but due to the popularity of this trail by backpackers and day hikers, there is not likely to be any noticeable change to social or resource conditions. The trail will not need to be maintained to the current level for stock travel, but will still be a major trail into the Park and will require high maintenance. It is expected the recent construction work will be adequate for up to 20 years without the stock present. Opportunities for solitude will likely not change.

Sawmill receives only occasional stock use, at most one or two trips a year. There will likely be no noticeable change in this area, either to resource or to social conditions.

Cottonwood Lakes Basin is a very popular area for backpackers and day hikers but relatively low commercial stock use compared to the public use. With no packer use, stock would be mostly used to assist with the Department of Fish and Game fish rearing project in the basin. This early season access may have more effects on the trails than mid to late season use and would still probably occur, with state or federal packers doing the work. Campsite conditions would stay the same as the general use is so high and conditions have stabilized. Opportunities for solitude would alone not change and remain low to moderate.

Mt Whitney currently has no stock use so the conditions of high use, high encounters, and high encounters with others camped will remain. However packers do drop parties on the west side of Trail pass with their commercial service ending there and the parties continuing over and travel down to Whitney Portal. Discontinuing this use will hardly be noticeable to visitors on the very popular Whitney trail.

Cumulative impacts are similar to Alternative 4.

John Muir Southwest – Alternative 1

Analysis

Commercial pack stock use will be light to moderate with stock use widely dispersed over this large geographic region. Overlap between operators is not likely to occur anywhere but in the northern portion of the region, in the Hobler unit. This overlap is expected to be only occasional. All other use throughout this region would be by one operator. Without direct controls on any of the destinations, use patterns can shift and concentrate at a point in time. Some destinations may get more use in the future and would be dependent on packer marketing and visitor demands.

A number of trailheads offer access in this region. Maxson has, by far, the highest packer use with a packer quota of eight persons a day. Single quota trailheads are also available at Crown Rancheria, Cliff Lake, and Woodchuck. These 3 trailheads offer up to 50 persons a day. With current public use being low, this allows for increases in use at these trailheads.

Many options for accessing destinations are allowed with use trail approvals in this region. Access to Crabtree Lake, Blackrock, Bench Valley, Hummingbird Lake, Sceptor Lake, Portal, Pearl Lake, and Ambition Lake are all open to the packer. There is the potential for repetitive use on any of these trails since the only control is at the trailhead. The scarcely visible use trails could become noticeable impacts and trails that may not be visible now could become visible paths, which could facilitate use into low use areas.

Cumulative Impacts

There is an effect on Kings Canyon National Park by pack station use occurring from the Rancheria Trailhead. Use from this trailhead enters the Park and concentrates in Tehipite Valley.

Cattle allotments in this unit also may affect trails, riparian corridors, and wilderness character. Trails may receive more impact as a result of the combination of both human/stock use and cattle use. Multiple trailing also may occur due to range cattle. The wilderness character of the Crown Valley area may be negatively affected due to the cattle allotments in the area.

The most heavily used trailhead in this geographic unit is the Maxson trailhead, which shares a trailhead with the Dusy-Ershim Off-Highway Vehicle (OHV) route. This proximity of this OHV route to the Maxson trailhead and the John Muir Wilderness may affect the wilderness character of nearby areas.

There is a private inholding in Crown Valley with cabins and other structures. The owners are actively rehabilitating the facilities. Use of helicopters into the property has been occurring. Many years ago the property was somewhat of a dude ranch but the intentions of the current owners are unknown. There is a negative effect on the wilderness character that is localized in the Crown Valley area because of activities—especially helicopter use—on this private land.

A second inholding at Statum Meadow near the Crown Valley trailhead and the wilderness boundary has structures that are used by the property owners. However, due to location and low intensity of the use there is minimal effect on the wilderness character. Overall this Geographic Area generally has the largest amount of private horse use within the Sierra NF portions of the planning area. Popular destinations include Red Mountain Basin, Crown Lake, Spanish Lake, and Geraldine Lakes. At these locations and along the trails accessing them there may be a

reduced sense of solitude, especially for those that find horses inappropriate for a wilderness setting.

John Muir Southwest – Alternative 2 – Modified

Analysis

In this region, 23 destinations or zones will be used by commercial pack stock. This region will have only one location where overlapping spot and dunnage services would occur, in the Hobler unit. The rest of the unit will have one operator.

Use throughout this region will be low and dispersed. Opportunities for solitude will remain high and may not be changed by these actions. Most destinations will have no more than 10 trips a year, with only one destination Chimney/Woodchuck with up to 15 trips. Most of this region is within a Recreation Category 1, managed for low use and this type of operation is consistent with those desired conditions.

Use will not be allowed to be higher than the current high use year at Rae Lake. This area receives a light amount of packer use but is a very popular destination for hikers and private stock parties. Capping packer use will reduce conflicts with other user groups and contain impacts. The use trail used by the packer to access Fleming Creek will be prohibited, concentrating the use onto the system trail. This will have a minor beneficial effect on the naturalness of the area.

Access to Crabtree Lake will be limited to the use trail up Bench Valley and packer use will be prohibited between Crabtree and Horsehead Lakes. This will insure that the area maintains a trail-less quality and will maintain high opportunities for solitude and wilderness character.

A trail that is used to bypass the Bench Valley trail—which is very difficult for stock—will be approved for use until the Bench Valley trail is fixed. There may be continued trail impacts occurring until such time as the system trail is improved. There would be minor to moderate effects to naturalness by allowing an entirely new trail system to be used, but with light use the trail impacts will have minor adverse effects.

Areas in the south end of this region, Woodchuck, Finger, Spanish, and Rodgers will all see occasional packer use. Very light use will continue from this region into Sequoia Kings-Canyon National Park, mostly to access Tehipite Valley and Blue Canyon.

Cumulative Impacts

Cumulative impacts are the same as Alternative 1.

John Muir Southwest – Alternative 2

Analysis

In this region, 22 discrete destinations or zones will be used by commercial pack stock. Collectively at these 22 destinations there are allowances for 9 additional spot and dunnage trips. This allowance for a slight potential in growth would take place over a large area. As with all areas of potential growth, this growth is in number of trips with an overall limit on number of stock based on the past few years of use. This region will have only one location where

overlapping spot and dunnage services would occur, in the Hobler unit. The rest of the unit will have one primary operator.

Use throughout this region will be low and dispersed. No destination will have more than 10 trips a year. The maximum number of trips to a destination will be at Pearl Lake. Much of this region is within a Recreation Category 1, managed for low use and this type of operation is consistent with those desired conditions. Opportunities for solitude will remain high and will not be changed by these actions.

Use will not be allowed to be higher than the current high use year at Rae Lakes. This area receives a light amount of packer use but is a very popular destination for hikers and private stock parties. Capping packer use will reduce conflicts with other user groups and contain impacts. The use trail used by the packer to access Fleming Creek will be prohibited, concentrating the use onto the system trail.

Access to Crabtree Lake will be limited to the use trail up Bench Valley and packer use will be prohibited between Crabtree and Horsehead. This will insure that the area maintains a trail-less quality and will maintain high opportunities for solitude and wilderness character.

A use trail that is used to bypass the Bench Valley trail—which is not passable to stock—will be approved until the Bench Valley trail is fixed. There may be continued trail impacts occurring until such time as the system trail is improved, which could be 5-10 years.

Areas in the south end of this region, Woodchuck, Finger, Spanish, and Rodgers will all see only occasional packer use. Very light use will continue from this region into Sequoia Kings Canyon, mostly to access Tehipite Valley and Blue Canyon.

Cumulative Impacts

Cumulative impacts are the same as Alternative 1.

John Muir Southwest – Alternative 3

Analysis

Only one pack stock operator will be authorized in this area. Under the No Action there had also been only one operator but there were no managerial constraints on other operators using this area. Generally throughout this geographic region use will be low to moderate with low use dispersed across many distinct destinations. Use patterns are not likely to change from current patterns noted in the No Action. However, few direct controls exist to assure this. If use patterns continue opportunities for solitude will remain high at most destinations in this region. Total use in the area is roughly 1500 people and less than 500 stock over a relatively large geographic area compared to the same amount of use on some trailheads on the east side of the John Muir where as many people and stock are generally concentrated on fewer trails.

In this alternative use will continue to be low into the Hobler unit with access from the Courtright trailhead. Destinations that will continue to receive use will be Burnt Corral and Red Rock Basin. Opportunities for solitude will be moderate in Burnt Corral and high in Red Rock Basin. The approved use trail into Red rock basin will allow access into a Recreation Category 1 area. Use pattern shifts into red rock basin are possible and would need to be monitored to insure use levels continue to be compatible with the desired condition of a RC1. Use levels would be at

the high end of a Recreation Category 1. The system trail access to Burnt Corral would be maintained at a slightly higher level than the No Action alternative (from a 1 to a 2) but is consistent with the desired recreation category of the Burnt Corral. Overall use, public and commercial is low to moderate, with 200-300 parties a year and commercial use would remain less than 10 percent of use in the area in this alternative.

The Courtright trailhead would also be used to access Post Corral unit. Use would continue to be moderate and stock numbers would be moderate in this area as it provides access to multiple destinations. This would be used primarily as a pass-through to other Fleming, Red Mountain, Blackcap Basin, and Bench Valley. Encounters between commercial pack stock and other visitors would be low to moderate in this alternative. Most of the encounters would be from Post Corral meadows to the Potholes.

Beyond Post Corral meadow, use will continue to disperse into various destinations. Fleming unit will continue to have moderate hiking and stock use. Commercial pack stock use will be concentrated but still low at Rae, lower Indian, Fleming Creek, and Dale Lake. Use will likely remain at about 50 stock to these locations a year.

Red Mountain Basin would receive use concentrated at low levels at Disappointment Lake, Devils Punchbowl, Little Shot, and Blackrock Lake. Approved use trails to Little Shot and Blackrock allow for the potential for use to shift over time to these more remote (off trail) destinations. Use to Blackrock, if it were to increase, could lead to a use trail that now is not visible to a more established route which could, over time, encourage or facilitate more use. The setting is such that there is little capacity for camping and opportunities for solitude are easily spoiled.

The Bench unit would have light use, less than 50 stock dispersed between Guest and McGuire, Crabtree, and Horsehead Lakes. Stock use to McGuire and Guest Lakes will likely not occur to any notable amount until the trail is improved. Use is prohibited between Crabtree and Horsehead in all alternatives.

Big Maxson will continue to have a low level of commercial pack stock use along the trail corridor at Halfmoon Lake and Maxson Meadow. Stock use levels will remain similar to the No Action alternative; about 100 stock a year total in these areas. This relatively light use will have no change in effect on opportunities for solitude, no increases in encounters between stock and hikers, and a high probability that any stock related impacts will be minimized and or improved over time with management.

Basin, entirely with a Recreation Category 1, will continue to see a low level of stock use dispersed in Blackcap Basin, Lightening Corral Meadow, Pearl Lake, and Portal Lake. Use pattern shifts will need to be monitored to assure that Recreation Category 1 conditions are maintained at these locations. A number of approved use trails allow for additional access to locations and may require monitoring for conditions. The Portal to Pearl use trail may particularly facilitate more use into the area over time.

Crown Basin and Crown Lake units have no recorded commercial stock use staying overnight in these units. It is used as pass-through to Blue Canyon in Sequoia Kings Canyon National Park. Use restrictions or allowances from the Park Service may affect use levels through this area. With no direct controls use patterns shifts could occur under this alternative. However no popular destinations are present that would draw stock use to this area and with a seasonal stock

quota of 55 from Crown /Rancheria trailhead, and multiple destinations accessible from this trailhead, it is not at all likely that stock use will increase. A use trail approval to Hummingbird Lake and Sceptor Lake could allow for more use. Stock related impacts into this area are possible at low levels of use if no stock use or very infrequent stock use has occurred to date.

Rodgers has low potential for commercial pack stock use more than at low infrequent levels. Geraldine Lake is the primary destination and commercial stock use will be concentrated at low levels, less than 30 stock a year at this lake. System trails maintained at a TC1 will help maintain the primitive character of the area.

Spanish unit will continue to have very low levels of commercial stock use. Less than 25 stock a year will be occurring at Spanish Lake, Statum Meadow, and the Crown Ridge area. Opportunities for solitude will be high and conditions will be closer to the desired condition of a Recreation Category 1 area instead of the Recreation Category 2 it now is classified.

The Woodchuck unit will have moderate commercial use relative to the rest of the John Muir West region. Use will continue to be concentrated at one destination in the unit, Woodchuck Lake, and along the trail corridors. Use trails that have been used as alternates and short cuts to the system trail will be unapproved reducing overall stock related impacts in the area. One use trail to the snow survey site at Loper Peak will allow for continue support to the State's program, and will be infrequently used. Woodchuck Lake will continue to have moderate opportunities for solitude with the commercial pack stock use a higher percentage of overall use than other locations in this region. Still the use is low, with less than 15 trips a year expected to this destination.

Chain Lakes and Duck Lakes will continue to receive light commercial pack stock use in the Finger area. Opportunities for solitude will remain high when no commercial pack stock are at these lakes. During the infrequent times that commercial pack stock are here, opportunities for solitude may be reduced.

Cumulative Impacts

Cumulative impacts are the same as those described under Alternative 1

John Muir Southwest – Alternative 4

Analysis

The primary access into this area is from the Maxson, Rancheria, and Woodchuck trailheads. Overall use levels being reduced by the 20 percent cut to service day allocations will be the primary difference between this alternative and the No Action in this geographic region. The number of locations where pack stock can only drop clients will be limited to 18 areas. The number of locations where pack stock can overnight will be limited to nine areas. Although in the No Action there are numerous possibilities for dropping clients, most use is currently spot and dunnage to these same primary locations. There will be no flexibility that exists in the other alternatives.

Five of 32 system trails would be designated Not Suitable for Commercial Stock, four more than in Alternatives 2 and five more than Alternative 3. This provides additional limits on access to destinations compared to Alternatives 2 and 3. Use trails would be limited more than system

trails in this alternative. Six additional use trails would be prohibited from commercial pack stock use than in Alternatives 2 or 3.

Areas where commercial pack stock would be excluded include Ambition Lake, Lightning Corral Meadow, Twin Buck Lakes, Roman Four Lakes, Hummingbird Lake, Heather Lake (from Mosquito Pass), North Fork Kings River (near Anderson Creek), and Blackrock Lake. These locations are relatively remote with few impacts. By excluding pack stock it would eliminate the chances that pack stock use could increase and/or contribute to impacts that may be associated with even light levels of stock use.

Use would still occur at relatively remote locations in this region such as Chimney Lake, Marsh Lake, Crabtree Lake, Horsehead Lake, Little Shot Lake, Jigger Lakes, Scepter Lake, and Maxson Lake. There would be more opportunity for dispersed pack stock use in this region than in other regions. These destinations will be vulnerable to impacts if use levels were to increase. Without direct controls on these destinations it can be possible that conditions will change over time and incremental increases in pack stock use can change the character of such remote locations if stock use displaced from other locations now prohibited were to disperse to these locations.

Cumulative Impacts

Cumulative impacts are the same as those described under Alternative 1.

John Muir Southwest – Alternative 5

Analysis and Cumulative Impacts

Packer use in this area is low and spread over a large area. The highest used destination is Woodchuck Lake with 100 stock a year. North Fork, Red Rock Basin, and Burnt Corral all receive some lesser amount of use with many other destinations receiving only occasional use. Many use trails are used by the packer in this area. Some are used to bypass trails that have not been maintained adequately for stock (Bench Canyon). Trails are rough even with light use. Conditions of the trail will not improve with the absence of stock. Encounters with stock parties will be less but may not be as noticeable since this area receives a higher level of private stock use than other parts of the wilderness. Few large packer camps exist, but they would remain and only improve by the fact that they will receive less use. They will likely remain as stock camps.

Cumulative impacts are the same as those described under Alternative 1.

4.1.3 Trails

Wilderness Scale

Methodology

Trails and use trails were assessed by evaluating their consistency with existing wilderness direction and desired conditions of the areas that they access, as well as their predicted stability (both of infrastructure and resource) under current and anticipated use.

Context: For the purposes of this analysis, local impacts are effects on resources in the immediate vicinity of specific trails because of instability, or at the trail destination as a result of relative inconsistency with area direction. Regional impacts vary slightly depending upon the type of resource affected. Regional impacts for physical resource effects are at the watershed scale, while effects related to consistency with area management are at the wilderness scale.

Intensity: Intensity considers whether the impacts of actions would have a negligible, minor, moderate, or major effect on trail and resource stability and consistency with wilderness-desired conditions. A negligible impact is one that is not readily evident and does not appear to affect trail or resource stability or consistency with management of a wilderness destination. A minor impact is evident, but the effect is not noticeable nor does it materially affect physical or wilderness resources. A moderate impact is readily apparent and clearly affects physical or wilderness resources. A major impact is one that creates substantial and potentially irreversible change in condition of physical or wilderness resources.

Duration: The duration of the impact considers whether the impact would occur in the short term or the long term. Short-term impacts would generally be those where an effect is evident in a relatively short time (1-10 years), and is not likely to have a permanent effect on the trail infrastructure or wilderness resource, such as the approval of sanding snow for early season access or social conflicts between different users. Long-term impacts are those which will not be fully evident until other events take place over a longer duration (generally 10-20 years or more), such as gradual natural recovery of resources, eventual implementation of active mitigation, or gradually increased stability of trails when trail management is well-aligned with anticipated uses and desired conditions of an area.

Type of impact: Impacts are determined to be either beneficial or adverse. Beneficial impacts are those in which actions enhance physical resource and trail stability, and provide a closer consistency with desired area management. Adverse impacts are evidenced by greater trail instability and greater discrepancy with desired area management.

System and Use Trails – Analysis Common to All Alternatives

General effects of stock and hiker use on trails

Effects of pack stock on trails consist primarily of churning of trail tread surface materials and compaction of subsurface tread materials. This action makes soils available for transport by water, or to a lesser extent, physical removal on hooves or feet, or in some cases, high winds. When a trail is incised through soil removal, it begins to channel surface runoff. Soils deeper than a few inches within the trail tread become compacted over time, making the soil less

permeable to surface runoff, increasing the intensity and velocity of water flows within the trail way. This loss of soil, if unchecked, can create unstable and awkward conditions, making trails less comfortable to travel for both hikers and equestrians.

Trail structures in the tread and supporting the trail are subject to very great forces by heavily laden pack animals, and can be loosened or damaged by such use. Soils, which are loosened in the tread, tend to be displaced to either side, creating berms, which further contain water on the trail. The loose soil can also plug waterbars and other drainage structures, requiring an increase in frequency of maintenance in order to keep them functional.

These impacts can combine to create degraded conditions of the trail itself, such as incision, loss of tread, clogging or failure of drainage structures, or collapse of support structures, making the trail hard to walk or ride on unless high levels of development and maintenance are performed. Additionally, these factors can result in increased off-trail resource effects, such as sedimentation into nearby streams and lakes, or a lowering of the water table in meadows when a trail becomes deeply entrenched. When trails become overly degraded, alternative routes are sometimes used by both hikers and by equestrians to bypass obstacles, creating multiple trails and added sources of impact.

In most scenarios, the effects of foot travel with no or only occasional stock use on a trail surface tend to be greater compaction of soils at the very surface of the trail and less compaction deeper in the soil structure. While this makes less loose soil available for off-trail sedimentation, berming, or filling drainage structures, it can reduce the absorption of water and increase velocity of surface flows. On trails with excessive grades for the soil type (generally >20 percent without tread retaining structures), increased water velocity can remove more soil, and deep incision and loss of soil can occur. In most cases, trails with only hiker traffic tend to be more stable and require less work and cost to maintain. As seen on certain trails that have been closed to stock long term, trails carrying only foot traffic tend to hold an outsloped surface (which sheds water), have firm tread, and require less drainage maintenance. Comparably built structures tend to last longer. Also, it is evident that there tends to be less susceptibility to incision at moderate water flows on comparable trail grades of foot-only trails relative to multiple-use trails.

Hardened trail surface in steep terrain can sustain repeated heavy stock use.

Trails that are well-designed with moderate grades and sufficient high-quality structural improvements and/or are in terrain and conditions with very few risk factors are more capable of resisting the impacts of heavy stock and hiker use, and generally will remain relatively stable with just basic recurring maintenance efforts. Trail structures, such as waterbars that deflect water from the trail, check dams or tread retainers that hold tread in place, or rock steps that help gain grade with less surface erosion potential can protect both the trail infrastructure and off-trail resources.

Conversely, trails with little or no design or structural improvements in areas with a higher intensity of risk factors, tend to be more susceptible to the effects of such use, potentially resulting in degradation of the trail itself and higher effects on resources in the trail area. Risk factors, such as steep natural slopes, steep trail grade, loose soils, connectivity to stream systems, or proximity to riparian habitat may complicate and multiply these effects.

Streambank damage and headcuts in trail where structural development is inadequate for use types and levels.

Preventing or mitigating these effects requires increased maintenance efforts and higher costs directly proportional to the amount of pack stock use when all other factors are equal. Trail

maintenance budgets on both forests have historically been inadequate to fully maintain all trails to standard. This has resulted in continuing degraded conditions on most trails, and has resulted in mainly the highest-use and highest-priority trails receiving the bulk of maintenance resources.

Consequences of specific trail-related actions taken in various alternatives

Trail-related action types in the various alternatives are limited to the following:

1. Adding a trail to the Transportation System inventory.
2. Deleting a trail from Transportation System inventory.
3. Increasing the Trail Management Class of an existing trail.
4. Decreasing the Trail Management Class of an existing trail.
5. Designating Trails as “Not Recommended for [private] Stock”.
6. Suitability of system trails for Commercial Stock. (Designation of trails “Not Suitable for Commercial Stock”).
7. Approval of Use Trails for commercial stock use.
8. Prohibition of Use Trails for commercial stock.
9. Sanding of snow by commercial operators to provide earlier access over passes.

Consequences of each action within these various categories will generally be similar on each trail. The difference between alternatives in the potential effects on an area is related primarily to the extent and number of actions within that area.

Trail System and Trail Classes

In all action alternatives (Alternatives 2-5), a trail transportation system is being designated, which includes adding trails or removing trails from past inventories and assigning trail maintenance and management levels on each trail consistent with destination management. These trail management levels are based primarily on the desired management condition of each destination within the wildernesses, which were determined in the 2001 Wilderness Plan, as well as other known or anticipated uses of the trail system. In all action alternatives, the intent is also

to align trail classes with the current or anticipated use types and levels, if such use is consistent with desired management conditions for the area. The long-term effect of correlating trail classes and the managed use types and levels will be trails with greater stability, less resource damage, and improved travel ability with limited maintenance funding.

Some additions and deletions from past (no action) trail system inventories are purely “paper” corrections. For example, some trails had been entered into the inventory more than once under slightly different names, or had been inadvertently dropped due to a typographical error or confusion with another similarly named trail. Correcting such errors will not have a material effect on the physical resource or costs associated with maintaining trails. Other errors in the inventory may have been caused by inadequate field information. For example, a trail was placed on the inventory because it was assumed that a trail existed. Leaving such trails on the system may lead to confusion for managers and wilderness visitors, and in rare circumstances, may inadvertently lead to an unnecessary use trail receiving maintenance.

(1) Adding trails to the system: Trails added to the system have generally been used by a moderate to large number of wilderness visitors, usually exceeding the capacity of an unmanaged use trail. Some have already been inadvertently managed as a system trail in the past, and appear to benefit from continued or future management as a system trail. Since the trails were added to the system with consideration of anticipated use types and levels expected in each alternative (including both commercial and private stock and hikers), the effects of adding these trails to the system is likely to be a reduction in direct resource effect in the immediate trail vicinity.

When trails are added to the system, they are assigned a trail management class, which defines the level of development, maintenance, and management the trail will receive (see discussion under Trail Classes below). Once a trail is added to the system, opportunities increase for management of the trail and its effects – including mitigating resource impacts – since trail maintenance funds can only be spent on system trails. Guided by trail class designation, appropriate structural improvements, such as drainage structures and tread retention structures, can be installed that will reduce erosion of the trail and sedimentation to off-trail resources. Whether such work is accomplished by Forest Service-funded efforts or by volunteers, the design standards of the designated trail class will apply, which helps ensure that intended management of a destination and the trail will be implemented.

Well-defined use trail, added to system as Trail Class 1 trail.

Additionally, since non-system trails have rarely been designed or intentionally aligned, the existing routes may be unnecessarily affecting sensitive resources. Once the trail is on the transportation system, there is a higher likelihood that trails will be rerouted away from particularly sensitive areas as funding or work resources become available. Signage consistent with wilderness and the trail class will also be installed. There should be a net reduction in total area trampled by dispersed use where signs or other improvements help keep wilderness visitors

on one alignment. In some cases, ensuring that all use stays on the one designated route may increase the direct effects on a trail. However, since use would not be causing as many dispersed and unmanaged effects, there will be a net beneficial effect on the wilderness resource.

Routes, which are completely undefined and so lightly used that there appeared to be no need for trail management, were not added to the system. Leaving these undefined routes off the trail system will likely prevent increased use and effects on those trails.

(2) Removing trails from the system inventory: Trails removed from the inventory generally did not exist on the ground, and there appeared no reason to provide transportation management to the destination. Inventory trail management-levels were sometimes moderately high for trails that neither had existed nor would have been practical to ever construct and maintain in these locations. In some cases, these trails appeared on published maps, even though no trail had ever existed.

Other trails removed may have been evident on the ground, but the original use type and reason for the trail may no longer be present. In some cases, existing use on these trails appeared very low and there appeared to be no wilderness, resource, or transportation management rationale for keeping it in the system. Examples include former mining roads or trails where mining activities have ceased; or trails accessing locations that formerly received intensive recreational use, but the activity (such as boat launches or historic lodges) is no longer occurring. Since use is at very low levels, and in most cases, maintenance activities have not occurred in recent decades, removing these trails from the system should have no noticeable effect on wilderness visitors or on resources.

Some trails removed from the inventory provided duplicate access to the same destination provided by another system trail. In these cases, travel patterns would change slightly, with a displacement of traffic to the trail that remains on the inventory. This would likely have a very slight increase in impact to this trail, with an incidental increase in costs to maintain the trail. This would be more than offset by reducing the full maintenance cost of maintaining a duplicate trail. Since access would still be provided to the same destination after the removal of a duplicate trail, there would be no overall effect on visitors' ability to access a destination or on resources at a destination.

Removal of these trails from the system should assist in providing information that is more accurate to the public, reducing confusion, and leading to a better experience. There may be a slight reduction in impacts caused by the dispersed use of visitors who attempt to find a trail on the ground after seeing the trail on a map. Without duplicate trails, expectations would be more accurate for those wilderness users who prefer to have trail access to their destinations. More importantly, removal of the trail from the system clarifies the intended management of routes for wilderness

Undetectable Trail Class 2 “system trail,”
removed from inventory

and trail managers who need to make maintenance and workload determinations for each system trail.

Where trails are somewhat evident, but have been removed from the system because of changes in original use type and demand, effects may include the gradual loss of a followable path, as slough or slides and brush encroach on the tread. In most cases, use is extremely low, so maintenance has become a low priority for these trails and this gradual naturalization has already occurred to a large degree. It is likely that some use will continue by private equestrians and hikers who are aware of the trail and are capable of traveling in its un-maintained condition. As long as such use is light and the route is in an area with few risk factors (such as riparian or aquatic habitat), resource effects should be minimal and the trail will gradually naturalize or stabilize.

Removing a trail from the system in Recreation Category 1 (primitive) areas also helps align trail system management more conceptually with other desired area management of desired conditions for destinations.

There is a slight risk of potential resource effects if a trail is removed from the system inventory, and if use levels increase beyond the capability of the unmanaged trail. These are the same potential effects as described for use trails, where a lack of development or maintenance relative to the type and amount of use increases susceptibility to degradation of both the trail and resources in the trail corridor. If the trail is not on the inventory, options for physical mitigation of these effects may be more limited, and, depending on the appropriateness of the type and level of use present, may lead to the possibility of adding the trail back into the system in a future process.

Trail Classes: Trail class designations define the development, maintenance, and characteristics of a trail. These are defined in Table 2.29 in Chapter 2. Generally, lower trail classes have a lower, more primitive development and management character, and tend to be of smaller scale in almost all design elements. Lower trail classes can accommodate lower use levels while remaining stable, and fit well with more primitive settings with limited visitation. Higher trail classes have greater development and more highly evident management. They tend to have more and larger scale structures, wider footprint, and tend to be more easily traveled. These trails are intended to remain stable under intensive use. Their character is more consistent with higher-use areas that have greater visitation and higher evidence of management.

Adjusting trail class for a particular trail may have a variety of potential effects. Actual physical effects on the environment – both beneficial effects and detrimental effects – would generally not occur until the time of actual repair or reconstruction of a given trail. The extent of actual effect on the

Trail Class 3 trail in high-use Recreation Category 3 area.

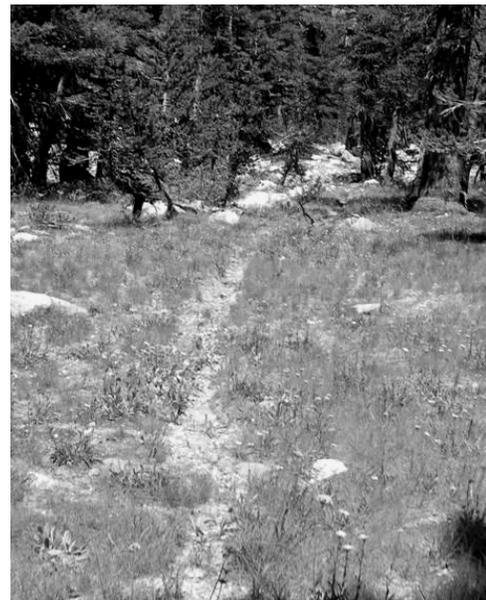

environment will vary depending upon a number of factors. If the change is only a “paper correction” that aligns the class to a trail’s current condition and management, and the current condition is consistent with area direction, then the only effect will be to provide more concise guidance about to what standard the trail will continue to be managed. Designating an appropriate development level will help prevent unintended change in the way a trail is physically managed. In this scenario, there would be little effect, even when work is performed to keep or bring the trail to standard.

(3) Increasing the Trail Management Class of an Existing Trail: As indicated above, if the increase in trail class simply makes the inventory consistent with existing trail management, and this management level is consistent with other area direction, there would be no notable effects on the trail, adjacent resources, or costs associated with maintenance.

When increasing the trail class designation will also require physically upgrading the trail above the past management of a trail, potential effects of increasing the management level (and future development levels) of a trail would primarily be in visitor perceptions of increased trail management. If the trail management level is currently insufficient for the existing or desired management of a destination, raising the trail management level may improve the experience of many wilderness visitors. Conversely, a trail managed at an excessively high level may appear to be out of character with more primitive environments, since the trail would be relatively easy to follow and travel, and may have more substantial structures than would be present in the most primitive wilderness destinations. In all action alternatives, trail management levels are designed with some consideration of desired management condition for destinations, so it is likely that in most alternatives, this effect will be minimal.

If a trail has previously been actively managed at a much lower level than is being designated, a number of effects could occur. When a trail is currently relatively undeveloped and extremely difficult to travel by either hikers or stock, bringing the trail to a much higher development level would potentially allow more ready access by types and/or quantity of wilderness visitors to a particular destination. If the designated standard requires lower trail grades, wider tread, and more substantial structural development than currently exists, there may be some additional site-specific effects at the time of reconstruction efforts. There could be a wider footprint and larger area of disturbance and potential disturbance of areas where rocks or other construction materials are obtained. Physical effects would occur at the time a trail is reconstructed to the designated standard and generally would not increase, due to subsequent recurring maintenance performed on the trails. Ongoing physical impacts to the trail and associated resources would generally be greatly reduced after a trail has been reconstructed to a higher standard.

In many cases, designating a higher trail class to meet an immediate or expected demand will have beneficial effects on the physical environment. If a use trail or low-development system trail with minimal

Low-use, lightly defined TC1 trail. Shares some characteristics with use trails.

management is not so difficult that it prevents travel, and it is currently receiving heavy use, it is likely that the trail is already causing some physical resource impacts that could be corrected by management that is more intensive. In these cases, designating a higher class and bringing the trail to standard would likely have a beneficial effect by stabilizing damaged sections of trail, improving drainage and reducing effects on various resources without significantly changing use patterns. Improving the trail's stability has the potential to reduce the overall footprint of disturbance by providing a single well-used trail, instead of multiple braided routes where hikers or stock bypass obstacles. In these scenarios, the greatest benefit would generally be in meadows, riparian areas, and at water crossings, where developing one stable route can substantially reduce hydrologic disturbance.

(4) Reducing Trail Management Class of an Existing Trail: Potential effects of reducing the management level (and future development levels) of a trail would primarily be in visitor perceptions of reduced trail management, and in potential future reduction of costs for reconstruction or maintenance. Some wilderness travelers prefer more primitive trails, which may be more difficult to negotiate, but which add to a feeling of remoteness and less management intrusion. Others may find the trails exceedingly difficult, especially equestrians or hikers carrying heavy backpacks.

Costs would likely be slightly reduced at the time of repairs or reconstruction if the trails can be built to a lesser standard. Trails with a lower management class will generally have fewer and smaller-scale structures, less width, and somewhat less frequent maintenance. However, savings in trail development may be offset in the long-term by the relative susceptibility of a less-developed trail to damage from natural events and heavy use. A potential effect of this would be an increased effect on physical resources in the trail corridor if structures do not adequately withstand the use types and levels present on the trail. As with undeveloped use trails, system trails with minimal development are more susceptible to catastrophic failure in high-risk areas or with a large runoff event. This could require a higher frequency of maintenance in order to maintain stability.

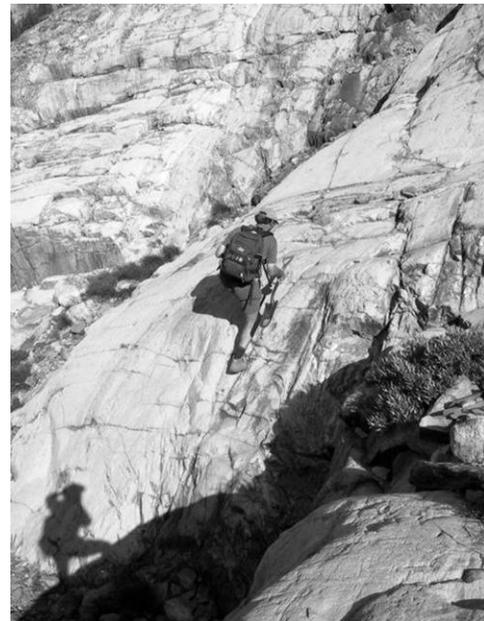

When trails are under-developed relative to the type and/or level of use, there is a high likelihood that both the trail stability and resources will be negatively affected over time. Trail class reductions proposed in the alternatives would only occur if the trail were receiving lower levels of use than the trail is currently managed for, and that less development and management would adequately meet the demands of the use and terrain. If this proves inaccurate, mitigation of these effects would require either restrictions that control the type and level of trail use and/or a higher future level of trail development and management to align the trail management to the demand.

(5) Trails Not Recommended for [private] Stock: In some alternatives, trails are designated "Not Recommended for Stock". The definition and application of this term have changed during the analysis process. These changes in the terminology and definition of this action make a difference in the effects by alternative.

In the proposed action, the term "Not Recommended for Stock" (NRFS) has dual implications of advising private stock users about severe trail conditions, combined with commercial stock-specific restrictions of the "Not Suitable for Commercial Stock" (NSCS) designation [see #6 - Trail Suitability]. In Alternatives 3, 4 and 5, the Forest Service separates the two actions by designating trails as either NRFS or NSCS, or both. The NRFS designation will be the basis for

providing advisories and expectations for private equestrians, but will not otherwise prohibit commercial or private equestrian use.

Trails designated as “Not Recommended for [private] Stock” in these alternatives are based on a subjective assessment of the difficulty and possible risks to equestrians who may not be familiar with uncharacteristically awkward conditions on a particular trail. While trail class provides some general description of development and management traits for a trail, it does not necessarily describe a trail that may have problems or obstacles that could create special concern for equestrians. For instance, a TC1 trail with minimal development that gradually climbs through a gentle, sandy canyon will have very different obstacles and potential problems than a TC1 trail which traverses very steep and/or rocky terrain with large jump-offs and/or difficult route finding.

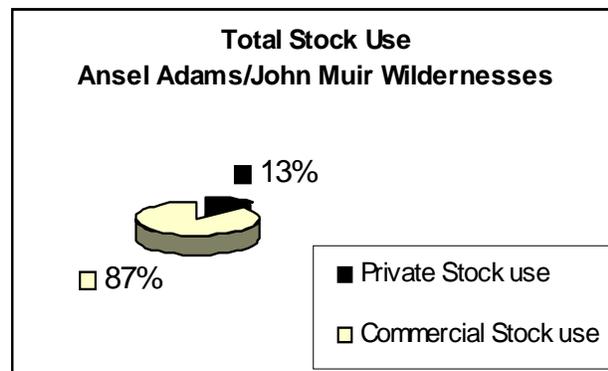

Severe bedrock obstacle on TC1 trail not recommended for stock. Awkward for hikers, potentially dangerous to stock.

Since this designation will assist private equestrians in ensuring they are prepared for such rugged trails or avoiding them altogether, the greatest effect would be a more realistic visitor expectation and increased safety for private stock users, who could make more informed choices about their travels. Even without actual restrictions of use, this will likely reduce the number of stock users who might otherwise unwittingly attempt these trails unaware of the trail conditions. Since these trails tend to be rough, undeveloped, relatively unstable, and susceptible to the impacts of stock use, this designation would likely cause a slight reduction to trail erosion and impacts to resources.

Most physical resource or trail stability effects resulting from designating trails as NRFS (if not also closed to commercial stock) will likely be insignificant, as the level of private stock on such trails is generally very low at present, and some private stock could still use these trails, if they choose. The effects of designating a trail as both NRFS and “Not Suitable for Commercial Stock” are more substantial and are described in the Suitability section below.

Figure 4.6 Comparison of Private and Commercial Stock Use in the Ansel Adams/John Muir Wildernesses

Trails designated “Not Recommended for Stock” will still receive basic recurring maintenance at a level consistent with the design and management considerations of the designated trail class. It is likely, however, that those conditions which are most impractical for equestrians, and which were the basis for the NRFS designation, will not be substantially repaired. The general character of the trails will likely remain the same, since the limited maintenance work will likely be focused primarily on trail and resource stability.

(6) System Trail Suitability – Trails “Not Suitable for Commercial Stock”: In all action alternatives, determinations will be made on which system trails are suitable for recurring use by commercial pack stock. Trails which either cannot be sufficiently managed in a stable condition under recurring pack stock use, or which provide access to areas which are determined to be inappropriate for commercial pack stock operations are designated as “Not Suitable for Commercial Stock” (NSCS). [In Alternative 2, this designation is “Not Recommended for Stock,” but carries the same implication for commercial operators.]

As noted previously, most trails designated “NSCS” have received low commercial use and practically no private equestrian use in recent years, since conditions on these trails have not been desirable for most private stock users. Therefore, after commercial stock are prohibited from using a trail, there will likely be very little if any equestrian use remaining on the trail. This would limit the majority of equestrian use to trails which are comparably stable with stock use, and that require relatively low investment of maintenance resources. Many of these trails will still have some sections that are substandard or damaged, but there would likely be no need to change current design standards for the trails in order to complete trail repair for non-stock users.

System trails that are in severely degraded condition and designated as NSCS may require physical repair even after all commercial stock has been removed. In these cases, removing commercial stock from degraded trails and high risk-factor areas will likely slow the rate of deterioration of resource condition and prevent further expansion of impacts. Actual physical improvement of resource and trail condition will not likely occur until implementation of future repairs and stabilization. Once accomplished, this rehabilitation has a much higher chance of success over the long term if no commercial stock (and only occasional private stock) uses the trail.

Considering very limited maintenance funding, reducing the need for expenditures on

trails closed to commercial stock will also allow greater trail maintenance and resource stability on the rest of the system. Assuming that maintenance funds remain stable, the net effect would likely be a slight improvement in trail condition on those trails that remain open to commercial use.

Trails that are designated both NSCS and NRFS would likely see the greatest potential trail and resource improvement, since no commercial stock will be present, and less private stock would inadvertently travel these trails unaware of the trail conditions.

A Forest Order has closed just over 16 miles of trail in the Mt. Whitney area to all equestrian use since the 1970s. Since this will continue in all alternatives, there will be no change in effect on trails, resources, or users.

Severe resource damage to stream bank and meadow from massive trail headcut. Risk factors make repair highly unlikely, and would be exceedingly intrusive.

Use Trails: The 2001 Wilderness Plan allows for a limited network of “use trails” (generally paths created by repeated hiker or equestrian use to access camps or other dispersed locations not accessed by system trails). Well-developed use trails may sometimes have similar characteristics to lower-development system trails. In most alternatives, a limited number of these are approved for commercial stock use. Some well-developed use trails are specifically addressed as “use trails,” while others are addressed within the context of approved campsites (which assume an access path to the site). There is no prohibition on the use of non-system trails or cross-country routes by private equestrians or hikers in any alternative. Guidance for managing use trails or adding use trails to the system is contained in the Wilderness Plan, but generally, if use levels and resource effects are low, and there is no other overriding need for maintaining or managing the trail, use trails are allowed to remain off the system.

Since use trails generally form in the line of easiest or most direct route for the user, with no designed alignment or construction, they are often located in areas that are not desirable for trail and resource stability. Use trails very rarely have or need structural improvements or active management, because the use tends to be relatively low. Structures are sometimes present on trails which were once managed as system trails or pre-wilderness roads, and which are no longer determined to be needed on the trail system because of changes in use patterns (see description under “deleting trails from existing inventory” #2 above).

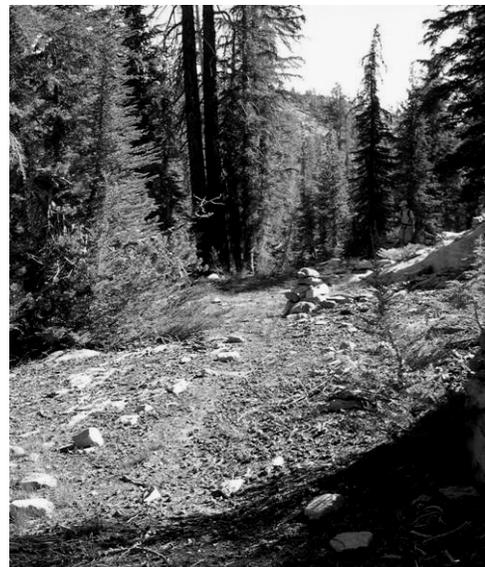

With no structural improvements, use trails may be especially susceptible to rapid degradation when they have high use and/or are in areas with many risk factors. Generally, structural solutions and improvements will not be used to mitigate resource effects; and if used, would be of limited scale. This makes use type and levels, both commercial and private, the primary factors in creating and/or mitigating effects on a use trail.

(7) Use Trails Approved: In general, when approving use by commercial pack stock on a non-system trail, the primary determining factor (aside from whether commercial stock are allowed to access the destination), is the current and predicted stability of the use trail under the anticipated commercial use levels. When the potential use on a trail is better known, such as when there is a destination quota, the approved trail is more likely to remain stable. If future use at a site-specific level is poorly understood, it is more difficult to predict whether a trail would be stable with future use.

Continuing commercial use on use trails that are currently well defined, and are located in stable areas with minimal risk factors will likely not affect trail or resource conditions if use remains at or below current levels.

Barely-defined use trails or routes would have the potential to change to a more evident route with potential resource effects, if use were to increase beyond current low levels. If use of this type of route were capped at existing or lower levels of use, the route would likely not become more evident than its existing condition.

Generally, commercial stock will repeatedly use the same use trail to access a specific destination, and in areas visited frequently by operators, use trails can become

Faint use trail, marked by cairn. Stable location with dry slopes, and few risk factors. Approved for use.

increasingly evident. Use trails that are approved for commercial stock will generally remain stable under anticipated low levels of use. If recurring use increases, however, there would likely be an increase in trail evidence, erosion, trail depth, and potential impacts at streams, riparian, or other sensitive areas. In all alternatives, commercially-used use trails will be monitored for changes in condition, which may result in reductions, prohibitions in use, or incidental physical treatments to prevent further degradation.

(8) Use Trails Prohibited: In some cases, use trails were prohibited when a high level of resource effect was occurring, and/or risk factors were present which created a high potential for degradation if use were to begin or increase. Use trails prohibited to commercial stock will generally have a reduction in negative effects to trails and resources. The scale of this reduction depends on how much the use trail is currently being used by commercial stock and how much the trail will continue to be used by private equestrians and hikers.

Barely-defined use trails or routes that currently receive so little use as to be nearly undetectable, even in sensitive areas such as stream crossings, will not change noticeably in character or in physical effects by the prohibition of commercial stock. The effect of prohibiting commercial pack stock from these undefined trails will be to ensure that use levels could not increase to the point that a trail becomes substantially evident, or that certain resources may become affected. This also ensures that dispersed trampling of potentially sensitive plants or amphibians, such as the Yosemite toad, will not occur by commercial pack stock. Depending upon the level of non-commercial use, private stock, and hikers may still cause some of these same effects.

(9) Sanding of Snow on Trails: Sanding of trails to melt snowdrifts—generally to allow earlier access over passes—can have both beneficial and detrimental effects on trails and resources. The negative effect of either shoveling snow or spreading sand to increase the melt of snow over the trail is that it may provide earlier access either to destinations that are still very wet from snow runoff or to trails that have other snow blockages. Such trails may continue to have effects with or without commercial use, but are most affected when use, especially equestrian use, occurs while water is actively flowing on the trail. Sanding provides this early access for both commercial and private stock. While the primary snow blockage may be sanded adequately to accommodate use over the trailway, smaller snowdrifts beyond the sanded area may force private or commercial stock or hikers to get off the trail tread for short distances, creating the potential for multiple trailing and other off-trail disturbance. Hikers, who make up the majority of trail use, increase in numbers at the end of June, and tend to walk around snowdrifts, trampling soils and vegetation outside of the trailway, potentially creating multiple bypass trails. Private stock, though low in numbers would also generally bypass these drifts where possible.

The potential benefits of sanding stem from the ability to keep commercial and private stock and hikers on the immediate trailway. The trail and resources in the immediate vicinity of the sanding would generally have a slight benefit from the sanding, since commercial and private stock use and hikers will generally remain in the immediate alignment of the trail, reducing multiple trails and off-trail damage. Since approval of the sanding material is required in any alternative where sanding is possible, the soil type should reasonably match that of the destination area, and would likely be of such a small quantity that the imported soils will not be readily discernible to visitors.

The number of trails and the length of time that they are affected by heavy snow drifting varies annually, depending on the quantity of snow on a given winter, and the rate at which natural melt

clears the trails. In some recent low-snow years, there have been no needs or requests for sanding. On heavy snow years, more trails would be covered for greater lengths and for longer periods, potentially until nearly the end of a normal summer use season. The longer time that snow blocks trails, the greater are the intensity and extent of both the negative and beneficial effects of sanding trails.

Actions Outside of this Analysis with a Cumulative Effect Related to the Above Actions

Other past, present, and future actions, which may have an incremental or added effect when combined with trail-related actions in all alternatives in this analysis, include:

- Funding levels for maintenance and repair.
- Trail maintenance activities and reconstruction projects.
- Various different trail user types and levels.
- Management activities of adjacent or cooperating agencies.
- Unclear past management direction for the wilderness transportation system.
- Recreational activities along the borders of these wilderness areas.
- These are addressed in the cumulative effects section of each alternative.

Maintenance to Standard

In this analysis, maintenance or reconstruction efforts and costs are considered which would maintain trails or bring them to standard. Certain trails in the planning area can clearly be described as meeting “standard” or conversely, are “substandard”. Determining whether a trail is “standard” or “substandard” is somewhat subjective, since there is a great deal of variability in any length of trail, as well as a range of acceptable characteristics within each trail class definition.

There are two different considerations in assessing the relative standard of trails in this area – development and condition. Development describes the characteristics of the trail, such as excavated trail width, constructed features, walls, drainage and stabilization structures, and designed grades. Condition describes the current relative functionality of the developed features – generally more recent maintenance and management. A trail with many features that are in need of reconstruction may still be seen as a high development trail (TC3) in poor condition; or, conversely, a very low development (TC1) trail with few developed features could be considered to be in good condition. If certain substandard conditions persist over the long term (20-30 years), the characteristics of a trail may change, so that a trail which was originally developed at high levels (or was even a road), may eventually appear to be a low-development trail.

In evaluating costs to bring trails to standard and to maintain them at standard, assumptions were made to classify trails in three broad categories:

- Trails determined to be generally at standard, and which would only require basic maintenance to assure stability at their designated class with anticipated use levels. Funding at or even slightly below normal annual maintenance level would be adequate to

make the minor repairs necessary to keep the trail within the general tolerances of the designated trail class and level of use.

- Trails determined to be moderately substandard are somewhat degraded so that normal maintenance would not likely keep the trail stable and fully functional at the standards of designated class with the anticipated use, but would not take full reconstruction to return them to this standard. Heavy maintenance efforts, including some replacement of structures and repair of more major failures would be needed.
- Trails which are clearly substandard, due to inadequate development or long-term backlog maintenance, or due to damaging event(s) that have not been repaired. In their current condition, such trails are not practical to perform basic maintenance on, and likely have instability causing resource impacts. These would require substantial reconstruction efforts to return them to designated standard and to make future maintenance efforts practical.

Estimates of recent past funding for trail maintenance and reconstruction are found in Chapter 3. In assessing backlog of maintenance for the trail system in the analysis, the estimated figure of \$170,000 is used as an annual baseline for what is currently spent on general trail maintenance in the AA/JM Wildernesses.

In addition to costs associated with returning the trail infrastructure to a stable condition that meets the designated trail class, there are often substantial costs associated with stabilizing resources within the trail corridor that have been impacted by the trail. The potential costs associated with such rehabilitation efforts can vary widely depending upon the current damage and risk factors at a specific location, as well as the extent and method of mitigation.

When the current resource effects of a trail are light to moderate and risk factors are low, simply removing a trail and use from a sensitive location and placing barriers may be adequate to mitigate impacts, and allow full natural recovery. However, in other cases, rehabilitation costs can potentially exceed the costs of trail infrastructure repairs – especially in the case of reroutes around highly impacted meadows with many risk factors, where the terrain for the realignment is in moderate or easy building terrain, but stabilizing the meadow could be very costly. In general, at the broad scale, resource stabilization costs related to trail affects probably amount to 30 percent to 40 percent of the associated backlog repair and reconstruction cost in any given area.

Trail Density

In Chapter 3, the approximate density of system trails is described for the AA/JM Wildernesses and within each geographic unit. There is slight variation of trail density evident between various units. For instance, Florence/Bear GU had the lowest density at ½ mile of trail per square mile of land, which equates to approximately four linear feet of trail per acre. For the AA/JM Wilderness, the density of trails equates to 6.3 feet of trail per acre or 0.00043 of the total wilderness area. The highest density of system trail was found in the Fish Creek/Convict/McGee Geographic Unit, at 1.3 miles of trail per square mile, which equates to about 10 linear feet of trail per acre. Even at this highest density, the trail area equates to 0.00073 of the total geographic unit.

While such density analyses show that certain broad areas have a higher density of trails, the densities are so low that they do not provide a good basis for comparison. Nor do these help to

establish evaluative thresholds for determining impacts. Additionally, in and of itself, such analysis cannot reflect variations in terrain or shapes of each of the geographic unit polygons or individual areas that may affect thresholds of resource or social effect caused by system trail or use trail density.

The importance of comparing densities of trail for this analysis would be to demonstrate measurable differences in effects between the alternatives. However, the variation of trail density between alternatives is so low as to be inconsequential – even at the geographic unit scale. The greatest variation in trail density between action alternatives was in the Florence/Bear GU where there was a difference of 8 miles of trail in the 88,500-acre unit. The variation between alternatives in each geographic unit was generally between one-half percent and three percent as a function of total trail miles in each geographic unit. For these reasons, trail density is not being used as a measure in differentiating between alternatives.

Table 4.2. Trail density summaries (by alternative)

Trail Density Summary - Acres to Mile of Trail	Alt. 1	Alt. 2 Modified	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Total Acres - AA/JM	811000					
Total System Miles - AA/JM	964	977	967	985	956	956
Density - Acres to 1 mile system trail	841	830	838	823	848	848

Trail Density Summary- Trail Length per Acre Wilderness	Alt. 1	Alt. 2 Modified	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Total acres - AA/JM	811000					
Total system miles - AA/JM	964.3	977.0	967.4	985.2	956.4	955.9
Mile of system trail to acre	0.00119	0.00120	0.00119	0.00121	0.00118	0.00118
Linear feet of system trail per acre	6.3	6.4	6.3	6.4	6.2	6.2

Approved use trails have a greater variation between the alternative with lowest density (Alternative 4) and the other alternatives that have approved use trails. Alternative 4 has approximately a third of the total approved trails, compared to the No Action alternative and the other action alternatives. Alternative 5 has no commercial pack stations, so no use trails would be designated. Approved use trail densities are displayed by alternative.

Table 4.3. Wilderness-wide use trail density summary by alternative

Use Trail Density Summary Wilderness Scale	Alt. 1	Alt. 2 Modified	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Total acres - AA/JM	811000.0					NA
Total approved use trail miles	99.0	111.0	102.0	103.0	30.0	NA
Approved use trails density - total miles use trails per acre	0.0001221	0.0001369	0.0001258	0.0001270	0.0000370	NA
Linear feet of all trails per acre wilderness	0.64	0.72	0.66	0.67	0.20	NA

Densities of system or use trails measured relative to any broad land base – including at the geographic unit and analysis unit scales – do not provide a meaningful measure of relative effect. Other factors, such as connectivity to hydrology, effects on riparian, impacts to specific resources, and the social impacts of allowing use to a specific destination each of these has a substantially greater and more quantifiable measurement between alternatives.

Alternative 1

Summary of Impacts – Alternative 1

The “No Action” Alternative has the fewest control mechanisms on use types and levels, the least amount of alignment between trail management levels and desired condition and management of destinations, and the highest conflict with physical resources. This allows for the continuation and possible expansion of degraded conditions in some areas, and continued negative effects as described in “general effects” above.

There is substantial conflict with recreation categories and trail management in this alternative. If implemented, many trails would have an unnecessarily high level of development and management intrusion on the wilderness character and on physical resources (for instance, over 15 percent of the total system and 28 percent of the Inyo National Forest system is designated at Class 4, a level defined as “rarely present in wilderness”). There are major inconsistencies with on-the-ground conditions and a high probability of physical resource impacts from inadequately developed and maintained trails (for instance, 37 percent of the Sierra system is designated TC1, and nearly 50 miles of managed trail is not on this inventory). Trail management designations for trails with similar characteristics are highly inconsistent between forests in this alternative.

This alternative allows commercial stock on any system trail. With no internal controls, there is very low predictability of use type and level on each system trail. This will likely cause some continued and potential expansion of resource effects, including some localized severe impacts and inefficient distribution of maintenance funds. Various use trails could be requested, approved, or prohibited annually, meaning this alternative would provide very little long-term predictability of use trail approvals, prohibitions or use levels. Currently, 102 use trails (99 miles) are approved for commercial use.

Since any trail could potentially be requested for sanding of snow to allow early season passage (though very few are requested in most years), there is a higher potential for expansion of effects from sanding—both beneficial effects in the immediate vicinity of the sanding, and potential adverse effects at trails and destinations accessed earlier in the season.

Overall, physical trail-related impacts in this alternative will be minor to moderate at the local level, with some isolated moderate to severe effects on certain resources at highly localized sites. Most localized adverse impacts are short-term and could be actively mitigated, but without active repair, many will likely continue into the long term (20 years or more). Trail impacts to physical resources at the watershed scale are negligible to minor intensity, while regional impacts resulting from inconsistency with area management are moderate.

Analysis

In this “No Action” Alternative, the trail inventory and management levels for trails on the Sierra National Forest are based on the inventory included in the 2001 Wilderness Plan (USDA Forest

Service 2001, Appendix C) and trails on the Inyo National Forest are based on the 1987 inventory. Both of these inventories have known inaccuracies, and were developed based on inconsistent direction and in some cases, minimal or no field assessment of each trail. Some trails that did not exist on the ground were added to the inventory, and others that do exist were not included. In general, it appears that maintenance levels in the 1987 Inyo N.F. inventory were designated at higher levels than exist on the ground, while in the 2001 Wilderness Plan, trails generally seemed to be designated at lower levels.

Both of these inventories were developed prior to the Wilderness Plan, which defined desired conditions for all areas through recreation categories. Recreation categories were therefore not considered when developing the inventories. The 2001 Wilderness Plan directed that recreation category should be one consideration when developing trail classes and maintenance levels. Recreation Category is only one of the various factors considered in trail management decisions, and any trail class could potentially be found in any recreation category. While there will always be some acceptable exceptions, in general, higher development trails (TC3) should be relatively uncommon in primitive (RC1) areas. Likewise, very low development trails (TC1) should be relatively uncommon in high use areas (RC3).

Table 4.4. Alternative 1 system trails summary

SYSTEM TRAILS SUMMARY AA/JM Wilderness Totals	Alt. 1
Total System Miles	964.3
TC1	227.6
TC2	170.7
TC3	416
TC4	150.3

This alternative has the most inaccurate inventory information and the least amount of consistency with both the current conditions on the ground and with the intended management of wilderness destinations. The effects of implementing potentially inaccurate trail service levels are either excessive expenditure of resources on trails that would not otherwise need a high level of development and maintenance or, conversely, inadequate development of trails which have very heavy use and/or resource demands exceeding the trail level designation.

In this alternative, there appears to be an oversight of approximately 50 miles of trail that have formerly been managed as part of the trail system but not included in this inventory. While this would not prohibit public use on the trails, they technically would not be maintained or managed as system trails under this alternative, and would likely degrade. The trails could become impractical for use by stock, and would likely have increasing effects on the resources in the trail corridor.

In some cases, no trail exists on the ground where a trail is shown in this inventory. Implementing this alternative would technically call for the construction of new trails where no existing path or only a poorly defined use trail exists on the ground, at the management level described in this inventory. Approximately 35 miles of such trail would need to be constructed to implement this inventory, including some sections that are currently rough mountaineering routes through rocky cols. Nearly half of these trails would be built at Level 2 and 3. This

conflicts with the 2001 Wilderness Plan direction, which states that no new trails will be constructed in the planning area. It also would have various unpredictable effects on new areas that these trails would provide access to, in addition to the site-specific disturbance of resources in the immediate vicinity of the trail footprint. When site-specific NEPA is completed for constructing each trail, they would likely not be approved for implementation, due to these substantial conflicts.

In Alternative 1, nearly 70 miles of Level 3 trail accesses Recreation Category 1 (primitive) destinations, indicating a disparity between trail management and intended area management. The effect is that the designated system, if fully implemented, would be incongruent with other management direction of the areas. Certain areas managed in a very primitive manner would be accessed by very highly developed trails, which would be out of place with the general character of these wilderness destinations and with the demands of wilderness visitors.

Table 4.5: Alternative 1 system trail summary by recreation category

Alternative 1 Maint. Level by Rec. Category	TC1	TC2	TC3	TC4	Total System
RC1	91	40	68	0	199
RC2	136	123	288	69	616
RC3	0	8	60	81	149
Total	227	171	416	150	964

This alternative shows over 15 percent of the system managed at Level 4, which is described in the Service Level definitions as an “exception in wilderness.” More than half of the remaining system is maintained at Level 3, which is most appropriate for high-use corridor trails. This alternative also has a large number of Class 1 trails (227 miles), and is tied with Alternative 5 for the highest number of TC1 trails in Recreation Category 2. While these discrepancies do not follow a consistent trend, it is obvious that there is vast inconsistency with direction for desired conditions as defined in the 2001 Wilderness Plan. If implemented, these trail development levels would be inconsistent with the destination management of the areas and would likely directly affect the wilderness character of the destinations. The extent of the inconsistencies would effectively render the trail plan meaningless. Table 4.5 summarizes the system mile breakdown by maintenance/service level and how these align with the destination recreation categories for Alternative 1.

Compared to the current development levels that actually exist on the ground, the trail classes described in this alternative have the least consistency – with only 46 percent of the trails generally consistent to current field conditions. This alternative has the most trails designated with trail classes higher than what is currently on the ground – 43 percent of the system. Implementing this alternative to the standards described in this alternative is exceedingly unlikely, since many of the trails appear to be designated at high levels. As stated above, funding for both forests has been generally inadequate to maintain all system trails to a stable standard under existing uses, and funding is expected to continue a gradual decline.

Even if funding were available at this level, developing trails to this level would be out of character with the desired conditions of the destinations, and would be highly impractical – especially for the relatively low anticipated levels of use.

Table 4.6. Alternative 1 trail class comparisons

Alternative 1 Trail Class Compared to Field-Observed level of Development	Miles
Miles of trail designated LOWER than existing development	103
Miles of trail designated HIGHER than existing development	412
Miles of trail designated CONSISTENT with existing development	449

There is a substantial discrepancy in the distribution of trail management levels between forests in this alternative, in part due to the different inventories that the forests used, and the slightly different definitions of “Trail Maintenance Level” for the 1987 inventory and “Service Level” in the 2001 Wilderness Plan. Different interpretations of both systems may have also added to this discrepancy. In general, it appears that maintenance levels in the 1987 Inyo inventory were designated at higher levels than exist on the ground, while in the 2001 Wilderness Plan inventory, trails generally seemed designated at lower levels for trails with similar characteristics. Since use levels on trails on the Sierra National Forest are somewhat lower, there is some basis for lower management levels, but not to the extent shown on the inventories. The two opposite variances tend to balance each other out when combined. The following tables compare the trail management level distribution between the two forests.

Table 4.7: Trail management level distribution between the Inyo and Sierra National Forests

INYO NF Maintenance Level Summary	Miles	Percent of system	SIERRA NF Service Level Summary	Miles	Percent of system
ML1	31	7%	SL1	196	37%
ML2	69	16%	SL2	102	19%
ML3	211	49%	SL3	204	39%
ML4	123	28%	SL4	27	5%
Total	434		Total	529	

Under this alternative, commercial operators are limited to traveling on system trails and on use trails that were approved during the most recent annual use trail approval process in 2004. There is no formal mechanism for designating trails as “Not Suitable for Commercial Stock” (NSCS) or “Not Recommended for [private] Stock” (NRFS), so all system trails in this unit are technically available to commercial stock, except where specifically addressed in operating plans. Roughly nine miles of system trails are specifically closed to commercial stock in their operating plans because of known conflicts with resource or destination conditions, and the rest of the system would be open.

Since operators are only limited by trailhead quotas and an overall service day cap, there are no controls on the frequency that the trail gets used by commercial stock. In some cases, this may result in commercial stock using trails that were not adequately designed for the level of recurring use. As noted in “Common to All,” the effects on these trails will likely be continuing degraded trail and resource condition. Since there are no caps at specific destinations, the extent

of effects would be limited only by the demand of clients to visit certain destinations, and whether the resulting level of use exceeds each trail's capacity.

Since 2001, the determination of what constituted a “system” trail used by commercial operators as compared to a “use” trail requiring approval prior to use, was based upon the system inventory included in the 2001 Wilderness Plan, which during the annual approval process was used as the baseline reference inventory. Commercial operators requested specific use trails to access areas where no system trail provides similar access. Under this alternative, use trails could be approved or prohibited annually. Because the approval process would occur annually, it is also possible that use trails that are currently approved could be prohibited in the future based on new information, or additional trails could be approved. This alternative provides the least long-term predictability of user trail approvals and prohibitions.

The lack of destination controls at each destination accessed by use trails means that in many cases, use trails could receive unpredictable use levels that are beyond the capability of the use trails. Though the extent of these situations is hard to predict, if use did increase on such trails, there is a high chance that impacts to resources in the trail corridor would increase. Due to this unpredictability, this alternative has potential for increased effects from use trails or the potential for barely defined routes to become more defined.

There are 202 use trails addressed in this alternative. All or part of six of these assumed use trails were technically system trails in the inventories for this alternative, so they are shown separately. Those trails are automatically approved because they are technically system trails, but are discussed here for comparison purposes because they will be use trails in one or more other alternatives (see Table 4.8 for a summary of the Use Trails in Alternative 1).

Table 4.8: Alternative 1 use trail summary

USE TRAILS Summary Alternative 1	Use Trails	Est. Miles
Use Trails/Miles Addressed	202	209
Approved Trails/Miles	102	99
Prohibited Trails/Miles	94	102
System in this Alternative	6	8

See Table 2.27 in Chapter 2 for the specific use trails approved in each alternative.

Additionally, based on court ordered direction, operators have approval to use non-system access paths to campsites or grazing areas that are within ¼ mile of system trails. Due to the short lengths and relatively dispersed low use that this type of trail receives, the effects of each specific use trail are likely to be of relatively limited extent and intensity. However, this alternative allows for expansion of the total number of these use trails.

In this alternative, sanding of trails to melt snowdrifts—generally to allow earlier access over passes—is allowed on a case-by-case basis approval in annual operating plans. The number of trails potentially affected by these approvals varies annually, depending on the snow pack and the rate at which natural melt clears the trails. In recent low-snow years, there has been no need or requests for sanding.

Annual and Backlog Maintenance costs – Alternative 1

Fully maintaining trails to standard in this alternative is estimated to cost just over \$500,000 per year. This assumes simply performing maintenance that would keep trails at their designated level, once the trail is at that level. Since the Forests are currently spending approximately \$170,000 a year on AA/JM trails, this leaves an annual maintenance deficit of nearly \$340,000 – the highest deferral of annual maintenance work of all the alternatives.

Table 4.9. Alternative 1 annual and backlog maintenance costs

Trail Annual Maintenance Costs AA/JM Wildernesses	Alt. 1
Total Estimated Cost	\$ 509,355
Current Annual Funding	\$ 170,000
Annual Maintenance Shortfall	\$ 339,355
Current Backlog (Repairs to Standard)	
Estimated Current Backlog	\$12,411,600.00

This alternative also shows the highest deferred maintenance and repair deficit – over 12 million dollars. This appears to be due to the high number of trails designated at Levels 3 and 4, as well as having the highest number of trails available to recurring commercial stock use. If implemented as shown in the Alternative 1 inventory, many trails would need to be upgraded from current field conditions to meet an exceedingly high standard. It would be expensive and physically impractical to bring trails from their current development levels and condition to the standards shown in the Alternative 1 inventory.

In addition to trail infrastructure maintenance and repair costs, repairing and stabilizing trail related effects on resources in the trail corridor is estimated to cost between 3 million and 4 million dollars.

Table 4.10. Summary of alternative 1 trail system by geographic unit

	Total system Alt 1	TC1	TC2	TC3	TC4	NRFS (Not Rec. for Private Stock)
AAEA	137.8	2.7	23.1	77.1	34.8

TOTAL	964.2	227.6	170.6	415.5	150.4	na

Cumulative Impacts

Other past, present, and future actions, which may have an incremental or added effect when combined with trail-related actions in this alternative, include:

- Funding levels for maintenance and repair.
- Trail maintenance activities and reconstruction projects.
- Unclear past management direction for the wilderness transportation system.
- Management activities of adjacent or cooperating agencies.
- Recreational activities along the borders of these wilderness areas.
- Various different trail user types and levels.

Annual Maintenance and Funding: Annual maintenance, when performed, keeps trails stable by ensuring that drainage structures are cleaned and functional, tread structures are maintained to prevent loss of soil, and trail structures are stabilized before failure. Most important, the timely removal of obstacles and awkward sections that are out of character with the trail standard, keeps the trail in a readily travelable and appropriately comfortable condition so trail users will stay on the trail instead of bypassing it. Over time, the effect of not performing any part of this maintenance is a gradual loss of trail infrastructure and likely impacts to resources in the trail corridor. When obstacles block passage to trail users, typically trail users form a parallel, bypass trail. Since these bypasses are not designed, they can have major localized effects – especially in areas with high use combined with high risk factors, such as steepness, loose soils, riparian or hydrologic connectivity. Generally, less maintenance performed, especially over the long-term, results in a less stable trail and higher effects on resources in the trail corridor.

Poor trail alignment and inadequate development, combined with moderate risk factors has led to long-term off-trail impacts, incision, headcutting and meadow damage on this primary system trail

Past and current funding levels are inadequate to maintain all trails to standard. This means that fewer Forest Service personnel and/or contractors are performing annual maintenance and incidental repairs on system trails. The effect of this is that many trails have become degraded to the point that they are either unstable under existing uses or are not fully serving their intended purpose. Reduced budgets will likely result in the need to either perform less maintenance on all trails, or increase the numbers of trails that receive greatly substandard levels of maintenance in order to allow continued maintenance on the highest use trails. This long-term funding deficit will have continued effects, since even a fully-funded maintenance program would not be able to immediately correct all of the trail problems and resource impacts.

Low funding levels combined with the actions in this alternative and the highly inconsistent management levels in the “No Action Alternative” inventory (described below), create an

unmanageable and unmaintainable system with no effective way to prioritize the extremely limited funds. At the wilderness scale, the effect of substandard maintenance is low to moderate. There will likely be some localized severe impacts that are exacerbated by the unrealistically high and low trail class designations in the Alternative 1 trail inventory.

Reconstruction: Trail reconstruction and stabilization efforts have been implemented on various trails in these wilderness areas in the past. In general, these have mostly occurred on primary trails, and have restored the trails to their original standard. Spur trails associated with those reconstructed trails were typically also repaired. Generally, once a trail has been reconstructed, maintenance needs on that trail are somewhat reduced for roughly the next decade or more. Since the repair and addition of drainage structures and other tread retention structures ensure a higher level of stability, these trails generally have a lower direct impact to resources in the immediate trail corridor. Historically, 20-30 miles of trail (or approximately 2-3 percent of the system) are reconstructed annually. In the past decade, this has occurred at a greater rate on the Inyo NF than on the Sierra NF.

Funding for recurring maintenance and major reconstruction efforts has been decreasing during the past decade and will likely continue to gradually decline, resulting in a large number of trails that receive very low maintenance. This has caused, and will likely continue, a loss of trail infrastructure, more substandard conditions, and resource impacts to resources within the trail corridor. Reductions in opportunities for large-scale repairs have resulted in an increasing backlog of repair “deferred maintenance”. It is not expected that funding will increase during the next decade, and it is more likely that it will continue to decline.

Trail reconstruction is currently occurring on a number of trails on the Inyo National Forest. They include completing reconstruction of the Bishop Pass Trail and the Pine Creek Pass Trail. The Pacific Crest Trail from Agnew Meadows to Donohue Pass is also slated for reconstruction work in summer 2006 and 2007. The McGee Pass Trail (and the associated spur trails from it) will be submitted for funding with implementation expected within the next 3-5 years. No large-scale reconstruction projects are expected to be funded on the Sierra NF trails in these wildernesses during the next three years. Other smaller-scale repair and rehabilitation efforts will occur on a variety of system and use trails as funding opportunities become available.

The effects on the trail system on the Sierra NF are expected to be moderate to major substandard conditions on the trail system, with localized major impacts to trail users and resources, until and unless additional funding allows for extensive repairs. Since trails on the Inyo NF have had more recent reconstruction activities, the effects on the Inyo of reduced reconstruction budgets will not have an immediately noticeable effect on most trails. Over the long term, if budget trends continue, eventually minor to moderate effects on trail condition and associated resource condition will expand, with potential severe effects at certain localized areas on trails.

Combined with the inaccurate inventories and lack of specific transportation system direction (described below), the potential effects of implementing Alternative 1 when reconstructing the McGee Pass Trail and the associated spur trails would be that McGee Pass trail would be upgraded to an exceedingly high development level (TC4), and most of the short, lower-use spurs would be constructed to Trail Class 3 – a level usually reserved for high use corridors. Since McGee Pass Trail is in a Recreation Category 2 and receives moderate use over its 14-mile

wilderness length, the direction in the Alternative 1 inventory would clearly conflict with the desired condition of the wilderness area and the demands of the trail use.

Unclear Past Management Direction for the Wilderness Transportation System: Past and current inventories on both forests are incongruent with existing trail development, in some cases were out of line with the realities of on-the-ground management, and (until the 2001 Wilderness Plan) there were no site-specific desired conditions for trail destinations in these wilderness areas. Because of this, the inventory was given very little credence, and it became generally meaningless. Managers have intuitively maintained and repaired the trail system, based on their subjective assessment of trail uses and demands. In many cases, these assessments have been on target, and management of the trail system has been well balanced with wilderness character and trails are stable under the recurring uses. In other cases, trails have either been over developed and maintained compared to the recreational demands, or have been inadequately managed for the uses, resulting in unstable trails.

The effect is a high level of inconsistency with existing (2001) desired conditions in wilderness areas, and localized moderate to major trail instability where trail demands exceed trail capability. Without an accurate inventory, expenditure of funds is potentially inefficient, with excessive funds spent on trails that are barely utilized, while heavily used trails in high-use areas may be under-funded. Under this alternative, the potential for such inconsistency remains and, if implemented, would continue to lead to locally major conflicts with wilderness recreation Category standards and available trail funding.

Unclear and inaccurate past and current inventories have also resulted in confusion for wilderness visitors and unrealistic expectations for their travel experience. While this is mostly an experiential impact, there are related effects on resources and trails when multiple visitors attempt to access an area with no actual trail after seeing a trail on a map. Additionally, under this alternative, trails are not yet designated as “Not Recommended for [private] Stock,” so it is likely that equestrian visitors may unknowingly attempt to access trails with exceedingly difficult obstacles and backtrack before attaining a destination. This has potential to create multiple trailing and off-trail impacts, as well as excessive use of a low-development trail, which may lead to localized moderate or major resource impacts.

Actions of Other Agencies: Decisions by other agencies may also have effects on trails in these wilderness areas. The California Department of Fish and Game anticipates changes in managing fish stocking at some lakes served by system trails – potentially removing fish from some lakes, and enhancing fisheries at other lakes. Past actions have changed the quantity of trail users, both commercially served and private, on individual trails.

In some trails, future actions would likely mean a change in use by those interested in fishing activities. Some trails would receive fewer stock and hikers, while others would see a slight increase. Over the short term, a reduction in total users on a trail would likely lead to a moderate increase in trail stability, and slightly less required maintenance. Over time, depending on the continuing use levels and trail-specific considerations, it may lead to a future determination that the trail class could be reduced and still meet the needs for stability and area desired conditions. Other destinations may see an increase in hiker and stock use, which could likely have minor to moderate increase in effects on a few localized trails. This may require the need for greater maintenance expenditures and over the long term may require a higher trail maintenance and development level.

The extent and severity of impacts related to potential Department of Fish and Game actions is highly dependent upon many currently unknown factors, and borders on the speculative. Most likely, the effects would not be immediately noticeable and would be minor at both the wilderness and local scale.

Many trails on the two Forests lead into National Park Service (NPS) lands, connecting with trails administered by that agency. In Alternative 1, little if any consideration was given to the existing or desired conditions at the destinations on NPS lands. This has led to a high level of inconsistency and, in some cases conflict with management with the national parks. Implementing Alternative 1 would perpetuate these conditions, which will likely have a minor effect regionally, with incidental moderate effects at specific destinations.

The NPS has not instituted a similar trail classification system to that used by the USFS, so there is not a direct comparison; but generally, trails in this alternative appear designated at levels higher than on the NPS side of boundaries. This is most evident in cases such as the PCT, which traverses through Kings Canyon National Park, Sierra National Forest, Inyo National Forest, Devils Postpile Monument, and Yosemite National Park. The PCT is designated Trail Class 4 in this alternative, which if implemented, would be highly inconsistent with the way the trail is managed in the National Parks. Other trails leading to the park would be developed at high levels in this alternative, including trails in Sierra Nevada Bighorn habitat.

Future management decisions on the National Parks could have effects on the development levels of system trails or commercial activities on the Inyo and Sierra National Forest, though these are unknown, and describing potential effects would be merely speculative.

Other Uses – Past, Current, and Anticipated: Past trail uses in these wilderness areas include access to mining operations, logging, sheep grazing, and other high intensity recreational services, such as boat services. Mining and logging activities often required substantial trail infrastructure – either as motorized roads or wide trails that could accommodate heavily laden wheeled vehicles or draft animals. Some of these operations had substantial numbers of workers and needs for equipment, requiring long, developed access trails.

As these activities declined, some roads and trails no longer received use – or at only an inconsequential level compared to the original purpose of the route. Mining roads on steep mountain sides, which once saw hundreds of workers every day, may only see a handful of curious recreationists each year. In many cases, these routes have not been on forest transportation inventories, and have not received maintenance since the original activity ceased. Some remain on forest inventories, including the inventory for this alternative, though they may have received very little maintenance, unless use demand appeared to be high.

Most of these trails/roads that no longer receive their original use have naturalized to varying degrees, and in most cases are not currently affecting resources. However, some of these abandoned routes continue to channel water, causing locally moderate to severe impacts to riparian and aquatic habitat. In this alternative, there are no restrictions on commercial operators if such trails if they are on the system inventory. Continued or new use of these unmaintained routes has potential to cause moderate to major localized effects.

In addition to commercial operations, an average of 700 private equestrian visitors to these wilderness areas use approximately 1100 private pack and saddle animals annually. This constitutes about 13 percent of total equestrian use. The majority of this private equestrian use is

on the west side of the sierra crest, on the Sierra NF. Additionally, there are between 60,000 and 70,000 overnight backpackers and hikers who use the same trail system annually. In general, the use is concentrated in the same areas, so in most cases it is nearly impossible to attribute the various effects on system and use trails to one type of activity or user group.

On trails and use trails where there is no (or very limited) evidence of commercial use, the effect from non-commercial use is dependent on local conditions and intensity of use, but can be substantial. Since non-commercial equestrians and hikers are not restricted to system trails, there are an exceedingly high number and mileage of user-created trails throughout these wildernesses with impacts ranging from negligible to severe. This is most evident on user-created trails in the immediate vicinity of stream banks and lakeshores – most commonly caused by anglers or hikers accessing camps. These effects are additive and in some cases may exceed the effects of commercial pack stock use in the same areas. Because of the proximity to riparian and aquatic habitat and other risk factors, these unrestricted use trails have potential to cause moderate to severe localized impacts.

Non-commercial equestrian and hiker use constitutes the vast majority of trail use. The physical effects on trails from hiker use and the very limited non-commercial equestrian use are generally minor, with occasional moderate to severe localized impacts, especially at stream crossings, where hikers often attempt to find “dry crossings,” creating use trails and bank damage on both sides of a creek. At the wilderness scale, the effects on the trail system and associated resources are minor, with localized major impacts.

Alternative 2 – Modified

Summary of Impacts – Alternative 2 – Modified

In general, the primary consequences from trail-related actions in this alternative would be a net improvement in the trail system and on the associated resources in the trail corridor and improved consistency between trail and area management. These benefits will be primarily evident in the following ways.

Trail management and desired area management are most closely aligned, with few anomalies between trail classes and desired conditions. For example, less than 1 percent of the total system is designated TC4 in this alternative and only four miles of TC3 trail access the most primitive (Recreation Category 1) areas. This will result in reduced potential trail conflicts with wilderness character.

Trail classes are closely aligned with current observed trail development levels. This will have beneficial effects by avoiding the need to upgrade many trails, unless there is an overarching benefit to do so. It also prevents the gradual loss of infrastructure that could lead to resource impacts if use continues at current levels.

Trail system management shows a very high level of consistency between the two managing forests.

Internal controls using the “destination management” concept ensures a high level of predictability of use types and numbers. Trail development will likely be very consistent with anticipated use and on-the-ground conditions, resulting in greater trail stability and reduced physical resource impacts.

Commercial stock is prohibited from approximately 10 percent of system trails, which were determined unstable with even low levels of recurring stock use, ensuring that the majority of stock use is limited to trails most capable of remaining stable under anticipated use. Reduced maintenance costs on these trails allows for more efficient distribution of trail maintenance and reconstruction funds and more stable conditions on other system trails.

This alternative allows for stabilizing nine miles of NSCS trail, then allowing future commercial use. This provides added flexibility for commercial operators to access areas, once resource and trail stability issues are corrected.

Commercial stock is limited to use trails that have relatively few risk factors and a high likelihood of continued stability. Highly dispersed undefined routes are approved for very limited use with temporal controls. In this alternative, anticipated use is highly predictable, and these use trails should remain stable or even improve slightly under the prescribed use levels.

Limiting commercial stock access over snow-drifted passes until the destination system and use trails are ready for such use will have moderate beneficial effects to these destination trails and resources.

Over the short term, this alternative will have negligible to minor localized and regional beneficial impacts, by reducing one of the contributing sources of adverse effects on the most susceptible trails. Physical trail and resource stability will not likely improve substantially during the short term, but will improve over the long term as physical treatments and/or natural recovery occurs. Over the long term, it is expected that there will be minor beneficial effects at the wilderness scale, with moderate to beneficial effects to resources and trails at the local level. There will likely be some minor reduction in user conflicts at remote destinations.

Analysis

In this alternative, as directed by the 2001 Wilderness Plan, a system of trails would be designated considering the desired conditions of destinations within the wilderness areas. Trail management levels and other trail management decisions must also consider the anticipated use types and levels on each trail, to provide a trail system that meets the transportation needs of wilderness visitors while limiting the effects on resources from the trail system.

The key difference affecting trails in Alternatives 2 – Modified and 2 compared to other alternatives is that commercial operators are limited by quotas and other specific management guidance at destinations. In this alternative, there is a very high level of predictability in anticipating use types and levels. This makes it easier for the Forests to designate appropriate trail management levels to ensure that trails are capable of stably handling commercial stock use at the predetermined level, in addition to anticipated private stock and hiker use. This will have long-term beneficial effects in aligning trail management with more predictable levels and types of use.

Trail Classes

In this alternative (and in the other action alternatives), management guidelines and trail class descriptions specific to the Ansel Adams and John Muir Wilderness trails are incorporated to clarify how the Forests intend to manage each trail. These are intended to mirror national standards so that conceptually the characteristics and costs associated with each trail are consistent with other forests. Implementing this guidance should allow expectations that are

more consistent for managers, work crews, and trail users, and lead to a more consistently managed system over the long term.

Table 4.11. Alternative 2 – Modified system trail summary

TRAIL CLASS SUMMARY AA/JM Wilderness	Number of miles
Total System Miles	977.1
TC1	166.5
TC2	410.9
TC3	391.9
TC4	7.8

The Pacific Crest National Scenic Trail (PCT) is one of very few trails in the planning area that has been designated as Trail Class 4 (or “Maintenance Level 4”) in past inventories. In this alternative, the PCT has been adjusted to TC3 to match recreation categories and wilderness direction – as well as to align its development more closely to what exists on the ground. This will have no effect on the trail infrastructure and physical resources, since the current definition of Trail Class 3 matches well with the existing and past management and development of the PCT on both Forests. Because the PCT is a high-profile and popular trail, it will continue to be a high priority for maintenance, and will continue to be cleared and maintained as early in the use season as is practical.

The eight miles of Mt. Whitney Trail on the Inyo National Forest is designated TC4 in this alternative. Due to the extremely high levels of use, the massive level of development and frequency of maintenance needed to keep a stable trail in place in the severe terrain and climate of the Mt. Whitney area, the trail is currently managed consistently with the definition of a Trail Class 4, so there would be no physical change from current management under this alternative.

Table 4.12 compares Alternative 1 and 2 – Modified in terms of system trail actions. Compared to the no action trail system, there is a total addition of roughly 10 miles of trail to the system inventory. About 48 miles of trail were added to the system inventory and 38 miles of trail were deleted. Additionally, adjustments in trail management levels were made, resulting in 135 miles of trail having an increase in designated trail class, and 241 miles of trail receiving decreased trail class. Since this was intended to match conditions on the ground with recreation categories and anticipated commercial and private use levels, it is expected that the overall effect will be a more stable system where use is present. There could also be reduced costs where unnecessary trails were removed from the system or where management levels are reduced to match anticipated use.

Table 4.12: System trail actions comparison of Alternative 1 and 2 - Modified

ACTION SUMMARY Compared to Alternative 1 (No Action)	Miles
Added	48
Deleted	38
TC Down	355
No Change	442
TC Up	136

See Table 2.26 in Chapter 2 for specific actions on each trail by alternative.

Given the regional differences in terrain and use levels, this alternative shows the highest consistency in trail class distribution between forests. In this alternative, both forests use the same trail class definitions and a more consistent interpretation of classes in determining management levels. Additionally, recreation categories and use levels were considered, so a consistent distribution of trail classes is evident in the Alternative 2 – Modified trail inventory. Since trail use levels on the Sierra National Forest are somewhat lower, there is some basis for slight differences in trail management levels between forests. Alternative 2 – Modified demonstrates a much higher level of consistency in the spread of trail class designations across the wilderness areas between forests as compared to the substantial differences in Alternative 1. Table 4.13 compares system trails on the Inyo and Sierra National Forests.

Table 4.13: Alternative 2 - Modified Inyo and Sierra N.F. trail class comparison

INYO NF Trail Class Summary	Miles	Percent of system	SIERRA NF Trail Class Summary	Miles	Percent of system
TC1	61	14%	TC1	105	19%
TC2	149	35%	TC2	262	48%

TC4	8	2%	TC4	0	0%
Total	426		Total	551	

In this alternative, the trail plan responds to the 2001 Wilderness Plan by designating a system of trails consistent with the desired conditions of the wilderness area, as defined by recreation categories. This alternative takes into consideration the anticipated level of commercial and private equestrian and hiker use, as well as the recreation category of destinations when designating trail classes. The goal of this alternative is to provide a system of trails that is generally stable for the anticipated use, without exceeding the desired condition of the wilderness area. In this alternative, only 4.3 miles of TC3 trail provide access to Recreation Category 1 areas and this is a “through-trail” (CA Riding and Hiking Trail), which continues on to other higher use areas. See Table 2.26 for a detailed listing of individual trail information.

Table 4.14. Alternative 2 – Modified trail class summary

Alternative 2 Modified	TC1	TC2	TC3	TC4	Total Miles in RC
RC1	85	111	4	0	200
RC2	80	285	257	0	622
RC3	1	15	130	8	154
Total	166	411	391	8	976

In this alternative, as in Alternatives 3, 4 and 5, a small number of recreation categories are adjusted to reflect the characteristics and intended management of the destinations. This better aligns the recreation categories to social and desired management conditions, including trail development and anticipated use types and levels. The effect of this will be more consistent alignment of management, and generally more stable trails that are responsive to the use types and levels at destinations. There is less likelihood that the trail system will either be inadequately developed or developed beyond the needs and character of the destinations. This alternative has the fewest anomalies of relationship between development levels and destination recreation categories. Over the long term, this will have a beneficial effect on the trail infrastructure and the associated resources, as well as wilderness character.

One consideration in designating trail classes for each trail is its current observed level of development on the ground. This is important for a number of reasons. First, considering limited maintenance funds, it is important that trails are not upgraded above their current levels unless there is a clear management need and resource benefit to increasing the development level in order to provide a stable trail under anticipated uses and terrain conditions. Secondly, the current level of development gives a good initial indication of how much development is needed for the existing trail demands. If trails appear to be stable under current use levels, and no dramatic changes in anticipated future levels are expected, then there is not likely a need to adjust trail classes from the observed development level. Since trails have been intuitively maintained and repaired by trail managers in response to perceived trail use and demands, there is a reasonable assumption that this level of development has some historical basis. Downgrading trails below their current observed development is prudent only if it is clear that the new (lower) development and maintenance level will not lead to degraded trail or resource conditions under the anticipated use.

Table 4.15. Alternative 2 – Modified trail class comparisons

Alternative 2 Modified - Trail Class compared to observed level of Development	Miles
Miles of trail designated LOWER than existing development	32
Miles of trail designated HIGHER than existing development	72
Miles of trail designated CONSISTENT with existing development	872

As shown in Table 4.15, comparing observed trail development with classes designated in this inventory, Alternative 2 – Modified has the greatest consistency with what is currently on the ground. The effect of this should be the least amount of change to the existing system, and the least need for structural improvement on trails.

Suitability

In this alternative, the term “Not Recommended for Stock” (NRFS), which was intended in the 2001 Wilderness Plan to both provide an advisory to private stock and to prohibit commercial stock use, has been changed to “Not Suitable for Commercial Stock” (NSCS). Trails designated NSCS in this alternative are driven by resource or destination limitations and/or risk factors along the trail.

Table 4.16: Alternative 2 – Modified, trail suitability summary

SYSTEM TRAILS SUITABILITY - Wilderness Totals	Alt. 2 Modified
Total System Miles	977.1
Not Suitable for Comm. Stock	*89.3
NSCS until repaired	9.2
Available to Comm. Stock	878.6
Percent of System Available to commercial stock	90%
*Includes 16.4 mi Whitney Area Closures	

Table 4.16 summarizes the system trails available to commercial stock in Alternative 2 – Modified. In this alternative, there will be roughly 977 miles of system trails in the two wildernesses, of which approximately 98 miles (or 10 percent) would be considered unsuitable for commercial stock. This means that approximately 880 miles of system trail would be accessible to commercial operators. Approximately 88 percent of the trails approved for commercial stock are Trail Class 2, 3, and 4, which should generally be managed to handle relatively high levels of recurring stock use. The remaining 12 percent TC1 trails with commercial stock present generally serve areas where very low quotas have been established. These low-development trails are expected to remain stable under these low levels of use.

By designating which system and use trails commercial operators can use, the vast majority of equestrian use will be limited to trails which are the most stable under stock use, and that require relatively low investment of maintenance resources. Most of these trails may also have some localized sections that are substandard, but are generally due to lack of maintenance rather than the trail’s designated class or design standards, so there would be no reason to adjust the current trail classes for the trails. Removing 89 miles of trail from recurring commercial stock use and

restricting the use from nine miles of trail until it is stabilized will reduce the potential for resource damage caused by stock using trails inadequately designed for such use. In turn, this may free up maintenance funds for other trails with heavier stock and hiker use, with the beneficial effect of stabilizing higher priority trails.

Destination controls on commercial operations will help ensure that recurring equestrian use will generally be on those trails that are sufficiently designed and managed to handle this type and level of use without excessive impacts to the trail system and to surrounding resources. Some system and use trails in the planning area are capable of handling only limited amounts of stock use, and corresponding destination quotas in this alternative will help ensure that each trail's capability will not be exceeded. In some cases, this has allowed certain trails to remain available to stock that would have otherwise likely been designated as NSCS. This also has a beneficial effect on the operators, who are able to access certain destinations (albeit at limited levels), which may otherwise have been unavailable to them.

Many trails, which may have conditions that are purely awkward or potentially risky for stock but which are not likely to cause substantial resource impacts, are still available to commercial stock in this alternative. Most of these trails are low-development (TC1) trails with minimal commercial or private equestrian use. Since commercial operators have familiarity with the trail system and likely have high skill levels and knowledge of the capability of stock and clients, decisions to utilize these trails would be based on the judgment of the operator. It is anticipated that use will remain low on these trails, so the effects to physical resources and wilderness character would be negligible.

In this alternative, trails will not be specifically designated as Not Recommended for [private] Stock, since this is purely an advisory to private equestrians that may not be familiar with trail conditions that are potentially impractical to stock on a particular trail. These advisories are considered an administrative action and, in the future, will be applied as needed either to trails that are permanently or temporarily in a condition which would be exceedingly difficult or risky for equestrian travel.

Use Trails

This alternative specifically addressed 202 use trails, totaling roughly 209 miles, (see Table 4.17). Based on either limiting factors of the use trails themselves or the destinations they accessed, 86 use trails totaling 81 miles were prohibited. There were 107 use trails, totaling about 111 miles, approved. Nine trails that were previously managed as use trails would be all or in part on the Alternative 2 – Modified trail inventory, so their use by commercial operators would be addressed as system trails in this alternative.

In this alternative, the ability to restrict commercial stock to low use levels to destinations through quotas has allowed for a number of use trails to be approved that can sustain only limited amounts of use. In other alternatives, these may have been closed completely. Most use trails approved in this alternative have relatively few risk factors, and are inherently stable. By keeping commercial stock off the most susceptible trails in this area and limiting use at destinations where trails can only sustain limited use, resource effects would be substantially reduced.

Table 4.17: Alternative 2 use trails summary

USE TRAILS Summary Alternative 2 - Modified	Use Trails	Est. Miles
Use Trails/Miles Addressed	202	209
Approved Trails/Miles	107	111
Prohibited Trails/Miles	86	81
System in this Alternative	9	17

See Table 2.27 in Chapter 2 for the specific use trails approved in each alternative.

Additionally, in this alternative operators have implicit approval to use non-system access routes to designated campsites or grazing areas or spot and dunnage sites which are within a reasonable travel distance (generally <1/4 mile) of system trails. Due to the short lengths and relatively dispersed low use that this type of trail receives, the effects are likely to be of a very limited extent and intensity.

Sanding – Early Season Access

In Alternative 2 – Modified, early season access over passes that would require sanding or shoveling snow will only be approved after a determination that trails, use trails, and other factors at the destination are capable of handling commercial stock parties without unacceptable impacts. This will have minor to moderate beneficial effects (as described in the general effects section) on trails beyond the passes and resources in the trail corridor and destination. Erosion will be reduced in trails that may otherwise have surface water flows, and use trails would likely remain more stable if soils are not saturated during early season use.

The need to shovel or sand snowdrifts will likely occur less than annually on typically fewer than four or five passes, and will depend upon seasonal snowfall and rate of snowmelt each season. The Piute Creek Trail and the area west of Piute Pass (primarily Golden Trout Lake) are the areas that are most affected by early-season access, and will see the greatest beneficial effect from delaying access until destination readiness.

Annual and Backlog Maintenance costs – Alternative 2 – Modified

Fully maintaining trails to standard in this alternative is estimated to cost approximately \$440,000 per year, assuming the trails were repaired so that annual maintenance would be effective. Since the Forests are currently spending approximately 170,000 dollars a year on AA/JM trails, this leaves an annual maintenance deficit of approximately \$270,000.

Table 4.18. Alternative 2 – Modified annual and backlog maintenance costs

Trail Annual Maintenance Costs	Alt. 2 - Mod
Total Estimated Cost	\$ 439,425
Current Annual Funding	\$ 170,000
Annual Maintenance Shortfall	\$ 269,425
Current Backlog (Repairs to Standard)	
Estimated Current Backlog	\$8,414,860.00

Though this shortfall is smaller than most other alternatives, it still means that the trail system cannot be fully maintained at standard using just the available forest funding. Funding levels below those needed to fully maintain the trail system would lead to the need to defer basic maintenance and repairs on certain trails. Trail classes provide guidance in prioritizing trail maintenance activities and funding expenditures. In general, trails with a higher-class designation will receive earlier and more frequent maintenance work, assuming other factors are equal. With reduced budgets, lower level trails may receive only the most basic of maintenance, such as clearing the most substantial obstacles or safety concerns to keep the trail open, but not repair structures or clean drainage structures as frequently. Other factors that are considered in prioritizing trail repair are described in Chapter 2.

In this alternative, trails are most consistently aligned with their existing development levels, and have been assigned the minimum development level that would be expected to maintain a stable transportation system under anticipated use. The effect of this is a reduction in maintenance shortfall as compared to Alternatives 1, 2 and 3. More significant is the reduction in backlog repairs and reconstruction. In this alternative, repairing trails to standard is estimated to cost approximately \$4 million less than in Alternative 1.

Restricting recurring commercial pack stock from roughly 10 percent of the trail system slightly reduces the costs of both maintenance and reconstruction for these sections. The cost savings in this alternative (and others), however, are somewhat limited, since the trails closed to commercial stock are trails rarely used or lightly used by commercial operators currently. In addition, most of these trails are lower development trails – roughly half are TC1 and half are TC2 – which cost less to repair and maintain than the overall average.

In addition to trail infrastructure maintenance and repair costs, repairing and stabilizing trail related effects on resources in the trail corridor is estimated to cost between \$3 million and \$4 million – as in all other alternatives.

Table 4.19. Alternative 2 – Modified trail summary by geographic unit

	Total system miles – Alt 2 Modified	NSCS (Not Suitable for Comm Stock)	NSCS (until Repaired)	Avail to comm. stock	TC1	TC2	TC3	TC4

Cumulative Impacts: Alternative 2 – Modified

Other past, present, and future actions that may have an incremental or added effect when combined with trail-related actions in this alternative include:

- Funding levels for maintenance and repair.
- Trail maintenance activities and reconstruction projects.
- Unclear past management direction for the wilderness transportation system.
- Management activities of adjacent or cooperating agencies.
- Recreational activities along the borders of these wilderness areas.
- Various different trail user types and levels.

Annual Maintenance and Funding: The effects of historical maintenance performed and the past inadequate funding levels is the same in this alternative as in Alternative 1. This leaves both forests with a substantial backlog maintenance load, which would take substantial funding to repair (see description of reconstruction below).

The greatest difference in this alternative is that the future effects of low funding levels on the trail system and resources are substantially reduced. Removal of commercial stock from some trails, removing some unnecessary trails from the system, and bringing trail classes into better alignment with ground conditions reduces the need for maintenance, and could allow the deferral of maintenance work and funds to longer maintenance intervals with less effect on trail stability and resources. This beneficial effect is likely to be minor to moderate at the wilderness trail system scale, but may have major beneficial effects at the local level.

The relatively well-defined management objectives for trails will help to prioritize maintenance activities. Regardless of the level of future maintenance funding, this clearer description should make future expenditures more efficient and effective across the system.

Reconstruction: The effects of past and current reconstruction efforts and the gradually declining budgets for repairs and reconstruction are the same in this alternative as in Alternative 1. The general effect is that long-term deferrals of maintenance and repairs have led to trail and

resource instability that will require extensive investment. The declining funding for such work will make it more difficult to regain lost infrastructure and bring trails to standard.

Combined with the actions in this alternative, future repair and reconstruction efforts will have clearer design and management guidance than in the “No Action Alternative” scenario. The effect of this will be seen primarily in improved financial efficiency and reduced conflict with wilderness character. Trails will be repaired at the minimum necessary level to remain stable under anticipated use types and levels. Additionally, trails that will have no commercial stock (and likely minimal if any private stock) may be reconstructed with somewhat lower scale structure and remain adequately stable.

In the example of the planned reconstruction of the McGee Pass trail, the primary McGee Trail leading over the pass and to the PCT corridor will be reconstructed at the TC3 level, so that it can handle the high use – stock and hiker – in the difficult terrain. Spurs accessing side destinations, such as Baldwin Canyon, Steelhead Lake, Big McGee Lake, and Tully Lake will be repaired at the TC2 level, capable of handling anticipated moderate stock and hiker levels. The trail leading to Lee Lake, which will not have commercial stock present, will be realigned and repaired at a low TC1 level, which should remain sufficiently stable for anticipated low hiker use and only occasional private stock use. The Pacific Crest Trail, which will be repaired in 2006, will meet the TC3 standard.

The relatively well-defined management objectives for trails will help to prioritize reconstruction projects and provide a baseline for design for each project. Regardless of the level of future repair funding, this clearer description should make future expenditures more efficient and effective across the system. Over the long term, despite declining budgets, this will have a moderate beneficial effect across the system.

Unclear Past Management Direction for the Wilderness Transportation System: The effects of past inventories with unclear or incorrect direction are the same in this alternative as in Alternative 1. In general, the effect has been to make such direction mostly meaningless, and force trail managers on the forests to manage trails intuitively, with varied success.

As described in the maintenance and reconstruction sections above, this alternative defines clear direction for the trail system and individual trails. Over the long term, this will likely create a much greater level of consistency across the wilderness trail system. This should have minor to moderate beneficial effects at the trail system scale, and moderate benefits at the individual trail level.

Management Activities of Adjacent or Cooperating Agencies: The effects of past actions on or by adjacent or cooperating agencies, such as the Department of Fish and Game or Park Service are anticipated to be generally the same in this alternative as in Alternative 1.

In this alternative, trails that cross boundaries to contiguous trail systems on the NPS, have been aligned so that there should be a high level of consistency and negligible effects on trails and resources. In this alternative, the Pacific Crest Trail is designated Trail Class 3, which is consistent with its management by both agencies.

Future management decisions on the National Parks could have effects on the development levels of system trails or commercial activities on the Inyo and Sierra National Forest. These are unknown, and describing potential effects would be merely speculative.

Other Trail Uses – Past, Current, and Anticipated: The activities and effects of past, current, and future private hikers and equestrians on trails in these wilderness areas are the same as described in Alternative 1.

Regardless of any actions that restrict commercial pack stock operations on trails, the effects of hikers and private pack stock will continue at similar levels under existing controls. The types and levels of use that would continue to be accommodated under this alternative will continue to have minor to moderate effects at the wilderness trail system scale, and moderate to isolated severe effects at localized trails.

The actions of reducing or eliminating commercial stock use from certain remote trails may have minor short-term beneficial effects on the trail experience of hikers and/or those seeking a more primitive experience.

Non-wilderness Trails: This document does not designate a trail system outside of wilderness or determine commercial operations on trails outside of wilderness. It is expected that commercial operators will continue to access the wilderness areas using the current non-wilderness trail system. Where actions in this document reduce use – especially day use – within wilderness, commercial stock use will likely increase on non-wilderness trails, unless or until future controls are put into place.

These trails tend to be near pack stations and near trailheads, where both public and commercial use is already highly concentrated. Most trails in these areas are relatively well developed, in response to a long history of high use, so physical effects on the trails and resources are likely to be minor overall, but may be evident in the need to increase future maintenance efforts – especially on less-developed or non-system trails. There is also likelihood that further increases in day use in these already concentrated use areas may cause an increase in conflicts between stock and non-stock groups. The potential effects on the trails and associated resources would likely be minor to moderate at the forest scale, and would likely result in isolated locally moderate to major trail and resource impacts.

Alternative 2

Summary of Impacts – Alternative 2

In general, the primary consequence from trail-related actions in this alternative would be a net improvement in the trail system and on the associated resources in the trail corridor and improved congruency between trail and area management. These benefits will be primarily evident in the following ways.

Trail management and desired area management are closely aligned, resulting in reduced potential conflicts with wilderness character. For example, nine percent of the total system is designated TC4 in this alternative.

Trail system management shows greater inter-forest consistency. Internal controls allow for greater predictability of use types and numbers, so trail development will likely be very consistent with anticipated use and on-the-ground conditions, resulting in greater trail stability and reduced physical resource impacts.

Commercial stock is prohibited from eight percent of system trails, which were determined unstable with recurring stock use, ensuring that the majority of stock use is limited to trails most

capable of remaining stable under anticipated use. Private equestrians will be advised that these trails are not recommended for stock, resulting in improved visitor expectation and safety. Reduced maintenance costs on these trails allows for more efficient distribution of trail maintenance and reconstruction funds and more stable conditions on other system trails.

One trail would be approved for sanding in this alternative, ensuring relatively localized effects, and ensuring that there would be no expansion of these effects to other trails.

Commercial stock are limited to 100 use trails (102 miles), including some undefined (cross-country) routes, and use levels on each trail are limited by destination quotas. In this alternative, anticipated use is highly predictable, and these use trails should remain stable or improve slightly under these use levels.

Over the short term, this alternative will have minor localized and regional beneficial impacts, by reducing one of the contributing sources of adverse effects. Physical trail stability conditions will not likely improve substantially until the long term, as physical treatments and/or natural recovery occurs. Over the long term, the localized beneficial impacts will be moderate, as funding can be distributed across the system more effectively, and more trails are managed at stable levels. There should be some minor reduction in user conflicts at remote destinations.

Analysis

In this alternative, as directed by the 2001 Wilderness Plan, a system of trails would be designated considering the desired conditions of destinations within the wilderness areas.

Trail management levels and other trail management decisions must consider the anticipated use types and amounts on each trail, to provide a trail system that meets the transportation needs of wilderness visitors while limiting the effects on resources from the trail. In this alternative, the use levels of commercial operations on each trail, in addition to the anticipated use by private equestrian and hiker traffic, can be accurately predicted and considered in making trail management decisions, since quotas for each destination (and thereby each trail) will have limits set on use levels instead of just limiting use at trailheads. This will have long-term beneficial effects in aligning trail management with more predictable levels and types of use.

In the proposed action, trail classes are defined using the most recent draft version of National Trail Management Class definitions. These definitions are general and apply to all ground-based trails, with very little specific consideration of wilderness direction. In this alternative, a management strategy specific to the Ansel Adams and John Muir Wilderness trails are incorporated to further clarify how the forests intend to manage each trail. While not directly tied to national standards, which are still being developed, these are intended to mirror them so that when final standards are adopted, trails are managed consistently with other national forests. Providing this guidance should allow for more consistent expectations for managers, work crews, and trail users, and lead to a more consistently managed system over the long term.

Table 4.20. Alternative 2 system trail summary

SYSTEM TRAILS SUMMARY AA/JM Wilderness Totals	miles
Total System Miles	967.4
TC1	168.3
TC2	372.6
TC3	347.8
TC4	78.8

Table 4.21 compares Alternative 1 and 2 in terms of system trail actions. Compared to the no action trail system, there is a total addition of roughly three miles of trail on the system inventory. About 49 miles of trail were added to the system inventory and 46 miles of trail were deleted. Additionally, adjustments in trail management levels were made, resulting in 135 miles of trail having an increase in designated trail class, and 241 miles of trail receiving decreased trail class. Since this was intended to match conditions on the ground with recreation categories and anticipated commercial and private use levels, it is expected that the overall effect will be a more stable system where use is present. There could also be reduced costs where unnecessary trails were removed from the system or where management levels are reduced to match anticipated use.

Table 4.21: System trail actions comparison of Alternative 1 and 2

WILDERNESS-SCALE ACTION SUMMARY Compared to No Action	Miles
Added	49
Deleted	46
TC Down	255
TC Up	135

See Table 2.26 in Chapter 2 for specific actions on each trail by alternative.

In this alternative, both forests use the same trail class definitions and more consistent interpretation of classes in determining management levels. Additionally, recreation categories and use levels were considered, so a more consistent distribution of trail classes is evident in the Alternative 2 trail inventory. Since wilderness use levels on trails on the Sierra National Forest are somewhat lower, there is some basis for slight differences in trail management levels between forests. Alternative 2 demonstrates a much higher level of consistency in the spread of trail class designations across the wilderness areas as compared to the substantial differences in Alternative 1. Table 4.22 compares system trails on the Inyo and Sierra National Forests.

Table 4.22: Alternative 2 Inyo and Sierra trail class comparison

INYO NF Trail Class Summary	Miles	Percent of system	SIERRA NF Trail Class Summary	Miles	Percent of system
TC1	47	11%	TC1	121	22%
TC2	146	35%	TC2	226	41%
TC3	173	41%	TC3	174	32%
TC4	52	12%	TC4	27	5%
Total	418		Total	548	

In this alternative, the trail plan responds to the 2001 Wilderness Plan by designating a system of trails consistent with the desired conditions of the wilderness area, as defined by recreation categories. This alternative takes into consideration the anticipated level of commercial and private equestrian and hiker use, as well as the recreation category of destinations when designating trail classes. The Forest Service would then be providing a system of trails that is generally stable for the anticipated use, without exceeding the desired management level of the wilderness area. In this alternative, only 6.5 miles of TC3 trail provide access to Recreation Category 1 areas and six miles of this is a thru-trail (CA Riding and Hiking Trail), which continues on to other higher use areas. See Chapter 2 for a summary of trail classes by alternative, and Tables 2.26 for a detailed listing of individual trail information.

Table 4.23: Alternative 2 System trail class summary by recreation category

Alternative 2- Trail Class by Rec Category	TC1	TC2	TC3	TC4	Total System
RC1	80	96	6	0	182
RC2	88	261	254	27	630
RC3	0	16	88	52	156
Total	168	373	348	79	968

In this alternative, a total of almost 80 miles (approximately 8 percent of system) of trail are designated as TC4, a very high level of development and management that is exceedingly rare in wilderness. About 71 miles of this is the Pacific Crest National Scenic Trail (PCT), which traverses multiple geographic units. Due to its high profile and direction in the 1988 Inyo Forest LRMP to maintain it at “Maintenance Level 4,” it has always been maintained with a higher priority, if not necessarily a higher development level than other primary trails. Under Alternative 2, it would remain TC4 to be consistent with the 1988 Forest LRMP. However, under the current definition in National Trail Management Classes, this level of development may exceed the needs of users and desired management goals in the areas through which it travels. Although it will remain TC4 in this alternative, it would be extremely costly and unrealistic to maintain to the targets of this class. Reconstructing it at a TC4 level, if funding at such a high level were available, would be out of character with most of the wilderness area the trail goes

through. In the following table, the 71 miles of PCT designation at TC4 (versus its current observed level of TC3) skews the numbers substantially.

Table 4.24. Alternative 2 annual and backlog maintenance costs

Alternative 2 Trail Class compared to Field-Observed level of Development	Miles
Miles of trail designated LOWER than existing development	34
Miles of trail designated HIGHER than existing development	189
Miles of trail designated CONSISTENT with existing development	745

The eight miles of Mt. Whitney Trail on the Inyo National Forest is designated TC4 in this alternative. Due to the extremely high levels of use, the massive level of development and frequency of maintenance needed to keep a stable trail in place in the severe terrain and climate of the Mt. Whitney area, the trail is currently managed consistently with the definition of a Trail Class 4, so there would be no physical change from current management under this alternative.

This alternative also provides for designating trails as “Not Recommended for Stock,” which provides an advisory to private equestrians that trail conditions may be impractical for stock; and restricts commercial stock from the trail. In this alternative, the same trails designated as “Not Recommended for Stock” for public advisory purposes are also closed to commercial stock use, as described in “Not Suitable for Commercial Stock.”

This means that all trails which have either awkward conditions especially difficult for stock OR resource/instability issues are designated both as “Not Recommended for [private] Stock” (NRFS) and closed to commercial stock. In some cases, this means that trails that have no notable resource issues are closed to commercial operators; and conversely, on some trails which have some resource problems but that are not particularly awkward for travel, private stock would be warned about awkward trail conditions that may not actually exist. This has the potential consequence of creating confusion about the NRFS designation and how private equestrians should interpret the advisory.

These spatial controls on commercial operations will help ensure that recurring equestrian use will generally be on those trails that are sufficiently designed and managed to handle this use without excessive impacts to the trail system and to surrounding resources. Some system and use trails in the planning area are capable of handling only limited amounts of stock use, and corresponding destination quotas in this alternative will help ensure that each trail’s capability will not be exceeded.

Table 4.25 summarizes the system trails available to commercial stock in Alternative 2. In this alternative, there will be roughly 970 miles of system trails in the two wildernesses, of which approximately 73 miles (or 8 percent) would be considered unsuitable for commercial stock and not recommended for private stock. This means that approximately 895 miles of system trail would be accessible to commercial operators in Alternative 2. These trails would be managed and maintained at various trail classes. More than 85 percent of the trails approved for commercial stock are Trail Class 2, 3, and 4, which generally are managed to handle relatively high levels of recurring stock use. The remaining 14 percent TC1 trails with commercial stock present generally serve areas where very low quotas are established. These low-development trails are expected to remain stable under this level of use.

Table 4.25. Alternative 2 summary of trails not recommended for stock and closed to commercial

ALTERNATIVE 2 Trails Not Recommended for Stock (and closed to Commercial)	Miles
Total System Miles	967.4
NRFS (and closed to commercial)	73.2
Trails Available to Comm. Stock	894.2
Percent of system available to commercial	92%

By designating which system and use trails commercial operators can use, the vast majority of equestrian use will be limited to trails which are the most stable under stock use, and that require relatively low investment of maintenance resources. Most of these trails will still have some sections that are substandard, but are generally due to lack of maintenance rather than the trail's level or design standards, so there would be no reason to change current design standards for the trails. Removing 73 miles of trail from recurring commercial stock use will reduce the potential resource damage caused by trails inadequately designed for such use, freeing up maintenance funds for other trails with heavier stock and hiker use. Most trails with designated NRFS probably have received little or no recent private equestrian use since conditions have not been desirable for most private stock users on these trails.

Although the effect might be minor overall, there should be reduced resource impacts on the trails designated NRFS and closed to commercial stock. Considering limited maintenance funding, it may also allow greater trail and resource stability on the remainder of the system. Assuming that maintenance funds remain basically stable, the net effect would likely be a slight improvement in trail condition on those trails which remain open to commercial use, and which are most commonly used by private equestrians. Most of these effects may be relatively minor in the short term, but will have increasing significance over the long term.

One hundred and eighty-seven use trails, totaling roughly 195 miles, were specifically addressed in the proposed action (see Table 4.26). Based on limiting factors of either the use trails themselves or the destinations they accessed, 82 use trails totaling 80 miles were prohibited. One-hundred use trails totaling about 102 miles were approved. Five trails that were previously managed as use trails would be all or in part on the Alternative 2 trail system, so their use would be approved in this alternative as system trails.

In this alternative, the ability to limit the number of commercial stock on use trails through destination quotas has allowed for a number of use trails to be approved that can sustain only limited amounts of use. Most use trails approved in this alternative have relatively few risk factors, and are inherently stable. By keeping commercial stock off the most susceptible trails in this area and limiting use at destinations where trails can only sustain limited use, resource effects would be substantially reduced.

Table 4.26: Alternative 2 use trails summary

USE TRAILS Summary Alternative 2	Use Trails	Est. Miles
Use Trails/Miles Addressed	187	195
Approved Trails/Miles	100	102
Prohibited Trails/Miles	82	80
System in this Alternative	5	13

See Table 2.27 in Chapter 2 for the specific use trails approved in each alternative.

Additionally, operators have implicit approval to use non-system access paths to designated campsites, grazing areas, or non-designated camps that are within ¼ mile of system trails. Due to the short lengths and relatively dispersed low use that this type of trail receives, the effects are likely to be of relatively limited extent and intensity.

Early-season Access

Since sanding of snowdrifts on Piute Pass Trail is allowed in this alternative, which would allow crossing of the pass prior to full snowmelt, there are potential effects on both trails and resources in the trail corridor. These are described in the general effects section above. The Piute Creek Trail and the area west of Piute Pass (primarily Golden Trout Lake) are the areas most affected by early-season access.

Annual and Backlog Maintenance Costs – Alternative 2

Fully maintaining trails to standard in this alternative is estimated to cost approximately \$470,000 per year once the trails are repaired, so that annual maintenance would be effective. Since the forests are currently spending approximately \$170,000 a year on AA/JM trails, this leaves an annual maintenance deficit of approximately \$300,000.

This alternative still shows a high-deferred maintenance and repair deficit – over \$10 million. A factor in this is having 70 miles of the Pacific Crest Trail at a level much above its current development and condition.

In addition to trail infrastructure maintenance and repair costs, repairing and stabilizing trail related effects on resources in the trail corridor is estimated to cost between \$3 million and \$4 million – as in all other alternatives.

Table 4.27. Alternative 2 annual and backlog maintenance costs

Trail Annual Maintenance Costs AA/JM Wilderness	Alt. 2
Total Estimated Cost	\$469,500
Current Annual Funding	\$170,000
Annual Maintenance Shortfall	\$299,500
Current Backlog (Repairs to Standard)	
Estimated Current Backlog	\$10,104,500.00

The restriction of recurring commercial pack stock from eight percent of the trail system slightly reduces the costs of both maintenance and reconstruction for these sections. The cost savings effect in this alternative (and others), however, is somewhat limited, since the trails closed to commercial stock are trails that are rarely or lightly used by commercial operators currently. In addition, most of these trails are lower development trails – roughly half are TC1 and half are TC2 – which cost less to repair and maintain than the overall average.

Table 4.28. Alternative 2 trail summary by geographic unit

Geo Unit	Total system miles – Alt 2	NSCS (Not Suitable for Comm Stock)	Avail to comm. stock	TC1	TC2	TC3	TC4	NRFS (Not Rec. for Private Stock)

JMSW	130.9	0.8	130.1	14.3	85.8	30.8	0	
TOTAL	967.4	73.1*	894.2	168.3	372.5	347.8	78.7	73.1

Cumulative Impacts – Alternative 2

Other past, present, and future actions that may have an incremental or added effect when combined with trail-related actions in this alternative include:

- Funding levels for maintenance and repair.
- Trail maintenance activities and reconstruction projects.
- Unclear past management direction for the wilderness transportation system.
- Management activities of adjacent or cooperating agencies.

- Recreational activities along the borders of these wilderness areas.
- Various different trail user types and levels.

Annual Maintenance and Funding: The effects of historical maintenance performed and the past inadequate funding levels is the same in this alternative as in Alternative 2 – Modified. Low funding leaves both forests with a substantial backlog maintenance load, which would take substantial funding to repair [see description of reconstruction below].

Destination quotas have a similar beneficial effect as in Alternative 2 – Modified for predictability of use types and levels, which in turn increases the efficiency of maintenance expenditures. Low funding levels combined with the actions in this alternative will still have some moderate adverse effects on trail stability and resource conditions.

As in Alternative 2 – Modified, this alternative designates a moderate number of trails (approximately 75 miles) as “Not Recommended for [private] Stock” and “Not Suitable for Commercial Stock.” Since this allows approximately 25 more miles available to stock, the beneficial effects of decreasing maintenance costs will not be as substantial as in Alternative 2 – Modified. There will likely be a long-term minor to moderate beneficial effect at the trail system scale, with localized moderate beneficial effects.

Reconstruction: The effects of past and current reconstruction efforts and the gradually declining budgets for repairs and reconstruction are the same in this alternative as in Alternative 1 and Alternative 2 – Modified.

Cumulative effects at the wilderness scale are generally the same as those described in Alternative 2 – Modified. Locally, over the long term, certain trails will have slightly different effects, since 25 more miles of trail are available to stock in this alternative.

The Pacific Crest Trail, which will be repaired in 2006, is designated TC4 in this alternative, so at the time of reconstruction would be reconstructed to a standard exceeding the wilderness character of the areas it traverses. It would also cost nearly twice as much to upgrade to this level from its current observed level of TC3. If implemented, this would have a moderate detrimental effect on the trail system, requiring diversion of funds from other maintenance or repair efforts.

Unclear Past Management Direction for the Wilderness Transportation System: The effects of past inventories with unclear or incorrect direction are the same in this alternative as in Alternative 1 and all other alternatives. In general, the effect has been to make such direction mostly meaningless, and force trail managers on the forests to manage trails intuitively, with varied success.

As described in Alternative 2 – Modified, implementing the direction in this plan is likely to have minor to moderate beneficial effects at the trail system scale, and moderate benefits at the individual trail level.

Management Activities of Adjacent or Cooperating Agencies: The effects of past actions on or by adjacent or cooperating agencies, such as the Department of Fish and Game or National Park Service, are anticipated to be generally the same in this alternative as in Alternative 1 and 2 – Modified.

In this alternative, most trails that cross boundaries to contiguous trail systems on the NPS, have been aligned so that there should be a high level of consistency, and negligible effects on trails and resources, with one major exception. In this alternative, the Pacific Crest Trail is designated

Trail Class 4, which would be inconsistent with management of adjacent sections of the PCT administered by the NPS.

Other Trail Uses: Past, Current, and Anticipated: The activities and effects of past, current and future private hikers and equestrians on trails in these wilderness areas are the same as described in Alternative 2 – Modified.

Regardless of any actions that restrict commercial pack stock operations on trails, the effects of hikers and private pack stock will continue at similar levels under existing controls. The types and levels of use that would continue to be accommodated under this alternative will continue to have minor to moderate effects at the wilderness trail system scale, and moderate to isolated severe effects at localized trails.

The actions of reducing or eliminating commercial stock use from certain remote trails may have minor short-term beneficial effects on the trail experience of hikers and/or those seeking a more primitive experience.

Non-wilderness Trails: The cumulative effects on non-wilderness trails are the same as those described in Alternative 2 – Modified.

Alternative 3

Summary of Impacts – Alternative 3

Trail management levels are consistently aligned with desired destination management levels, with a minimal amount of conflict with recreation categories (for instance, less than one percent of trail system is TC4). This alternative very closely aligns trail management with anticipated use types and levels and on-the-ground conditions. There are fewer internal controls than Alternative 2, so there is less predictability about commercial use levels. This may cause slightly less efficient distribution of maintenance funding. There are 107 approved use trails, including undefined or cross-country routes. Fewer destination controls are present, so there is a higher potential for resource impacts and for increase of evidence of use trails until monitoring determines that mitigation or closure are needed. This would likely have a minor to moderate effect at the wilderness scale, and moderate to severe effects at specific use trails with high risk factors.

“Not recommended for stock” (NRFS) designation becomes a public advisory without restricting commercial use. There are 140 miles of trail (approximately 15 percent) designated NRFS due to trail difficulty and awkward conditions for stock. This will likely provide better and safer experiences to private equestrians. Alternative 3 has more trails available to commercial stock than Alternative 2, with 63 miles (approximately six percent) of system designated as “Not Suitable for Commercial Stock” (NSCS), but little or no noticeable effect likely, since additional trails available are simply awkward for stock, and should remain stable under anticipated use. Reduced costs of maintenance and reconstruction on NRFS and NSCS trails allows for slightly better condition on overall system, resulting in more stable trails and resource condition.

Over the short term, this alternative will have negligible to minor localized and regional impacts, by reducing one of the contributing causes of adverse effects, but physical trail stability conditions will not likely improve substantially until the long term, as physical treatments and/or natural recovery occurs. Some of these beneficial effects are highly dependent upon funding levels.

Over the long term, the beneficial impacts will be moderate, as more trails are managed at stable levels and which do not exceed area needs. At the regional scale, this alternative will have negligible adverse impact for both the long and short terms. Over the long term, the close alignment of trail management and desired area management would have moderate beneficial effects on wilderness resources.

Since any trail could potentially be requested and approved for sanding of snow to allow early season passage (though very few would likely be requested in most years), there is a higher potential for expansion of effects from sanding than in Alternative 2. Sanding will likely occur on between one and five trails annually, depending upon the severity of the winter. Sanding protects the immediate trail corridor from widening and multiple trails, but may allow early access to trails and areas still wet and easily damaged.

Analysis

As in the other action alternatives, this alternative designates a system of trails considering the desired conditions of destinations within the wilderness areas, as directed by the 2001 Wilderness Plan. The effects are somewhat different, as this alternative tends to provide a higher development trail system (with some exceptions) in order to remain stable under less predictable use types and levels.

The key difference affecting trails between Alternative 3 and Alternative 2 is that commercial operators are not limited by quotas at destinations, with the exception of a small number of areas. Instead, commercial pack stock user numbers are limited only at trailheads. This means that predicting an anticipated level of commercial stock use on each trail is much more difficult, especially trails farther from trailheads. This puts a higher burden on the forests to ensure that more trails are capable of stably handling commercial stock use at an undetermined level, in addition to anticipated private stock and hiker use, even if this use is only occasional or speculative.

Table 4.29. Alternative 3 system trail summary

SYSTEM TRAILS SUMMARY AA/JM Wilderness Totals	Alt. 3
Total System Miles	985.2
TC1	113
TC2	443.2
TC3	421.2
TC4	7.8

Compared to the Alternative 1 trail system, there is a total addition of roughly 20 miles of trail on the system inventory (see Table 4.30). In determining which trails should be on the system, about 51 miles of trail were added to the inventory and about 30 miles of trail were deleted. Additionally, adjustments in trail management levels were made, resulting in 130 miles of trail having an increase in designated trail class, and 293 miles of trail receiving decreased trail class. Since this was intended to match conditions on the ground with recreation categories and anticipated commercial and private use levels, it is expected that the overall effect will be a more

stable system where use is present. There could also be reduced costs where unnecessary trails are removed from the system or where management levels are reduced.

Table 4.30: System trail actions comparison of Alternative 1 and 3

WILDERNESS-SCALE ACTION SUMMARY Compared to No Action	Miles
Added	51
Deleted	30
TC Down	306
TC Up	159

See Table 2.26 in Chapter 2 for specific actions on each system trail by alternative.

Table 4.31 compares system trails between the Sierra and Inyo National Forests. In this alternative (as in Alternative 2), both forests use the same definitions and more consistent interpretation of trail classes in determining management levels. Additionally, recreation categories and use levels were considered, so a more consistent distribution of trail classes is evident in this trail inventory. Some modifications were also made based on better field knowledge and a better understanding of the anticipated use types and levels. Since wilderness use levels on trails on the Sierra National Forest are somewhat lower, there is some basis for slight differences in trail management levels between forests. This demonstrates a much higher level of consistency in the spread of trail class designations between the two forests as compared to the substantial differences in Alternative 1.

Table 4.31: Alternative 3 Inyo and Sierra N.F. trail class comparison

INYO NF Trail Class Summary	Miles	Percent of system	SIERRA NF Trail Class Summary	Miles	Percent of system
TC1	45	10%	TC1	70	13%
TC2	162	37%	TC2	278	50%
TC3	217	50%	TC3	204	37%
TC4	8	2%	TC4	0	0%
Total	432		Total	552	

In this alternative, a small number of recreation categories would be adjusted to reflect the characteristics and intended management of the destinations. This would align the recreation categories to social and management conditions, including trail development and anticipated use types and levels. The effect of this would be more consistent alignment of management, and generally more stable trails that are consistent with the use types and levels at destinations. There is less likelihood that the trail system would either be inadequately developed or developed beyond the needs and character of the destinations. Over the long term, this will have a beneficial effect on the trail infrastructure and the associated resources, as well as wilderness character.

Table 4.32: Alternative 3 system trail class summary by recreation category

Rec Category	TC1	TC2	TC3	TC4	Total System
RC1	70	132	6	0	208
RC2	46	292	283	0	621
RC3	0	16	131	8	155
Total	116	440	420	8	984

In this alternative, the Pacific Crest National Scenic Trail (PCT), one of very few trails in the planning area that has been designated as Trail Class 4 (or “Maintenance Level 4”) in past inventories, has been adjusted to TC3 to better match recreation categories and wilderness direction – as well as to align its development more closely to what exists on the ground. This will have no effect on the trail infrastructure and physical resources, since the current definition of Trail Class 3 matches well with the existing and past management and development of the PCT on both forests. Because the PCT is a high-profile and popular trail, it will continue to be a high priority for maintenance, and will continue to be cleared and maintained as early in the use season as is practical.

Table 4.33. Alternative 3 trail class comparisons

Alternative 3 Trail Class compared to Field-Observed level of Development	Miles
Miles of trail designated LOWER than existing development	27
Miles of trail designated HIGHER than existing development	180
Miles of trail designated CONSISTENT with existing development	778

This alternative, in general, designates a higher development trail system than other alternatives (with the exception of the Pacific Crest Trail). Part of the reason for this is that there are fewer controls and less ability to predict commercial use levels on trails, so there is a need to ensure that more trails are developed and maintained at suitable use levels. Additionally, more trails are available to commercial operators in this alternative. A total of 922 miles of trail (or 94 percent) of the system, are available to commercial stock. This has an effect on the financial needs for trails, but because the additional trails that are being allowed for commercial operators in this alternative versus Alternative 2 tend to be those with low commercial use and low development levels, this effect would be slight.

Assuming that these trail levels can be attained, this would provide a mostly stable trail system. Since funding is anticipated to be less than what is necessary to fully implement the classes in this alternative, many trails would remain at less than full standard. Depending on many factors, this could lead to some further instability in trails and resources in the trail corridor.

Table 4.34. Alternative 3 annual and backlog maintenance costs

Trail Annual Maintenance Costs AA/JM Wilderness	Alt. 3
Total Estimated Cost	\$467,500
Current Annual Funding	\$170,000
Annual Maintenance Shortfall	\$297,500
Current Backlog (Repairs to Standard)	
Estimated Current Backlog	\$9,274,680.00

With the 70 miles of PCT reduced to level three, the additional costs to reconstruct and maintain the remaining high development trails is offset in this financial analysis. Alternatives 2 and 3 have very similar costs and backlogs.

In Alternative 3, approximately 25-30 destinations (and the trails accessing these areas) will have quotas for a maximum number of commercial trips. Effects of these limitations on these particular trails are beneficial. In some cases, this is because the quota materially reduces the number and effect of commercial pack stock use on the trails; in other cases, the benefit lies in the ability to predict the likely stock use levels and to adjust the management of the trail for that use.

Generally, the trails that will benefit from the implementation of destination quotas in this alternative are relatively short segments that provide access between higher use corridor trails and the specific destination. The net benefit to the high use corridor will likely be negligible, as both commercial and other uses will continue at similar levels on these trails. In isolated cases, limiting the use at certain destinations may slightly increase the level of commercial use on a segment of primary trail since the use will not disperse to a particular destination. The effects of this displacement on the trail system and resources in the corridor would not likely be measurable.

Trails designated “Not Suitable for Commercial Stock” (NSCS) in this alternative are driven by either resource or destination limitations and/or resource risk factors along the trail. In this alternative, about 25 more miles of trail would be available to commercial stock use than in the proposed action (Alternative 2). Part of this increase is due to the addition of certain use trails to the system, and part is due to the different meaning of the term “not recommended for stock.” In Alternative 2, the NRFS designations would affect both the commercial operators and the public. In Alternative 3 and 4, two separate designations would allow some trails to be closed to commercial operators while private equestrians need not be warned about safety or difficult conditions. Conversely, these two designations would allow commercial operators to use their best judgment and knowledge of the trail system in operating on trails that do not have resource or destination limitations, but which may be extremely difficult or risky for private equestrians.

Table 4.35: Alternative 3 trail suitability summary

SYSTEM TRAILS SUMMARY Alternative 3	Miles
Total System Miles	985.2
NSCS	62.9
Trails Available to Comm.	922.3
NRFS (Approx)	135

Table 4.35 summarizes trail suitability and trails “not recommended for (private) stock” for Alternative 3. While approximately 25 more miles of trail are available to commercial stock in this alternative than in Alternative 2, the difference in effects to either physical resources or the costs of maintenance would be negligible and nearly undetectable. The trails that would become available to commercial stock under this alternative are almost all very low development (TC1) trails that also have very few risk factors that would lead to trail or resource degradation. They are mainly trails that are awkward for equestrians, and in many cases receive very low or no private equestrian use and are currently only occasionally visited by commercial stock. Since only trails, which are not particularly susceptible to the effects of stock use, are being made available to commercial stock in this alternative, it is unlikely that these additional trails or resources would show noticeable effects.

In this alternative, the designation of NRFS is defined to mean “Not Recommended for [private] Stock.” The effects of this designation are described in the “general effects” area at the beginning of Chapter 4. In Alternatives 3, 4, and 5, roughly 65 trails, totaling just over 135 miles, are designated “Not Recommended for Stock,” in addition to the 16 miles of trail which are closed to all stock in the Mt. Whitney area. While the same trails are designated “NRFS” in Alternatives 3, 4, and 5, variations between these alternatives is dependent upon whether some of these trails are on the system. If a trail is not on the system in this alternative, it does not receive the NRFS designation.

There are more use trails available to commercial operators in this alternative in order to provide access to additional grazing areas, campsite locations and areas that can sustain at least a certain amount of use. If use were to increase above current levels on any of these use trails, there is a potential for some additional impacts in isolated areas. However, since the total cap on use to most areas is based on the entry trailhead, the addition of certain approved use trails would allow for greater dispersal, which could slightly reduce impacts on some of the fewer use trails that were approved in Alternative 2. Table 4.36 summarizes use trails for Alternative 3. With 103 miles of use trail approved, there would be an average density of 0.67 feet (8”) of approved use trail per acre.

Table 4.36: Alternative 3 use trails summary

USE TRAILS SUMMARY Wilderness Scale	Use Trails	Est. Miles
Use Trails/Miles Addressed	202	209
Approved Trails/Miles	107	103

USE TRAILS SUMMARY Wilderness Scale	Use Trails	Est. Miles
Prohibited Trails/Miles	87	87
System in this Alternative	8	19

See Table 2.27 in Chapter 2 for specific actions on each use trail by alternative.

Sanding of passes to allow earlier season access can be authorized by the Forest Service on a case-by-case basis for a number of passes in this alternative. While the extent of the perceived need for sanding and the effects are highly dependent upon natural events (primarily quantity of snow fall and early season temperatures), trails affected by potential sanding would likely be limited to three to five trails. During heavy snow years, these trails would likely include Piute Pass, Pine Creek Pass, Bishop Pass, McGee Pass, and Kearsarge Pass, with isolated sections of other primary trails, where a drift may block access to otherwise clear trails. Low to moderate snow years may only affect two or fewer of these trails. The potential effects of sanding snow drifts, both beneficial and negative, are described in the “general effects” area above.

Table 4.37. Alternative 3 trail summary by geographic unit

	Total system miles – Alt 3	NSCS (Not Suitable for Comm Stock)	Avail to comm. stock	TC1	TC2	TC3	TC4	NRFS (Not Rec. for Private Stock)

Cumulative Impacts – Alternative 3

Other past, present, and future actions, which may have an incremental or added effect when combined with trail-related actions in this alternative, include:

- Funding levels for maintenance and repair.
- Trail maintenance activities and reconstruction projects.
- Unclear past management direction for the wilderness transportation system.
- Management activities of adjacent or cooperating agencies.
- Recreational activities along the borders of these wilderness areas.

- Various different trail user types and levels.

Annual Maintenance and Funding: The effects of historical maintenance performed and the past inadequate funding levels is the same in this alternative as in Alternative 2 – Modified. Low funding leaves both forests with a substantial backlog maintenance load, which would take substantial funding to repair [see description of reconstruction below].

Since there are very few destination quotas in this alternative and more trails are available to commercial stock than other action alternatives, this means a greater maintenance and repair expenditure to ensure trail stability over time. This could have moderate detrimental effects on trails and resources outside of these wilderness areas, as funding levels decrease and limited funds are prioritized.

As in Alternative 2 – Modified, this alternative designates a moderate number of trails (approximately 65 miles) as “Not Recommended for [private] Stock” and “Not Suitable for Commercial Stock.” Since this would allow approximately 35 more miles available to stock, the beneficial effects of decreasing maintenance costs would not be as substantial as in Alternative 2 – Modified. There would likely be a long-term, minor to moderate beneficial effect at the trail system scale, with localized moderate beneficial effects.

Reconstruction: The effects of past and current reconstruction efforts and the gradually declining budgets for repairs and reconstruction are generally the same in this alternative as in Alternative 1 and Alternative 2 – Modified.

Cumulative effects at the wilderness scale are generally the same as those described in Alternative 2 – Modified. Locally, over the long term, certain trails will have slightly increased effects, since 35 more miles of trail would be available to stock in this alternative.

The Pacific Crest Trail, which will be repaired in 2006, is designated TC3 in this alternative. As in Alternative 2 – Modified, this would repair the trail consistent with desired conditions of the areas it traverses.

Unclear Past Management Direction for the Wilderness Transportation System: The effects of past inventories with unclear or incorrect direction are the same in this alternative as in Alternative 1 and all other alternatives. In general, the effect has been to make such direction mostly meaningless, and force trail managers on the forests to manage trails intuitively, with varied success.

As described in Alternative 2 – Modified, implementing the direction in this plan would likely have minor to moderate beneficial effects at the trail system scale, and moderate benefits at the individual trail level.

Management Activities of Adjacent or Cooperating Agencies: The effects of past actions on or by adjacent or cooperating agencies, such as the Department of Fish and Game or National Park Service, are generally the same in this alternative as in Alternative 1 and 2 – Modified.

In Alternative 3, more trails are at a high development than Alternative 2 – Modified. A small number of these access the NPS, so may have a minor localized effect at those locations. The Pacific Crest Trail would be designated as TC3 in this alternative, making it consistent with contiguous sections of the trail in NPS lands.

Other Trail Uses – Past, Current, and Anticipated: The activities and effects of past, current, and future private hikers and equestrians on trails in these wilderness areas are the same as described in Alternative 2 – Modified.

Regardless of any actions that restrict commercial pack stock operations on trails, the effects of hikers and private pack stock would continue at similar levels under existing controls. The types and levels of use, which would continue to be accommodated under this alternative, would continue to have minor to moderate effects at the wilderness trail system scale, and moderate to isolated severe effects at localized trails.

The actions of reducing or eliminating commercial stock use from certain remote trails may have minor short-term beneficial effects on the trail experience of hikers and/or those seeking a more primitive experience.

Non-wilderness Trails: The cumulative effects on non-wilderness trails are the same as those described in Alternative 2 – Modified.

Alternative 4

Summary of Impacts – Alternative 4

This alternative provides the most restrictive controls to commercial stock use, and limits them to the lowest number of system and use trails. One hundred and seventy-three miles (approximately 18 percent of system) is designated Not Suitable for Commercial Stock (NSCS), effectively confining commercial stock to the 80 percent of higher development (and generally higher use) trails. Forty-three use trails (approximately 30 miles) are approved for commercial stock, and no undefined cross-country routes were approved, so this alternative provides the lowest potential for expansion of use trails. However, there is potential for adverse impacts on the limited number of approved use trails. With no destination controls, there is less predictability of how much use will be present on each system or use trail.

The trail system has the most primitive character, relative to anticipated use types and levels so will provide the least appearance of management intrusion and character that is more primitive. No trails are designated TC4, and over 25 percent of the system is designated TC1. Lower development levels are likely more susceptible to instability, so there is a higher likelihood of adverse physical resource and trail degradation over the long term. The same trails are designated “Not Recommended for [private] Stock” as in Alternatives 3 and 5, providing a clear expectation and better/safer experience to private equestrians.

In this alternative, no trails are eligible for sanding to provide early-season access, so there would be a reduction in impacts on trails and destinations beyond the drifts or passes that would otherwise be sanded. There would likely be an increase in site-specific impacts to trail structures and resources in the immediate trail vicinity from non-commercial equestrians and hikers bypassing snowdrifts.

In remote locations, there would be minor to moderate benefits through reduced conflicts between different user types, as users choose to segregate. It is likely there will be an increase in localized conflicts between users in high-use trail corridors and destinations. On the regional scale, there will be a minor reduction in conflict overall. Over the long term, there will be localized moderate improvements on stability of specific trails and resources with no commercial stock present. At the watershed scale, these improvements would be negligible to minor. In the

long term, the remainder of trails may have minor to moderate adverse localized impacts resulting from inadequate development relative to use levels.

Analysis

As in the other action alternatives, this alternative designates a system of trails considering the desired conditions of destinations within the wilderness areas, as directed by the 2001 Wilderness Plan. The effects are somewhat different. This alternative tends to provide a lower development trail system to reduce the perceived development of trails in wilderness.

The most substantial difference potentially affecting trails in this alternative compared to Alternatives 1 through 3 is that there will be an overall reduction in commercial stock use on the trail system. There would be a 20 percent reduction of commercially served visitors at most trailheads, and slightly larger reductions at certain trailheads where there are greater concerns. This reduction affects the number of visitors served by commercial pack stock, but does not necessarily reduce the number of stock by the same ratio, so actual stock numbers will not likely drop as much as 20 percent. As in Alternative 3, there would be very few other spatial controls that could provide greater predictability for commercial stock numbers at destinations and on each trail.

Table 4.38. Alternative 4 system trail summary

SYSTEM TRAILS SUMMARY AA/JM Wilderness Totals	Alt. 4
Total System Miles	956.4
TC1	244
TC2	393.4
TC3	319
TC4	0

Compared to the no action trail system, the Alternative 4 trail system has eight less total miles. About 48 miles of trails were added to the inventory and about 56 miles of trails were deleted. Additionally, adjustments in trail management levels were made, resulting in 69 miles of trails having an increase in designated trail class, and 427 miles of trails receiving decreased Trail Class (see Table 4.39).

Table 4.39: System trail miles comparison of Alternative 1 and 4

WILDERNESS-SCALE ACTION SUMMARY Compared to No Action	Miles

Deleted	56
TC Down	427
TC Up	69

See Tables 2.26 in Chapter 2 for specific actions on each trail by alternative.

In Alternative 4, as in all action alternatives, both forests use the same definitions and more consistent interpretation of trail classes in determining management levels. Additionally, recreation categories and use levels were considered, so a more consistent distribution of trail classes across the wilderness areas is evident in this trail inventory. Some adjustments were made recognizing that a smaller number of trails would be available to commercial stock. Since wilderness use levels on trails on the Sierra National Forest are somewhat lower, trail management levels would also tend to be lower; however, many more trails on the Inyo National Forest were designated as “Not Suitable for Commercial Stock” in this alternative, so a few more trails could be managed at a lower level. In this alternative, the Inyo National Forest total inventory was also reduced 4.5 percent from the no-action inventory, while the Sierra National Forest inventory is increased by 2.5 percent (see Table 4.40).

Table 4.40: Alternative 4 Inyo and Sierra N.F. trail summary

INYO NF Trail Class Summary	Miles	Percent of system	SIERRA NF Trail Class Summary	Miles	Percent of system
TC1	84	20%	TC1	160	29%
TC2	141	34%	TC2	252	46%
TC3	187	45%	TC3	132	24%
TC4	0	0	TC4	0	0
Total	412		Total	544	

In this alternative, Trail Classes are determined based on the same general factors as described in Alternatives 2 and 3, with two additional considerations. First, fewer trails will be used by commercial stock and, as a result, these trails may not require as high a level of development to maintain stability. Secondly, this alternative provides a very primitive trail system—even in areas with moderately high use. The effects of this will depend largely upon the distribution of private equestrian use. Even with the removal of the vast majority of stock from a particular trail, private stock will still be accommodated on the trail, so a standard of development is needed which both provides for adequate travel ability and stability of a trail with continued stock use. In areas with heavy non-commercial equestrian and hiker use and a high recreation category, trails with low development levels would likely become highly degraded and cause moderate to severe localized effects under the anticipated use.

Table 4.41: Alternative 4 system trail class summary by recreation category

Alternative 4	TC1	TC2	TC3	TC4	Total System
RC1	106	72	1	0	179
RC2	133	298	191	0	622
RC3	5	23	127	0	155
Total	244	393	319	0	956

A key consideration in determining trail classes in this alternative is to provide a system of trails that would maximize the primitive character of trails, by limiting development to the lowest possible levels. This alternative minimizes visitor perception of management intrusion, by creating a system of minimally developed trails. This will result in more primitive trails, which may be more difficult to negotiate, but which may add to an increased feeling of remoteness. For other trail users, this alternative may make certain trails exceedingly difficult to travel, especially equestrians or hikers carrying heavy backpacks.

This alternative has the greatest number of trails designated with Trail Classes lower than what currently exists on the ground. For the short-term, this would have minimal effect, but over the long-term—as maintenance and reconstruction are performed at levels lower—trails would likely change character as they degrade from their current condition toward a lesser standard.

Table 4.42: Alternative 4 Inyo and Sierra trail class comparison

Alternative 4 Trail Class compared to Field-Observed level of Development	Miles
Miles of trail designated LOWER than existing development	170
Miles of trail designated HIGHER than existing development	43
Miles of trail designated CONSISTENT with existing development	743

As with undeveloped use trails, system trails with minimal development are more susceptible to catastrophic failure in high-risk areas or when a large climatic event occurs—likely causing resource impacts. Other effects could be increased impacts to physical resources in the trail corridor if trail conditions deteriorate beyond a certain threshold of difficulty, or if structures do not adequately withstand the use types and levels present on the trail. In such cases, it is likely that trail users would be forced to bypass obstacles and particularly rough sections of trail, causing multiple trailing or new trail alignments.

The Pacific Crest Trail will be reduced from a TC4 to a TC3 in this alternative, and (as described in Alternative 3), is not expected to have a material effect on the trail or associated resources, since the trail is currently being managed at a level consistent with the current TC3 definition.

In this alternative, the Mt. Whitney Trail is also reduced from TC4 to TC3. Currently, this trail is managed at a higher development level and more frequently and intensively maintained than any other wilderness trail in the planning area. Due to the extremely high level of overnight and day use present along the entire length of this trail, and the comparatively limited experience that many visitors have, actually managing this trail to a lower level would likely have minor beneficial effects and moderate detrimental resource effects at the trail level.

As described above, the primary potential benefit would be to provide a lower level of perceived management intrusion for those who prefer trails that are more primitive and less managed. It is likely, however, that most Mt. Whitney trail travelers—especially those carrying heavy packs—prefer a well-developed trail, and are less-inclined to feel that a high-development trail is an intrusion on their experience. Because of the nearly constant presence and passing of visitors traveling in both directions on the trail, and the severe terrain through which much of the trail passes, a more primitive trail could actually increase the perception of other visitors being an intrusion on their wilderness experience. In the most severe terrain, nearly constant structural improvement and substantial annual maintenance is needed simply to keep the trail in place.

Reducing this development and management level may lead to a gradual loss of trail infrastructure, increased instability, and moderate impacts to resources in the trail corridor.

In this alternative, fewer system trails would be available to commercial stock than in Alternatives 1 through 3, reducing the direct resource and infrastructure impacts to the trails closed to commercial stock. Approximately 783 miles would be available to commercial pack stock, while roughly 173 miles (almost 20 percent) of system trails would be designated Not Suitable for Commercial Stock (NSCS) (see Table 4.43).

The criteria used to designate additional trails beyond those in Alternatives 2 and 3 as NSCS in this alternative, are based primarily in reducing perceived social conflicts in relatively remote areas, rather than physical resource impacts, and trail stability on these trails. While these trails will have a slight benefit in reduced needs for maintenance, trail and resource stability will generally not see as great a beneficial effect as on those trails where current or potential physical impacts are the primary driver of an action (as in Alternatives 2 and 3).

The primary effect will be a reduction in interaction and potential conflict between commercial stock parties and non-stock-supported parties on certain remote trails and destinations. On trails with no commercial stock, trails would tend to have somewhat less dust and no manure, which would also have a beneficial effect on some hikers. At the wilderness trail system scale, there will likely be a minor beneficial effect, while at specific trails and destinations, the perceived benefits for some would be at least moderate.

The trails that are available to commercial stock would generally be higher development trails in higher use corridors. Since these trails are used heavily by other wilderness visitors, it may concentrate use further, increasing the amount of interaction and conflict between commercial stock parties and non-stock parties in the primary corridors. However, once off these main routes, the opportunities greatly increase for those seeking an experience with minimal or no stock presence, and a more primitive trail experience. Over time, those visitors seeking minimal interaction with stock would likely adjust their trip planning to maximize this experience.

Certain trails designated NSCS in this alternative are primary access routes that provide ingress and egress for loop trips into vast areas west of the sierra crest area, including some trails that have historically and consistently received low to moderate commercial and private equestrian use. Four of the five system trails providing access into the NPS in the JMSE Geographic Unit—Taboose, Sawmill, Baxter, and Shepherd Passes—are closed to commercial pack stock. Kearsarge Pass Trail would be the only trail available to commercial stock to access the Sequoia and Kings Canyon National Parks between Bishop Pass and New Army Pass, a distance of approximately 100-trail miles. These trails would still be maintained adequately to accommodate private equestrians, but stock use would drop substantially, reducing the overall frequency and intensity of maintenance.

The trails and areas west of the crest accessed by these trails would see some reduction in stock use, except where alternative routes provide access from other points. As in all alternatives, if there is an emergency need to evacuate via these routes, they could still be utilized; however, the frequency of this is anticipated to be extremely low.

Table 4.43: Alternative 4 system trails suitability summary

SYSTEM TRAILS SUMMARY AA/JM Wilderness Totals	Number of miles
Total System Miles	956.4
NSCS	173.2
Trails Available to Comm.	783.2
NRFS (Approx)	130

Not Recommended for [private] Stock (NRFS) trails are the same as described in Alternative 3, and the effects would be the same. It appears that slightly fewer trails are designated as NRFS in this alternative, because some of these trails are not on the system inventory in this alternative so would not show as being designated NRFS.

A very small number of use trails are approved for commercial operators in this alternative (see Table 4.1.15). Of 202 use trails (totaling 209 miles), only 43 use trails (totaling 30 miles) are approved. Use trails approved are generally those where analysis showed that the trails would be most stable under the anticipated use. The overall reduction in commercial pack stock visitors may mean a slight overall reduction in commercial stock on use trails as a whole, but distribution of this use is not predictable except where destination quotas are in effect. The reduction in the number of available use trails will likely lead to a slight increase in the numbers of commercial stock on the approved use trails or system spur trails unless controls, such as destination quotas, are in place for the trail's destination.

Certain grazing areas and other destinations will not be accessed by commercial operators in this alternative, so use trails which were formerly used or approved in other alternatives, will not be approved for use in Alternative 4. Also, "use trails" which were not readily found on the ground and had characteristics more like that of a cross-country route are not approved in this alternative. Since these undefined trails currently receive very low use, prohibiting use from them will not likely displace a substantial amount of use or contribute additional effects to more defined use trails. Prohibiting even light use on undefined routes will likely prevent the expansion of additional use trails over time, except for those created by non-commercial users. In this alternative, the average trail density is 0.20 feet (or 2.5") per acre. This is approximately one-third the density of approved use trails in other alternatives.

Table 4.44: Alternative 4 use trails summary

USE TRAILS SUMMARY Wilderness Scale	Use Trails	Est Miles
Use Trails/Miles Addressed	202	209
Approved Trails/Miles	43	30
Prohibited Trails/Miles	153	165
System in this Alternative	6	14

See Table 2.27 in Chapter 2 for specific actions on each use trail by alternative.

In this alternative, sanding would not be allowed on snowdrifts to allow earlier season access to destinations. As in all alternatives, commercial operators would be required to stay on system trails. In this alternative, they would not be allowed to bypass snowdrifts, unless they traveled directly over the snow. This would likely reduce impacts at destinations beyond the passes or drifts since commercial stock would not utilize the destinations until conditions were drier and more stable.

Hikers and private equestrians would still attempt to access the destinations. Private equestrians and hikers would likely cause some increased impact to trail structures and off-trail resources in the immediate vicinity of the drift, while attempting to bypass drifts that would otherwise be cleared. This will result in localized minor to moderate impacts to trail structures and off-trail resources in the immediate area of the snowdrifts. Since hikers and a small number of private equestrians will access the trails, use trails, and campsites at the destinations, there will be some continuing impacts. However, since commercial operators may not get to the destinations until the snow has melted from trails (and destinations will likely have dried out and stabilized), it is likely that there will be a moderate localized reduction of impacts at destination trails and camps.

If snow blocks a key operating area for a commercial operator, use could increase to other areas until the trail becomes passable. This may increase the effects to certain trails and areas that are snow-free, if there is not another control, such as a trailhead or destination quota.

Reconstruction costs will likely be slightly reduced at the time of repairs, or reconstruction if the trails and structures can be built to a lesser standard. For the short-term, less maintenance will need to be performed on some trails, and the interval for maintenance may be extended, which could reduce costs. However, there is a risk that the trail class assigned in this alternative may provide inadequate development to maintain stability under the anticipated use types and levels. Cost benefits may be offset over the long-term by the relative susceptibility of a less-developed trail to damage from natural events and heavy use. This condition would likely drive up annual maintenance needs, deferred maintenance, and costs over time, and ultimately may require repairs that are more extensive after damaging events.

Table 4.45. Alternative 4 annual and backlog maintenance costs

Trail Annual Maintenance Costs AA/JM Wilderness	Alt. 4
Total Estimated Cost	\$379,000
Current Annual Funding	\$170,000
Annual Maintenance Shortfall	\$209,000
Current Backlog (Repairs to Standard)	
Estimated Current Backlog	\$6,820,500

This alternative has the second lowest total trail backlog, at approximately seven million dollars. More trails are closed to commercial stock (almost 20 percent of the system) so certain trails will have fewer maintenance and reconstruction needs.

Table 4.46. Alternative 4 trail summary by geographic unit

Cumulative Impacts—Alternative 4

Other past, present, and future actions, which may have an incremental or added effect when combined with trail-related actions in this alternative, include:

- Funding levels for maintenance and repair.
- Trail maintenance activities and reconstruction projects.
- Unclear past management direction for the wilderness transportation system.
- Management activities of adjacent or cooperating agencies.
- Recreational activities along the borders of these wilderness areas.
- Various different trail user types and levels.

Annual Maintenance and Funding: The effects of historical maintenance performed, and the past inadequate funding levels, is the same in this alternative as in Alternative 1. This leaves both forests with a substantial backlog maintenance load, which would take substantial funding to repair [see description of reconstruction below].

The greatest difference in this alternative is that the future effects of low funding levels on the trail system and resources are substantially reduced. Removal of commercial stock from 20 percent of system trails, removing more low standard trails from the system, and bringing trail classes into better alignment with what's on the ground reduces the need for maintenance, and could allow the deferral of maintenance work and funds to longer maintenance intervals with less effect on trail stability and resources. This beneficial effect is likely to be minor to moderate at the wilderness trail system scale, but may have major beneficial effects at the local level.

This alternative reduces trail classes on 50 percent of the trail system, which would reduce trail expenditures during the short term—especially when doing more substantial repairs, which could then be accomplished at a lower structural development. Over the long-term, however, it is

highly likely that a large number of the trails would not be developed, maintained, or repaired at a level capable of remaining stable with the continuing uses on the system—both commercial and non-commercial. These effects would be almost unnoticeable in the short-term, but would gradually increase over time, causing a higher level of future repair and resource stabilization cost.

Since non-commercial trail use is expected to continue at similar or slightly increased levels, and commercial use will still be present on 80 percent of the system, most impacts to the trail system that have occurred in the past, will continue to have effects on this lower-level trail system. As trails degrade, it is likely that there will be on and off trail effects to resources in the trail corridor. Less developed trails are more susceptible to climatic events and the effects of continued use, leading to erosion, sedimentation, and multiple trailing as stock and hikers bypass deteriorated sections of trail. Over the long-term, these effects would likely be moderate, with localized major impacts.

Reconstruction: The effects of past and current reconstruction efforts and the gradually declining budgets for repairs and reconstruction are the same in this alternative as in Alternative 1. The general effect is that long-term deferrals of maintenance and repairs have led to trail and resource instability that will require extensive investment. The declining funding for such work will make it more difficult to regain lost infrastructure and bring trails to standard.

The effects of implementing a clear management strategy and defined targets for trails on the system are the same as those described for Alternative 2 – Modified and the other action alternatives.

For reconstruction efforts on primary travel corridor (TC3) trails and spur trails in these high-use corridors, the effects should be generally similar to Alternative 2 – Modified, unless any of the spurs are additionally closed to commercial use. These trails would not require as high a scale of structural development for stability, so costs would be slightly reduced at the time of repairs.

Trails, which have degraded in recent decades, would likely be repaired to a lower standard than originally developed. Where use by commercial and non-commercial trail users is controlled or eliminated, this would not lead to instability, and would likely have some minor beneficial effects on wilderness character and resources in the trail corridor. Over the long-term, some trails that had once been primary corridor trails which provide access over the sierra crest (especially in the JMSE area) would likely be repaired to a lower standard than historically, and may become increasingly difficult to travel for all use types.

Past Management Direction for the Wilderness Transportation System: The effects of past inventories with unclear or incorrect direction are the same in this alternative as in Alternative 1. In general, the effect has been to make such direction mostly meaningless, and force trail managers on the forests to manage trails intuitively, with varied success.

As in other action alternatives, the effects of unclear management direction and inconsistent past trail inventories will gradually be corrected in this alternative as trails are managed with the new definitions, and consistently with area direction. In this alternative, there may be some long-term minor to moderate impacts on trails that may have inadequate development for anticipated use types and levels.

Adjacent or Cooperating Agencies: The effects of past actions on or by adjacent or cooperating agencies, such as the Department of Fish and Game or Park Service, are anticipated to be generally the same in this alternative as in Alternative 1.

In this alternative, trails that cross boundaries to contiguous trail systems on the NPS, have been aligned so that there should be a high level of consistency and negligible effects on trails and resources. Four of the five system trails providing access into the NPS in the JMSE Geographic Unit—Taboose, Sawmill, Baxter, and Shepherd Passes—are closed to commercial pack stock. Kearsarge Pass trail would be the only trail available to commercial stock to access the Sequoia and Kings Canyon National Parks between Bishop Pass and New Army Pass, a distance of approximately 100-trail miles. This will clearly affect travel patterns of commercial operators in the Parks, though it is unclear exactly how operators would adapt. It is likely commercial use would increase on trails near Bishop Pass, Kearsarge Pass, Cottonwood, and New Army Pass in order to provide services to some of the same destination in Sequoia and Kings Canyon, and use would decrease in areas immediately west of the four closed passes.

In this alternative, the Pacific Crest Trail is designated Trail Class 3, which is consistent with management by both agencies.

Future management decisions on the National Parks could have effects on the development levels of system trails or commercial activities on the Inyo and Sierra National Forests. These are unknown, and describing potential effects would be merely speculative.

Other Trail Uses—Past, Current, and Anticipated: The activities and effects of past, current, and future private hikers and equestrians on trails in these wilderness areas are the same as described in Alternative 1.

Regardless of any actions, which restrict commercial pack stock operations on trails, the effects of hikers and private pack stock will continue at similar levels under existing controls. The types and levels of use, which would continue to be accommodated under this alternative, will continue to have minor to moderate effects at the wilderness trail system scale, and moderate to isolated severe effects at localized trails.

The actions of reducing or eliminating commercial stock use from a large number of remote trails may have minor to moderate short-term beneficial effects on the trail experience of hikers and those seeking a more primitive experience. With only very rare use of these trails by private equestrians, it is likely that the trails will have less dust and little or no manure, which will improve the trail experience of some.

Non-wilderness Trails: Effects on non-wilderness trails are similar in this alternative as in Alternative 2 – Modified, except that there would be a slightly greater effect, due to greater limitations on wilderness use by commercial operators. There would likely be a displacement of use—primarily day use, but also overnight—to non-wilderness trails. It is expected that commercial operators will continue to access the wilderness areas using the current non-wilderness trail system. Where actions in this document reduce use—especially day use—within wilderness, commercial stock use will likely increase on non-wilderness trails, unless or until future controls are put into place.

These trails tend to be near pack stations and trailheads, where both public and commercial use is already highly concentrated. Most trails in these areas are relatively well developed, in response to a long history of high use, physical effects on the trails and resources are likely to be minor

overall, but may be evident in the need to increase future maintenance efforts—especially on less developed or non-system trails. There is also likelihood that further increases in day use in these already concentrated use areas may cause an increase in conflicts between stock and non-stock groups. The potential effects on the trails and associated resources would likely be minor to moderate at the Forest scale, and would likely result in isolated locally moderate to major trail and resource impacts.

Alternative 5

Summary of Impacts – Alternative 5

In this alternative, with the complete elimination of commercial stock from all trails, one of the contributors of trail-related impacts will not be present on any trail, so matching trail management to desired area management is more tied to the anticipated private use and recreation categories.

This alternative provides a very high consistency of trail management and desired area management. Reductions in overall stock use will result in some reduction in maintenance needs, reconstruction frequency and scale, and overall costs. This will allow mitigation of local resource problems on all trails, resulting in improved trail and resource stability.

The same trails as in Alternative 3 and 4 will be designated “Not Recommended for Stock,” which will provide clear visitor expectations and a better and safer experience for private equestrians. It is likely that private equestrian use will increase slightly, and would be expected to remain mostly on the more developed, comfortable, and stable trail system, which would result in very limited effect on trail or resource stability.

Use trails will not be used by commercial operators, but most will likely continue to be used at slightly lower levels by private equestrians and hikers. There is a lower likelihood for expansion of use trails, and slightly lower intensity of impacts, so some use trails would likely show minor improvement over the long term.

Overall, this alternative would provide a reduced intensity of adverse impacts on physical resources. Over the short term, there would be negligible to minor beneficial impacts, until physical mitigation is actually implemented. In the long term, this mitigation and other trail management would be more effective and long lasting, resulting in a more stable system. User conflicts between equestrians and non-stock users will be nearly eliminated, except in high-use corridors, where minor conflicts between private stock users and non-stock parties may continue.

Analysis

In Alternative 5, no commercial pack stock use would be present on the trail system. This would leave a very small number of privately owned pack and saddle animals using the system—currently estimated at 750 visitors using 1,100 animals each year. This constitutes less than 2 percent of overall current use, and just over 10 percent of the total equestrian use. The actual effect of such a small number of stock (assuming private stock did not increase substantially above current numbers) on the trail system is difficult to quantify, but would likely have very minimal trail infrastructure or resource effect.

Because no commercial stock would be present on 100 percent of the trail system, the resulting effects of stock on the trails would be minimal and on certain trails may cease altogether. Trail

development levels would not generally need to be as high and remain relatively stable, since the vast majority of stock use would cease. Trails would continue to be maintained at levels consistent with the anticipated use types, so non-commercial pack stock would still be allowed and accommodated. Trails which are currently very rugged and remote (and which are not practical for any but the most experienced stock and riders) would likely receive almost no recurring equestrian use, so trail and resource stability would increase over time. As shown in Table 4.47, this allows for the lowest development trail system.

Table 4.47. Alternative 5 system trail summary

SYSTEM TRAILS SUMMARY AA/JM Wilderness Totals	Number of miles
Total System Miles	955.9
TC1	229.6
TC2	417.3
TC3	301.2
TC4	7.8

It is expected private stock use would gradually increase somewhat above current levels since many who prefer to travel in this method, (and would otherwise have used commercial operations), would likely borrow or rent stock for their own use. It is unknown to what extent this use will expand, but the total would likely be considerably lower than current commercial stock levels.

Most private stock users would have somewhat less experience and skills with backcountry stock travel, and would have less knowledge of the specific trails and destinations than commercial packers. It is likely that most private or rented stock use would stay on the higher quality, well-developed trails, as compared to more remote and rugged trail systems. Primary TC3 trails—especially those serving busy trailheads—would still require high development and relatively frequent maintenance. Overall, there would likely be a reduced effect on trails and resources, because of the relative capability of well-developed trails to handle stock use.

Table 4.48: System trail miles comparison of Alternative 1 and 5

WILDERNESS-SCALE ACTION SUMMARY Compared to No Action	Miles
Added	46
Deleted	54
TC Down	421
TC Up	69

See Tables 2.26 in Chapter 2 for specific actions on each trail by alternative

As in Alternative 2, 3, and 4 in this alternative, both forests use the same definitions and more consistent interpretation of trail classes in determining management levels. Additionally, recreation categories and use levels were considered, so a more consistent distribution of trail

classes is evident in this trail inventory. Some adjustments were made recognizing that no commercial stock would be present on the trail system, and that private equestrians would still be present in low numbers. Since wilderness use levels on trails on the Sierra National Forest are somewhat lower, trail management levels would also tend to be lower. In this alternative, the Inyo National Forest total inventory was reduced 4.5 percent from the no action inventory, while the Sierra inventory was increased by 2.5 percent (see Table 4.49).

Table 4.49: Alternative 5 Inyo and Sierra N.F. trail summary

INYO NF Trail Class Summary	Miles	Percent of system	SIERRA NF Trail Class Summary	Miles	Percent of system
TC1	63	15%	TC1	167	31%
TC2	162	39%	TC2	255	47%
TC3	180	44%	TC3	121	22%
TC4	8	2%	TC4	0	0
Total	413		Total	543	

The greatest effect would be in the relative effectiveness and longevity of maintenance actions, which would reduce the long-term costs needed for maintaining the trails most heavily used by commercial stock. This would allow more trails to be maintained at close to their designated standard, improving the conditions for private equestrians and hikers on higher development, primary trails. Over time, it is likely that very little development of trails would be needed in more remote areas, and maintenance would be performed for resource stability. Higher development and maintenance would occur only in the highest recreation category areas.

Table 4.50: Alternative 5 system trail class summary by recreation category

Alternative 5	TC1	TC2	TC3	TC4	Total System
RC1	92	86	1	0	179
RC2	136	306	181	0	623
RC3	2	26	120	8	156
Total	230	418	302	8	958

In Alternative 5, some trails (which would then receive no commercial stock and very little private stock) could be managed at lower development levels than currently exist on the ground. However, since commercial stock make up less than 15 percent of current trail use, and since the majority of this use is on trails already heavily used by other wilderness visitors, most system trails would still require close to the same level of development and trail management.

Table 4.51: Alternative 5 trail class comparison

Alternative 5 Trail Class compared to Field-Observed level of Development	Miles
Miles of trail designated LOWER than existing development	155
Miles of trail designated HIGHER than existing development	52
Miles of trail designated CONSISTENT with existing development	749

Trails which currently receive commercial pack stock use (roughly 80 percent), especially those with moderate to high levels of recurring commercial stock use (50 to 60 percent of the trail system), would see the greatest improvement in condition and in reduced recurring maintenance needed. However, trails which are currently degraded and are subject to many risk factors—especially steepness and connectivity to water sources—would likely continue to degrade or, at best, remain in current condition. Conversely, the 20 percent of system trails, which have received little or no commercial or private pack stock, would see no noticeable change because of this alternative, and will mainly be influenced by trends in continuing hiker use of such trails.

The trails Not Recommended for Stock are the same as described in Alternative 3, and the effects would be the same. Since private equestrians would be the only stock present on the system, and private stock use might increase, this advisory would have an increased importance for educating and advising these trail users who may be less familiar with the trail system. There would be very incidental physical benefit to trail and resource stability, since fewer private stock parties may inadvertently travel these rough trails they may have otherwise avoided.

Table 4.52: Alternative 5 system trails suitability summary

SYSTEM TRAILS SUMMARY AA/JM Wilderness Totals	Alt. 5
Total System Miles	955.9
NSCS	All
Trails Available to Comm.	None
NRFS (Approx)	135

Compared to the trail system proposed in Alternative 1, there are a total of eight fewer miles of trail on the system inventory (see Table 4.52). About 46 miles of trail were added to the inventory and about 54 miles of trail were deleted. Additionally, adjustments in trail management levels were made, resulting in 68 miles of trail having an increase in designated trail class, and 407 miles of trail receiving decreased Trail Class. Since this was done to match conditions on the ground with Recreation Categories and anticipated commercial and private use levels, it is expected that the overall effect will be a more stable system where use is present. There could also be potential reduced costs where unnecessary trails were removed from the system or where management needs are reduced.

In this alternative, the primary factor affecting both the stability and the relative need for development on a trail, other than natural risk factors such as steepness or proximity to water, becomes the amount of non-commercial use by both hikers and equestrians. It is possible for large numbers of hikers to create effects similar to smaller numbers of stock—especially when certain risk factors exist, such as steepness, water connectivity, and loose soils. Currently, many trails are already degraded from the combined effects of past uses and will not improve unless all use is removed or physical mitigation performed. The most likely effect under Alternative 5 is trails, which have already degraded due to the combination of past uses, will continue to be disturbed by foot-traffic and occasional private equestrian use, which will keep vegetation from establishing in the trail tread. This leaves the potential for continued susceptibility to erosion and some resource damage, though somewhat less soil will be loosened and available for transport from the trail way, slowing the rate of degradation.

Commercial stock will not be present in the Ansel Adams and John Muir Wilderness areas under this alternative, so use trails that are currently serving their campsites and grazing areas would no longer be used by many equestrians. Since use levels will be reduced, and most equestrian use would be removed from the use trails, there would likely be some reduction in surface disturbance and soil loss. On a small percent of use trails, it is likely that there would be a slight upward trend in trail and resource stabilization over the long-term. However, most commercial stock operate in areas where there is a high level of other users, so most of the use trails addressed in this analysis will likely continue to be utilized by those other users at some level. Depending upon the level of use on each trail by private equestrians and hikers, most use trails that exist today would likely continue to exist, though many will become less evident over time.

With the reduction of stock use on highly degraded use trails, it is probable that the rate of degradation would slow and the trails would become somewhat more stable. However, current degraded use trails would not likely recover purely by the removal of commercial pack stock until physical mitigation is undertaken. Use trails in areas with many risk factors, whether used by commercial stock or only by other users, will likely continue to degrade. Physical stabilization of use trails will not likely occur during the short-term, as funding appropriate for such stabilization is highly limited and system trail funds cannot be utilized for stabilizing these non-system access routes. Over the long-term, these will gradually be repaired, with an emphasis on those with the greatest continuing resource effect.

Social conflicts between equestrians and non-stock users will be greatly reduced under this alternative, as the remaining private stock use will be considerably lower and more dispersed than current commercial stock use. Additionally, most private equestrians will likely utilize the most improved and least awkward trails of the system, and would probably self-limit their use away from those trails. Over time, hikers seeking an experience with little or no equestrian presence would likely adjust their trip planning to reduce interaction and potential conflict with the remaining private stock.

With the substantial reduction of pack stock, system trails will be subject to fewer impacts, such as those described in “common to all” above, which would otherwise degrade the trail surface and trail structures. In general, there would be reductions in resource effects, such as soil loss and off-trail sedimentation. Additionally, the trails would likely be more stable and easier to walk and ride on with a slightly reduced need for maintenance. This would allow maintenance resources to be allocated at higher levels and greater frequency to trails that currently receive substandard maintenance. This would also result in a reduction in the need for future larger-scale reconstruction efforts.

Table 4.53. Alternative 5 annual and backlog maintenance costs

Trail Annual Maintenance Costs AA/JM Wilderness	Cost
Total Estimated Cost	\$267,500
Current Annual Funding	\$170,000
Annual Maintenance Shortfall	\$97,500
Current Backlog (Repairs to Standard)	
Estimated Current Backlog	\$5,720,000

Alternative 5 has the lowest total maintenance costs, as well as the lowest backlog of heavy maintenance and reconstruction to bring trails to their designated standard. This is attributable to generally lower trail classes—with the rationale described above. With no commercial pack stock on any trails, and likely only small numbers of private stock on mostly higher development primary trails, trails will generally remain stable at lower development levels and lower annual maintenance treatments. It is likely that initial repair and mitigation of effects on resources in the trail corridor would be similar to the other alternatives—approximately three- to four-million dollars.

Long-term financial effects of removing all commercial stock from the wilderness trails would be a slight continuing reduction in maintenance expenditures. The greater cost reduction would be on heavy maintenance and reconstruction efforts over time, since trail structures would tend to last longer without the effects of frequent stock use. It is also likely that there would be somewhat less effect on resources within the trail corridor—primarily off-trail deposits of sedimentation transported by trails, and headcuts originating at trails. Over the long-term, this would reduce future expenditures for off-trail resource stabilization.

Cumulative Impacts—Alternative 5

Other past, present, and future actions, which may have an incremental or added effect when combined with trail-related actions in this alternative, include:

- Funding levels for maintenance and repair.
- Trail maintenance activities and reconstruction projects.
- Unclear past management direction for the wilderness transportation system.
- Management activities of adjacent or cooperating agencies.
- Recreational activities along the borders of these wilderness areas.
- Various different trail user types and levels.

Annual Maintenance and Funding: The effects of historical maintenance performed and the past inadequate funding levels is the same in this alternative as in Alternative 1. This leaves both forests with a substantial backlog maintenance load, which would take substantial funding to repair [see description of reconstruction below].

The greatest difference in this alternative is that the future effects of low funding levels on the trail system and resources are substantially reduced. Removal of commercial stock from all system trails, removing more low standard trails from the system, and bringing trail classes into better alignment with what's on the ground reduces the need for maintenance, and could allow the deferral of maintenance work and funds to longer maintenance intervals with less effect on trail stability and resources. This beneficial effect is likely to be moderate at the wilderness trail system scale, but will likely have major beneficial effects at the local level. These beneficial effects will increase over the long-term.

This alternative reduces trail classes on almost half of the trail system, which would reduce trail expenditures both short and long term—especially when doing more substantial repairs, which could then be accomplished at a lower structural development. Because there would be no commercial stock on any trail, and most private equestrians would be on higher development,

readily maintained trails, the development and maintenance levels in this alternative would be adequate to ensure a stable trail system over the long-term. These actions decrease the effects of reduced funding levels to a minor impact on trails and resources.

Reconstruction: The effects of past and current reconstruction efforts and the gradually declining budgets for repairs and reconstruction are the same in this alternative as in Alternative 1. The general effect is that long-term deferrals of maintenance and repairs have led to trail and resource instability that will require extensive investment. The declining funding for such work will make it more difficult to regain lost infrastructure and bring trails to standard.

The effects of implementing a clear management strategy and defined targets for trails on the system are the same as those described for Alternative 2 – Modified and the other action alternatives.

For reconstruction efforts on primary travel corridor (TC3) trails and spur trails in these high-use corridors, the effects should be generally similar to Alternative 2 – Modified, unless any of the spurs are additionally closed to commercial use. These trails would not require as high a scale of structural development for stability, so costs would be slightly reduced at the time of repairs.

Trails, which have degraded in recent decades, would likely be repaired to a lower standard than originally developed. Based on anticipated use and actions in this alternative, trails would still likely remain stable and adequate for both hikers and equestrians, though more trails would be of a primitive nature.

Past Management Direction for the Wilderness Transportation System: The effects of past inventories with unclear or incorrect direction are the same in this alternative as in Alternative 1. In general, the effect has been to make such direction mostly meaningless, and force trail managers on the forests to manage trails intuitively, with varied success.

As in other action alternatives, the effects of unclear management direction and inconsistent past trail inventories will gradually be corrected in this alternative as trails are managed with the new definitions, and consistently with area direction.

Adjacent or Cooperating Agencies: The effects of past actions on or by adjacent or cooperating agencies, such as the Department of Fish and Game or Park Service are anticipated to be generally the same in this alternative as in Alternative 1.

In this alternative, trails that cross boundaries to contiguous trail systems on the NPS, have been aligned so that there should be a high level of consistency and negligible effects on trails and resources. All trails leading to contiguous NPS trails would be closed to commercial stock. Many of these trails are long, rugged trails, and would probably have very little private equestrian use. This would likely have a minor beneficial effect on trails and resources in the trail corridors of NPS trails in the localized areas near the Forest boundaries.

In this alternative, the Pacific Crest Trail is designated Trail Class 3, which is consistent with its management by both agencies. Conditions of the PCT in the Parks would likely improve due to the elimination of commercial stock accessing it from the Forests.

Future management decisions on the National Parks could have effects on the development levels of system trails or commercial activities on the Inyo and Sierra National Forests. These are unknown, and describing potential effects would be merely speculative.

Other Trail Uses—Past, Current, and Anticipated: The activities and effects of past, current, and future private hikers and equestrians on trails in these wilderness areas are the same as described in Alternative 1.

Regardless of any actions that restrict commercial pack stock operations on trails, the effects of hikers and private pack stock will continue at similar levels under existing controls. The types and levels of use, which would continue to be accommodated under this alternative, will continue to have minor to moderate effects at the wilderness trail system scale, and moderate to isolated severe effects at localized trails.

The actions of reducing or eliminating commercial stock use from a large number of remote trails may have minor to moderate short-term beneficial effects on the trail experience of hikers and/or those seeking a more primitive experience. With only very rare use of these trails by private equestrians, it is likely that the trails will have less dust and little or no manure, which will improve the trail experience of some.

Non-wilderness Trails: Potential savings in trail expenditures on wilderness trails may allow additional maintenance work to be performed on non-wilderness system trails. If use did not change from current levels, this would help to create a more stable and enhanced non-wilderness trail system.

It is likely in the Alternative 5 scenario, that commercial use would be displaced to non-wilderness trails—primarily for day rides. Certain areas and trails would also provide overnight trail opportunities, and it is likely that additional maintenance funds would be expended to keep the non-wilderness trails stable under the anticipated increased use. There is also likelihood that further increases in day use in these already concentrated use areas may cause an increase in conflicts between stock and non-stock groups. It is likely that future controls would be necessary on pack station operations to ensure that physical resource impacts and social conflicts in these non-wilderness areas do not increase beyond an acceptable level.

These trails tend to be near pack stations and near trailheads, where both public and commercial use is already highly concentrated. Most trails in these areas are relatively well developed, in response to a long history of high use, so physical effects on the trails and resources are likely to be minor overall, but may be evident in the need to increase future maintenance efforts—especially on less developed or non-system trails. Non-system trails that currently receive incidental use may need to be added to the transportation system in future years. The potential effects on the trails and associated resources would likely be moderate at the Forest scale, and would result in isolated locally moderate to major trail and resource impacts.

Geographic Scale

The project file includes a geographic unit-level summary of system and use trails and use trail densities. These summaries include the following:

- System Trails Summary—Miles of trail-by-trail class and NSCS by alternative for each geographic unit.
- Use Trail Summary—Miles of use trail by alternative for each geographic unit.
- Use Trail Density—Densities of use trails per acre by geographic unit.

4.1.4 Heritage Resources and American Indian Concerns

Methodology

The specific methodology used in this analysis is provided in the Strategy for Compliance with Section 106 of the National Historic Preservation Act for Issuance of Special Use Permits for Pack Station Operations on the Inyo and Sierra National Forests. The strategy defines the area of potential effect, inventory methods, and determination of which resources are being impacted by the undertaking.

Context: The context of the impact considers whether the impact would be local or regional. For the purposes of this analysis, local impacts would be those that occur at site-specific locations within the wilderness. Regional impacts would be impacts to the entire wilderness, American Indian tribes, and communities with traditional cultural ties to the wilderness, and the academic community.

Intensity: The intensity of the impact considers whether the impact will be negligible, minor, moderate, or major.

Intensity of impact to heritage resources depends upon the data or commemorative value they contain and the extent of disturbance. If the resource is also traditional cultural sites, intensity considers access by traditional users and inappropriate use by others.

Duration: The duration of impacts is considered at short- and long-term scales. Impacts to resources of interest are irreversible and therefore long-term. Impacts to traditional plant collection areas may be short-term or long-term.

Type of Impact: Impacts to heritage resources were evaluated in terms of whether the impact is an adverse effect. An adverse effect is any action that alters the characteristics of a heritage resource that qualify it for eligibility to the National Register of Historic Places. Impacts to traditionally used plants are dealt with in the Biological Environment section.

Heritage Resources—Introduction

A number of Section 106 compliance documents (i.e., Archaeological Reconnaissance Reports, Cultural Resources Reports, and Heritage Resources Reports) and other reports were written about the Area of Potential Effects (APE) prior to the development of the Wilderness Programmatic Agreement. Work for the current analysis has focused on additional inventory, monitoring site condition, and updating vintage site records. Some sub-surface testing was conducted in the Mono Trail Corridor.

On the Sierra National Forest, data were collected on the location and condition of heritage sites during the 2000 through 2004 field seasons, resulting in intensive coverage of the majority of the APE. On the Inyo National Forest, work focused on rapid assessment conducted for the Cumulative Effects Analysis on both forests. This work included monitoring the condition of previously recorded sites and preliminary recording of newly discovered sites. Additional Section 106 work will be required. However, with four years of monitoring results and intensive inventory and rapid assessment data, sufficient information is available to determine the effects of the various alternatives on heritage resources. Specific inventory, evaluation, and assessment needs are identified in the Programmatic Agreement: Identification, Evaluation and Treatment of

Historic Properties within the Area of Potential Effect of Pack Station Operations on the Inyo and Sierra National Forests, California and Nevada.

A total of 506 individual heritage sites were found in the APE. Some of these are elements of historic landscapes and Traditional Cultural Properties (TCP) under consideration.

Methodology Discussion

Four steps will be taken to determine the effects of alternatives on heritage resources and the actions that will be taken to mitigate adverse effects:

1. Is the heritage resource a Resource of Interest?
2. Is the Resource of Interest affected by the alternative?
3. What is the nature of the effect?
4. What is the appropriate management option?

Resources of Interest

Resources of Interest are those heritage resources that may be affected by pack station operations and trail use. In 2001, a monitoring program was instituted to examine heritage resources in the wildernesses for condition and evidence of impacts. Over 300 sites were monitored. As can be seen in Table 4.54, impacts found were confined to some site types.

Table 4.54 Heritage monitoring results

Heritage Resource Type	Impacts	Resource of Interest
Historic trash dumps	Impacts noted near pack camps.	Yes
Historic drift fences	Removal will affect historic drift fences.	Yes
Historic mines	None noted.	No
Historic buildings	None noted.	No
Historic Dendroglyphs	None noted.	No
Historic & Prehistoric Rock structures (historic & prehistoric)	Structural elements removed for modern fire rings.	Yes
Heritage Resource Type	Impacts	Resource of Interest
Prehistoric Rock Art	None noted.	No
Prehistoric obsidian quarries & workshops	Trampling, erosion, soil compaction at campsites & in holding areas, disturbance of surface constituents, sub-surface disturbance in campsites, introduction of recent carbon in campsites, introduction of chemicals through manure spreading.	Yes
Sparse lithic scatters	Same as above	Yes
Prehistoric habitation sites	Same as above	Yes

Based on this analysis, Resources of Interest are historic trash dumps, rock structures, drift fences over 50-years old, and all prehistoric sites with the exception of rock art. Traditional American Indian values are discussed below.

It should be noted that archaeologists and historians also rely on fens and tephra deposits as sources of information about past environments and climates. Impacts to fens and soils are dealt with in other sections.

Historic Properties

Section 106 of the National Historic Preservation Act (NHPA) requires Federal agencies to consider the effects of their actions on historic properties. These are defined in the implementing regulations of the NHPA (36 CFR 00.16.1[1]): “Historic property means any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the National Register of Historic Places maintained by the Secretary of the Interior. This term includes artifacts, records, and remains that are related to and located within such properties. The term includes properties of traditional religious and cultural importance to an Indian tribe or Native Hawaiian organization and that meet the National Register criteria.”

Of the 506 known heritage resources within the APE, 458 were found to be Resources of Interest; 359 (88 percent) on the Sierra National Forest and 99 (22 percent) on the Inyo National Forest. For purposes of this analysis, Resources of Interest will be assumed historic properties as defined above unless further analysis demonstrates otherwise.

A table containing information on the Resources of Interest, including the effects of the alternatives, is available in the project record.

Type of Effect

Impacts to Resources of Interest may or may not constitute “adverse effects.” An adverse effect is one that diminishes the characteristics of a historic property that qualify it for inclusion in the National Register. Generally, these characteristics include integrity, association with important people and events, outstanding or the only remaining examples of architecture, etc., and scientific value (36 CFR 60).

We have classified effects as ambiguous and potentially adverse. Ambiguous effects are actions, which appear not to have an adverse effect on Resources of Interest; however, the current state of knowledge is not sufficient to positively state that such is the case. They comprise of dispersed grazing, existing trails going through sites in which it appears that continued trail use by either hikers or stock will not cause further impacts, and concentrated use (e.g., camping) near Resources of Interest.

Potentially adverse effects are those actions that directly affect Resources of Interest. Whether the impact is an adverse effect may require additional analysis in some cases. In some cases, consideration will be made regarding effects to the site as it stands alone and as it may contribute to a larger historic property type such as the Mono Trail Corridor TCP.

Table 4.55 provides a breakdown of the effects of particular pack station operations and trail use on Resources of Interest.

Table 4.55 Effects on resources of interest

Activity	Effect
Trail use	Ambiguous Effects/Potential Adverse Effects: Continued use in and of itself does not appear to be an adverse effect. Where use contributes to erosion, etc. there are adverse effects. Where the trail is of poor quality or blocked, thereby forcing detours, additional impacts may occur. Proximity to trails provides access to sites, some of which have backpacker camps on them.
Lunch stops, etc.	Potential Adverse Effects
Campsites	Potential Adverse Effects
Holding Areas	Potential Adverse Effects
Watering Areas	Potential Adverse Effects
Dispersed grazing	Ambiguous Effects

In addition to potentially adverse and ambiguous effects, there are heritage resources for which the impacts are not yet known, and heritage resources that are receiving no impacts from pack station operations or trail use.

Our present state of knowledge indicates that there are no impacts to 134 (29 percent) of the Resources of Interest, 86 (19 percent) are receiving potentially adverse effects, and 180 (39 percent) are in areas of ambiguity. Additional analysis will be required to determine whether impacts are occurring to 58 (13 percent) Resources of Interest (Table 4.1.20).

Management Options

Ambiguous Effects: A monitoring program to test the hypothesis that these impacts are not adverse effects will be designed when the final alternative is chosen. A representative sample will be chosen of Resources of Interest and effect type.

Adverse Effects: Where potential adverse effects to sparse lithic scatters are found, the Forests may make use of the CARIDAP: California Archaeological Resource Identification and Data Acquisition Program: Sparse Lithic Scatters (Jackson et al. 1988).

Where potential adverse effects to other Resources of Interest occur, one of the management options provided for in the Wilderness PA (VI)(a)(2) will be employed. These are:

- (a) No action, where after consulting with the PA parties, a Forest Supervisor determines that protective actions are inappropriate or infeasible;
- (b) Relocating or redirecting activities and programs causing impacts;
- (c) Capping or covering sites with earth, rock, plants, or plants that hold the soil and discourage excavation or other appropriate material;
- (d) Monitoring disturbance and intervention to halt, limit, or correct such disturbance;
- (e) Monitored deterioration without intervention;
- (f) Educational and interpretive use consistent with the Wilderness Act;
- (g) Law enforcement;
- (h) Stabilization; and

(i) Data recovery.

An implementation and monitoring program to monitor site condition and the effectiveness of mitigation measures will be designed when the final alternative is chosen. A representative sample of resource types, impacts, and mitigation measures will be chosen.

Unknown Effects: The treatment of unknown effects will be monitoring and conducting an assessment of effect. Assessment of effect will range from a review of existing information to data recovery depending upon the resource type and its location to pack stock operations and trail use.

Wilderness Scale

Analysis

Direct impacts include camping on sites, removal of structural elements of historic and prehistoric rock structures for campfire rings, trampling of flaked stone artifacts, loss of horizontal and vertical integrity due to erosion caused by soil compaction, loss of site constituents due to illegal collection, excavation into sites for latrines, and introduction of recent carbon and other chemical elements into site deposits.

Indirect effects to heritage resources include all the above activities that take place near but not directly on Resources of Interest. Impacts may be less severe but sufficiently damaging to warrant managerial treatment to reduce or eliminate impacts. Indirect effects also include illegal collection, excavation, and vandalism.

Adverse effects caused by illegal artifact collection and vandalism cannot be assigned to any one user group or activity. Evidence of illegal collection at prehistoric sites was found throughout the two wildernesses. This impact may be mitigated through educational partnerships between the Forests and the commercial stock packers and public education directed toward backpackers and day-use recreationalists.

Cumulative Impacts

A number of past actions have had impacts on existing heritage resources and, in some cases, given rise to new ones such as Gem Lake Dam, a significant historic structure. Past actions have also affected traditional Native American uses. Dam and water impoundments have caused inundation of heritage resources, traditionally used travel corridors, and plant collection areas, with continuing impacts to sites along shorelines through wave action and the raising and lowering of water levels. Mines and cabins appear to have had less impact to prehistoric sites and traditional activities. Grazing hugely affected the Sierran environment in the 19th century and affected the presence and abundance of traditionally used plants. Historic grazing that adversely affected prehistoric sites may be assumed based on the observed effects of modern grazing impacts. Where existing adverse effects are allowed to continue there will be a downward trend in heritage values, e.g., site integrity, data potential, and character.

Geographic Scale

Alternative 1

Analysis

The number and types of Resources of Interest impacted under this alternative are presented in the table below.

Because pack station operations may expand beyond existing areas, and all camps are open for use, new adverse effects may occur. Evidence of this is seen in holding areas that are spreading out. Removal of drift fences will require historic evaluation.

Table 4.56 Alternative 1 effects to resources of interest by geographic unit

Analysis Unit	Potential Adverse Effect	Ambiguous Effect	Unknown	No Effect	total
Ansel Adams East	21	45	5	14	85
Ansel Adams West	13	38	16	49	116
Fish Creek/Convict/McGee	18	20	5	15	58
Rock Creek/Mono Creek	25	26	8	16	75
Bishop/Humphreys	5	15	4	13	37
Florence/Bear	1	19	16	23	59
John Muir SW	2	16	3	4	25
John Muir SE	1	1	1	0	3
Total	86	180	58	134	458
	18.78%	39.30%	12.66%	29.26%	100.00%

Cumulative Impacts

The constant expansion of the effects of pack station operations will result in the loss of additional heritage values, leading to a wilderness-wide loss of prehistoric information. This would be particularly tragic because the area has received so little scientific study.

Alternative 2—Modified, Alternative 2, and Alternative 3

Analysis

With designated overnight camping and holding areas for pack station operations, adverse effects will be more confined and easier to mitigate. Impacts from trail use and non-commercial campsites will continue.

Drift fences scheduled for removal will require historic evaluation.

The following table summarizes the impacts of Alternatives 2 and 3 on heritage resources.

Table 4.57 Alternatives 2—Modified, 2 and 3 effects to resources of interest by geographic unit

Analysis Unit	Potentially Adverse Effects	Ambiguous Effects	Unknown Effects	No Effect	total
Ansel Adams East	22	45	4	14	85
Ansel Adams West	13	38	16	49	116
Fish Creek/Convict/McGee	18	20	5	15	58
Rock Creek/Mono Creek	25	26	8	16	75
Bishop/Humphreys	5	15	4	13	37
Florence/Bear	1	20	16	22	59
John Muir SW	2	16	3	4	25
John Muir SE	1	1	1	0	3
total	87	181	57	133	458
	19.00%	39.52%	12.45%	29.04%	100.00%

Cumulative Impacts

Where existing impacts are allowed to continue there will be a downward trend in heritage values.

Alternative 4

Analysis

With designated overnight camping, holding areas, and spot and dunnage sites for pack station operations, adverse effects will be even more confined and more easily mitigated. Impacts from trail use and non-commercial campsites will continue. Drift fences scheduled for removal will require historic evaluation.

The following table summarizes the impacts of Alternative 4 on heritage resources.

Table 4.58 Alternative 4 effects to resources of interest by geographic unit

Analysis Unit	Potentially Adverse	Ambiguous Effects	Unknown Effects	No Effect	total
Ansel Adams East	21	45	5	14	85
Ansel Adams West	13	38	16	49	116
Fish Creek/Convict/McGee	18	20	5	15	58
Rock Creek/Mono Creek	19	29	9	18	75
Bishop/Humphreys	3	17	4	13	37
Florence/Bear	1	20	16	22	59
John Muir SW	2	16	3	4	25
John Muir SE	1	1	1	0	3

Analysis Unit	Potentially Adverse	Ambiguous Effects	Unknown Effects	No Effect	total
total	78	186	59	135	458
	17.03%	40.61%	12.88%	29.48%	100.00%

Alternative 5

Analysis

With commercial packing removed from the project area, there will be a substantial decrease in impacts to Resources of Interest, however impacts from private stock and backpacking will continue.

The following table summarizes the impacts of Alternative 5 on heritage resources.

Table 4.59 Alternative 5 Effects to effects to resources of interest by geographic unit

Analysis Unit	Potentially Adverse Effects	Ambiguous Effects	Unknown Effects	No Effect	total
Ansel Adams East	8	42	8	27	85
Ansel Adams West	8	39	19	50	116
Fish Creek/Convict/McGee	11	24	5	18	58
Rock Creek/Mono Creek	13	32	11	19	75

	9.39%	42.14%	14.85%	33.62%	100.00%

American Indian Concerns Common to All Alternatives

Analysis

While tribal communities may not focus on the scientific value as much as the archaeologist, they assign cultural value of all prehistoric and some historic sites. In addition to historic sites, there are traditionally used plants, collecting areas, and spiritual and cultural use areas impacted. The sacredness of some areas and access by traditional users may be affected by too many visits and activities by the public.

Areas of special American Indian concern are Blayne Hot Springs and Iva Bell Hot Springs sacred sites, Summit Lake mythological area, Hutchinson Meadow traditional meeting site, Quail Meadow basketry material gathering area, and the Bloody Canyon, Mono, Piute, and Taboose Pass traditional trails.

In the Ansel Adams East Analysis Unit, a Traditional Cultural Property evaluation of the Bloody Canyon Trail needs to be prepared and a management plan developed to protect traditional values and ensure access to traditional users.

In the Ansel Adams East and Bishop/Humphreys Analysis Units, a Traditional Cultural Property evaluation and management plan for the Mono Trail Corridor has been prepared and its recommendations included in this analysis.

In the Rock Creek/Mono Analysis Units, a traditional gathering area of *Carex* sp. in Quail Meadow (Second Recess Analysis Units) requires protection from grazing impacts.

In the Florence/Bear Analysis Units, the Summit Lake area in the Dutch Analysis Unit, and Blayney Hot Springs in Sallie Keyes Analysis Unit are areas of traditional cultural value.

Access to the Taboose Pass trail in Taboose Analysis Unit and Kearsarge Pass trail in Kearsarge Analysis Unit for traditional uses will be protected.

In addition to prehistoric sites, there are traditionally used plants and collecting areas impacted by current use. The sacredness of some areas may be affected by too many visits and activities. On the positive side, traditional activities and access by elders to traditional areas is facilitated by pack stock.

Cumulative Impacts

Unabated adverse effects to prehistoric sites also affect traditional cultural values and erase the landscape history of native people. Impacts to spiritual and cultural use areas, as well as traditionally used plants, adversely affect the ability of the people to practice traditional lifeways. Degradation of what the western world terms “wilderness values” affects the sacred quality of the wilderness to Native Americans.

Downward trend in heritage values, potential loss of sacred character of sacred sites. A discussion of plants is provided in the Botany section.

4.1.5 Socioeconomics and Operations

The impacts analysis evaluated two separate socioeconomic areas, the regional economy, and the pack station operators. Quantitative analysis of potential effects on socioeconomic conditions was measured with the IMPLAN model. In addition, professional judgment was applied to reach reasonable conclusions as to the context, intensity, and duration of potential impacts. The analysis identified how potential management actions under each alternative would affect operations operated by the primary permittees.

Context: The context of the impact considers whether the impact would be local or regional. For the purposes of this analysis, local impacts would be those that occur within the wilderness and cities and towns surrounding it. The regional impacts are the impacts at the county-level scale. As discussed in the analysis, the context for a majority of the effects analysis will be at the regional scale. There is little data available at the local scale.

Intensity: The intensity of the impact considers whether the impact would be negligible, minor, moderate, or major. Negligible impacts were effects considered not detectable and would have no discernible effect on the socioeconomic environment. Minor impacts were effects on the socioeconomic environment that would be slightly detectable but would not be expected to have an overall effect. Moderate impacts would be clearly detectable and could have an appreciable effect. Major impacts would have a substantial, highly noticeable influence on the socioeconomic environment and could permanently alter the socioeconomic environment. These designations, negligible, minor, moderate, and major are used to describe both beneficial and adverse impacts

Duration: The duration of the impact considers whether the impact would occur in the short term or the long term. A short-term impact would be temporary in duration and would be associated with transitional types of activities. A long-term impact would have a permanent effect on the socioeconomic environment.

Type of Impact: Impacts were evaluated in terms of whether the impact would be beneficial or adverse to the socioeconomic environment. Beneficial socioeconomic impacts would improve the social or economic conditions in the affected region. Adverse socioeconomic impacts would negatively alter social or economic conditions in the affected region.

Wilderness Scale – Summary of Effects

Alternative 1

This alternative will continue 2001 Wilderness Plan management and lift the 20 percent court-ordered reduction in use. This will likely lower some of the costs to commercial pack stock operations and may allow some increase in revenue. The regional economy will experience negligible economic gain from this revenue increase. Under this alternative, there are no known effects to the social environment.

Alternative 2 Modified

This alternative will provide some modest opportunities for growth in pack station revenue (compared to Alternative 1), but will also implement a number of controls that will likely increase the costs to pack stations providing commercial services in the Ansel Adams and John

Muir Wildernesses. Cost increases are likely to be minimal-to-moderate and long-term. This will likely push the costs of commercial pack stock supported trips higher than their current levels. Compared to the No Action alternative, the regional economy will likely experience increased employment and labor income contributions from commercial pack stock operations. When compared to the economy as a whole, however, these increases are likely to be negligible-to-minor. Under this alternative, there are no known effects to the social environment.

Alternative 2

For Alternative 2, the operations and economic effects are expected to be similar to that for Alternative 2 – Modified. There are no known social effects associated with Alternative 2.

Alternative 3

For Alternative 3, the operations and economic effects are expected to be similar to that for Alternative 2 – Modified. There are no known social effects associated with Alternative 3.

Alternative 4

This alternative will impose restrictions on commercial pack stations that will likely cause the greatest cost increases when Alternatives 1 through 4 are compared. Compared to Alternative 2 – Modified and Alternatives 2 and 3, Alternative 4 will likely result in decreased commercial pack stock related employment and labor income contributions. The effects to the regional economy are expected to be negligible and virtually undetectable. There may be some minor social effects as some low income groups find the price of commercial packs stock trips have increased to unaffordable levels.

Alternative 5

This alternative eliminates commercial pack stock in the Ansel Adams and John Muir Wildernesses. With this alternative, there will be no commercial pack stock related labor income and employment contributions to the regional economy. The effect of this is likely to be minor and long-term. There may be some social effects associated with this alternative. Groups and individuals that rely upon commercial pack stock to access the wilderness will experience major effects. Likewise, those that have close ties to the historical and cultural significance of pack stock in the wilderness will experience major effects (although there is no abolishment of private stock under this alternative). Conversely, others will approve of the elimination of commercial pack stock in the wilderness and will likely believe that their wilderness experience will be enhanced.

Introduction

This section combines the operations and economics section and discusses the effects of the six alternatives on the regional economy and the operations of the pack stations. First, using the IMPLAN model, the regional economic contribution of pack station operations of Alternatives 1 through 5 will be analyzed. The alternatives will be compared using labor income and employment figures. Next, the impact of the six alternatives on the operations of the pack stations will be analyzed. Lastly, using reported pack station revenue figures, use numbers, and prices of various pack supported services, the impacts of the six alternatives on the public's

demand for the service will be examined. A short discussion of the social effects of the six alternatives will follow the economic and operations analysis.

This discussion focuses on the wilderness activities of the pack stations. Most, if not all, of the pack stations also have activities on non-wilderness lands that are not analyzed in the discussion below.

Regional Economic Analysis—All Alternatives

Analysis

The Impact Analysis for Planning (IMPLAN) model was used in Chapter 3 to provide the baseline or current economic contribution of commercial pack station operations. The economic analysis in Chapter 3 is at the county scale; reliable economic data is generally available at this scale. Reliable economic data is generally not available at the city or town scale. In Chapter 3, then, the economic analysis is at the county scale and it reveals that commercial pack stations make up a relatively small percentage of labor income and jobs in the project area.

It is important to note that while at the county scale, impacts to commercial pack station operations would not cause a noticeable effect to county economies; the changes to this baseline may be profoundly felt in small communities located in close proximity to a pack station. Big Pine, California, a small town in Eastern Sierra Nevada (population 1,200), for example, is located close to Glacier Pack Station. Glacier Pack Station employs a handful of full time and seasonal employees and in 2003 serviced 437 people. Although this is considered a small pack station in terms of gross revenue and people serviced, the economy of Big Pine will surely feel the economic impact to Glacier Pack (both in terms of local employment and visitor spending) more profoundly than the county as a whole. The drawback of an analysis at the county scale is that these localized economic impacts go virtually undetected.

The IMPLAN model will be used to determine the economic impact of the different alternatives. As discussed in Chapter 3, this model is a standard input/output model. For this project, the inputs needed to determine the economic contribution of commercial pack stations is the gross revenue generated by commercial pack stations and the number of people serviced by the operations. The output is the number of jobs and labor income generated from commercial pack station activities.

Table 4.60 shows the number of people serviced and gross revenue figures for the east and west side pack stations. The five alternatives that permit commercial pack stock have different control mechanisms to regulate use and these mechanisms are not easy to compare to one another. The intent of the analysis is to determine the maximum number of people that may be served under each alternative. In order to generate the number of overnight people serviced for Alternatives 1 and 4, the overall service day numbers were used. To reflect the average night stay of commercial pack clients, the service day number was divided by two. This number was added to the day ride service day allocations. For Alternative 2 – Modified, a range of economic impacts are given. The range is derived from the description of Alternative 2 – Modified which provides an overnight range of 3,000 to 5,500 clients and a day use range of 3,000 to 4,000 clients. In Alternatives 2 and 3, the stock number threshold is used and multiplied by .58 (the average number of stock per person in a party) to generate the total number of people serviced. This number is added to the day use numbers provided for Alternatives 2 and 3. To generate the gross revenue of all the pack stations, the overnight people serviced number is multiplied by \$250 (the

average cost per person of an individual utilizing overnight pack station services) and the day ride number is multiplied by \$100 (the average amount of money spent for day ride commercial pack services). Table 4.60 shows these calculations and the total number of people serviced under each alternative and the expected gross revenue to the pack stations from these clients.

Table 4.60 Overnight people serviced and gross revenue by alternative

	Alternative 1	Alternative 2 - Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
East Side Pack Stations						
People Serviced	10,750 (13,300 service days /2 + 4,100 day rides)	6,000-9,500 (3,000-5,500 overnight + 3,000-4,000 day rides)	11,001 (Seasonal Stock Threshold 10950 x .58 + 4650 day rides)	10,216 (Seasonal Stock Threshold 9510 x .58 + 4700 day rides)	8320 (10,640 service days/2 + 3000 day rides)	0
Gross Revenue	\$2,072,500 (6,650 x \$250/person + 4,100 x \$100/person)	\$1,050,000-\$1,775,000 (3,000-5,500 x \$250 + 3,000-4,000 x \$100)	\$2,052,750 (6,351 x \$250 + 4,650 x \$100)	\$1,849,000 (5,516 x \$250 + 4,700 x \$100)	\$1,630,000 (5320 x \$250 + 3000 x \$100)	\$0
West Side Pack Stations						
People Serviced	2,028 (2855 service days/2 + 600 day rides)	Included above in Alternative 2 – Modified	3,191 (Seasonal Stock Threshold 3605 x .58 + 1100 day rides)	3,158 (Seasonal Stock Threshold 3980 x .58 + 850 day rides)	1,492 (2284 service days/2 + 350 day rides)	0
Gross Revenue	\$417,000 (1428 x \$250/person + 600 x \$100/person)	Included above in Alternative 2 – Modified	\$632,750 (2091 x \$250 + 1100 x \$100)	\$662,000 (2308 x \$250 + 850 x \$100)	\$320,500 (1142 x \$250 + 350 x \$100)	\$0

Using the IMPLAN model, the labor income and employment by alternative were determined. Both the labor income and employment numbers were generated using the gross revenue figures from above and taking the people serviced, dividing by two (the average party size on the forest) and multiplying that number by the average spending per party as described in the Spending Profiles of National Forest Visitors report. This study identifies the average spending per party as approximately \$200 per day. The IMPLAN model determines the labor income and employment contributions of commercial pack station wilderness-based activities. The gross revenue of pack stations and the public's spending associated with the visit (on gas, lodging, food, etc.) are inputted into the model. Both the labor income and employment figures represent the results from the combined contribution of direct, indirect, and induced pack station related spending.

Table 4.61 Labor income and employment contribution by alternatives

	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
East Side Pack Stations						
Labor income (in dollars from gross revenue and visitor spending)	\$2,177,162	\$1,157,523-\$1,893,490	\$2,191,203	\$2,003,921	\$1,669,052	\$0
Employment (in number of jobs from gross revenue and visitor spending)	118.9	62.5-103.1	119.3	108.8	93.1	0
West Side Pack Stations						
Labor income (in dollars from gross revenue and visitor spending)	\$477,306	Included above in Alternative 2 – Modified	\$740,306	\$749,058	\$357,440	\$0
Employment (in number of jobs from gross revenue and visitor spending)	18.5	Included above in Alternative 2 – Modified	28.6	29	13.8	0

As shown in Table 4.61, Alternative 2 provides the greatest economic contribution to the east side project area—\$2,191,203 in labor income and 119 direct, indirect, and induced jobs created. By comparison, the east side project area, in 2000, had 19,176 jobs and total personal income of \$783,593,000. Comparing these numbers to those of Alternative 2 shows that pack station activities are a small percentage of the overall county economy (approximately .3 percent of the total county employment and approximately .4 percent of total personal income).

In the west side project area, in 2000, there were a total of 270,482 jobs and \$20,218,630,000 in total personal income. In Alternative 3 (the alternative with the greatest labor income and employment numbers), the economic contribution of the pack station industry is .01 percent of total project area employment and .004 percent of total personal income. Again, these economic outputs reflect inputs that may overstate the number of clients serviced under each alternative. The intent of the analysis is to provide a maximum labor income and employment number for each alternative.

Similarly, under Alternative 2 – Modified commercial pack stations provide a small percentage of the personal income and employment when compared to overall county numbers. For the entire project area, the employment contribution of commercial pack stations is .02 to .04 percent of all employment. In terms of labor income, commercial pack station operations make up .006 to .009 percent of the income for the entire project area.

The discussion above needs to be balanced with the uncertainty associated with how all the various components and mechanisms in the alternatives will interact. Alternative 2 – Modified, for example, has a number of mechanisms to control commercial pack station use. Exactly how a destination quota, combined with a grazing zone strategy, along with a maximum stock in the wilderness at one time, concept will affect the pack stations' gross revenue is difficult to determine. Likewise, the effect of these mechanisms on the public's use of the service is difficult to quantify. It may be that the operators can pass their increased costs of doing business on to consumers in the form of increased prices and there will be no effect to the public's demand for

the service. It may also be, however, that increased costs associated with the alternatives cannot be passed on to the customer and will be simply absorbed by the business.

The discussion below focuses on the impact of the alternatives on various aspects of the commercial pack station operations. These impacts are discussed in a context of how the alternatives affect the overall costs and ultimately the gross revenues of the commercial pack stations. No attempt is made to quantify the effects that these alternatives may have on the costs and gross revenue of commercial packers. Rather, the discussion centers on portions of the commercial pack station business that would expect to see increased costs as a result of the six alternatives. Likewise, where the alternatives provide opportunities for revenue growth, these opportunities are also discussed.

Effects to Operations—All Alternatives

Analysis

Methodology: A team of Forest Service employees, including auditors, was assembled to analyze and determine the impact that the six alternatives would have on the operations and the revenue stream of commercial pack station operators. This analysis had several steps. First, all known records of commercial pack stock use and operations data were assembled and examined. Next, the six alternatives were thoroughly reviewed and analyzed. These alternatives were deconstructed to determine the individual components that might effect pack station operations and revenue. The following components were identified and analyzed using the indicators (see indicators below):

- Use Levels and Stock Numbers
- Grazing Management
- Trail Suitability
- Campsites
- Campfires

Once the components of each alternative were identified, indicators were developed that would help measure the impact of a particular alternative component on pack station revenue or operations. These indicators were also used as a means to compare and contrast the alternatives. The team concluded that the following operational indicators would effectively measure the differences between alternatives and their effects to commercial pack stock operations.

- Number of employees
- Number of stock (including training, veterinarian care, shoeing, stock-related facilities, tack)
- Stock support needs while in wilderness (including additional animals to pack in feed and/or holding facilities)
- Truck transportation to alternative trailheads (including fuel costs, contracting for transportation services, and cost of time for transport)
- Revenue (overall expected increase or decrease in revenue)

To analyze the operations at an industry scale, the team determined that current and proposed pack stock operations fall into three “complexity” groups. These complexity groups are high complexity, moderate complexity, and low complexity. Of the twenty-one current or proposed commercial pack stock operations eight are low complexity, eight are moderate complexity, and five are high complexity.

Eight low complexity operations had these practices in common:

- largest proportion of business is day rides, dunnage, and/or spot trips
- generally operate within a discrete area, utilizing trailheads closest to pack station base facility; trucking seldom used to access these main trailheads
- generally service groups of 8 to 10 clients per trip, very seldom maximize allowed party size and stock numbers
- generally hold less than 50 head of stock at the base facility for overall operation (including wilderness, non-wilderness, and other lands)
- minimal to no (less than 5 percent of trips) holding stock overnight in the wilderness
- grazing of stock within wilderness not critical to, and is not used, for current operations

Eight moderate complexity operations had these practices in common:

- largest proportion of business is day rides, dunnage, and/or spot trips
- generally operate within a discrete area, utilizing trailheads closest to pack station base facility; trucking may be used to access these main trailheads
- generally service groups of 8 to 10 clients per trip, maximize allowed party size and stock numbers a few trips per year
- generally hold between 50 to 100 head of stock at the base facility for overall operation (including wilderness, non-wilderness, and other lands)
- moderate to minimal (20 to 30 percent of trips) holding stock overnight in the wilderness
- grazing of stock within wilderness not critical to current operations, though it is a benefit when grazing can be utilized

Five high complexity operations had these practices in common:

- extensive operating area, use of in-house or commercial trucking to access distant trailheads
- often maximizes allowable group size and stock numbers
- generally higher percentage of business (relative to other pack stations) are full service as opposed to day rides, dunnage, and/or spot trips
- generally hold more than 100 head of stock at the base facility for overall operation (including wilderness, non-wilderness, and other lands)
- extensive (greater than 30 percent of trips) holding stock overnight in the wilderness
- grazing of stock both inside and outside wilderness critical to current operations

The indicators were used to analyze the various components of the alternatives and determine whether the component would, for example, increase or decrease the number of employees needed. Each alternative is discussed and analyzed in terms of the impact to low, moderate, and high complexity operations. Alternative 1 is the baseline alternative (and, essentially, the current situation) and all other alternatives are compared to it.

Summary of Operational and Expected Revenue Changes for All Alternatives

A full analysis of the expected effects to operations and revenues is available at the end of the section. Comparing alternatives, the following proposed management components are likely to result in no measurable change to commercial pack stock operations or expected revenue: primary operating areas and trail suitability for system and user trails (with the exception of Alternative 4 which does not allow commercial pack stock on some trails currently utilized by these operations).

Comparing alternatives, the proposed grazing strategy is likely to result in the greatest change to commercial pack stock operations (specifically, the high complexity operations). This change will likely take the form of packing in more feed with an increased number of stock and employees needed for the average overnight trip. Increased costs associated with increased stock and employees per trip will likely result in a decrease in net revenue.

Operational Changes by Alternative

Alternative 1 should result in no measurable operational changes. The removal of the court-ordered 20 percent reduction, however, may increase gross revenue.

In Alternative 2 – Modified, the following components are likely to result in the greatest change to commercial pack stock operations and expected revenue:

- Destinations quotas/management
- Maximum stock in the wilderness at one time limit
- Grazing Strategy
- Decreased group size at identified locations
- Campfire policy

In Alternative 2 the following components are likely to result in the greatest change to commercial pack stock operations and expected revenue:

- Destination quotas
- Grazing strategy
- Decreased group size at identified locations
- Campfire policy

In Alternative 3 the following components are likely to result in the greatest change to commercial pack stock operations expected revenue:

- Decreased group size at identified locations
- Grazing strategy

In Alternative 4 the following components are likely to result in the greatest change to commercial pack stock operations expected revenue:

- Day ride allocation
- Service day allocation
- Trailhead quotas (no borrowing)
- Decreased party size
- Designated campsites
- Grazing strategy
- Trail Suitability

In Alternative 5, the elimination of commercial pack stock operations in the project area will severely affect operations and expected revenue.

Results of Operations Effects Analysis

The indicators were used to analyze the various components of the alternatives and determine whether the component would, for example, increase or decrease the number of employees needed. Each alternative is discussed and analyzed in terms of the impact to low, moderate, and high complexity operations. Alternative 1 is the baseline alternative (and, essentially, the current situation) and all others alternatives are compared to it.

Alternative 1

Low Complexity Operations:

Determination: No change in number of employees, number of stock, wilderness stock support, or transportation practices is expected. Availability of temporary service day pool (unassigned service days) allows for some flexibility in meeting market demand if grazing and other resource concerns are within prescribed standards. No increase or decrease in revenue is expected.

Moderate Complexity Operation:

Determination: No change in number of employees, number of stock, wilderness stock support, or transportation practices is expected. Availability of temporary service day pool (unassigned service days) allows for some flexibility in meeting market demand, if grazing and other resource concerns are within prescribed standards. No increase or decrease in revenue is expected.

High Complexity Operation:

Determination: No change in number of employees, number of stock, wilderness stock support, or transportation practices is expected. Availability of temporary service day pool (unassigned service days) allows for some flexibility in meeting market demand, if grazing and other resource concerns are within prescribed standards. No increase or decrease in revenue is expected.

Alternative 2 – Modified

Low Complexity Operations:

Change in number of employees, number of stock, stock support in wilderness, and/or transportation needed:

1. Determination: No change in number of employees, stock, or transportation needs expected as a result of the institution of destination quotas, limits on the number of stock in the wilderness at one time, party size of 15 to 25, grazing strategy, system and user trail suitability determinations, or overnight stock holding campsite designations. No increase or decrease in revenue is expected.

Rationale: In general, even though destination quotas should be less restrictive than trailhead quotas for total number of trips available, the maximum number of stock in the wilderness at one time limit are likely to result in no operational changes compared to Alternative 1. Low complexity operations rarely expand their use outside existing “operating areas,” rarely reach the 15 to 25 party size limit, and as a rule, do not utilize overnight campsites or overnight stock grazing in the project area. Most of the trails identified as “not suitable for commercial stock” have minimal or no current pack station use, although there are some significant exceptions, particularly in the John Muir Southeast Geographic Unit.

2. Determination: If fully utilized by operators in this category, day ride use allocations and the campfire policy in this alternative could result in an opportunity for increased revenue for commercial pack station operations.

Rationale: In general, these operators would realize an increase in allocated day use days (from those described in Alternative 1). Expanding the business in this arena would result in increased need for both employees and number of stock. Allowing pack station operators case-by-case exceptions to the elevation fire closure and the ability to have charcoal fires above the current 10,000 foot closure in Alternative 1 is likely to draw customers who want campfires at higher elevations, resulting in increased number of employees and stock to provide for additional clients and presumably a potential increase in revenue for pack stations.

Moderate Complexity Operation:

Change in number of employees, number of stock, stock support in wilderness, and/or transportation needed:

1. Determination: No change in number of employees, stock, or transportation needs expected as a result of the institution of day-ride allocations, destination quotas, limits on the number of stock in the wilderness at one time, party size of 15 to 25, system and user trail suitability determinations, or overnight stock holding campsite designations. No increase or decrease in revenue is expected.

Rationale: In general, day-ride allocations remain similar to those allocated in Alternative 1. Even though destination quotas should be less restrictive than trailhead quotas for total number of trips available, the maximum number of stock in the wilderness at one time limit are likely to result in no operational changes compared to Alternative 1. Generally, moderately complex operations rarely service clients in areas outside the assigned destination management zones. There is no expected change in transportation operations. Most of the trails identified as “not

suitable for commercial stock” have minimal or no current pack station use, although there are some significant exceptions, particularly in the John Muir Southeast Geographic Unit.

Designated campsites are those identified with historic use and should not limit or increase business operations.

2. Determination: If fully utilized by operators in the moderate complexity category, instituting the campfire policy in this alternative could result in an opportunity for increased revenue for commercial pack station operations.

Rationale: By allowing pack station operators case-by-case exceptions to the elevation fire closure and the ability to have charcoal fires above the current 10,000 foot closure in Alternative 1 is likely to draw customers who want campfires at higher elevations, resulting in increased number of employees and stock to provide for additional clients.

3. Determination: Grazing strategy identified in Alternative 2 – Modified may require an increased number of employees and wilderness stock support. While this will likely increase costs for commercial pack stations, it is unknown if revenue would decrease or remain stable.

Rationale: In general, moderate complexity pack station operations do not rely on overnight grazing in the project area. However, grazing limitations proposed in Alternative 2 – Modified are nonetheless likely to require more wilderness pack stock support, including increased employee time supervising grazing stock to keep them out of sensitive meadow areas and the need to pack feed in for stock where grazing nights are not available. Since most of these operators, either graze little or pack in feed as a matter of business, implementing these grazing limitations may require a few additional pack stock and additional employees to manage the stock. Furthermore, Alternative 2 – Modified proposes to rest, rather than close, approximately ten meadows. These meadows will be reevaluated for grazing suitability in three to five years. If these meadows are reopened to grazing, commercial operators may find they need to pack less feed into some areas.

High Complexity Operation:

Change in number of employees, number of stock, stock support in wilderness, and/or transportation needed:

1. Determination: No change in number of employees, stock, or transportation needs expected as a result of Alternative 2 – Modified day ride allocation, institution of destination quotas, limits on the number of stock in the wilderness at one time, party size of 15 to 25, system and user trail suitability determinations, or overnight stock holding campsite designations. No increase or decrease in revenue is expected.

Rationale: In general, day-ride allocations remain similar to those allocated in Alternative 1. Even though destination quotas should be less restrictive than trailhead quotas for total number of trips available, the maximum number of stock in the wilderness at one time limit are likely to result in no operational changes compared to Alternative 1. Instituting destination management for pack station operators in this category may reduce some flexibility, but since there is some allowance made for all-expense trips, this concept should not result in either more or fewer employees or stock. The majority of trails identified as “not suitable for commercial stock” have minimal or no current pack station use. Designated campsites are those identified with historic use and should not limit or increase business operations.

2. Determination: If fully utilized by operators in the high complexity category, institution of the campfire policy in this alternative should result in an increased number of employees and stock. An increase in revenue could be realized.

Rationale: Allowing pack station operators case-by-case exceptions to the elevation fire closure and the ability to have charcoal fires above the current 10,000 foot closure in Alternative 1 is likely to draw customers who want campfires at higher elevations, resulting in increased number of employees and stock to provide for additional clients and presumably a potential increase in revenue for pack stations.

3. Determination: Grazing strategy identified in Alternative 2 – Modified will likely result in increased number of employees and will result in increased stock numbers. While this will undoubtedly drive costs up, it is unknown if revenue would decrease or remain stable.

Rationale: In general, moderate complexity pack station operations do not rely on overnight grazing in the project area. However, grazing limitations proposed in Alternative 2 – Modified are nonetheless likely to require more wilderness pack stock support, including increased employee time supervising grazing stock to keep them out of sensitive meadow areas and the need to pack feed in for stock where grazing nights are not available. Since most of these operators, either graze little or pack in feed as a matter of business, implementing these grazing limitations are likely to be a small change in business operations but may require a few additional pack stock and additional employees to manage the stock. Alternative 2 – Modified proposes to rest, rather than close, approximately ten meadows. These meadows will be reevaluated for grazing suitability in three to five years. If these meadows are reopened to grazing, commercial operators may find they need to pack less feed into some areas.

Alternative 2

Low Complexity Operations:

Change in number of employees, number of stock, stock support in wilderness, and/or transportation needed:

1. Determination: No change in number of employees, stock, or transportation needs expected as a result of Alternative Two's institution of destination quotas, seasonal and daily stock number limits, primary operating areas, party size of 15 to 25, grazing strategy, system and user trail suitability determinations, or overnight stock holding campsite designations. No increase or decrease in revenue is expected.

Rationale: In general, even though destination quotas should be less restrictive than trailhead quotas for total number of trips available, daily trailhead stock number limits and seasonal stock total limits are likely to result in no operational changes compared to Alternative 1. Low complexity operations rarely expand their use outside existing "operating areas," rarely reach the 15 to 25 party size limit, and as a rule, do not utilize overnight campsites or overnight stock grazing in the project area. Most of the trails identified as "not suitable for commercial stock" have minimal or no current pack station use, although there are some significant exceptions, particularly in the John Muir Southeast Geographic Unit.

2. Determination: If fully utilized by operators in this category, day ride use allocations and the campfire policy in this alternative could result in an opportunity for increased revenue for commercial pack station operations.

Rationale: In general, these operators would realize an increase in allocated day use days (from those described in Alternative 1). Expanding the business in this arena would result in increased need for both employees and number of stock. Allowing pack station operators to provide firewood and firepans for clients above the current 10,000' closure in Alternative 1 is likely to draw customers who want campfires at higher elevations, resulting in increased number of employees and stock to provide for additional clients.

Moderate Complexity Operation:

Change in number of employees, number of stock, stock support in wilderness, and/or transportation needed:

1. Determination: No change in number of employees, stock, or transportation needs expected as a result of Alternative Two's institution of day ride allocations, destination quotas, seasonal and daily stock number limits, implementation of primary operating area, party size of 15 to 25, system and user trail suitability determinations, or overnight stock holding campsite designations. No increase or decrease in revenue is expected.

Rationale: In general, day ride allocations remain similar to those allocated in Alternative 1. Even though destination quotas should be less restrictive than trailhead quotas for total number of trips available, daily trailhead stock number limits and seasonal stock total limits are likely to result in no operational changes compared to Alternative 1. Generally, moderately complex operations rarely service clients in areas outside the proposed primary operating areas. The relatively small number of trips outside the primary operating area would be accounted for by the allowance of unassigned trips in the destination quota in Alternative 2. There is no expected change in transportation operations. Most of the trails identified as "not suitable for commercial stock" have minimal or no current pack station use, although there are some significant exceptions, particularly in the John Muir Southeast Geographic Unit.

Designated campsites are those identified with historic use and should not limit or increase business operations.

2. Determination: If fully utilized by operators in the moderate complexity category, instituting the campfire policy in this alternative could result in an opportunity for increased revenue for commercial pack station operations.

Rationale: By allowing pack station operators to provide firewood and firepans for clients above the current 10,000' closure, Alternative 1 is likely to draw customers who want campfires at higher elevations resulting in an increased opportunity for revenue for commercial operators.

3. Determination: Grazing strategy identified in Alternative 2 may require an increased number of employees and wilderness stock support. While this will likely increase costs for commercial pack stations, it is unknown if revenue would decrease or remain stable.

Rationale: In general, moderate complexity pack station operations do not rely on overnight grazing in the project area. However, grazing limitations proposed in Alternative 2 are nonetheless likely to require more wilderness pack stock support, including increased employee time supervising grazing stock to keep them out of sensitive meadow areas and the need to pack feed in for stock where grazing nights are not available. Since most of these operators, either graze little or pack in feed as a matter of business, implementing these grazing limitations may require a few additional pack stock and additional employees to manage the stock.

High Complexity Operation:

Change in number of employees, number of stock, stock support in wilderness, and/or transportation needed:

1. Determination: No change in number of employees, stock, or transportation needs expected as a result of Alternative 2 day ride allocation, institution of destination quotas, seasonal and daily stock number limits, implementation of primary operating area, party size of 15 to 25, system and user trail suitability determinations, or overnight stock holding campsite designations. No increase or decrease in revenue is expected.

Rationale: In general, day ride allocations remain similar to those allocated in Alternative 1. Even though destination quotas should be less restrictive than trailhead quotas for total number of trips available, daily trailhead stock number limits and seasonal stock total limits are likely to result no operational changes compared to Alternative 1. Instituting primary operating areas for pack station operators in this category may reduce some flexibility, but since primary operating areas, in some cases, can be shared by high complexity operations, this concept should not result in either more or fewer employees or stock. No change in transportation operations because number of trips requiring stock to be hauled distant trailheads in Alternative 1 should be accommodated in the allowance for unassigned trips in the destination quotas for Alternative 2. The majority of trails identified as “not suitable for commercial stock” have minimal or no current pack station use. Designated campsites are those identified with historic use and should not limit or increase business operations.

2. Determination: If fully utilized by operators in the high complexity category, institution of the campfire policy in this alternative should result in an increased number of employees and stock. An increase in revenue could be realized.

Rationale: Allowing pack station operators to provide firewood and firepans for clients above the current 10,000’ closure in Alternative 1 is likely to draw customers who want campfires at higher elevations resulting in increased number of employees and stock to provide for additional clients.

3. Determination: Grazing strategy identified in Alternative 2 will likely result in increased number of employees and will result in increased stock numbers. While this will undoubtedly drive costs up, it is unknown if revenue would decrease or remain stable.

Rationale: In general, high complexity pack station operations rely heavily on overnight grazing to provide needed feed for their stock. Limitations on grazing nights are likely to require more wilderness pack stock support operations, including increased employee time supervising grazing stock to keep them out of sensitive meadow area and the need to pack feed in for stock where grazing nights are not available. For these operators, changing from a high percentage of grazing to a substantial increase in packed feed will require additional pack stock and additional employees to manage the stock.

Alternative 3

All Operations:

Except in some areas of concern, Alternative 3 represents a 25 percent increase over the highest client numbers from the last eight years. The alternative attempts to lower the stock/client ratio.

The intention is to increase the number of clients serviced while lowering the number of stock used to service those clients. If this stock/client ratio can be lowered, there is an opportunity for increased revenues for the commercial operators.

Also in this alternative, the commercial packers have a separate quota that is essentially the same as now thereby eliminating the competition for quota between the packers and other outfitter/guides.

Low Complexity Operations:

Change in number of employees, number of stock, stock support in wilderness, and/or transportation needed:

1. Determination: No change in number of employees, stock, or transportation needs expected as a result of Alternative 3's implementation of the daily trailhead quota for number of people, seasonal thresholds for number of clients and stock, some destination quotas, primary operating area, party size of 15 to 25, grazing strategy, system and user trail suitability determinations, overnight stock holding campsite designations or campfire policy. No increase or decrease in revenue is expected.

Rationale: Daily quota for people serviced by commercial pack stock has decreased at some trailheads, but since operators are able to borrow from the next day's quota for larger groups sizes, no change for low complexity operations is expected. Seasonal thresholds were determined based on reported high use in the past four years and should not result in an increase or decrease in operations. Institution of some destination quotas are not likely to result in a change in operations due to the lack of restriction on areas that remain available for commercial pack stock use. In general, low complexity operations rarely service clients outside exiting "operating areas". These operations rarely reach the 15 to 25 party size limit and as a rule, do not utilize overnight campsites or overnight stock grazing in the project area. The majority of trails identified as "not suitable for commercial stock" have minimal or no current pack station use. Since the proposed campfire policy would only apply to full service trips, and these operations rarely provide full service trips, it is unlikely business operations would change.

2. Determination: If fully utilized by operators in this category, day ride use allocations in this alternative should result in an increased number of employees and stock. An increase in revenue could be realized.

Rationale: In general, these operators would realize an increase in allocated day use days (from those described in Alternative 1). Expanding the business in this arena could result in increased revenue for the operations.

Moderate Complexity Operation:

Change in number of employees, number of stock, stock support in wilderness, and/or transportation needed:

1. Determination: No change in number of employees, stock, or transportation needs expected as a result of Alternative Three's day ride allocation, daily trailhead quota for number of people, seasonal thresholds for number of clients and stock, some destination quotas, implementation of primary operating area, system and user trail suitability determinations, or overnight stock holding campsite designations. No increase or decrease in revenue is expected.

Rationale: Although day ride allocations seem to increase compared to those in identified in Alternative 1, the increased allocation should be accommodated without increasing employees, stock, or transportation operations. The quota is unlikely to change operations, as operators are able to borrow from the next day's quota for larger group size. This borrowing should also allow for the accommodation of smaller groups that would otherwise push the total number over the daily trailhead quota. In addition, in some cases a separate commercial pack stock quota would be established, which would result in less competition with either the public or non-stock commercial outfitters. Seasonal and daily thresholds were determined based on reported high use in the past four years and should not result in an increase or decrease in operations. Institution of some destination quotas are not likely to result in a change in operations due to the lack of restriction on areas that remain available for commercial pack stock use. Most moderately complex operations rarely service clients in areas outside the proposed primary operating areas. The majority of trails identified as "not suitable for commercial stock" have minimal or no current pack station use. Designated campsites are those identified with historic use and should not limit or increase business operations.

2. Determination: If fully utilized by operators, institution of the proposed campfire policy in Alternative 3 could result in a slight increase number of employees, stock, and stock support. This policy may also increase operational flexibility by adding destination areas that would be more attractive to clients wanting campfires. An increase in revenue could be realized.

Rationale: Allowing pack station operators to provide firewood and firepans for full service trips above the current 10,000' closure in Alternative 1, is likely to draw new full service customers who want campfires at higher elevations. If maximized, this new business opportunity should result in an increased opportunity for revenue.

3. Determination: Party size of 15 to 25 is limited further at specified locations in the project area. This rationing could result in a decrease in number of employees, stock, and stock support. A decrease in revenue could be expected.

Rationale: Some of the identified locations where party/stock size is further limited are relatively long distances in from the base operations. Longer trips are more cost effective when the operator can maximize the number of clients. A reduction in the number of clients to these areas is likely to reduce the number of employees, stock and stock support for moderate complexity operations.

4. Determination: The grazing strategy identified in Alternative 3 should result in increased number of employees. It is unknown if revenue would decrease or remain stable.

Rationale: In general, moderate complexity pack station operations do not rely on overnight grazing in the project area. However, grazing limitations proposed in Alternative 3 are nonetheless likely to require more wilderness pack stock support, including increased employee time supervising grazing stock to keep them out of sensitive meadow areas and the need to pack feed in for stock where grazing nights are not available. Since most of these operators, either graze little or pack in feed as a matter of business, implementing these grazing limitations are likely to be a small change in business operations but may require a few additional pack stock and additional employees to manage the stock.

High Complexity Operation:

Change in number of employees, number of stock, stock support in wilderness, and/or transportation needed:

1. Determination: No change in number of employees, stock, or transportation needs expected as a result of Alternative 3 day ride allocation, seasonal thresholds for number of clients and stock, some destination quotas, implementation of primary operating area, system and user trail suitability determinations, or overnight stock holding campsite designations. No increase or decrease in revenue is expected.

Rationale: In general, day ride allocations are a slight decrease from those allocated in Alternative 1. Seasonal and daily thresholds were determined based on reported high use in the past four years and should not result in an increase or decrease in operations. Institution of some destination quotas are not likely to result in a measurable change in operations due to the lack of restriction on areas that remain available for commercial pack stock use. Instituting primary operating areas for pack station operators in this category may reduce some flexibility, but since primary operating areas can be shared in some cases affecting high complexity operations, designating primary operating areas should not result in either more or fewer employees or stock. The majority of trails identified as “not suitable for commercial stock” have minimal or no current pack station use. Designated campsites are those identified with historic use and should not limit or increase business operations.

2. Determination: If fully utilized by operators, institution of the proposed campfire policy in Alternative 3 could result in a slight increase number of employees, stock, and stock support. This policy may also increase operational flexibility by adding destination areas that would be more attractive to clients wanting campfires. An increase in revenue could be realized.

Rationale: Allowing pack station operators to provide firewood and firepans for full service trips above the current 10,000 foot closure in Alternative 1, is likely to draw new full service customers who want campfires at higher elevations. If maximized this new business opportunity should result in an increased opportunity for increase pack station revenue.

3. Determination: Grazing strategy identified in Alternative 3 should result in increased number of employees and stock, and will result in increase stock support. It is unknown if revenue would decrease or remain stable.

Rationale: In general, high complexity pack station operations rely heavily on overnight grazing to provide needed feed for their stock. Limitations on grazing nights are likely to require more wilderness pack stock support operations, including increased employee time supervising grazing stock to keep them out of sensitive meadow areas, and the need to pack feed in for stock where grazing nights are not available. For these operators, changing from a high percentage of grazing to a substantial increase in packed in feed will require additional pack stock and additional employees to manage the stock.

4. Determination: Daily trailhead quota for number of people is decreased at some trailheads used mostly by high complexity operations. Party size of 15 to 25 is limited further at specified locations in the project area. Both could result in a decrease in number of employees, stock, and stock support. A decrease in revenue could also be expected.

Rationale: Daily quota for people serviced by commercial pack stock decreased at some trailheads, but there is no longer competition for quota. Borrowing on the next day’s quota

provides some level of flexibility for the operations. Some of the identified locations where party/stock size is further limited are relatively long distances in from the base operations. Longer trips are more cost effective when the operator can maximize the number of clients. A reduction in the number of clients to these areas is likely to reduce the number of employees, stock and stock support for high complexity operations.

Alternative 4

Low Complexity Operations:

Change in number of employees, number of stock, stock support in wilderness, and/or transportation needed:

1. Determination: No change in number of employees, stock, or transportation needs expected because of Alternative 4, day ride allocations, party size of 12/20, institution of primary operating areas, grazing strategy, system and user trail suitability determinations, or campfire closure policy. No increase or decrease in revenue is expected.

Rationale: Day ride allocations in Alternative 4 for low complexity operations change slightly from those in Alternative 1, no change in business operations should result. Low complexity operations service few parties over 12 people. In general, these pack stations rarely expand operations outside existing “operating areas” within the project area. These operations rarely utilize overnight campsites or overnight stock grazing in the project area. The majority of trails identified as “not suitable for commercial stock” have minimal or no current pack station use. Elevation campfire closures represent no change from current operations.

2. Determination: Allocated service days, trailhead quotas, campsite designations proposed in this alternative are likely to reduce number of employees and stock. Decrease in revenue could also be expected.

Rationale: Without alternative areas to provide overnight services outside the project area, the proposed decrease in overnight service days is likely to result in a concomitant decrease in operations. Compared to Alternative 1, Alternative 4 proposes decreases in overnight service days and daily quota for approximately 40 percent of trailheads in the project area. In addition, the practice of borrowing quota from the following day to allow for parties larger than the daily quota (but within the maximum group size limit) is no longer allowed. Since campsite designations include overnight, spot, and dunnage sites, the loss of flexibility and freedom to clients to choose a campsite would likely negatively affect business operations and expected revenue. Low complexity operations often have few employees and stock, these restrictions would likely reduce these operations even further.

Moderate Complexity Operation:

Change in number of employees, number of stock, stock support in wilderness, and/or transportation needed:

1. Determination: No change in number of employees, stock, or transportation needs expected as a result of Alternative 4, institution of primary operating areas, system and user trail suitability determinations, or campfire closure policy. No increase or decrease in revenue is expected.

Rationale: Most moderately complex operations rarely service clients in areas outside the proposed primary operating areas. The majority of trails identified as “not suitable for commercial stock” have minimal or no current pack station use. Designated campsites are those identified with historic use and should not limit or increase business operations. Elevation campfire closures represent no change from current operations.

2. Determination: The proposed 20 percent decrease in overnight service day allocation and variable (from 10 percent to over 100 percent) decreases in day use allocation is likely to result in a decrease in number of employees and stock, stock support and transportation operations to distant trailheads. Trailhead quotas, party size limitations, and campsite designations proposed in this alternative are likely to reduce number of employees and stock. A decrease in revenue could be expected.

Rationale: Without alternative areas to provide both day use overnight services outside the project area, the proposed decreases in both day use and overnight service days is likely to result in a concomitant decrease in operations. Compared to Alternative 1, Alternative 4 proposes decreases in daily quota for approximately 40 percent of trailheads in the project area. In addition, the practice of borrowing quota from the following day to allow for parties larger than the daily quota (but within the maximum group size limit) is no longer allowed. Without alternative areas to provide service these operations are likely to lose the business of larger groups completely thereby reducing the number of employees and stock needed. Over night stock holding campsites would be reduced and spot and dunnage trips would be allowed only at designated sites. This would result in the loss of flexibility to the operator and freedom of choice for the clients. This is expected to negatively affect business operations and expected revenue.

3. Determination: Grazing strategy identified in Alternative 4 should result in increased number of employees. It is unknown if revenue would decrease or be stable.

Rationale: In general, moderate complexity pack station operations do not rely on overnight grazing in the project area. However, grazing limitations proposed in Alternative 4 are none-the-less likely to require more wilderness pack stock support, including increased employee time monitoring grazing stock to keep them out of sensitive meadow areas and the need to pack feed in for stock where grazing nights are not available. Since most of these operators, either graze little or pack in feed as a matter of business, implementing these grazing limitations are likely to be a small change in business operations, but may require a few additional pack stock and additional employees to manage the stock.

High Complexity Operation:

Change in number of employees, number of stock, stock support in wilderness, and/or transportation needed:

1. Determination: No change in number of employees, stock, or transportation needs expected as a result of Alternative 4 institution of primary operating areas, system and user trail suitability determinations, or campfire closure policy. No increase or decrease in revenue is expected.

Rationale: Instituting primary operating areas for pack station operators in this category may reduce some flexibility, but since primary operating areas can be shared in some cases affecting high complexity operations, designating primary operating areas should not result in either more or fewer employees or stock. The majority of trails identified as “not suitable for commercial

stock” have minimal or no current pack station use. Elevation campfire closures represent no change from current operations.

2. Determination: General decreases in day use allocation, the proposed 20 percent decrease in overnight service day allocation, and campsite designations are likely to result in a decrease in number of employees and stock, stock support and transportation operations to distant trailheads. Trailhead quotas and party size limitations proposed in this alternative are likely to reduce number of employees and stock. A decrease in revenue could also be expected.

Rationale: Without alternative areas to provide both day use overnight services outside the project area, the proposed decreases in both day use and overnight service days is likely to result in a concomitant decrease in operations. Compared to Alternative 1, Alternative 4 proposes decreases in daily quota for approximately 40 percent of trailheads in the project area. In addition, the practice of borrowing quota from the following day to allow for parties larger than the daily quota (but within the maximum group size limit) is no longer allowed. Without alternative areas to provide service these operations are likely to lose the business of larger groups completely thereby reducing the number of employees and stock needed. Over night, stock holding campsites would be reduced and spot and dunnage trips would be allowed only at designated sites. This would result in the loss of flexibility to the operator and freedom of choice for the clients. This is expected to negatively affect business operations and expected revenue.

3. Determination: Grazing strategy identified in Alternative 4 should result in increased number of employees and stock, and will result in increase stock support. It is unknown if revenue would decrease or remain stable.

Rationale: In general, high complexity pack station operations rely heavily on overnight grazing to provide needed feed for their stock. Limitations on grazing nights are likely to require more wilderness pack stock support operations, including increased employee time supervising grazing stock to keep them out of sensitive meadow areas, and the need to pack feed in for stock where grazing nights are not available. For these operators, changing from a high percentage of grazing to a substantial increase in packed in feed will require additional pack stock and additional employees to manage the stock.

Alternative 5

Low Complexity Operations:

Assumption: similar business opportunities do not become available or are not authorized on alternative lands therefore a decrease or cessation of revenue can be expected.

Change in number of employees needed: Most low complexity operations need few if any employees outside the business owners/operators. These businesses would not have the margin to reduce employees further and still maintain an intact business.

Change in number of stock needed: Fewer, and in some cases no stock would be needed to meet client demand.

Change in stock support within wilderness: No change from Alternative 1, as most Low Complexity operations do not provide support to (feed, etc.) for overnight stock holding.

Change in transportation (trucking/hauling) practices: No change from Alternative 1, as most Low Complexity operations do not rely on trucking of stock to distant trailheads.

Moderate Complexity Operation:

Assumption: similar business opportunities do not become available or are not authorized on alternative lands therefore a decrease or cessation of revenue can be expected

Change in number of employees needed: Number of employees would decrease in relation to that portion of the business reliant on client services in the project area. Some operations would be unable to hire any employees beyond the owner/operator. Some operations would not have the margin to reduce employees further and still maintain an intact business.

Change in number of stock needed: Fewer, and in some cases no stock would be needed to meet client demand.

Change in stock support within wilderness: No stock support would be needed within the project area.

Change in transportation (trucking/hauling) practices: No hauling of stock would be needed to reach distant trailheads accessing the project area.

High Complexity Operation:

Assumption: If similar business opportunities do not become available or are not authorized on alternative lands, a decrease or cessation of revenue can be expected.

Change in number of employees and stock needed: Severe reduction of employees for operations with no alternatives to use in the project area.

Change in stock support within wilderness: No stock support will be needed in the project area.

Change in transportation (trucking/hauling) practices: No hauling of stock would be needed to reach distant trailheads accessing the project area.

Conclusions

The overall effect that the alternatives will have on pack station operations is not fully understood. While the alternatives can be taken apart and individual components can be analyzed (e.g., a destination quota), the cumulative effect of a destination quota, combined with a primary operating area, along with a seasonal stock threshold is difficult to determine. It may be that the cumulative impact of all the regulations will affect the greatest change to current pack station operations.

Overall, it is expected that the Alternatives 2 through 5 will have a profound effect on pack station operations. In many cases, this effect will take the form of increased costs associated with a need to pack in more feed and use additional stock/employees to service an overnight trip. Flexibility is also likely affected by the control mechanisms in the alternatives. Clearly, commercial operators offer some trips (e.g., full service trips) that are more profitable than others. Seasonal client and stock thresholds and destination quotas may force pack station operators to turn down a less profitable trip early in the season when there is a chance for a more profitable trip later on the year. Some operators may choose to hold on to threshold numbers until the right trip is booked. There is certainly the likelihood that some portion of the quota or threshold is unused when the desired trip never comes in. Flexibility and increased costs seem to

be the two main effects to pack station operators. The effect that this will have on public demand for commercial pack station services is discussed next.

Effects to Public Demand for Commercial Pack Station Services

All Alternatives

Based on the effects to operations discussion, it seems clear that the six alternatives, to varying degrees will change the operations of commercial pack stations and may impact the revenue stream of these operations. It should be noted that a number of other variables can affect the revenue of these operations and are not analyzed here. Some of these other variables include larger market forces (for example a downslide in the economy) and the ability of the pack stations themselves to accommodate the changes and continue to provide affordable services to the public. Like any other business, success will depend on the ability of the operation to incorporate the changing environment into their operations including using advertising and changing the focus of the business to more profitable ventures (for example, if full service trips are impossible because of new regulations, other opportunities may exist that can take the place of this service that may help provide a substitute revenue stream). Some of these variables are difficult to account for and do not lend themselves to a reasonable analysis.

A recurring theme in public comment and discussion is the effect that the 2001 Wilderness Plan and court-ordered restrictions have had on the revenue of commercial pack stations. Three elements will be examined: gross revenue from 2000 (pre court order) to 2003, use numbers from 2000 (pre court order) to 2003, and the prices of commercial trips over the last five years. These elements will be displayed and discussed in the context of public demand for commercial pack stock supported services.

Gross Revenue, Use Numbers, and Prices of Services

Table 4.1.27 displays the reported gross revenue of commercial pack stations operating in the Ansel Adams and John Muir Wildernesses (Inyo and Sierra National Forests, 2004). For all types of operations, the reported gross revenue either increased or stayed essentially the same from 2001 (the first year of the court-ordered restrictions) and 2003. This indicates that additional restrictions (including a 20 percent reduction in service days) did not affect the gross revenue of the pack stations.

Similar to 4.1.27, use numbers are compared for 2000/2001 and 2002/2003. Table 4.1.28 shows this comparison. Looking at Table 4.1.27 and Table 4.1.28, an interesting pattern is seen. Since the court ordered restrictions on pack station operations in 2001, gross revenue has generally increased while use of the services, particularly for moderate and high complexity operators, has decreased. It seems that for some services, however, the costs were passed on to the consumer and no change in demand was experienced. For other types of trips—presumably the types of trips that moderate and high complexity operators specialize in—the additional costs resulted in a decrease in demand. Curiously, even the decreased demand for the services of these types of operators did not result in a decrease in the gross revenue. For all three operators, gross revenue increased over the study period. This gross revenue increase may be explained, in part, by the increased ratio of stock to people on some types of trips. Compared to the period prior to the court-ordered reductions, 2002 through 2003 use figures indicate an increase in the average number of stock used to support pack stock operations in the wilderness. The increased costs of

stock would likely push the cost of the trip up and, therefore, push the gross revenue for these operations up.

Of course, a critical portion of this analysis is missing net revenue. It may very well be that commercial operators experienced an increase in gross revenue but if their costs also increased dramatically as a result of the court ordered restrictions, it may be that the net revenue either stayed the same or even decreased as the gross revenue increased.

A possible explanation for the increased gross revenue numbers in Table 4.1.27 is that the commercial packers increased their prices to accommodate the increased costs of doing business. A survey of the prices for different commercial pack station supported services reveals significant price increases from 2001 to 2004(5). Table 4.1.29 below shows the price increases for different services offered by commercial packers.

Table 4.62 Pack stations' gross revenue 2000-2003

Type of Pack Station	2000-2001 Gross Revenue (averaged)	2002-2003 Gross Revenue (averaged)	% Change
Low Complexity	\$47,714	54,028	+13%
Moderate Complexity	\$66,600	\$69,936	+5%
High Complexity	\$389,549	\$467,610	+20%

Note: These figures are raw numbers; they have not been adjusted for inflation

4.63 Clients serviced 2000-2003

Type of Pack Station	2000/2001 People Serviced (averaged)	2002/2003 People Serviced (averaged)	% Change
Low Complexity	239	285.25	+19%
Moderate Complexity	441.75	358.25	-19%
High Complexity	798	712	-11%

Table 4.64 Costs of stock-supported services 2000-2003

Type of trip	2001	2004/5	Increase from 2001 to 2004
All-expense trip (average costs of a trip with three people)	\$195 per person per day	\$300 per person per day	30% increase
Spot trip (round trip and depending on destination) (three people)	\$340-\$465	\$400-\$675	40% increase
Average charge (packer and mule per day)	\$85 per day	\$110-\$125 per day	50% increase
Average charge (packer and horse)	\$125 per day	\$200-\$235 per day	75% increase
All day ride	\$70 per person	\$125 per person	78% increase

Note: These are raw numbers only; no adjustment for inflation has been made.

**For many pack stations, a minimum fee is charged for any pack station related trips (industry average \$250 to \$300). For some operations, this is a new charge, for others this is as much as a 300 percent increase.

Conclusions

Looking at gross revenue and use figures from 2000 through 2003, it appears as though pack stations were able to incorporate the court-ordered restrictions into their business plans and maintain a constant stream of revenue. Undoubtedly, the court-ordered restrictions increased the price of doing business and the pack stations were able to pass these costs on to consumers in the form of more expensive trips. It appears that for Alternatives 2 through 4, additional regulations will further push up the costs of doing business. (It has been estimated by the packing industry that additional limitations on campsites, trailheads, meadows and number of trips, will push the costs of these trips further by at least 25 to 30 percent.)

It is not clear, however, how much more the public will be willing to pay for these services. At some point, the additional costs cannot be passed on to consumers. The pack stations may find that their gross revenue and use drops because of additional prices increases. It is not clear what that point is, but it may be that additional regulations, leading to additional costs to the pack stations cannot be passed along to the consumer. As with any other good, there is a point at which the price of a service or good affects the demand for that good or service. Research (Phaneuf and Smith, 2004) shows that prices for services such as those offered by commercial pack stations are elastic. That is, the demand for a good or service is responsive to a change in the price. In addition to price, other factors also contribute to the elasticity of demand for a service including the income of the consumer and the distance traveled to utilize the service. At some point, it would be expected that increased prices would result in a decreased demand for these services and subsequently a decrease in revenue.

These higher prices also carry along an equity issue. Some segments of the population may not be affected by the increased price of these trips. For this segment, the increased costs of a stock-supported will have little or no effect on the demand for the service. For other segments of the population, the increased price will have considerable effect on the demand for the service. It may be that even if commercial operators are able to continue supply pack stock supported services, these trips may be no longer affordable to the lower and middle class consumer.

Cumulative Impacts—All Alternatives

Cumulative impacts are impacts on the regional economy and commercial pack station operators when the proposed project is combined with past, present, and foreseeable activities. For the regional economy, a relevant past action is the Wilderness Plan and reasonably foreseeable actions include future wilderness designations in the project area along with other planning efforts including the Inyo National Forest route designation process. Recreation is an important part of the economy of the project area, particularly for the east side counties. The impact of future wilderness designation or greater reliance on non-motorized access into areas on the forest on the economy of the project area is not clear. Some studies (Power, 1996; Rasker 1994; 1994b; Loomis and Richardson in press) show wilderness designation or greater reliance on environmental protection as a valuable amenity that drives local economic expansion.

The cumulative impact of the alternatives on the commercial pack stock operators when combined with past, present, and reasonably foreseeable actions in the project area are also not fully known. Future wilderness designation, for example, may limit activities of these operators

as some proposed wilderness additions are in areas currently serviced by operators. As a past action, the Wilderness Plan certainly changed the way operators ran their businesses. It would be expected that additional restrictions or controls would have an impact on the commercial pack stock industry. Exactly what this impact will be is not known, as there are many factors that help to determine the viability of a particular operation including flexibility, use of advertising, and willingness and ability to create new business opportunities in a changing business environment. Overall, (with the exception of the Wilderness Plan) there are no known past, present, or future actions or activities that will definitively, when combined with the current project, have a cumulative impact on commercial pack station operations.

Social – All Alternatives

Analysis and Cumulative Impacts

With the exception of Alternative 5, it is not thought that the Proposed Action and alternatives will significantly affect the social environment of the project area. Alternatives 1 through 4 will continue to allow for the use of commercial pack stock in the Ansel Adams and John Muir Wildernesses although the additional control mechanisms certainly have the potential to push the costs of trips higher than they currently are. There are known direct, indirect, or cumulative impacts of the proposed project on specific races or ethnicities in the project area. Generally, wilderness research has found that the average wilderness user is white and affluent (Lucas 1980 and Hendee et al., 1976).

In terms of race and ethnicity, wilderness user surveys on the Inyo and Sierra National Forests show that the overwhelming majority of wilderness users are white. The 2003 National Visitor Use Monitoring Results study found that 87.6 percent of wilderness users reported a race/ethnicity of white. Similarly, on the Sierra National Forest, 94 percent of wilderness users surveyed reported a race/ethnicity of white. Wilderness research over the years has found that wilderness users (and outdoor recreationists in general) have a higher income than the public. Although socioeconomic data was not collected on pack station clients, there is no reason to expect that the socioeconomic composition of pack station clients differs much from the overall characteristics of forest wilderness visitors.

The 2003 National Visitor Use Monitoring Results study also found that a relatively high percentage of wilderness users were 50 or older. On the Inyo National Forest, for example, nearly a quarter of the wilderness visitors surveyed reported an age of 50 or older. On the Sierra National Forest, nearly 35 percent of wilderness users on the forest reported an age of 50 or older. Given the relatively high percentage of older wilderness users on both forests, reductions in commercial pack stock use may affect these groups.

Although it is unlikely that low-income visitors make up a significant percentage of wilderness users, there may be an impact to low-income users of commercial pack stock to access the wildernesses. This impact is difficult to analyze, as it is not clear what the future prices of these trips will be or the extent to which low-income groups utilize these services today. Likewise, handicapped or elderly users who rely on commercial pack stock may be impacted if these services are discontinued or priced out of the reach of the majority of the population. Again, there is no known data that specifically identifies elderly or handicapped individuals regularly relying upon commercial pack stock to access the Ansel Adams or John Muir Wildernesses. American Indian considerations as it relates to access into these wildernesses are discussed in the

Heritage Resources section. Overall, it is not believed that the project will have any known direct, indirect, or cumulative impacts to individual social and demographic groups in the project area.

Another consideration is the effect of the alternatives on the social environment of the project area in terms of custom and history. It is well documented in the public comment on past wilderness-related projects that a segment of the population feels that pack stock use in the wilderness is an important historical and cultural activity. Any actions that severely limit this type of activity may negatively affect these individuals and groups. Others, again well documented in public comment, view high levels of commercial pack stock in the wilderness as an affront to their wilderness experience. These individuals and groups do not agree with the perspective that providing commercial pack stock for wilderness visitors will continue an important historical and traditional activity. Clearly, the public is sharply divided on this issue. The intent of an environmental impact statement is to disclose the expected environmental effects of a decision but in this case there is little analysis—either quantitative or qualitative—that can point a decision maker to the “right” answer in resolving these social disagreements. This analysis acknowledges the very obvious disagreement as to the appropriateness of commercial pack stock use in the Ansel Adams and John Muir Wildernesses but makes no attempt to quantify or qualify the disagreement further.

4.2 Physical Environment

4.2.1 Soils and Hydrology

Wilderness Scale

Methodology

Context: The context of the impact considers whether the impact is local or regional. For the purposes of this analysis, local impacts are those that occur at site-specific locations and regional impacts are impacts on the watershed at the geographic unit to wilderness scale.

Intensity: The intensity of the impact considers whether the impact is negligible, minor, moderate, or major. Negligible impacts are effects considered not detectable and have no discernible effect on the hydrology, soil productivity, or water quality. Minor impacts are effects on hydrologic or soil processes that are slightly detectable but not expected to have an overall effect on the watershed. Moderate impacts are clearly detectable and could have an appreciable effect on the hydrologic function and processes. Major impacts have a substantial, highly noticeable, influence on the hydrologic environment and could significantly alter hydrologic functions and processes or soil productivity.

Duration: The duration of the impact considers whether the impact occurs in the short term or the long term. A short-term impact is temporary in duration and is associated with processes that can occur or recover within a few years. An example is sod fragmentation from one-time grazing, because as long as the meadow hydrology is not altered, vegetation can grow back and eliminate sod fragmentation within years. A long-term impact has a permanent effect on the hydrologic function of a meadow, wetland, stream, or other water body. An example is stream incision below the rooting depth of meadow vegetation. Incision can lower a meadow's water table, prevent a meadow stream from accessing its floodplain, and alter the vegetation composition of the meadow. Without active restoration, it is likely that stream aggradations to its previous depth would not occur within decades or centuries.

Type of Impact: Impacts are evaluated in terms of whether they are beneficial or adverse to the hydrologic environment. Beneficial impacts sustain or improve soil productivity, water quality, or hydrologic function of streams and meadows. Adverse impacts would negatively affect hydrologic or soil processes.

Analysis Common to All Alternatives

Commercial pack stock operating areas cover about 9 percent of the Ansel Adams and John Muir Wilderness Areas. This has been estimated as the area of campsites, trails, and grazing areas that are used by commercial pack stock, or their clients, and has a potential for hydrologic and soil effects from that use. (For a table showing area of requested use by geographic unit and wilderness-wide, see the table *Area of use within each commercial pack station's operating area* in the project record). Therefore, changes in commercial pack stock operations could have no effect on 91 percent of the wilderness area.

Water Quality – Animal Waste: Water-borne bacteria and nutrients from pack stock manure is a minor concern over most areas of the wilderness, although the risk is not understood very well.

Derlet and Carlson (2002) found that 15 of 81 samples (approximately 19 percent) of fresh pack stock manure on trails in Yosemite and Sequoia/Kings Canyon National Parks contained bacterial or protozoa pathogens capable of causing human disease. Because many of the same pack stock that are used in the Ansel Adams and John Muir Wildernesses are also used in the adjacent National Parks, it is assumed that pack stock using the forests have similar levels of pathogens in their waste. About 19 percent of the manure that is deposited directly into water, or is washed into water, contains the human pathogens sampled for in this study.

Giardia and *Cryptosporidium* are also human pathogens of concern in the Sierra Nevada area and both can be found at low levels in livestock or pack stock manure (Atwill et al., 2000; Atwill, 1995). In the Sierra Nevada area, few studies have sampled pack stock manure to determine whether *Giardia* or *Cryptosporidium* are present. Johnson et al. (1997) found no *Giardia* or *Cryptosporidium* cysts in 91 horses used in the California backcountry in 1993 and 1994. In a later study (Atwill et al., 2000), fecal specimens from 305 horses and mules used as pack stock in the backcountry were examined for *Giardia duodenalis* and *Cryptosporidium parvum*. They found 14 pack stock (4.6 percent) shedding *Giardia duodenalis* and none shedding *Cryptosporidium parvum*. Derlet and Carlson (2002) found *giardia* in one of their 81 samples of pack stock manure. Although these studies sampled a relatively small proportion of horses used in the backcountry of California, and the samples were not from pack stock used in the AA/JM Wildernesses, the information available suggests that the risk of *giardia* entering water from pack stock is low, but possible. The risk of *Cryptosporidium* entering water from pack stock is lower, as none has been found in pack stock manure.

In all of the above studies, the manure was relatively fresh. Although few studies have been completed on the bacterial retention qualities of pack stock manure, bacteria in cattle manure decreases logarithmically with time (Buckhouse and Gifford, 1976; Kress and Gifford, 1984), and solar radiation and drying reduces changes of bacterial contamination (McClaran, 2000). Derlet and Carlson (2003) found *E. coli* below cattle grazed meadows in the Golden Trout Wilderness nine months after the last cattle-grazing activity, suggesting that some human pathogens can remain in grazed areas through winter and contaminate water in the spring. It is unknown whether pack stock manure contains *E. coli* or whether grazing levels proposed in the alternatives are high enough to cause water contamination, as was found in Derlet and Carlson (2003).

In areas where pack stock cross streams, drink, or are held near water, the water body could have fecal contamination. Concentrations could be reduced by dilution to harmless quantities downstream. It is unknown how far downstream from a single manure pile the bacteria is diluted enough to be rendered harmless, and it likely varies based on flow, velocity, turbidity, temperature, and other factors.

Most of the lakes and streams in the study area have low nutrient levels, and therefore do not support bacteria preservation. In the few studies that have been completed on water quality impacts of recreational users in California wilderness, it has been found that there are generally higher coliform densities in watersheds where human, pack animal, or livestock use is higher (Derlet et al 2004, Derlet and Carlson 2004). It has not been determined whether pack stock or human users were responsible for the increased bacteria levels in those studies. However, Derlet et al. (2004) found that all sites sampled below alpine meadows used for sheep and cattle grazing contained coliforms. No sampling was completed below meadows used for pack stock grazing. Although there was presence of some fecal contamination (from unknown sources) in this study,

only one out of 37 water samples taken in the study was found to contain a known human pathogen.

Humans, beavers, deer, dogs, and other animals can also carry human pathogens and deposit them in soil, on the soil surface, or in water (Derlet et al., 2004; Derlet and Carlson, 2002; Atwill, 1995). While the few studies completed suggest that there may be a risk of pack stock transmitting human pathogens into surface water, the severity and extent of actual transmission is unknown. From the low prevalence of pathogens found in pack stock manure, and in most water sampled in the Sierra Nevada area the risk appears to be low.

Beyond human pathogens, pack stock manure could lead to increased nutrient levels in lakes. Alteration of nutrient levels can lead to alteration of aquatic ecosystems and create a more fertile environment for bacterial preservation and reproduction. It is unknown whether any nutrient level increase has occurred within the study area. Sickman et al. (2003) found that there was an increase in phosphorous (P) in over 70 percent of 28 lakes sampled between 1985 and 1999 in Yosemite and Sequoia Kings/Canyon National Parks, surrounding the AA/JM Wildernesses. The increased levels were found throughout the Sierra Nevada area, independent of use levels. Therefore, the authors believe that site-specific phosphorous sources, such as surface runoff, are not likely causes of the nutrient increase. It is currently impossible to determine whether changes in commercial pack stock use would alter nutrient levels in surface water.

Information about water quality within the wildernesses was mainly obtained by observing inputs into surface water, such as evidence of rilling reaching water, or evidence of manure in or adjacent to water. The Forest Service did not complete quantitative water quality sampling, because it was not deemed necessary to do so to make an informed decision about commercial pack stock management. Water quality degradation has not been found to be a major concern according to the few studies completed within the wilderness and downstream municipal sampling.

In summary, although pack stock manure deposited in water, or carried into water by runoff, is obviously a non-natural addition to the water, it is unknown whether the quantity and extent of manure in water is enough to cause measurable water quality degradation wilderness-wide or locally. It is not likely a significant issue, because the existing water quality sampling within the wilderness, observance of effects to beneficial uses, and downstream water quality sampling at the point of use does not indicate that there is degraded water quality within the AA/JM Wildernesses.

Meadow/Wetlands: Commercial pack stations requested 385 meadows for grazing. These 385 meadows are considered to have been grazed in the past, or likely to be grazed in the future. Due to lack of time, not all the requested meadows were visited in the field. Of those meadows, 227 were visited, including all with moderate to high recently reported grazing. Other meadows were analyzed in the office using historical records, past field visits, and air photos. The current meadow condition, suitability for grazing, and possible effects of pack stock grazing were determined in the field using rapid qualitative assessment methods explained in the Study Plan (available in the project record). This section describes the effects to soil productivity, hydrologic function, stream condition, and water quality.

The desired condition for meadows and other wetlands is that they are hydrologically functional (USDA Forest Service, 2004), and sites of accelerated erosion, such as gullies and headcuts, are stabilized or recovering.

Under the Wilderness Plan (2001) and the Sierra Nevada Forest Plan Amendment Riparian Conservation Objectives (2004), the direction for meadows and wetlands is as follows:

Assess the hydrologic function of meadow habitats and other special aquatic features during range management analysis. Ensure that characteristics of special features are, at a minimum, at Proper Functioning Condition, as defined in the appropriate Technical Reports (or their successor publications): (1) “Process for Assessing PFC” TR 1737-9 (1993), “PFC for Lotic Areas” USDI TR 1737-15 (1998) or (2) “PFC for Lentic Riparian-Wetland Areas” USDI TR 1737-11 (1994).

Over half of the meadows that were analyzed for condition and grazing suitability were analyzed for stream functional condition using the Proper Functioning Condition (PFC) protocol. The projected effects on stream functional condition are discussed under all alternatives, although the future PFC rating was not predicted. Instead, the trend toward or away from, potential stream functional condition was predicted. For example, a stream that is currently properly functioning could be predicted to have a trend away from its potential. It is impossible to predict whether the trend will move far enough away from its potential to change the stream rating to functional at-risk. Each stream was only projected as to whether it is likely to move away from or toward its potential, and not as to what the final condition of the stream may be.

All 227 meadows that were analyzed in the field for condition, grazing suitability, and overall meadow hydrologic function. Meadow hydrologic function differs from stream hydrologic function because it applies to the entire meadow, not just the stream corridor. Meadow hydrologic function depends on soil condition, the ability of the meadow to act as a floodplain and store groundwater, and the vegetation composition. The projected effect to meadow hydrologic function watershed-wide and at a site-specific scale is discussed under each alternative.

In general, if an area is not grazed, vegetation can recover relatively quickly with its water source unaltered, but hydrologic function and geomorphic recovery can take decades longer (Kondolf, 1993). The more severe the current alteration from a potential natural condition, the longer the recovery will likely take. Vegetation composition and vigor can quickly recover as long as the meadow hydrologic function is intact, with a water source remaining. In some cases, where the meadow hydrologic function is severely altered, vegetation vigor may improve, but vegetation composition may not return to its potential natural vegetation because there is an altered hydrologic regime.

Under all alternatives, the expected change to meadow hydrologic function was predicted to remain the same, improve, or have a downward trend. The predictions were based on the severity and extent of hydrologic function alteration, meadow productivity, water source type, source of current hydrologic function alteration, and type and levels of use expected. The process was completed by the biologists, physical scientists, and grazing specialist on the IDT. These predictions were made for a simple comparison between alternatives, but are qualitative and are considered rough estimates.

The Forest Service BMP program requires protection of wetlands. In this analysis, we did not map jurisdictional wetlands, but we did map all known moist and wet meadows. These meadows are considered wetlands, because they likely qualify as jurisdictional wetlands. BMP Practice 7-3 (USDA Forest Service, 2000), requires that:

The Forest Service will not permit the implementation of activities and new construction in wetlands whenever there is a practical alternative. Factors relevant to the effect of the proposal on the survival

and quality of the wetlands will be considered when evaluating proposed actions in wetlands. Factors to be evaluated include, but are not limited to water supply, water quality, recharge areas, functioning of the wetland during flood and storm events, flora and fauna, habitat diversity and stability, and hydrologic function of riparian areas...and that the actions maintain the hydrologic and biologic function of the wetlands.

The evaluations described above, including the meadow hydrologic function analysis and PFC determinations, as well as qualitative water quality observations and soil quality observations, fulfill the above requirement that these factors be evaluated. All action alternatives consider hydrologic and biologic function of the wetlands, and the degree of certainty in their maintenance is discussed under each alternative.

The predictions for the effects of each alternative on meadows/wetlands are estimates. It is difficult to predict any effects of natural changes in the environment, such as climate change. There is also little research about the long-term effects and recovery rates of light grazing such as would be done by commercial pack stock under Alternatives 1 through 4, and so assumptions are based on field observations and the little existing research available.

Air Quality: Forest Service actions have little effect on air quality in the Ansel Adams and John Muir Wildernesses. Most air pollutants originate outside of the wilderness (Sickman et al., 2003), and will not be affected by any of the alternatives. Air quality effects should be the same under all alternatives, because commercial pack stock use of the wilderness does not affect air quality either positively or negatively over more than local areas for a few minutes at a time. Stock traffic causes more dust to enter the air than foot traffic and, therefore, even total removal of commercial pack stock use would reduce, but not eliminate, the very short duration and very small volume of airborne dust caused by recreational use. Because air quality would not be affected by this action, it will not be discussed further.

Alternative 1

Summary of Alternative 1 Impacts

Water quality is generally good and will remain so except at few local areas where there may be slight adverse water quality impacts. There will remain areas of local soil erosion, bare soil, and sedimentation into surface water from commercial grazing, campsites, and trails. Of 60 streams found to be functional at-risk (151 evaluated), an estimated 30 percent could have improved condition, 15 percent could have a more degraded condition; and 55 percent will remain in their current condition. Meadow hydrologic function has the greatest potential for increased downward trend and least potential for improvement. Of the 41 meadows found to currently have hydrologic function alteration (237 evaluated), about 24 percent are projected to have improved condition, 63 percent should remain in the same condition, and about 12 percent could have a downward trend.

Past and present grazing from production livestock and pack stock is the largest contributor to meadow hydrologic function alteration. Although it is assumed that grazing would continue at the same levels, and in the same locations as in recent years, this is the only alternative where grazing would not be limited to certain meadows or limited by number of stock nights. Therefore, grazing could occur in almost any of the 1,500 meadows and grazing numbers could increase or decrease in almost any meadow.

Analysis

Under Alternative 1, it is likely there would be almost the same water and soil resource effects as there currently are, although effects may move from one location to another due to lack of Forest Service control over changes in pack station operations. The lack of site-specific controls over the locations and quantity of commercial pack stock use means that commercial packers have the most freedom under this alternative to change their operations and move to areas previously not used.

The main difference in potential effects to soil and water resources between Alternative 1 and Alternatives 2 through 4 would likely be the difference in meadow management and trail management. Under Alternative 1, all meadows are open to grazing until the Forest Service closes them. In Alternatives 2 through 4, all meadows are closed to grazing unless they are deemed suitable by the Forest Service.

There should be no major differences in effects from trails and campsites under Alternative 1 relative to current conditions. Depending on client desires, some trails and destinations could have increased use and impacts while others could have decreased use and impacts. As under all alternatives, campsites within 100 feet from water (or 50 feet if topography does not allow them to be 100 feet away) would, over time, be obliterated. Packers could continue to hold pack stock at any campsite, as long as the stock holding was over 100 feet from water and not contributing sediment or manure to surface water. Therefore, the number of stock holding sites could increase if the packers decide to access a new destination or move their stock holding sites. It is unlikely that more sites overall would be used annually.

Meadows/Wetlands: Under Alternative 1, soil and hydrologic resource effects in meadows would likely remain good overall, with a few local exceptions. About 6 percent of all existing meadows are known to have at least slight impacts to soil or hydrologic resources. Impacts would likely remain the same as today, because use should remain the same. Soil quality, vegetation utilization, and stream bank trampling standards would apply to all meadows suitable for grazing. However, even though the above standards would likely be met in most cases, continued grazing could slightly increase bare soil, soil compaction, sod fragmentation, stream bank trampling, and vegetation removal. In meadows where there is currently degradation of meadow or stream functional condition, it would likely continue.

Under all alternatives, where allowed, pack stations would continue to use the same destinations, campsites, trails, and grazing areas at the same levels as they have in the past, with annual differences based on client demand. Under Alternative 1, there would be no restriction on using new areas. Therefore, there could be entirely new areas that would have campsites and grazing areas that have never or rarely been used in the past.

Meadow/Wetland Hydrologic Function: Most meadows in the Wildernesses should remain in good hydrologic function condition. About 5 percent of all known meadows and 40 percent of all analyzed meadows have at least slight hydrologic function alteration. About 2 percent of all known meadows and 16 percent of analyzed meadows have moderate to severe hydrologic function alteration. Roughly, 90 percent of analyzed meadows should not show any major changes in hydrologic function under Alternative 1 (Figure 4.5). Wilderness-wide, there should be a very small difference between the effects of all alternatives. The change in hydrologic function alteration severity of individual meadows could be measurable, although in most cases is not likely to experience major change within 20 years.

It is estimated that, under continued current grazing practices, approximately 7 percent of meadows may have improved hydrologic function while about 5 percent could have hydrologic function move away from potential (Table 4.65). In most locations, the changes away from current condition should be minor. For a list of the projected change in meadow hydrologic function and PFC for each analyzed meadow, see the table, *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under All Alternatives* in the project record.

Most of the 19 meadows that are expected to have improved hydrologic function condition have not been recently grazed by commercial pack stock. They all currently have slight to severe hydrologic function alteration, all related to past cattle grazing, pack stock grazing, or incised trails. Only five of the meadows are currently grazed by commercial pack stock and are expected to be grazed in the future. These meadows are all expected to receive light grazing, similar as past use, at no more than 20 to 40 nights of grazing per year. Without substantial grazing, the meadows could have minor reductions in soil compaction, minor aggradations of slightly incised stream channels, or trail aggradations that could allow a minor improvement in water retention and possibly a higher water table. It is possible that any of these meadows could have increased grazing, because areas of use are seldom defined or regulated under Alternative 1. If these meadows were grazed to their full 30 to 40 percent vegetation utilization or 20 percent annual

Chetwood Cabin Meadow, in the Ansel Adams West Geographic Unit. This photo shows the widened stream and collapsing stream banks in the middle of the photograph. Vegetation is growing in the channel, suggesting that the stream functional condition has a static or upward trend. This meadow has not been recently grazed by pack stock, and effects are attributed to cattle grazing that continued until the mid 1990s or other unknown factors.

stream bank disturbance, it is likely that the hydrologic function in these previously impacted meadows would either stay the same or trend away from potential.

The meadows that would be expected to have no change in their current hydrologic function have variable reasons for the predicted static trend. Almost half have no altered hydrologic function currently and have not been grazed by commercial pack stock in the past, and so are not expected to be grazed in the future. There should not be a change in the hydrologic function in these meadows, unless grazing levels or other use changes substantially.

Other meadows, such as Alger Lakes and Superior Lake Meadows in the Ansel Adams East Geographic Unit, currently have substantial grazing, but do not appear to have altered hydrologic function. We assume those meadows will remain in good hydrologic functioning condition with continued grazing. Other meadows, including many in the Ansel Adams West Geographic Unit, currently have moderate to severe altered hydrologic function, likely from historical cattle grazing (see photo).

Some of these meadows would likely have light grazing and others would have no grazing under Alternative 1. Regardless, they have severe enough hydrologic function alteration, or low enough productivity, that any noticeable recovery of hydrologic function is unlikely within decades. Any of these meadows could begin to be grazed more heavily than recently reported, although it is not expected. If that occurred, some would likely have a downward trend in hydrologic function. Others could be grazed much less than reported in recent years. In that case, it is possible that hydrologic function could improve. It was assumed grazing would remain about the same in our projections of hydrologic function alteration.

Of the 14 meadows expected to have a downward trend in hydrologic function, 12 have a substantial commercial pack stock grazing under Alternative 1. All have previous hydrologic function alteration or areas that never reach range readiness, which makes them vulnerable to future impacts. Eleven of these meadows have current impacts that appear to be related to recent pack stock use (likely along with past uses or other stressors). The impacts include stream bank trampling and erosion, sod fragmentation, soil hummocking, and soil compaction. Two of these meadows, Martin's Meadow, (mcg4), and the meadow adjacent to Waterfall Camp (fre3) do not have recent reported grazing. However, they would both be expected to receive commercial pack stock grazing or travel in the future. Martin's Meadow was closed for Yosemite Toad protection, but would be open under Alternative 1. It has severe headcutting with an unknown cause. There was heavy commercial pack stock grazing in Martin's Meadow through the late 1980s and trails cross the creek where the headcuts occur. The meadow adjacent to Waterfall Camp is not grazed, but pack stock travel through the meadow when released from Waterfall Camp to graze at a nearby meadow.

Under Alternative 1, grazing numbers could increase substantially at any meadow in the wilderness other than in the four meadow complexes that are currently closed (Pioneer Basin, Second Crossing, Minnow Creek/Cascade Valley, and Holcomb Meadow). Therefore, the projections above could be under predicting negative impacts. However, as stated previously, increased grazing is not expected because overall overnight commercial pack stock use is expected to remain similar to today, or decrease.

Figure 4.5. A comparison of the effects of alternatives on meadow hydrologic function condition.

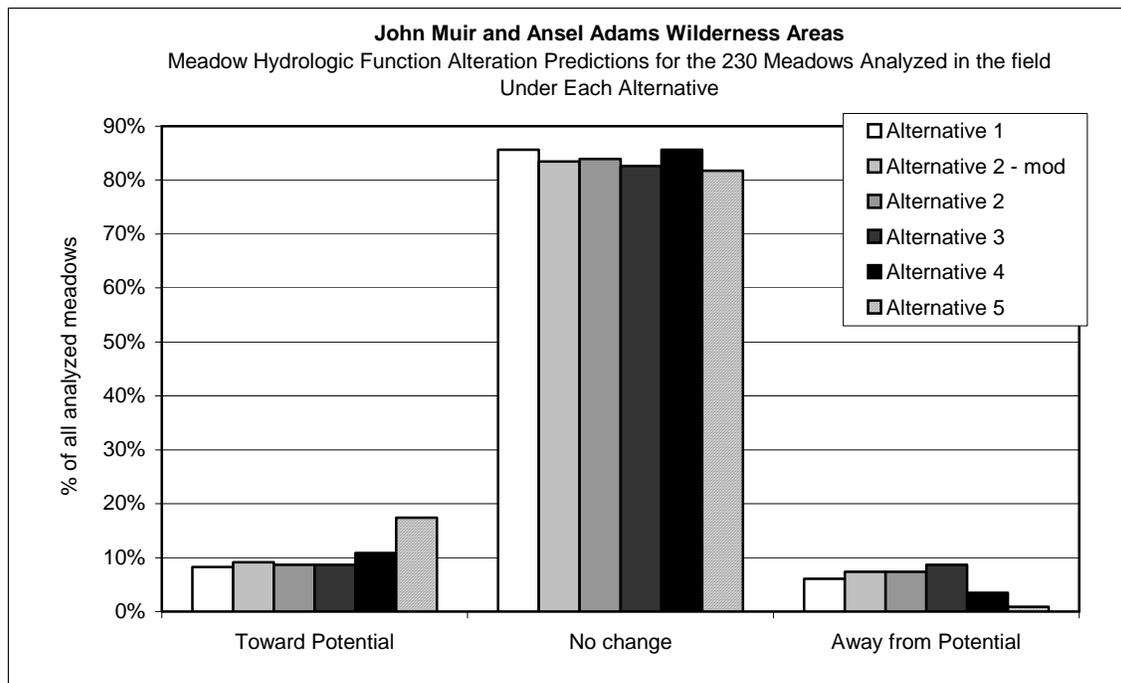

Table 4.65. Hydrologic function alteration predictions for all meadows visited in the field. The number of meadows predicted to have each trend was estimated by the IDT, using the meadow’s characteristics such as soil moisture, stream bank stability, and meadow productivity. The predictions assume that some meadows would not receive their allocated stock nights, if they were in an area not likely to received increased use. The prediction underestimates the worst possible effects, but is a more realistic estimation. The potential effects if all stock nights were used are included in the text.

Trends By Number of Meadows						
Current Meadow Hydrologic Function Condition (# of meadows with that condition)	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
No hydro alteration (137)						
Toward Potential	0	0	0	0	0	0

Toward Potential	19	21	20	20	25	40
No change	197	192	193	190	197	188
Away from Potential	14	17	17	20	8	2

Meadow Stream Functional Condition (PFC): Under Alternative 1, most meadow streams should remain in good condition, with about 5 percent of all meadows' streams known to be functional at-risk. More streams would likely have a downward trend in stream functional condition under Alternative 1 than under any other alternative (Figure 4.6). However, the difference between the effects of Alternative 1 and the current condition should be small. Under Alternative 1, it is expected that about 22 percent of analyzed meadows might see a minor change in their current condition. Grazing is less restricted than under all other alternatives. Meadows might be closed over time due to their unsuitability for grazing, but the changes would occur piecemeal and slowly. In the mean time, all meadows other than the few currently closed could be grazed, regardless of existing impacts or suitability for grazing. For a list of all meadows with predicted change to stream functional condition under all alternatives, see the table *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under All Alternatives* in the project record.

Management direction in the 2001 Wilderness Plan (USDA Forest Service 2001, p. 24) requires that meadows and streams, fens, springs, and other special aquatic features within potential grazing areas be at Proper Functioning Condition (PFC). Some meadows and streams currently are not at PFC, and the interpretation of the requirement in that case is that the meadow should trend toward PFC where possible. Of particular concern are streams that are functional at-risk with a downward trend, because they have the potential to move toward a non-functional condition that provides little to no aquatic or riparian habitat.

Table 4.66 shows that an estimated 19 of the 151 meadows analyzed for PFC might have improved stream functional condition under Alternative 1. Those projections are based on continued current use and were determined by the IDT. Assumptions about the potential for improved conditions were based on the degree and types of previous impacts, the stream resiliency, and the type of use expected.

Figure 4.6. A comparison of predicted changes to stream functional condition (PFC) among alternatives for the streams where PFC was analyzed. A total of 151 meadows were analyzed for PFC, all within meadows or other grazed areas. This chart includes all streams analyzed, whether they are at proper functioning condition or whether they are currently functional at-risk. Stream functional condition is moving closer to potential when it is moving closer to its highest ecological status the riparian-wetland area can attain. A stream that is currently at proper functioning condition can still move toward its potential, because properly functioning can be at a lower ecological state than its potential.

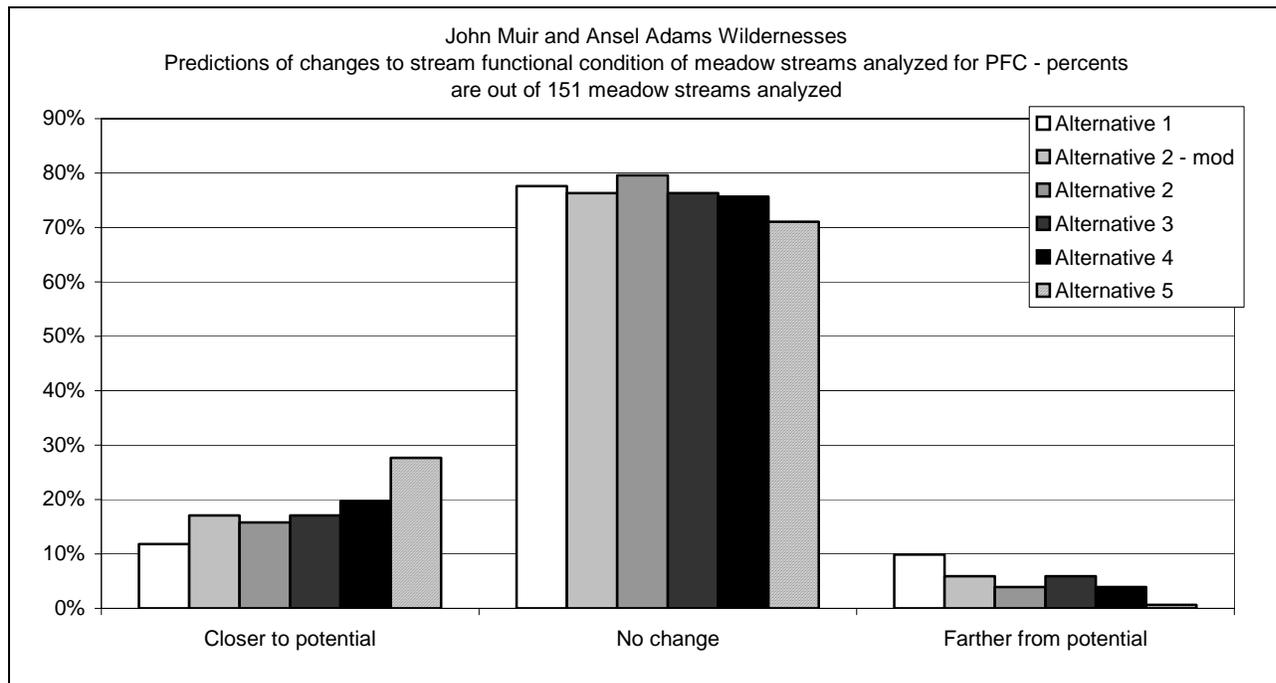

Table 4.66. A summary of all meadow stream functional condition predictions under all alternatives. Stream functional condition was determined using the Proper Functioning Condition (PFC) protocol. The streams are separated by those that are currently properly functioning, those that are functional at-risk with an upward trend, those that are functional at-risk with a non-apparent trend, and those that are functional at-risk with a downward trend. The predictions are based on assumptions that grazing will continue about as it has in the past in most areas, except in meadows that are closed to grazing and those nearby meadows where grazing might move to.

Current stream functional condition rating (# with each rating)	Number of Meadows expected to have each trend					
	Alternative 1	Alternative 2 - Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
Proper Functioning Condition (91)						
Toward potential	2	1	2	1	2	7
No change	81	82	84	82	83	83
Away from potential	8	8	5	8	6	1
Functional at-risk upward trend (15)						
Toward potential	6	6	6	6	7	8

Current stream functional condition rating (# with each rating)	Number of Meadows expected to have each trend					
	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
No change	8	9	9	9	8	7
Away from potential	1	0	0	0	0	0

Away from potential	15	9	6	9	6	1

The 19 meadows that could have some improvement in stream functional condition are mostly the same meadows that are likely to have improved hydrologic function, with a few additions. None of the 19 meadows are expected to receive more than 40 stock nights, and 14 of them should not receive any commercial pack stock grazing. One, Second Crossing, is closed to commercial pack stock grazing, and the others are expected to receive little or no grazing because they have not been used in the past. These streams are all functional at-risk or have a small segment that is functional at-risk. The streams are mostly functional at-risk currently due to historical cattle grazing, historical pack stock grazing, trails, or some unknown reason. Continued rest from grazing should allow the streams to have at least minor increases in stream bank vegetation and reduction in stream bank disturbance, and therefore at least a minor improvement in functional condition.

Of the 116 meadow streams to have no change in functional condition, about half are expected not to be grazed. Some of those that could be grazed currently have good condition streams, and either have stream banks armored with boulders or vegetation and are able to withstand grazing, or have low levels of grazing that should not affect more than a small portion of the stream. Others are currently functional at-risk, either due to recent pack stock grazing or other factors. Continued grazing is likely to sustain the functional at-risk condition created by commercial pack stock use, or prevent recovery of a functional at-risk condition created by another use.

Seventeen stream meadows are predicted to have worse condition under Alternative 1; more than predicted under any other alternative. All of these meadows are expected to receive substantial grazing or commercial pack stock travel, and are the same meadows that are expected to have a downward trend in hydrologic function plus two more. These meadows have streams where current impacts have made them vulnerable to further impacts due to lack of armoring by strong-

rooted vegetation or boulders. Therefore, continued use at the recent levels could allow amplified degradation.

Grazing Water Quality Effects: Water quality should remain good overall, with sediment and manure entering streams in a few heavily grazed meadows. There are some meadows where bank sloughing, stream incision, and soil erosion increases fine sediment in streams within and directly downstream of the meadows. These are generally the meadows with a stream functional condition rating of “functional at-risk,” or those with high levels of sod fragmentation. Under Alternative 1, fine sedimentation into surface water from meadows will likely remain the same overall. Those few meadows where stream functional condition is expected to improve from its current state will likely have a decrease in streambank erosion and therefore a decrease in fine sedimentation into surface water. These meadows were grazed in the past, usually by cattle, but are not currently grazed by commercial pack stock. The continuation of rest from grazing should allow for streambank vegetative growth that prevents erosion and helps trap excessive sediment, rebuilding stream banks and floodplains.

Pack stock would continue to deposit manure in meadows, adjacent to and in surface water. While most manure is deposited out of surface water, pack stock walk through streams to graze, drink, or cross the stream. Further, manure deposited near streams can wash into the stream during rainfall or snowmelt runoff. This would occur under all alternatives other than Alternative 5. Although there must be some local increase in nutrients, bacteria, and other pollutants directly at the site of manure entry into water, it is unknown whether there is enough manure to cause water quality degradation downstream under Alternatives 1 through 4. This information gap should not affect the decision being made under this EIS. Water quality has not been found to be harmful to beneficial uses within or downstream of the wilderness, although studies have been limited. Therefore, the effects to water quality are not considered major enough to warrant altering pack stock management for that purpose only.

Under Alternative 1, pack stock grazing would likely remain the same as today. While commercial pack stock manure would continue to enter water under this alternative, the volume should remain the same. There should be no degradation of what is assumed to be overall good water quality.

Meadow Soil Effects: Under Alternative 1, soil productivity within the AA/JM Wildernesses should remain about the same, with general overall good soil productivity and a few locations with moderate to severe negative soil productivity effects. Of the roughly 1,500 meadows in the wilderness, 45 (3 percent) are known to have moderate to severe soil compaction (defined as having platy structure, mashed roots, and evidence of plant vigor reduction), and 60 (4 percent) are known to have moderate to severe sod fragmentation. However, only about 200 meadows were analyzed for soil effects, and the soil condition in the other meadows is unknown. However, the other meadows are generally not those being used regularly by commercial pack stock, and therefore this action should have no effects in those areas.

It is assumed that soil conditions should remain about the same in most meadows, because it is expected that use should remain about the same. Some of the meadows that currently have severe sod fragmentation could have increased sod fragmentation with continued or increased pack stock use. This includes many wet meadows such as Third Recess in the Fourth Recess Analysis Unit, or Third Crossing in the Cascade Valley Analysis Unit. In many cases, wet meadows have sod fragmentation after grazing, but they are so productive that the sod fragmentation fills in

with vegetation the next spring. In very wet meadows that are too wet to be compacted, sod fragmentation may not reduce long-term soil productivity. However, in steep meadows or in areas with severe sod fragmentation (see photos), it may lead to soil erosion and reduced productivity.

Photos (a) and (b). Jackson Meadow, tributary to Minnow Creek. Photos taken in August 2001 (top) and 2005. The arrow shows the same point in space; there is a different perspective because the photos were taken from a slightly different location. In 2001, the headcut was raw at the right side of the photo, and due to hoof punching and trailing, along with dry conditions, there was extensive fragmented sod directly above the headcut. By 2005, the headcut had advanced up into the bare sod area, forming a new stream with raw banks that will likely continue to incise upstream. One headcut advanced toward the right of the photo, and another headcut advanced along a perpendicular trail, shown at the top of both photos. The 2005 photos show that while the vegetation has grown back in the sod fragmented area, the headcut continues to advance. Just downstream of the location of this photograph, some of the incised channel had filled in with sediment and vegetation from 2001 to 2005, showing that degradation and recovery can occur in the same time in different locations in one meadow.

Trails: Although trails cause local water diversions, soil loss, sedimentation into surface water, and groundwater table lowering, their effects are not substantial wilderness-wide. In the project area, 350 trails were evaluated for trail condition and effects on water and soil resources and 236 were analyzed for overall resource rating. Generally, resource impacts are site specific and do not include the entire trail. Of those 236 trails analyzed, 43 percent are causing little or no alteration to soil or hydrologic processes. Another 31 percent are causing minor alteration, 17 percent are causing moderate alteration, and 8 percent are causing severe alteration of soil or hydrologic processes.

Under Alternative 1, there are likely to be few overall changes to trails effects on soil and hydrologic processes compared to the current condition. Trail use by pack stock as well as backpackers would likely remain about the same. Although the commercial pack station operators could begin to use new trails and abandon old trails, it is unlikely that they would change their use dramatically unless client demand changed.

Trails that currently have moderate to severe impacts would likely not recovery without active repair, no matter what use types occur. Most of the trails causing noticeable sedimentation into surface water or diverting surface water will be gradually repaired over the next 20 years under all alternatives. Therefore, there should be little difference in trail contribution to soil and water resource degradation between alternatives. There is, however, more potential for unknown future change under Alternative 1. Trails that are not currently causing soil or water resource impacts could have increased pack stock use and become less stable over time with increased erosion. These effects could occur whether or not a trail is used by pack stock. However, pack stock are heavier than hikers are and more able to displace soil on the trail. Therefore, trails used by pack stock are more likely to have soil removal, erosion, and subsequent sedimentation into surface water. There are trails, such as the system trail between Ediza and Iceberg Lakes, where commercial pack stock has not used the trail in about a decade, but it continues to erode because it is incised and captures surface runoff. The surface runoff will likely continue to run down the trail and incise it until check dams or water bars are placed into the trail.

Campsites: Other than at a few sites, campsites do not appear to have major contributions to water quality degradation. The negative impacts of campsites on water quality should improve slightly under Alternative 1, although less than all other alternatives. The effect of campsites should improve because under all alternatives, campsites within 50 feet of water would no longer be used by anybody; whether they are commercial pack stock parties or backpackers. Sites close to water are more likely to contribute sediment and manure to surface water as snowmelt and rainfall runoff wash sediment and manure into streams and lakes, as was found by evaluating 163 sites under the BMPEP protocol (see Hydrology Section, Chapter 3). Obliteration of these sites may take many years, and it would be difficult to enforce for backpackers. However, commercial packer permits would require that all stock holding and drop off sites be located over 100 feet from water where possible, and at least over 50 feet from water if topography permits.

Under all other alternatives, stock holding sites will be designated, or in the case of Alternative 5, there will be no stock in the wilderness and therefore no need for designated stock holding camps. All stock holding camps will be pre-approved by the Forest Service only in locations where they are not likely to contribute to surface water-quality degradation. A foreseeable future action is that sites causing water quality degradation or excessive soil compaction or soil loss would eventually be contained or closed under Alternative 1. The stock holding sites would more quickly come into compliance with BMPs and other standards under all other alternatives.

Therefore, while the soil and water quality impacts might be the same within 20 years, negative impacts could persist the longest under Alternative 1.

Cumulative Impacts: This alternative has been analyzed in terms of the effects of past, present and reasonably foreseeable future actions to soil and hydrologic processes. Although past actions have caused some alteration to watershed processes over much of the project area, and most of the project area is not pristine, watershed conditions here are likely some of the least altered in California or the contiguous United States. Less than 1 percent of the entire area is estimated to have any ground disturbance. Under Alternative 1, that condition should not change because uses within the wilderness would not change substantially.

Past actions negatively affecting soil and water resources include historical cattle, sheep and pack stock grazing, historical recreational activity, construction of small and large dams, and a minor amount of mining. Sheep and cattle grazing have been prohibited over most of the AA/JM Wildernesses since the 1950s, likely allowing soil and hydrologic function to improve in those areas.

Historical cattle, sheep, and pack stock grazing all likely had similar negative effects to watershed processes. The effects were probably similar to current pack stock grazing, although in the past, were likely more severe and widespread due to the larger extent and intensity of grazing. Documentation suggests that extensive cattle and sheep grazing and pack stock use between the mid 1800s and the early 1900s denuded vegetation, compacted soils, and altered stream morphology within Sierra Nevada Wilderness areas (Muir, 1894; van Wagtendonk and Parsons, 1996). These changes likely contributed to headcuts, stream downcutting and lowering of the water table existing today in some of the meadows within the project area. These conditions are attributable to grazing because grazing animals chisel and compact soil, and remove the protective sod and productive topsoil. Stream incision and gully erosion can result. If gullies are deep enough, they can intercept and divert surface and groundwater. This can lower the water table and alter the meadow's hydrologic function as the meadow is effectively drained by the gully (Hagberg, 1995). Trails through meadows can become incised and have a similar dewatering effect on a meadow. While vegetation can recover relatively quickly on an overgrazed meadow, with its water source unaltered, hydrologic function and geomorphic recovery can take decades longer (Kondolf, 1993).

Past recreational activity includes historical pack stock and hiker use. The effects of recreational use were the same in the past as today, although the greater party size associated with organized trips (such as Sierra Club trips) likely had more widespread effects with each trip. Effects at campsites included denuding vegetation, compacting soil, and increasing erosion into surface water. Effects on trails included likely creation of new user trails and the associated bare, compacted soil, expansion of trails to wider or multi-trailed paths, and possible associated soil loss on trails. The soil lost on trails probably entered water at stream crossings and where a trail was near a stream, slightly increasing sediment supply into surface water. Because trails are near streams in only discrete locations, the effects were local in extent. The effects were likely severe in a few cases, where a trail became severely incised or led to stream morphology changes, but in most cases likely caused minor input of sediment into surface water or minor soil loss along trail tread. These effects on trails could last indefinitely without trail repair. For example, when a trail incises, it captures more surface water, and that surface water continues to incise the trail. While the water quality effects are likely short-term, only occurring during heavy use or during rainstorms, there could be long-term effects to stream morphology and soil loss.

The effects of small dams include slight alteration in flow, blockage of large sediment such as gravel or boulders, and in some cases, alteration of lake levels that could affect riparian vegetation. The effects are local, only near the dams, and are not widespread throughout the wilderness, because there are not many known small dams. The effects of dams are only severe when the dam is large enough and waterproof enough to reduce the volume of water entering the stream over or through the dam. In these cases, flow would be less during the first part of runoff (such as early in the summer when snowmelt is high), but would increase to normal levels as soon as the lake filled to the dam level. The effects are unlikely to be compounded by commercial pack stock use, because most commercial pack stock operations do not affect water flow. However, when the dams reduce the extent of riparian vegetation growth, and commercial pack stock grazing or trailing reduces the extent of riparian vegetation, the effects could be cumulative loss of riparian vegetation.

The effects of mining that could affect surface water are the dumping of tailings into meadows or surface water, the diversion of water for mine use, and water pollution from mining practices such as use of toxic materials or deposition of mining equipment into surface water. These effects exist in discrete locations of the wilderness, and are not widespread. In some cases, dredger tailings can alter surface water flow when a stream must divert to get around the tailings. In this case, the effects would only be cumulative with commercial pack stock use if the pack stock use led to changes in stream morphology. This may have occurred in a few meadows, such as Minaret Mine Meadow. In this meadow, a small, mining related dam cut off coarse sediment supply to a downstream meadow, a tailings pile forced the stream to divert around the pile, and it is assumed that the associated pack stock grazed in the nearby meadow. The current stream incision and drier meadow vegetation in some locations may be a result of the cumulative effects of pack stock use and mining. However, in this case, there would likely be little commercial pack stock grazing under Alternative 1, and therefore the effect could continue to recover.

Present actions include implementation of the Ansel Adams, John Muir, and Dinkey Lakes Wilderness Management Plan, which was adopted in 2001. Cattle grazing continues mainly in the western portion of the Ansel Adams West Geographic Unit and the very western portion of the Mono Creek/Rock Creek Geographic Unit. Recreational use, including hiking, backpacking, and private pack stock use continues throughout the area.

One reasonably foreseeable future action is trail maintenance and repair. The frequency of repair is likely to decrease due to reduced trail maintenance/repair funds. Trails with severe water and soil resource impacts may be repaired within 10 to 30 years. Closure of meadows that are found to be unsuitable for grazing is also a reasonably foreseeable future action. Meadow closure or other specific meadow management would likely occur in a piecemeal fashion as meadows are identified as unsuitable or suitable for limited use. Meadow closure would improve soil conditions and provide for improved hydrologic function. Long-term soil productivity would be enhanced.

In localized areas, the combination of past, present and future grazing and recreational use would allow continuation of stream morphology alteration, meadow hydrologic function alteration and slight water quality degradation. The largest contributor to cumulative soil and water effects appears to be historical and current grazing of meadows and trailing to access grazing of meadows. Trails (system and user) and campsites also contribute to possible cumulative soil and water quality effect.

The areas with the greatest possible commercial pack stock contribution to cumulative effects are the Mono Creek Watershed and the Fish Creek Watershed. These areas receive some of the highest recurring levels of commercial pack stock use, and have some of the greatest impacts to meadows from grazing, and to streams from grazing and campsites. Under Alternative 1, the uses from today would continue in a similar pattern, and therefore there could be continued additive effects. For example, Grassy Meadow has extensive stream bank trampling, incised and widened channels, vegetation composition change, and compacted soil over much of the meadow. The meadow has been used for decades by commercial pack stock, and because it is a moderately large meadow, was likely used for cattle and/or sheep grazing in the 1800s and early 1900s. Although the effects from past grazing are unknown specifically in Grassy Meadow, it can be assumed that Grassy Meadow had widened, incised channels, compacted soil, and vegetation composition change from historical grazing that was likely heavier than recent commercial pack stock grazing. It is assumed that the past grazing made the meadow more vulnerable to some current impacts, although the meadow could have recovered during decades with low levels of grazing. Therefore, the additive effect of current commercial pack stock grazing with past livestock grazing is likely responsible for the current condition of Grassy Meadow. Continuation of the current uses would allow the negative hydrologic and soil effects to continue in meadows such as Grassy, which receive high levels of current commercial pack stock grazing.

In cattle allotments active within the past 15 years, pack stock use has been very low and appears to have contributed less to cumulative water and soil effects than recent and historical cattle grazing. In those areas, Alternative 1 would allow continued slow recovery of soil and water resource conditions.

The effect of Alternative 1 on cumulative wilderness water quality outside of grazed areas is unknown. Effectors to water quality within the wilderness include human waste, pack stock waste, human products such as soap and shampoo, domestic animal waste, wild animal waste, atmospheric deposition, cattle waste, and in some locations, possibly mine tailings. While there is evidence of increased coliform and bacteria below heavily used pack stock areas, there is also increased coliform in areas with little to no pack stock use, and no coliform found in areas with high levels of pack stock use. No studies have directly correlated heavy pack stock use with water contamination, although IDT observations of pack stock defecating directly in water suggests that pack stock manure does enter water, and could have negative effects to water quality. What is known is that one or a combination of the above listed effectors has increased nutrient levels across the Sierra Nevada, and that there are levels of human pathogens and other bacteria in some lakes capable of affecting human health. Pack stock and the clients supported by commercial pack stock likely add some fraction of the contaminants to surface water throughout the AA/JM Wildernesses, but the degree of their contribution is unknown. Under Alternative 1, the contribution should remain at the same unknown levels as today.

In some areas, such as near Sadler Lake in the Ansel Adams West Geographic Unit, continued pack stock use, especially grazing and grazing related activities could prevent recovery of stream condition, meadow hydrologic function, and soil productivity. With the reasonably foreseeable future actions related to grazing including reducing use, implementing site-specific management, or prohibiting grazing in meadows that are found to be unsuitable for grazing, there could be long-term beneficial effects to soil compaction, meadow hydrologic function, and stream function condition. This would lead to enhancement of long-term soil productivity.

Cumulative Watershed Effects (CWEs)

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis* in the project record.

In summary, many individual areas appear to have local watershed effects that have been cumulative over time, but only three watersheds have what could be CWEs transported from upstream land uses. The greatest contributor to CWEs appears to be grazing, although trails also have noticeable effects. Effects from grazing are especially evident in meadows that have been grazed both historically and recently. The watershed effects are commonly stream incision, streambank collapse, stream widening, increased fine sedimentation in meadow streams, vegetation composition change, gully erosion, meadow compaction, and lowered water tables. In many cases, these effects cannot be associated with recent pack stock grazing, but pack stock grazing could exacerbate the impacts or slow the rate of recovery.

Under Alternative 1, there could likely remain potential for CWEs in the East Fish Creek Watershed (Upper Fish Creek, Purple Bench, Silver Divide, and Cascade Valley Analysis Units in the Fish/Convict McGee Geographic Unit), with little to no change in potential. The potential CWEs existing currently in the East Fish Creek Watershed can be attributed at least partially to past and present commercial pack stock use, including grazing and trail use. Other uses that could have contributed to possible CWEs are past cattle and sheep grazing, and past and present non-pack stock use of trails and campsites. Other watersheds with possible current CWEs include the Edison Reservoir Watershed (Ansel Adams West Geographic Unit, Graveyard Analysis Unit), and Granite Creek Watershed (Ansel Adams West Geographic Unit; Sadler, Triple Divide, Lillian, Staniford, and a portion of Cora Analysis Units). Both of those watersheds have possible CWEs that are likely attributable to historic and recent cattle grazing, with little contribution from commercial pack stock.

Alternative 2 – Modified

Summary of Alternative 2 – Modified Impacts

Water quality is thought to be good and will remain so except at a few local areas where there may be slight degradation. There will remain areas of local soil erosion, bare soil, and sedimentation into surface water from pack stock grazing, campsites, and trails. There would be a minor reduction of bare, compacted soil and sedimentation into surface water from designating stock holding camps, reducing the number of meadows where grazing is allowed, and limiting grazing stock nights in all meadows. Of 60 streams found to be functional at-risk (151 evaluated), it is estimated that 42 percent could have improved condition, about 1 percent could have a more degraded condition; and about 57 percent should remain functional at-risk. Meadow hydrologic function has some potential for improvement. Of the 41 meadows found to currently have hydrologic function alteration (230 evaluated), about 22 percent could have improved condition, 65 percent should remain in the same condition, and about 13 percent could have a downward trend.

Past and present grazing from production livestock and pack stock is thought to be the largest contributor to meadow hydrologic function alteration. Unlike Alternative 1, Alternatives 2 through 4 limit grazing to meadows that have been analyzed and designated as suitable for grazing. Under Alternative 2 – Modified, meadows where streams are rated non-functional or

functional at-risk, with a downward trend, are rested for grazing until conditions improve enough to support use. The two exceptions are Jackson Meadow and Purple Meadow. Jackson Meadow has portions where streams were rated functional at-risk, but those sections would be closed to grazing and the segments with streams at PFC would be grazed. Purple Meadow, where the stream was rated functional at-risk with a downward trend in 2001, showed an upward trend in 2004 and 2005. Therefore, it is determined to be resilient and able to support about one-third of the grazing that it experienced in the past. This alternative also limits grazing in those suitable meadows to a given number of stock nights. The restriction of grazing to meadows found to be suitable for grazing and not highly vulnerable to impacts should limit future adverse grazing impacts.

Analysis

Under Alternative 2 – Modified, there likely would be some slight overall improvement in stream and meadow hydrologic function, soil productivity, and water quality. Locally, there could be larger changes. The greatest improvement to soil and hydrologic resource condition would be from elimination of grazing on meadows that currently have soil or hydrologic function alteration or are unsuitable for grazing. Designation of stock holding campsites away from water, implementation of destination quotas, disapproval of user trails with resource impacts, and designation of system trails with resource impacts as not suitable for commercial stock until repaired, might also help reduce soil and hydrologic resource impacts. In a few locations, there could be minor increases in negative effects to soil and water resources because use may be moved to new locations that are more suitable for that use.

The main benefit to soil and hydrologic resources would be from the concentration of use. While use could be high in some destinations, retaining the current extent of bare, compacted soil, use will be contained to only specific destinations. No spot/dunnage trips could occur outside of destinations and no overnight stock holding trips could occur outside of about 170 designated campsites. Use could not expand into currently lightly used areas or areas unsuitable for pack stock use. Therefore, the extent of disturbed areas related to commercial pack stock use should remain the same or lessen.

Meadows/Wetlands: Under Alternative 2 – Modified, effects in meadows should be slightly improved relative to current conditions and Alternative 1. Only 94 meadows were actually grazed between 2001 and 2003, and this alternative would allow 135 key area meadows to be grazed by commercial pack stock. More meadows (about 155) within zones would also be open to grazing, but due to their lack of past reported grazing, it is unknown if these meadows would actually be grazed. Meadows found to be unsuitable for grazing, outside of designated grazing zones, or that have currently unacceptable impacts would be closed to use and only meadows found to be suitable for grazing would be open for grazing.

Although 135 field-analyzed meadows (and about 155 more non-field analyzed meadows) would be open to grazing, it is unlikely for commercial pack stock operators to have grazing in each of those meadows every year. Over the long term, it is likely that they would graze all or most of those meadows, some annually and some only every few years. The commercial pack stock operators requested to use 385 meadows, and are allowed to use about 1,500 under Alternative 1. However, they only used 94 between 2001 and 2003, and it is assumed that they will continue to use about the same total number of stock nights used in the past, or fewer, under Alternative 2. The range of stock nights reported was between 3,000 and 5,000, and it is expected the number

will continue in the lower end of that range. Grazing might decrease because the number of overnight traveling trips would be reduced and therefore there would be less need for grazing.

Elimination of grazing on meadows found to be unsuitable would allow for some local soil and hydrologic condition recovery. Of the roughly 95 meadows that were grazed from 2001 through 2003, about 25 will be closed or rested and about 10 will have substantially reduced grazing (at least 20 stock nights less) under Alternative 2. About 1/3 of the meadows/wetlands that were grazed from 2001 through 2003, therefore, could have reduced impacts from rest or reduced stock nights. About 70 meadows with no reported grazing from 2001 through 2003 will be opened to grazing. It is assumed that because those meadows were found to be suitable for grazing, and because they were given a grazing allocation designed to meet utilization standards, any negative effects, although they may occur, will be minimal and within standards.

Meadow/Wetland Hydrologic Function: The degree of hydrologic function alteration is unlikely to show any major changes in the majority of meadows. Effects are likely to be similar to Alternative 1, although slightly fewer meadows will have a downward hydrologic function trend (Figure 4.6). Meadow hydrologic function recovery may take decades in meadows even without any grazing or other disturbance because it depends on slow-acting geomorphic processes such as soil decompaction, stream aggradation and lateral migration. Because the proposed action was designed to attempt meeting desired conditions, no meadow should show more than slight negative alteration of hydrologic function under this alternative and the rest will likely have a static or minor to moderate upward trend.

Of the 230 meadows analyzed for hydrologic function alteration, 137 meadows were found to have no hydrologic function alteration. Of these 137 meadows, three to five are expected to have some minor reduction in hydrologic function under Alternative 2 – Modified (Table 4.65). A list of all meadows and the projected effects to hydrologic function under all alternatives is available in *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under All Alternatives* table in the project record. If the maximum recommended high grazing nights were used in all meadows, up to five might have minor reduction in hydrologic function. However, it is unlikely that the proposed stock nights would all be used in all meadows because although they are suitable for grazing, some are not in areas that have high enough past levels of traveling commercial pack stock trips or allowed overnight spot/dunnage trips to use all the grazing.

The Box Canyon above Grassy (sil2), Olive Lake West (sil15) and Second Recess meadows (sec14), are considered likely to receive near their recommended high stock nights of grazing regularly. While there could be some compaction, increase in bare soil, hoof punching, and stream bank trampling with grazing, the effects on hydrologic function should be minor and should not be permanent because the proposed stock nights were designed to protect meadow critical areas and meet vegetation utilization and stream bank trampling standards.

The two meadows considered unlikely to be grazing to near their recommended high are Meadowbrook (bim5) and Middle Deer Creek (ccd17). Meadowbrook's recommended high stock nights are 145 and 70 was the recent high. There will likely be no reduction in hydrologic function if near 70 stock nights is used. If it is grazed for 145 stock nights due to some change in use patterns, there could be increased bare soil, increased stream bank trampling, and increased sod fragmentation that could cause the hydrologic function to have a slight downward trend. Under Alternative 2 – Modified, the critical fen area in this meadow would be closed to stock

entry, and therefore should remain in good condition. Deer Creek had 95 stock nights reported in the past, but the proportion that grazed in Middle Deer Creek Meadow (ccd17) is unknown. The recommended high for ccd17 is 230 stock nights. Because the numbers of traveling trips should not have any major increase to this area, and because the location is close enough to the pack stations that grazing will not be necessary on spot/dunnage trips, it is unlikely that grazing would double.

Of the 93 meadows with at least slight hydrologic function alteration, about 65 percent would be expected remain in their current condition, about 22 percent would be expected to show minor to moderate improvement, and about 13 percent could show a minor downward trend in hydrologic function.

A few different processes could occur in meadows that are expected to have continued hydrologic function alteration. Many of them have current commercial pack stock grazing contributing to hydrologic function alteration, and could continue to have similar grazing intensity and impacts under this alternative. Others have hydrologic function alteration due to conditions unrelated to recent commercial pack stock use, such as cattle grazing, drought or incised trails, and will not likely recovery their hydrologic function even without grazing. A few of the meadows have hydrologic function alteration due at least partially to recent pack stock grazing, and even if that grazing is removed, the hydrologic function alteration will take decades or centuries to recover. Lastly, a few meadows have hydrologic function alteration due to something other than recent pack stock use, and would show some recovery except that they would be allowed to be grazed substantially by commercial pack stock.

It is assumed that meadows with more severe hydrologic function alteration will be less likely to begin an upward trend, even in the long term. Of the 17 meadows with current severe hydrologic function alteration, we expect only two, Grassy Meadow (sil22) and the Box Canyon above Jackson Meadow (sil3), to have potential for some minor recovery in hydrologic function. These meadows both have their water source intact. Though streams are incised, springs contribute a major portion of water to the meadows, thereby watering the meadow and allowing for vegetative recovery over time.

It is assumed that severe hydrologic function alteration takes many years to occur, but in some meadows, such as at Rodgers Lake in the URU analysis unit, recent pack stock grazing has caused slight hydrologic function alteration in just a few years. Therefore, it is assumed that the 6 percent of meadows that could have a downward trend in hydrologic function would likely only have a slight downward trend in the next few years. However, even small, incremental reduction in the ability of a meadow to absorb water, and the ability of stream banks to withstand high flows could allow for sudden severe stream incision or gully formation if a large flood occurs before recovery.

Jackass Meadow is the one meadow that could have even greater hydrologic function alteration. Most of Jackass Meadow is outside of the wilderness, but it is discussed here because there are portions within the wilderness. The meadow currently has severe hydrologic function alteration because it is downstream from Edison Dam, and flow is regulated, preventing flooding to overflow the meadow banks as should occur in a natural meadow setting. The pack stock use does not appear to be causing hydrologic function alteration with the current annual stock nights around 400 for the entire 135-acre meadow complex. Alternative 2 – Modified recommends increasing the annual grazing up to 2,025 stock nights in the entire 135-acre meadow. This could

increase the extent of hydrologic function alteration to beyond that being caused by dam operations. If the meadow begins to show a major increase in hydrologic function alteration, the grazing numbers would be reduced.

For a list of predictions for each meadow's hydrologic function and stream functional condition under all Alternatives, see the project record.

Stream Functional Condition (PFC): Functional condition of streams might improve in some areas that are currently Functional at-risk, and might remain static in others. The overall difference from Alternative 1 should be minor, but there should be slightly more streams with a trend toward potential and slightly fewer streams with a trend away from potential.

For streams in the project area that are functional at-risk, the Proposed Action designates the stream banks as critical areas, where negligible stock entry is allowed. In some of these cases, especially in wet meadows, removal of pack stock from the stream banks would allow vegetation to grow quickly on banks and in-stream bars, improving stream functional condition quickly. In areas with lower fine sediment loads or lower productivity, vegetation would not quickly grow on stream banks or on point bars, even if there was little trampling near the stream banks.

Not all meadows would have worsened stream functional condition with increased grazing. Those streams that have well-armored stream banks, such as Davis Lakes Meadows (uru1), are not likely to have negative impacts from increased grazing. Also, in those meadows where streams are functional at-risk with a downward trend due to cumulative impacts over many years, such as Johnston Meadow (min11) and Detachment Meadow (cor6), pack stock grazing at the levels proposed should not have noticeable further impacts to the stream condition. However, when a stream is not well armored by sod or boulders, and when the stream is not already in poor condition, greatly increased grazing has a chance of affecting stream functional condition.

Of the 151 streams in meadows where stream functional condition was analyzed, 91 (60 percent) are at PFC. These streams will likely remain at PFC as long as any grazing in the meadows does not exceed streambank disturbance standards of 20 percent, they do not receive increased private pack stock grazing, and no new trails are created that parallel the stream closely or have a major stream crossing. In these meadows, if the streambank trampling standard is exceeded, there is a chance that stream segments could have a slight decrease in function. Monitoring will ensure that the stream meets the 20 percent streambank trampling standards and does not reach a functional at-risk condition. If standards are not met, it is a foreseeable future action that meadows would have reduced stock nights or be closed to grazing. However, eight currently PFC meadows are projected to have some potential for a minor trend away from potential stream functional condition, although not enough to lead to a functional at-risk condition.

Of the 60 stream segments that are currently functional at-risk, about 40 percent are expected to have some improvement in stream functional condition. About 60 percent are expected to remain in their current functional at-risk state, while only one is expected to have a minor reduction in stream functional condition.

Of the 16 stream segments where condition was rated functional at-risk with a downward trend, 10 are expected to have improved condition under Alternative 2 – Modified. Six of the stream segments have the potential to remain with a downward trend and none should have an accelerated downward trend. Four of the eight expected to continue in their current condition are experiencing effects that will not be altered by removal of commercial pack stock. One will

probably continue to be grazed by cattle (Graveyard Meadow), one is functional at-risk due mainly to trails that will continue to be used (Ram Meadow), and two are functional at-risk due to an unknown reason (Crater Meadow and Dorothy Outlet Meadow). The other two meadows that could remain with a downward trend, McClure to Sadler and Jackson, have similar or reduced grazing nights than they have had in the past. In these cases, if the pack stock are successfully managed to avoid the disturbed stream segments, and to prevent streambank disturbance over 20 percent in the areas not yet disturbed, the banks could begin to grow vegetation that could improve the stream functional condition. However, the extensive stream networks and sensitivity of stream banks suggests that it may be difficult to manage stock if they graze at large.

Of the 29 stream segments where stream condition was rated functional at-risk with a non-apparent trend, 9 are expected to have some improvement, while 19 should remain in their current condition. One is expected to have a trend away from potential. Either the 19 that are expected to remain in their current condition appear either to be experiencing effects that will not be altered by removal of commercial pack stock, or they will be grazed to a level that could prevent recovery. Many of these meadows have been grazed by cattle within the past 10 years, and those cattle grazing effects are in their beginning stages of recovery or have not yet recovered. Vegetation has begun to fill in bare areas, but soil compaction remains, streams have some banks continuing to collapse, and water tables remain lowered. These streams may stabilize with further vegetation growth, but most such streams will not even in the long-term, and therefore incision will remain even with removal of all grazing. Jackass Meadow is the one meadow expected to have a downward trend under Alternative 2 – Modified. Grazing would increase from 400 to 2,025 stock nights. Currently, the stream is functional at-risk primarily due to flow regulation, but concentrated increased use could increase stream bank trampling and vegetation loss near the stream.

Fifteen stream segments were found to be functional at-risk with an upward trend. We expect six to improve at least slightly from their current condition, and nine to remain in their current functional at-risk state. The same streams that are currently functional at-risk with an upward trend should have the same effects as under Alternative 1 because the proposed management is similar to what is occurring currently.

Grazing water quality effects: Under Alternative 2 – Modified, fine sedimentation into surface water from meadows will likely decrease overall relative to Alternative 1, and remain in a small fraction of locations wilderness-wide. At some local areas, it could substantially decrease. There could be minor increases in fine sedimentation into surface water in locations with increased grazing.

Although water quality is thought to be good on a wilderness scale, there are some meadows where bank sloughing, stream incision, and soil erosion increases fine sediment in streams within and directly downstream of the meadows (see photo).

Stream through Grassy Meadow. The IDT members in the photo are walking on a sandy bar in the widened stream, though to be a result of increased sedimentation from meadow and bank erosion over time.

These are generally the meadows with a stream functional condition rating of “functional at-risk,” or those with high levels of sod fragmentation. Those meadows where stream functional condition is expected to improve from its current state will likely have a decrease in streambank erosion and therefore a decrease in fine sedimentation into surface water. About 30 percent of meadows analyzed have moderate to severe sod fragmentation, which could be leading to soil erosion and subsequent fine sedimentation into surface water. However, much sod fragmentation is not adjacent to water, and the reduction in fine sedimentation due to reduced sod fragmentation should be small.

Under Alternative 2 – Modified, pack stock use would be reduced or eliminated in over 1,000 meadows where it is allowed today. The actual days of pack stock use and grazing are expected to remain about the same wilderness-wide, although some watersheds, such as Fish Creek, will have reduced grazing. Therefore, pack stock manure is not expected to degrade water quality from its assumed current overall good condition. Sediment from pack stock grazing should be reduced relative to Alternative 1, due to grazing being limited to meadows suitable for grazing and less likely to have major erosion.

Meadow Soil Effects: As under Alternative 1, changes in commercial pack stock management, which is only part of total recreational use, will likely have little affect on overall soil productivity wilderness wide or on the Geographic Unit scale. There should be a slight overall improvement in soil productivity over current conditions and Alternative 1. Meadows with grazing reduced or eliminated could have increased soil productivity, reduced soil compaction, reduced bare soil, and reduced sod fragmentation. Fewer could have slightly decreased soil productivity, increased soil compaction, increased bare soil, and increased sod fragmentation because they could receive more grazing than currently. The negative effects should be within standards. However, even if standards are met, there could be some increased erosion, increased stream bank disturbance, and decreased stream stability. If this occurs, grazing management would likely be altered to arrest the degradation.

Under Alternative 2 – Modified, soil compaction effects could vary. It is uncertain how long it will take compaction to recover in meadows where Alternative 2 recommends grazing management changes to help reduce compaction. Soil compaction recovers with frost action, shrink and swell due to drying and wetting, and biotic activity such as vegetation growth and

rodent burrowing (Alexander and Poff, 1985). Studies have shown various rates of recovery for compaction, depending on climate, soil type, and depth of compaction. Soil Orr (1960) found that recovery times for compacted surface soils in South Dakota to return to their pre-compacted bulk densities on grazing lands was 9 years. However, in the 15 to 23 cm layer there was no compaction recovery detected after 9 years. In Colorado, Wheeler et al. (2002) found that compaction from a one-time heavy cattle grazing event in a montane meadow compacted soils at the 5 to 15 cm soil depth. That compaction recovered to pre-disturbed values one year later. The authors assumed the high rate of recovery was due to frequent freeze-thaw events and high organic matter in soils. The observations of the IDT between 2001 and 2004 in the project area suggested that severe compaction (in this case, from cattle grazing) shows little recovery over a 10 to 15 year period at a depth below the top few centimeters.

Of the 179 meadows analyzed for compaction, 45 were found to have moderate to severe compaction (25 percent). Of these 45 meadows, 34 were found to be suitable for grazing and have stock nights allocated under Alternative 2 – Modified. In 21 meadows, the compaction is assumed unrelated to recent pack stock use and mainly due to cattle grazing. In these meadows, the recommended high number of commercial pack stock grazing nights is probably much less than cattle grazing densities. Therefore, compaction from past uses should decrease over time, but the improvements will be slower than if the meadows were not grazed. In the other 13 meadows, recent pack stock grazing is thought to have at least partially contributed to the compaction. In three of those meadows, the recommended stock nights are considerably less than from 2001 to 2003. The reduced trampling should allow for slow reduction of compaction. In the remaining seven meadows, grazing will continue near or above recent levels. This may allow compaction to continue, as the meadows should continue to receive the same impacts that led to the compaction.

Most of the 133 meadows that are known to have slight or no compaction should not have major increases in compaction severity or extent under Alternative 2. About 80 of them are considered suitable for grazing. Only about 12 of those meadows could likely have high enough grazing density and soil moisture and type to be able to have increased compaction. In these meadows, if compaction or other impacts begin to occur, the stock nights of grazing allowed would be reduced, preventing any major increase in compaction.

Meadow sod fragmentation would likely decrease overall, but there may be some meadows where sod fragmentation remains or increases. Of the 223 meadows analyzed for sod fragmentation, about 60 currently have moderate or severe sod fragmentation. Of those, 38 were determined to be suitable for grazing. Only about five of those that could be grazed have a high potential for increased sod fragmentation extent, due to the stocking density recommended and the soil moisture and type.

Most meadows with slight to no sod fragmentation would not have major increases in sod fragmentation under Alternative 2. Of the meadows analyzed, 140 were found to have slight to no sod fragmentation. Eighty-four of those were determined to be suitable. Of those, about 17 have the potential for increased sod fragmentation if all of the recommended stock nights are used regularly. These meadows have much higher grazing recommended than has been used in the past. If they begin to show a major increase in sod fragmentation, the grazing numbers would be reduced, reducing the chance that the meadow would have substantial increases in long-term sod fragmentation.

Trails: Trail effects are not substantial to water and soil processes wilderness-wide, because trails cover such a small portion of land. Local effects, however, do occur and are sometimes severe. Under Alternative 2 – Modified, negative trail effects on soil and hydrologic condition will likely be slightly less than Alternative 1. Trails would likely have greater hydrologic impacts than under Alternatives 4 and 5. However, the differences between alternatives would likely be minor, as much of the trail condition depends on levels of funding for trail repair and maintenance, and less depends on pack stock management.

Under this alternative, stock use and impacts to trails will remain similar to current conditions and Alternative 1. However, 20 of 59 system trails that currently have severe soil or hydrologic impacts, and are used by commercial pack stock, would be closed to commercial pack stock. While hiker use would remain on these trails, it should allow for slower erosion rates. These trails would likely stop widening but could continue to deepen and therefore divert more overland flow and stream flow even with removal of pack stock use. Removal of pack stock use is not likely to allow severely incised or widened trails to aggrade or narrow. The deepening and widening would likely cease only with trail repair, which could occur in a few years or decades. However, removal of pack stock could slow future incision and widening, because pack stock are thought to loosen soil and allow it to be transported down the trail more than hikers. Cole (1991) found that trampling is the primary agent of trail widening, while the primary agent of deepening is running water. Consequently, the critical factors that influence depth are more likely to be related to environment (soil characteristics or slope steepness) rather than use.

Erosion levels from trails closed to commercial pack stock should also decrease. Studies comparing the effects of pack stock use and hiker use on trail erosion in the Rocky Mountain Region have presented evidence that horse traffic tends to cause greater trail erosion than hiker traffic (Deluca et al., 1998; Wilson and Seney, 1994; Whittaker, 1978; Dale and Weaver, 1974). Deluca et al. (1998) found that soil loss directly at the time of horse traffic was more pronounced on dry trails, but that soil was compacted more on pre-wetted trails, possibly leading to increased runoff velocity and later trail erosion.

The above literature suggests that trails do not become less incised or narrower through short time frames, but either stabilize or become more incised and widened.

On the 878 miles of system trail that would be open to commercial pack stock use, their future condition would likely depend on trail maintenance and repair. These trails could become more incised, widened, and have more multi-trailing than without pack stock use. As with trails not used by commercial pack stock, they are not likely to have reduced incision, widening or multi-trailing without repair.

Campsites: The differences in effects from campsites should be small enough to be undetectable on a wilderness scale. Negative hydrologic and soils effects from campsites should be slightly less than under Alternatives 1 and 3, but slightly more than under Alternatives 4 and 5. Under all alternatives, sites closer than 100 feet from water will gradually be closed and rehabilitated, slightly reducing the area of compaction near surface water. This could reduce erosion and sedimentation.

Under Alternative 2 – Modified, all stock holding campsites would be designated. Because designated sites would have to meet BMPs, all stock holding sites within 100 feet of water or affecting water quality would be closed and obliterated. This could slightly reduce local sedimentation into surface water as at least 28 stock holding sites would be obliterated or

contained away from water. The IDT did not visit all stock holding sites, and therefore more could be obliterated when the designation process occurs. The designation of stock holding sites would have little effect on the total number of stock holding sites. However, it would prevent any expansion of sites that could occur under Alternative 1, preventing increased soil compaction, bare soil extent, loss of soil productivity, and erosion from campsites. It is possible that individual stock holding camps would become large and have more soil erosion because stock holding would be concentrated in 170 locations. Many of those sites would be used rarely, as they are not in popular destinations. While there could be more soil loss at individual sites, the overall potential extent of soil loss from stock holding sites should decrease because there will be very few new sites created over time.

Under Alternative 2 – Modified, there would be about 170 designated stock holding camps. Under Alternative 3, there would be 101 designated stock holding camps. Under Alternative 4, there would be 59 designated stock holding camps.

Cumulative Impacts

This alternative has been analyzed in terms of the effects of past, present and reasonably foreseeable future actions to soil and hydrologic processes. This analysis separates cumulative effects into general cumulative effects to soil and water resources that are a result of past, present and reasonably foreseeable future actions, and cumulative watershed effects, which are the effects of upstream land uses transported downstream. The differences between Alternative 1 and Alternative 2 – Modified should be small on a wilderness-wide scale. In local areas, particularly within the Fish Creek/Convict/McGee Geographic Unit, Alternative 2 – Modified is likely to result in improved soil and water resource condition and provide a reduced risk for an adverse cumulative watershed effect.

The past, present and reasonably foreseeable future actions are the same under Alternative 2 – Modified as under Alternative 1, other than the differences in management prescribed in the alternative.

Alternative 2 – Modified would reduce the levels and extent of pack stock use on trails and at campsites, by prescribing destination quotas and grazing levels. Grazing would be prohibited in areas that were determined to be unsuitable for grazing, preventing future soil loss, stream bank trampling, sod fragmentation, and other soil and water impacts in those areas. This alternative also allows only negligible stock entry or utilization in critical areas that are usually very wet.

The implementation of more stringent guidelines for commercial pack stock management should reduce the risk of adverse cumulative effects resulting from campsites and commercial pack stock grazing. It would provide protection of unsuitable grazing areas, preventing fragmented sod, vegetation removal, stream bank trampling, and meadow surface and stream bank erosion. Limitations on stock nights of grazing were designed to prevent vegetation utilization, stream bank trampling, and soil disturbance from exceeding standards (USDA Forest Service, 2001; USDA Forest Service, 2004; Forest Service Handbooks 2509).

Overall, the risk of adverse cumulative effects would be minor, except in the Upper Fish Creek, Silver Divide, Cascade Valley and Purple Bench Analysis Units in the Fish Creek/Convict/McGee Geographic Unit. In these areas, it appears that recent commercial pack stock use combined with historical grazing or recreational use has contributed to moderate intensity adverse cumulative effects from campsite use, commercial pack stock use of trails, and moderate

to heavy grazing in meadows. These effects are also likely connected to historical cattle sheep and pack stock grazing, non-commercial pack stock users, and hikers, but the commercial pack stock also appear to have contributed. The more stringent management proposed under Alternative 2 – Modified in this area has the potential to reduce adverse cumulative effects to soil and water resources, although some would likely remain over the short term. In the long term, the commercial pack stock related impacts would likely be reduced due to a reduction in grazing in meadows with current moderate to severe hydrologic function alteration and functional at-risk streams.

Cumulative Watershed Effects – Alternative 2 – Modified

On a wilderness-wide scale, this action would not contribute to cumulative watershed effects (CWEs), and should reduce the potential for CWEs in one watershed.

Cumulative watershed effects are different from general cumulative effects because CWEs refer to effects from land uses upstream that have been transported downstream through the fluvial system. General cumulative effects can refer to any combination of effects from past, present and reasonably foreseeable future actions that could cause greater effect to soil and hydrologic processes than each action by itself. General cumulative effects can occur in one location, and do not have to be transported downstream to qualify as cumulative effects.

Under Alternative 2 – Modified, East Fish Creek is the only watershed that will likely have a change in CWE potential. There should be a slight reduction in CWE potential. The watershed condition should improve under all action alternatives, to varying degrees. The greatest contributor to CWEs in the East Fish Creek watershed appears to be grazing, although trails' erosion, surface water diversion and stream crossing incision may have contributed. Under Alternative 2 – Modified, grazing would be eliminated in meadows where it is unsuitable, and limited in all other meadows. A one-night stay limit for traveling trips would also likely reduce the number of successive days where each meadow was grazed, possibly allowing some vegetative recovery before the next grazing episode.

Along with the foreseeable future action that the trails causing the most severe soil and water resource impacts would be repaired within 20 years, it is likely that the restrictions on commercial pack stock use under Alternative 2 – Modified would gradually reduce soil erosion, stream bank disturbance, vegetation removal, stream incision lowering of water tables in meadows. Thus, there would likely be a reduction of cumulative watershed effects in this area. The potential for cumulative watershed effects in the other two watersheds that currently may have cumulative watershed effects (Edison Reservoir and Granite Creek) would be the same as under Alternative 1. Most of those impacts appear to be related to recent and historical cattle grazing, and the effects of commercial pack stock management would have little to no effect on their condition.

Alternative 2

Summary of Alternative 2 Impacts

Water quality is thought to be good and will remain so, except at few local areas where there may be slight degradation. There will remain areas of local soil erosion, bare soil, and sedimentation into surface water from pack stock grazing, campsites, and trails. There would be a minor reduction of bare, compacted soil and sedimentation into surface water from designating

stock holding camps, reducing the number of meadows where grazing is allowed, and limiting grazing stock nights in all meadows. Of 60 streams found to be functional at-risk (151 evaluated), it is estimated that 36 percent could have improved condition, 2 percent could have a more degraded conditions; and 62 percent will remain functional at-risk. Meadow hydrologic function has some potential for improvement. Out of the 230 meadows evaluated, 93 were found to have hydrologic function alteration; approximately 21 percent could have improved condition, 66 percent should remain in the same condition, and 13 percent could have a downward trend.

Past and present grazing from production livestock and pack stock is the largest contributor to meadow hydrologic function alteration. Unlike Alternative 1, Alternatives 2 through 4 limit grazing to those meadows that have been analyzed and designated as suitable for grazing. They also limit grazing in those suitable meadows to a given number of stock nights. The restriction of grazing, to meadows found to be suitable for grazing and not highly vulnerable, should limit future adverse grazing impacts.

Analysis

Under Alternative 2, there likely would be some slight overall improvement in stream and meadow hydrologic function, soil productivity, and water quality relative to Alternative 1. Locally, there could be larger changes. The effects should be the same as under Alternative 2 – Modified in most locations. The overall management strategy is the same, with destination quotas, designated stock camps, grazing stock night allocations for meadows deemed suitable for grazing, and de facto operating areas for all spot/dunnage trips. The only differences are a greater number of stock camps (about 175 versus about 100), a greater number of destinations, and a difference in stock night allocations for 15 meadows.

As with Alternative 2 – Modified, the greatest improvement to soil and hydrologic resource condition would be from elimination of grazing on meadows that currently have soil or hydrologic function alteration or are unsuitable for grazing. Designation of stock holding campsites away from water, implementation of destination quotas, disapproval of user trails with resource impacts, and reduction in pack station overlap might also help reduce soil and hydrologic resource impacts. In a few locations, there could be slight increases in negative effects to soil and water resources because use may be moved to the new locations that were found to be more suitable for the use. The areas where the use moved from, however, should have improved condition with removal of commercial pack stock uses such as grazing or camping.

Meadows/Wetlands: Under Alternative 2, effects in meadows should be almost the same as under Alternative 2. Grazing is different in only 17 meadows, listed below.

Nine meadows would be open to grazing or have substantially greater stock nights (over 20) under Alternative 2 than under Alternative 2 – Modified (see Table 2.30 for more detailed management by meadow).

Table 4.67. Nine meadows open to grazing or allowing substantially greater stock nights in Alternative 2 compared to Alternative 2 – Modified.

Meadow Name	Geographic Unit	Alternative 2 – Modified management	Alternative 2 management
Ashley Lake Meadows	Ansel Adams East	Closed to grazing	44 stock nights
Johnston Meadow	Ansel Adams East	Rest for resource recovery	193 stock nights
Northwest Delta Thousand Island Lake	Ansel Adams East	Rest for resource recovery	106 stock nights
Rainbow to Margaret Meadow	Fish Creek/Convict/McGee	Rest until trail repair/recovery	127 stock nights
Baldwin (Scheelore) Meadow	Fish Creek/Convict/McGee	Closed to grazing	12 stock nights
Martin's Meadow	Fish Creek/Convict/McGee	Rest for resource recovery	25 stock nights
Box Canyon Above Grassy	Fish Creek/Convict/McGee	Rest until trail repair	67 stock nights
Upper Graveyard Meadow	Mono Creek/Rock Creek	Rest for resource recovery	127 stock nights
Middle Graveyard Meadow	Mono Creek/Rock Creek	Rest for resource recovery	41 stock nights

Eight meadows would be closed to grazing or have substantially fewer stock nights (over 20) under Alternative 2 than under Alternative 2 – Modified (see Table 2.30 for more detailed management by meadow).

Table 4.68. Eight meadows closed to grazing or allowing substantially fewer stock nights in Alternative 2 compared to Alternative 2 – Modified.

Meadow Name	Geographic Unit	Alternative 2 – modified management	Alternative 2 management
Pond Meadow	Ansel Adams West	58 stock nights	No action
Olive Lake West	Fish Creek/Convict/McGee	114 stock nights	25 stock nights
Horse Heaven	Fish Creek/Convict/McGee	65 stock nights in wet years, 150 in normal or dry	65 stock nights
Cascade Valley	Fish Creek/Convict/McGee	20 stock nights	Closed to grazing
Double Meadow (pasture)	Florence/Bear	1251 stock nights	No stock nights allocated
Lower Blayney Meadow (pasture)	Florence/Bear	544 stock nights	60 stock nights
Hell Hole Meadow (pasture)	Florence/Bear	442 stock nights	200 stock nights
Jackass Meadow (pasture) (mostly outside Wilderness)	Florence/Bear	2025 stock nights	400 stock nights

Elimination of grazing on some meadows found to be unsuitable for grazing would allow for some local soil and hydrologic condition recovery. Of the 94 meadows that were grazed from 2001 through 2003, 20 would be closed or rested and 15 would have substantially reduced grazing (at least 20 stock nights less) under Alternative 2. Therefore about 1/3 of the meadows/wetlands that were grazed from 2001 through 2003 would have reduced impacts from rest or reduced stock nights. About 70 meadows with no reported grazing from 2001 through 2003 would be opened to grazing. It is assumed that because those meadows were found to be suitable for grazing, and because they were given a grazing allocation to meet utilization standards, the negative effects, although they may occur, will be minimal and within standards.

Meadow/Wetland Hydrologic Function: The degree of hydrologic function alteration is unlikely to show any major changes in the majority of meadows. Effects would likely be similar to Alternative 1, although slightly fewer meadows would have a downward hydrologic function trend (Figure 4.6, Table 4.65). Effects would be very similar as Alternative 2 – Modified, because management is the same in all but 17 meadows, except for the following differences.

Six meadows are anticipated to have different hydrologic function trend under Alternative 2 than under Alternative 2 – Modified. Three of those meadows are expected to have a trend away from potential rather than no change or an upward trend. Those meadows are the Box Canyon above Grassy (sil2), Rainbow to Margaret (mar4), and Middle Graveyard Meadow (gra2).

One meadow, the Northwest Delta of Thousand Island Lake (thi12), should have no change instead of an upward trend under Alternative 2 relative to Alternative 2 – Modified.

Two meadows are projected to have no change in meadow hydrologic function rather than a downward trend as was predicted under Alternative 2 – Modified. Those meadows are both pastures, Lower Blayne Meadow (sak17), and Jackass Meadow (eaf1).

Overall, because nine meadows would be open and eight would be closed under Alternative 2, and most of those meadows should not have differences in hydrologic function effects, the net effects to hydrologic function across the Wilderness should be about the same.

For a list of predictions for each meadow's hydrologic function and stream functional condition under all Alternatives, see Project Record, *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under all Alternatives*.

Stream Functional Condition (PFC): Functional condition of streams might improve in some areas that are currently Functional at-risk, and might remain static in others. The overall difference from Alternative 1 should be minor, but there should be slightly more streams with a trend toward potential and slightly fewer streams with a trend away from potential. The difference between Alternative 2 and Alternative 2 – Modified would be minor because management is the same in all but 17 meadows and most of those management changes should not affect stream functional condition. Only six meadows are expected to have different trend in stream functional condition under Alternative 2 than under Alternative 2 – Modified.

Overall, 25 meadows are expected to have an upward trend, 121 meadows are expected to remain in their current condition, and 6 meadows are predicted to have a downward stream functional condition under Alternative 2 – Modified.

The three meadows that should have a downward or static trend instead of an upward trend in stream functional condition are Johnston Meadow (min11), the Northwest Delta of Thousand

Island Lake (thi12), and Upper Graveyard Meadow (gra11). All of these meadows would have grazing under Alternative 2, but would be rested under Alternative 2 – Modified.

Four meadows should have stream functional condition that is improved relative to Alternative 2 – Modified. Those meadows are Silver Pass Lake Meadow (sip7), Stevenson Meadow (lac1), Jackass Meadow/pasture (eaf1), and Lower Blayne Meadow/Pasture (sak17). All of these meadows would be grazed under Alternative 2 – Modified, but would be closed under Alternative 2.

Not all meadows would have worsened stream functional condition with increased grazing, or improved functional condition with reduced grazing. However, the streams listed above are either not well armored by sod or boulders, the stream is already functional at-risk, or the meadow has very low productivity, and so greatly increased grazing has a chance of affecting stream functional condition.

Grazing Water Quality Effects: Under Alternative 2, fine sedimentation into surface water from meadows will likely decrease overall relative to Alternative 1, and remain in a small fraction of locations wilderness-wide. At some local areas, it could substantially decrease. There could be minor increases in fine sedimentation into surface water in locations with increased grazing. The difference between Alternative 2 and Alternative 2 – Modified should be negligible, because management activities and project use is the same in most locations.

Although water quality is thought to be good on a wilderness scale, there are some meadows where bank sloughing, stream incision, and soil erosion increases fine sediment in streams within and directly downstream of the meadows.

Under Alternative 2, pack stock use would be reduced or eliminated in over 1,000 meadows where it is allowed today (although only 94 have had reported use). The actual days of pack stock grazing is expected to remain about the same wilderness-wide, although some watersheds, such as Fish Creek, will have reduced grazing. Therefore, pack stock manure is not expected to degrade water quality from its assumed current overall good condition. Sediment from pack stock grazing should be reduced relative to Alternative 1, due to grazing being limited to meadows suitable for grazing and unlikely to have major erosion.

Meadow Soil Effects: As under Alternative 1, changes in commercial pack stock management, which is only part of total recreational use, will likely have little affect on overall soil productivity wilderness wide or on the Geographic Unit scale. There should be a slight overall improvement in soil productivity over current conditions and Alternative 1, but the improvement would likely be greater under Alternatives 4 and 5. Meadows with grazing reduced or eliminated could have increased soil productivity, reduced soil compaction, reduced bare soil, and reduced sod fragmentation. Fewer could have slightly decreased soil productivity, increased soil compaction, increased bare soil, and increased sod fragmentation because they could receive more grazing than currently. The negative effects should be within standards. However, even if standards are met, there could be some increased erosion, increased stream bank disturbance, and decreased stream stability. If this occurs, grazing management would be altered to arrest the degradation.

Under Alternative 2, soil compaction effects could vary. It is uncertain how long it will take compaction to recover in meadows where Alternative 2 recommends grazing management changes to help reduce compaction. The observations of the IDT between 2001 and 2004 in the

project area, along with existing research, suggests that severe compaction (in this case, from cattle grazing) shows little recovery over a 10 to 15 year time period at a depth below the top few centimeters.

Meadow sod fragmentation would likely decrease overall, but there may be some meadows where sod fragmentation remains or increases. Of the 223 meadows analyzed for sod fragmentation, about 60 currently have moderate or severe sod fragmentation. Of those, 36 were determined to be suitable for grazing. Only about five of those that could be grazed have a high potential for increased sod fragmentation extent, due to the stocking density recommended and the soil moisture and type.

Most meadows with slight to no sod fragmentation would not have major increases in sod fragmentation under Alternative 2. Of the meadows analyzed, 140 were found to have slight to no sod fragmentation. Eighty-three of those were determined to be suitable. Of those, about 15 have the potential for increased sod fragmentation if all of the recommended stock nights are used regularly. These meadows have much higher grazing recommended than has been used in the past. If they begin to show a major increase in sod fragmentation, the grazing numbers would be reduced, reducing the chance that the meadow would have substantial increases in long-term sod fragmentation.

Trails: Trail effects are not substantial to water and soil processes wilderness-wide, because trails cover such a small portion of land. Local effects, however, do occur and are sometimes severe. Under Alternative 2, negative trail effects on soil and hydrologic condition will likely be slightly less than Alternative 1, and almost the same as under Alternative 2 – Modified. Under Alternative 2 – Modified, 878 miles of system trail would be open to commercial pack stock use. Under this alternative, 894 miles of trail would be open to commercial pack stock use. Therefore, about 16 additional miles would be open to commercial pack stock relative to Alternative 2 – Modified, but 61 fewer than under Alternative 1.

Eleven of 59 system trails that currently have severe soil or hydrologic impacts and are used by commercial pack stock would be closed to commercial pack stock. While hiker use would remain on these trails, it should allow for slower erosion rates. These trails would likely stop widening but could continue to deepen and therefore divert more overland flow and stream flow even with removal of pack stock use. Removal of pack stock use is not likely to allow severely incised or widened trails to aggrade or narrow. The deepening and widening would likely cease only with trail repair, which could occur in a few years or decades. However, removal of pack stock could slow future incision and widening, because pack stock are thought to loosen soil and allow it to be transported down the trail more than hikers.

Erosion levels from the 61 miles of system trails closed to commercial pack stock should also decrease. The literature suggests that trails do not become less incised or narrower through short time frames, but either stabilize or become more incised and widened.

On the 894 system trail miles that would continue to see commercial pack stock use, their future condition would likely depend on trail maintenance and repair. These trails could become more incised, widened, and have more multi-trailing than without pack stock use. As with trails not used by commercial pack stock, they are not likely to have reduced incision, widening or multi-trailing without repair.

Campsites: The differences in effects from campsites should be small enough to be undetectable on a wilderness scale. Negative hydrologic and soils effects from campsites should be slightly less than under Alternatives 1 and 3, but slightly more than under Alternatives 4 and 5. Under all alternatives, sites closer than 100 feet from water will gradually be closed and rehabilitated, slightly reducing the area of compaction near surface water. This could reduce erosion and sedimentation.

Under Alternative 2, all stock holding campsites would be designated. Because designated sites would have to meet BMPs, all stock holding sites within 100 feet of water or affecting water quality would be closed and obliterated. This could slightly reduce local sedimentation into surface water as at least 28 stock holding sites would be obliterated or contained away from water. The IDT did not visit all stock holding sites, and therefore more could be obliterated when the designation process occurs. The designation of stock holding sites would have little effect on the total number of stock holding sites. However, it would prevent any expansion of sites that could occur under Alternative 1, preventing increased soil compaction, bare soil extent, loss of soil productivity, and erosion from campsites. It is possible that individual stock holding camps would become large and have more soil erosion because stock holding would be concentrated in 94 locations. While there could be more soil loss at individual sites, the overall potential extent of soil loss from stock camps should decrease because there will be very few new sites created over time.

Under Alternative 2, there would be 94 designated stock camps. Under Alternative 2 – Modified, there would be over 200 designated stock camps. Under Alternative 3, there would be 101 designated stock holding camps. Under Alternative 4, there would be 59 designated stock holding camps.

Cumulative Impacts

This alternative has been analyzed in terms of the effects of past, present and reasonably foreseeable future actions to soil and hydrologic processes. This analysis separates cumulative effects into general cumulative effects to soil and water resources that are a result of past, present and reasonably foreseeable future actions, and cumulative watershed effects, which are the effects of upstream land uses transported downstream. The differences between Alternative 1 and Alternative 2 should be small on a wilderness-wide scale. In local areas, particularly within the Fish Creek/Convict/McGee Geographic Unit, Alternative 2 is likely to result in improved soil and water resource condition and provide a reduced risk for an adverse cumulative watershed effect.

The past, present and reasonably foreseeable future actions are the same under Alternative 2 as under Alternative 1, other than the differences in management prescribed in the alternative.

Alternative 2 would reduce the levels and extent of pack stock use on trails and at campsites, by prescribing destination quotas and grazing levels. Grazing would be prohibited in areas that were determined to be unsuitable for grazing, preventing future soil loss, stream bank trampling, sod fragmentation, and other soil and water impacts in those areas. This alternative also allows only 5 percent trampling or 5 percent vegetation utilization in critical areas that are usually very wet.

The implementation of more stringent guidelines for commercial pack stock management should reduce the risk of adverse cumulative effects resulting from campsites and commercial pack stock grazing. It would provide protection of unsuitable grazing areas, preventing fragmented

sod, vegetation removal, stream bank trampling, and meadow surface and stream bank erosion. Limitations on stock nights of grazing were designed to prevent vegetation utilization, stream bank trampling, and soil disturbance from exceeding standards (USDA Forest Service 2001, USDA Forest Service 2004, and Forest Service Handbooks 2509).

Overall, the risk of adverse cumulative effects would be minor, except in the Upper Fish Creek, Silver Divide, Cascade Valley, and Purple Bench Analysis Units in the Fish Creek/Convict/McGee Geographic Unit. In these areas, it appears that recent commercial pack stock use has contributed to moderate intensity adverse cumulative effects from campsite use, commercial pack stock use of trails, and moderate to heavy grazing in meadows. These effects are also likely connected to historical cattle sheep and pack stock grazing, non-commercial pack stock users, and hikers, the commercial pack stock appear to have contributed. The more stringent management proposed under Alternative 2 in this area has the potential to reduce adverse cumulative effects to soil and water resources, although some would likely remain over the short term. In the long term, the commercial pack stock related impacts would likely be reduced due to a reduction in grazing in meadows with current moderate to severe hydrologic function alteration and functional at-risk streams.

Cumulative Watershed Effects

On a wilderness-wide scale, this action would not contribute to cumulative watershed effects (CWEs), and should reduce the potential for CWEs in one watershed.

Cumulative watershed effects are different from general cumulative effects because CWEs refer to effects from land uses upstream that have been transported downstream through the fluvial system. General cumulative effects can refer to any combination of effects from past, present and reasonably foreseeable future actions that could cause greater effect to soil and hydrologic processes than each action by itself. General cumulative effects can occur in one location, and do not have to be transported downstream to qualify as cumulative effects.

Under Alternative 2, East Fish Creek is the only watershed that will likely have a change in potential for CWEs. There should be a slight reduction in CWE potential. The watershed condition should improve under all action alternatives, to varying degrees. The greatest contributor to CWEs in the East Fish Creek watershed appears to be grazing, although trails' erosion, surface water diversion and stream crossing incision may have contributed. Under Alternative 2, grazing would be eliminated in meadows where it is unsuitable, and limited in all other meadows. A one-night stay limit for traveling trips would also likely reduce the number of successive days where each meadow was grazed, possibly allowing some vegetative recovery before the next grazing episode.

Along with the foreseeable future action that the trails causing the most severe soil and water resource impacts would be repaired within 20 years, it is likely that the restrictions on commercial pack stock use under Alternative 2 would gradually reduce soil erosion, stream bank disturbance, vegetation removal, and stream incision lowering of water tables in meadows. Thus, there would likely be a reduction of cumulative watershed effects in this area. The potential for cumulative watershed effects in the other two watersheds that currently may have cumulative watershed effects (Edison Reservoir and Granite Creek) would be the same as under Alternative 1. Most of those impacts appear to be related to recent and historical cattle grazing, and the effects of commercial pack stock management would have little to no effect on their condition.

Alternative 3

Summary of Alternative 3 Impacts

Water quality is generally good and will remain so except at few local areas where there may be slight degradation. There will remain areas of local soil erosion, bare soil, and sedimentation into surface water from pack stock grazing, campsites and trails. Meadow/wetland condition should improve overall relative to Alternative 1. Grazing would be prohibited in meadows that currently contain streams that are functional at-risk with a downward trend. Of 60 streams found to be functional at-risk (with any trend), (an estimated 40 percent could have improved condition, 3 percent could have a more degraded conditions; roughly 57 percent will remain functional at-risk. There would be a minor reduction of bare, compacted soil and sedimentation into surface water from designating stock holding camps. Meadow hydrologic function has some potential for improvement relative to Alternative 1. Out of 237 meadows evaluated, 41 meadows were found to have hydrologic function alteration; about 29 percent could have improved condition, 59 percent should remain in the same condition, and 12 percent could have a downward trend.

Past and present grazing from production livestock and pack stock is the largest contributor to meadow hydrologic function alteration. Unlike Alternative 1, Alternatives 2 through 4 limit grazing to those meadows that have been analyzed and designated as suitable for grazing. They also limit grazing in those suitable meadows to a given number of stock-nights. Alternative 3 limits the future adverse impacts that could occur to hydrologic and soil resources to a lower intensity and smaller extent relative to Alternative 1. Alternative 3 would have similar impacts as Alternative 2, although there could be more widespread adverse effects from trails and campsites and less widespread adverse effects from grazing in meadows.

Analysis

As under all alternatives, the wilderness soil and water resources should remain in good condition overall, but local effects could continue to alter soil and water resources. Due to the lack of control over destination use levels, there is a greater risk of negative effects to soil and water resources from campsites and some grazing areas under Alternative 3 than there would be under Alternative 2 and 2 – Modified. There is more uncertainty about commercial pack stock use patterns and the effect on soil and hydrologic resources. This uncertainty in effects is due to having only a trailhead quota, grazing limitations and designated stock holding sites as controlling factors for commercial pack stock use within the wilderness. The lack of certainty means that packers could change their use patterns. Overall, it is expected that the effects to soil and hydrologic resources should be similar to Alternative 2 and 2 – Modified in most places. A few locations, however, could have greater negative impacts to soil and hydrologic processes, and a few areas could have reduced impacts.

Meadows: The proposed grazing management and therefore the effects are the same as Alternative 2 – Modified in all but six meadows. Meadows are closed to grazing unless they are within a grazing zone and grazing is expressly allowed. The main difference expected is that there could be more overnight trips with pack stock and the highest allowed annual grazing will be more likely to be used in more meadows than under Alternative 2 – Modified. Further, instead of meadow closure in meadows with resource impacts, the meadows would be rested until they could support grazing. The effects of rest versus closure should not be different within the 20-year period of this analysis.

Three meadows have higher stock night recommendations than in Alternative 2 – Modified. (see *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under All Alternatives* in the project record). The meadows are:

- Horse Heaven in the Fish Creek/Convict/McGee Geographic Unit
- Cascade Valley in the Fish Creek/Convict/McGee Geographic Unit
- Chute Meadow in the Fish Creek/Convict/McGee Geographic Unit

Three meadows would be closed or rested under Alternative 3 that were open under Alternative 2 – Modified. Those meadows are:

- Box Canyon Above Grassy (Fish Creek/Convict/McGee Geographic Unit)
- Between Rainbow and Margaret (Fish Creek/Convict/McGee Geographic Unit)
- Middle Graveyard Meadow (Mono Creek/Rock Creek Geographic Unit)

In addition, 13 meadows that were rested until resource recovery under Alternative 2 – Modified would be closed indefinitely under Alternative 3.

Meadow/Wetland Hydrologic Function: The effects to meadow hydrologic function should be almost the same Alternative 2 – Modified overall, but there could be slightly greater negative effects in some areas and slightly reduced negative effects in a few others (Figure 4.6). Of the six meadows that have different stock nights allocated to them, three should have different effects to meadow hydrologic function (see project record, *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under all Alternatives*). All three of these meadows would be those listed above that closed or rested under Alternative 3. Because of the rest, they could have soil and water resource conditions improved over Alternative 1 and Alternative 2 – Modified. Other than the three meadows listed above, the other meadows have the same predicted effects to meadow hydrologic function.

There is a possibility that more meadows would be used to their full allocation under Alternative 3 than under Alternative 2 – Modified, because there would be less control over where overnight trips go. However, there is little difference in effects predicted, because under the analysis for Alternative 2 – Modified, it was assumed that most meadows would be used to their full-allocated stock nights.

Stream Functional Condition (PFC): The effects on stream functional condition should be almost the same as Alternative 2 – Modified, although there is the potential for slightly more widespread negative effects (Figure 4.6). There is only different grazing management in six meadows, and none of the meadows analyzed for PFC should have different effects from that management.

There is a possibility that more meadows would be used to their full allocation under Alternative 3 than under Alternative 2 – Modified, because there would be less control over where overnight trips go. However, there is no difference in effects predicted, because under the analysis for Alternative 2 – Modified, it was assumed that most meadows would be used to their full-allocated stock nights, and that full use of those meadows would not affect stream PFC.

One meadow, the Box Canyon above Grassy Lake, could have worse stream functional condition under Alternative 2 than under Alternative 3. The current stream functional condition was not

evaluated using the PFC protocol and therefore this meadow is not included in Table 4.66. The currently rarely uses access trail to the meadow is in a stream bed, and with grazing use to this meadow, there could be vegetation loss along the stream banks, altered stream morphology, and stream headcutting. Use of the trail for grazing use of this meadow at 67 stock nights could lead to a stream condition trend away from potential, due to access to that grazing.

Of the 60 stream segments that were rated functional at-risk, about 40 percent are expected to have some improvement in stream functional condition (Table 4.66). About 57 percent are expected to remain in their current functional at-risk state, while about 3 percent are expected to have a minor reduction in stream functional condition. Two functional at-risk meadow streams could be grazed more heavily in Alternative 3: Jackass Meadow and Lower Blayney Meadow. These two meadows could have minor negative effects to hydrologic function. Three meadows where streams are currently functional at-risk with a downward trend would be closed to grazing and those meadows could move closer to PFC under Alternative 3 because they would not be grazed. The meadows are Johnston, Purple, and Northwest Delta Thousand Island. Although Martin's Meadow would be closed to grazing under Alternative 3, the stream is non-functional (since 2003) and without repair, headcuts would continue to advance and threaten the meadow's hydrologic function.

Grazing Water Quality Effects: Under Alternative 3, fine sedimentation into surface water from meadows will likely decrease overall relative to Alternative 1, and at some local areas, it could substantially decrease. The changes would likely be almost the same as under Alternative 2 – Modified. In a few local areas, namely the meadows that could receive more grazing, there could be minor increases in fine sedimentation into surface water.

The 24 meadows out of 60 where stream functional condition is expected to improve from its current state will likely have a decrease in streambank erosion and therefore a decrease in fine sedimentation into surface water. About 30 percent of meadows analyzed have moderate to severe sod fragmentation, which could be leading to soil erosion and subsequent fine sedimentation into surface water. Under Alternative 3, the number of meadows grazed, and therefore the number of meadows with sod fragmentation, should be reduced.

Water quality effects from pack stock manure in meadows should not change from their current negative effects of unknown magnitude, because the overall number of stock grazing should not be different from under Alternative 1, and there should be no degradation of the current apparently good water quality. While water quality is likely to be affected within and just downstream of grazed meadows, it is assumed there will not be enough manure entering surface water to affect beneficial uses.

Meadow Soil Effects: Changes in commercial pack stock management, which is only part of that recreational use, will likely have little affect on overall soil productivity wilderness wide or on the geographic-unit scale. There should be a slight improvement in soil productivity over Alternative 1, and it should be about the same as under Alternative 2 – Modified. Some analysis units and local areas, such as Grassy Meadow (sil22) and the meadow adjacent to Waterfall Camp, could have increased soil productivity, reduced soil compaction, reduced bare soil, and reduced sod fragmentation. This is because grazing is being reduced, eliminated, or relocated in these meadows. Others, such as Goodale Pass Meadow (gra18) and Lower Laurel Creek Meadow (lau1) could have slightly decreased soil productivity, increased soil compaction, increased bare soil, and increased sod fragmentation. The increased soil disturbance would be

due to increased grazing numbers more likely to cause hoof punching and remove vegetation. Although these same meadows could be grazed the same amount under Alternative 2 – Modified, the lack of specific limits on traveling trips and lack of destination quotas would make it more likely that these meadows will be grazed to their full allocations. The negative effects should be within soil quality standards because only suitable meadows would be grazed and all were given a grazing allocation commensurate with meadow soil and vegetation capability.

Of the 179 meadows analyzed for compaction, 45 were found to have moderate to severe compaction (25 percent). Of these 45 meadows, 28 were found to be suitable for grazing and have stock nights allocated under Alternative 3. The difference between Alternatives 2 – Modified and Alternative 3 is that there could be three more meadows with increased grazing, and these three meadows could have slightly increased compaction. However, there would also be three meadows rested from grazing where it could occur under Alternative 2. There could be slight reduction in compaction risk in those meadows.

It is uncertain how long it will take compaction to recover in meadows where Alternative 3 recommends grazing management changes to help reduce compaction.

Trails: Under Alternative 3, trail effects to soil and water resources are likely to very similar as under Alternative 2 – Modified and slightly reduced relative to Alternative 1. Because Alternative 3 will not have destination quotas, it is possible that the packers will take more or fewer trips on a particular trail than they do currently or than they would under Alternative 2 – Modified. Trails with substantially increased use could have more soil loss and incision through direct removal by hooves and subsequent water erosion. Conversely, trails with substantially less use would be less likely to have increased incision and soil loss. Most likely, use patterns would remain about the same as today except on those roughly 20 trails where destination quotas would reduce use under Alternative 3. Alternative 3 would have less predictability for the effects to trails than Alternatives 2 and 2 – Modified due to the lack of destination quotas and designated destinations.

The effects to soil and water resources from the 33 miles of system trails closed to commercial pack stock use should remain about the same or have slight improvement over Alternative 1. Because the length of trail closed is about 3 percent of the entire trail system, the overall effects to soil and water resources should be minimal.

Passes would be allowed to be sanded under Alternative 3. The passes expected to be sanded would be Piute and Pine Creek. The effect to the trail themselves and to water and soil impacts related to the trail would be none to minimal. However, sanding of passes would allow access to more areas while they still had more snow and saturated soils than if the passes were not sanded. This could increase the amount of erosion from trails beyond the pass, as wet trails are more likely to be eroded with use. Further, pack stock tend to walk outside of muddy trails, and therefore are more likely to create multiple trails during wet periods. Hikers are not likely as restricted by snowy passes and therefore their impacts to wet trails should be about the same whether the passes are sanded or not.

Campsites: There should be little difference between the impact from stock camps to soil and water resources between Alternatives 3 and 2. There is no substantial difference in stock campsite management in most areas, although 101 stock camps would be designated under Alternative 3, and 94 would be designated under Alternative 2. Therefore, the extent of bare, compacted soil from stock holding camps could be slightly higher under Alternative 3. The

designated sites would be located at locations over 100 feet from water and so they would meet BMPs and not affect water quality or stream functional condition.

The effects from spot/dunnage sites should be more like Alternative 1 effects than Alternative 2. Commercial pack stations could drop clients at any site that meets BMPs, because there would be no specific designated destinations. Use could occur as often as the pack stations needed to fulfill client wishes at any spot/dunnage site. There could be new spot/dunnage sites created in almost any location with a trail open to the site, and therefore it would be possible for more spot/dunnage sites to be created that would increase the extent of bare, compacted soil. It is, however, unlikely that spot/dunnage use patterns would substantially change, and therefore the extent of bare soil from spot/dunnage campsites should remain about the same as under Alternative 1.

Cumulative Impacts

All past and reasonable foreseeable future actions are the same as under Alternatives 1 and 2. Because the direct and indirect effects between Alternative 2 – Modified and Alternative 3 should be about the same, cumulative effects should be about the same. The main difference should be that meadows should have slower recovery and in fewer meadows than under Alternative 2. More meadows are likely to be grazed to their full allocated stock nights under Alternative 3 because there will not be a specific limit on the number of traveling trips as was proposed under Alternative 2. Further, the pastures Poison, Jackass, Blayney and Double Meadows could have greater negative hydrologic function alteration and soil productivity effects. Combined with past grazing, and in the case of Jackass Meadow, flow alterations from Edison Reservoir operations, this could allow for further degradation in these pastures. The effects should not be substantial enough to cause loss of meadow habitat or meadow vegetation, because all pastures were given grazing quotas based on the meadow capability to withstand that level of grazing.

Cumulative Watershed Effects

On a wilderness-wide scale, this action would not contribute to cumulative watershed effects in any watershed. For a more thorough discussion of Cumulative Watershed Effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

The effects should be the same as under Alternative 2, because the area of bare ground and disturbed soil would be about the same. There could be a very slightly greater area of bare ground under Alternative 3, because about 10 more stock holding sites would be designated, and about the same number of destinations would be open to pack stock that would not be open under Alternative 2. However, these differences of a few acres would have no effect to CWEs on a watershed-wide scale.

Alternative 4

Summary of Alternative 4 Impacts

Water quality is assumed good, and will remain so, except at a few local areas where there may be slight degradation. In Alternative 4, there is a greater potential for local improved water quality relative to Alternative 1. Areas of local soil erosion, bare soil, and sedimentation into

surface water from pack stock grazing, campsites, and trails will remain. Of 60 streams found to be functional at-risk (151 evaluated), an estimated 48 percent could have improved condition, 0 percent should have a more degraded condition, and 52 percent should remain functional at-risk. Meadow hydrologic function has the second highest potential for improvement of the five alternatives. Out of 237 meadows evaluated, 41 meadows were found to have hydrologic function alteration; about 37 percent could have improved condition, 61 percent should remain in the same condition, and 2 percent could have a downward trend. There would be a minor reduction of bare, compacted soil, and sedimentation into surface water from designating stock holding and spot/dunnage camps.

Past and present grazing and activities associated with grazing (trailing, stock movement) from production livestock and pack stock is the largest contributor to meadow hydrologic function alteration. Unlike Alternative 1, Alternatives 2 through 4 limit grazing to those meadows that have been analyzed and designated as suitable for grazing. They also limit grazing in those suitable meadows to a given number of stock nights. Alternative 4 limits the future adverse impacts that could occur to hydrologic and soil resources to a lower intensity and smaller extent relative to Alternative 1. Alternative 4 would have similar impacts as Alternatives 2 – Modified and Alternatives 2 and 3, although there should be slightly less widespread adverse effects from trails, campsites, and meadow-grazing.

Analysis

Under Alternative 4, there would likely be some slight overall improvement in stream and meadow hydrologic function, soil productivity and water quality. Locally there could be larger changes, and the improvement would likely be greater than under Alternatives 1, 2, 2 – Modified and 3. The greatest improvements would likely be in meadows where grazing is eliminated, of which there would be more under Alternative 4 than Alternatives 1 through 3. Elimination of grazing would allow for some local soil and hydrologic condition recovery, although in a few cases the grazing would likely move somewhere else and cause new alteration of soil and hydrologic condition.

A greater number of trails would be closed to commercial pack stock, eliminating some destinations. This could slightly reduce the number of large stock holding camps and therefore eventually slightly reduce the area of bare, compacted soil. The difference would probably be too small to make a difference on a wilderness-wide scale. However, at the local scale it could cause slight to moderate reductions in soil erosion, soil compaction, and possibly reduced surface water sedimentation.

Meadows: Fewer meadows would be open for grazing under Alternative 4. In Alternatives 2 through 3, the number of specific key area meadows or meadow complexes open for grazing is almost the same, ranging from 138 in Alternative 2 to 133 in Alternative 3. Under Alternative 4, the meadows open to grazing is reduced substantially to 113. Under Alternatives 2 through 4, meadows are closed to grazing until they are deemed suitable for grazing. Therefore, only 113 specific meadows would be open to grazing (along with a few others within grazing zones). Under current management, four meadows or meadow areas are closed to grazing, and most of the roughly 1,500 others are open to use as desired until standards are surpassed. While reduction of grazing might allow for a greater improvement in the meadows where grazing is eliminated, it could push grazing to other areas within established grazing zones, where hydrologic and soil conditions could worsen.

Meadow hydrologic and soil conditions are expected to improve overall because the meadows that are unsuitable for grazing and therefore most susceptible to soil and hydrologic alteration would not be grazed. Further, under Alternative 4, the meadows with severe hydrologic functional condition or streams rated functional at-risk with a downward trend would not be grazed. Therefore, the worst condition meadows would be less likely to have a greater downward trend.

Actual grazing use changes are not likely to be as dramatic as the proposal would allow. Of the 248 meadows where some action was proposed under any alternative, only 94 had grazing reported from 2001 to 2003. So, if all the meadows where grazing was proposed in Alternatives 2, 3 and 4 were grazed, all alternatives would actually increase the number of meadows grazed from recent reported. It is assumed, however, that not all grazing was reported by meadow, and that different meadows may have been grazed before 2001. Alternatives 2 through 4 all greatly reduce the possible areas where commercial pack stock are allowed to graze, but merely change the areas where they are likely to graze to only those suitable. Further, some meadows deemed suitable that have not been used in the past are in areas not desirable for grazing. These areas, such as Volcanic Knob Meadow, are in unpopular destinations. It is not likely that commercial packers would begin taking trips to new areas where clients do not want to go simply because grazing is allowed.

Meadow Hydrologic Function Alteration: Alternative 4 should have more meadows with improved hydrologic function alteration than Alternatives 2, 2 – Modified and 3, and a substantial improvement over Alternative 1 (Figure 4.6).

Sixty percent of the meadows visited in the field (137 meadows) were found to have no hydrologic function alteration. Of these, none should have the potential for increased hydrologic function alteration. In one meadow, Second Recess Meadow, there could be areas where stock might congregate, such as stream banks and dusting areas, there could be increased compaction, increased bare ground, and increased stream bank trampling. Over time, these effects could lead to a minor reduction in meadow hydrologic function locally, but the effects should not have a large extent, because the grazing allocation was designed to avoid substantial impacts.

Of the 90 meadows with at least slight hydrologic function alteration, about 60 percent would be expected to remain in their current condition. This is roughly the same prediction as under Alternatives 2 and 3. However, only 6 percent of the currently altered meadows are expected to have a trend away from their potential hydrologic function, less than Alternatives 2 and 3.

Of the six meadows that could have worsened hydrologic function under Alternative 4, only three are expected to receive as much grazing as is allocated. Therefore, only those three meadows (Second Recess Meadow [sec14], Upper Deer Creek [ccd18a] and Long Canyon [sil4]) are actually likely to experience increased hydrologic function alteration. The others; between Upper Crater Meadow (ccd2), and above Lower Indian Lake (fle12) are not in areas that do not currently receive very much use, nor are they near areas where use will be eliminated. Therefore, although it is possible they are not expected to receive increased use or have increased hydrologic function alteration.

Under Alternative 4, more meadows with severe hydrologic function alteration would be likely to have improved condition than under Alternatives 1, 2 and 3. This is because fewer meadows with severe hydrologic function alteration would be grazed. Two meadows should have a trend toward potential under Alternative 4 that might under Alternatives 2 and 3. These meadows are

Jackson Meadow (sil8) and Upper Graveyard Meadow (gra11). They would not be grazed under Alternative 4, and therefore should have some potential for hydrologic function recovery.

Meadow Stream Functional Condition (PFC): Alternative 4 is likely to have the greatest increase in number of streams moving toward PFC of all alternatives other than Alternative 5 (Figure 4.1.8). The difference is not large, however, and the percent of stream segments that are functional at-risk will not have major changes. Locally, however, changes could occur to improve or degrade stream functional condition.

Under Alternative 4, it is predicted that out of the 91 streams found to be at proper functioning condition, most will remain so. About 93 percent should remain in their current condition, or improve, and the remaining 7 percent (6 streams) could have a trend away from PFC. The meadows could trend away from potential because they may have grazing increased from current levels. As in Alternatives 2 and 3, grazing practices will determine whether streams' function really trend away from their potential. Five meadows would probably receive all the grazing allocated to them, and therefore could have a stream condition trend away from potential. The other one (Volcanic Meadow) is unlikely to be grazed at its proposed level of 250 stock nights, and therefore the streams are less likely to have increased stream bank trampling and vegetation removal. In addition, if meadows are grazed to avoid more than 20 percent stream bank trampling, over 40 percent vegetation utilization, and soil compaction increases, stream conditions may not worsen. In meadows with lower productivity, the existing standards may not be enough to prevent some reduction in stream functionality with increased grazing.

There are 60 stream segments in meadows that were found to be functional at-risk using the PFC protocol. Of these 60 streams, about 50 percent could have improved stream function, about 50 percent are expected to remain in their current condition, and none are expected to have stream function move away from PFC.

Grazing Water Quality Effects: Under Alternative 4, fine sedimentation into surface water from meadows will likely decrease slightly relative to Alternative 1, and at some local areas, it could substantially decrease. The improvement would likely be greater than Alternatives 2, 2 – Modified and 3. In fewer local areas, there could be minor increases in fine sedimentation into surface water.

Although water quality is generally thought to be good on a wilderness scale, there are some meadows where bank sloughing, stream incision, and soil erosion increases fine sediment in streams within and directly downstream of the meadows. These are generally the meadows with a stream functional condition rating of “functional at-risk,” or those with high levels of sod fragmentation. Those 29 meadows out of 60 where stream functional condition is expected to improve from its current state will likely have a decrease in streambank erosion and therefore a decrease in fine sedimentation into surface water. Under Alternative 4, the number of meadows grazed, and therefore the number of meadows with sod fragmentation, should be reduced.

Water quality impacts from pack stock manure should be slightly less than under Alternatives 1 through 3, because there would be fewer trips into the wilderness areas and fewer stock nights of grazing over all. Because the current effects to water quality are not well understood, the degree of improvement cannot be determined.

Meadow Soil Effects: There should be a slight improvement in soil productivity wilderness-wide, with a probable greater improvement than under Alternatives 1 through 3. Changes in

commercial pack stock management, which is only part of the total recreational use, will have little effect on overall soil productivity wilderness wide or at the geographic-unit scale. Some analysis units and destinations would continue have minor negative effects to soil productivity, soil compaction, bare soil and sod fragmentation. The negative effects should be within soil quality standards.

Forty-five meadows were found to have moderate to severe compaction currently. Of those 45 meadows, 25 would be open to grazing under Alternative 4 (versus 32 in Alternatives 2 and 3). Thirteen of the meadows that will be open to grazing have compaction assumed not related to recent pack stock use. In these meadows, it is assumed that the compaction is due to either historical cattle or pack stock grazing. The proposed grazing attempted to be less intense than what created the compaction in the first place. In some cases, this may not be true, but we will monitor compaction and if it approaches standards, stock nights will be reduced or the meadows will be closed. Twelve currently compacted meadows that will be open to grazing do have compaction that appears to be related to recent pack stock grazing. Three of these meadows have proposed stock nights that are considerably less than recent high levels. The remaining nine meadows could have greater use than what caused the compaction, likely preventing compaction recovery. All but one of these has a high likelihood of being grazed near their proposed high.

Most of the 133 meadows that are known to currently have slight or no compaction should not have substantial increases in compaction severity or extent. About 80 of them would be suitable for grazing. Only about 12 of those meadows could likely have high enough grazing density to have increased compaction. In these meadows, if compaction begins to approach standards, grazing would be reduced or eliminated.

Meadow sod fragmentation will likely decrease overall, but there may be some meadows where sod fragmentation remains or increases. Of the 60 meadows found to have moderate to severe sod fragmentation, 32 would be suitable for grazing under Alternative 4. Only about five of those have a high potential for increased sod fragmentation extent, due to the stocking density recommended and their wet condition making them susceptible to sod fragmentation.

Most meadows with slight to no sod fragmentation will likely not have major increases in sod fragmentation under Alternative 4, and more meadows should have reduced sod fragmentation. Of the 140 meadows with slight to no sod fragmentation, 80 are considered suitable for grazing under Alternative 4. Of those, about 14 have a large increase in grazing and could have increased sod fragmentation if the entire allocated grazing is used.

Trails: Alternative 4 is different than the other alternatives in the number of trails and, therefore, destinations that would be closed to commercial pack stock use. Under Alternative 4, more trails will be made unsuitable for stock than in Alternatives 2, 2 – Modified, and 3. The effect of trails on soil and hydrologic resources should not improve quickly with removal of stock. However, removal of stock could prevent further widening or incision.

Under Alternative 4, almost 50 system trails would be closed to commercial pack stock use that would not be closed under either Alternatives 2 – Modified, 2, or 3. About 35 user trails would have commercial pack stock use prohibited where it would be allowed under Alternatives 1 through 3. Some of those trails provide a short cut or duplicate access to a destination, but about 50 destinations would be made inaccessible to commercial pack stock.

Closing trails to commercial pack stock use may have a greater impact on the destinations serviced by the trails. If commercial pack stock does not access a destination, it means that there could be fewer campsites needed, and fewer stock tie-up areas needed. Therefore, there could be a slight reduction in bare, compacted soil area under Alternative 4. More importantly, closing a trail to commercial pack stock could help prevent commercial pack stock parties from accessing the area and creating new camps or stock tie-up areas. Stock use is only about 15 percent of all wilderness use, however, and because hikers would be free to access the destinations, the difference with a trail closed to commercial pack stock could be small.

Under Alternative 4, sanding trails for earlier access over passes would be prohibited. While the sanding itself does not likely cause direct impacts to water quality or soil quality, it does allow earlier access into some areas of the wilderness. When pack stock can access areas earlier, it means that there are more likely to be wet meadows, trails, and campsites. The stock can cause greater sod fragmentation in meadows and soil loss from trails when the soil is wet, because they are more likely to sink into the soil and displace topsoil. If there is still snowmelt occurring, the snowmelt can carry displaced soil into surface water, reducing local water quality. Under Alternative 4, access to areas beyond a snowy pass might occur later and might not cause as much soil displacement on trails, campsites and meadows.

Campsites: Under Alternative 4, the number of campsites and the total area of bare, compacted soil due to campsites would likely decrease from its current level. The decreases would probably be the largest under all alternatives except Alternative 5. The reduction in campsite numbers would probably only be slight, because backpackers would still be free to camp wherever they wished, and most major stock holding campsites would likely remain although a few would be closed and may naturalize over time.

As stated in the previous “trails” section, use to 50 destinations that would be open under Alternatives 1 through 3 would be prohibited under Alternative 4. This could prevent creation of some new campsites at those destinations and could eventually result in a reduction of bare and compacted soil area at those destinations. Unless sites were actively rehabilitated, they would likely remain for many years,

Cumulative Impacts

This alternative has been analyzed in terms of the effects of past, present and reasonably foreseeable future actions to soil and hydrologic processes. Although past actions have caused some alteration to watershed processes over much of the project area, and most of the non-rocky project area is not pristine, watershed conditions here are likely among the least altered in California or the contiguous United States. Less than 1 percent of the entire area is estimated to have any ground disturbance from campsites, trails, or grazing. Under Alternative 4, the condition should slightly improve in local areas, with less ground disturbed and fewer water quality impacts. However, overall, the condition is unlikely to show much change under Alternative 4 because the proposed actions apply only to pack stock use and commercial pack stock use is only a portion of entire wilderness recreational use.

Alternative 4 would likely allow the most extensive recovery of watershed impacts of any alternative other than Alternative 5. Past impacts from cattle, sheep, and recreational pack stock grazing would remain in many areas, but slow recovery would be allowed in more meadows than under Alternatives 1 through 3 because more meadows with hydrologic function and stream

function alteration would be closed to grazing. The recovery of meadows degraded by cumulative impacts would be quicker in this alternative than under Alternatives 1 through 3; however, it would be slower than under Alternative 5.

Cumulative watershed impacts from trails would not likely be noticeably different under Alternative 4 than they would under Alternatives 1 through 3. Hikers and recreational pack stock users would continue to use almost the entire trail system, even where commercial pack stock would not be allowed to go. Although some trails could have a slightly improved condition with removal of pack stock, the continuation of hiker use on those trails would not allow for recovery of vegetation growth or decompaction of soils. Soil decompaction on a trail would likely take decades even with removal of all use, and therefore trails are not likely to show much reduction in erosion and incision unless they are actively rehabilitated.

There would be fewer campsites used by commercial pack stock users under Alternative 4, but the difference should be small enough that it would not affect cumulative impacts on a wilderness-scale. There would also be some reduction in proliferation of new sites, as all spot/dunnage and stock holding sites would be designated. However, sites for non-commercial pack stock users and backpackers would not be designated. Sites used for stock holding have usually been in their current location for decades, and if they are closed to commercial pack stock, they may continue to be used by recreational pack stock and backpackers. Over time, the area of individual campsites that are closed to commercial pack stock might be reduced as duff covers up stock holding areas and soils slowly naturalize over time. However, this process is slow and the uncertainty of whether sites will continue to be used by recreational pack stock or backpackers makes it difficult to determine whether campsite area and impacts to soil and water resources would be reduced. 59 stock holding sites and 96 spot/dunnage sites will still be designated under Alternative 4, and those sites, along with backpacker and private pack stock camps, would perpetuate bare compacted soil and some soil loss.

Cumulative Watershed Effects

Cumulative Watershed Effects (CWEs) are different than general cumulative effects because CWEs refer to effects from land uses upstream that have been transported downstream through the fluvial system. General cumulative effects can refer to any combination of effects from past, present and reasonably foreseeable future actions that could cause greater effects to soil and hydrologic processes than each action by itself. General cumulative effects can occur in one location, and do not need to be transported downstream to qualify as cumulative effects.

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

In summary, many individual areas appear to have local watershed effects that have been cumulative over time, but only three watersheds (Edison Reservoir in the Ansel Adams West and Mono Creek/Rock Creek Geographic Unit, Granite Creek in the Ansel Adams West Geographic Unit, and East Fish Creek in the Fish Creek/Convict/McGee Geographic Unit) have what appear to be CWEs transported from upstream land uses. Only the East Fish Creek watershed appears to have possible CWEs that are related to past and present commercial pack stock use.

The greatest contributor to potential CWEs in the East Fish Creek Geographic Unit appears to be grazing. Because Alternative 4 has more meadows closed to commercial pack stock grazing and

fewer stock nights proposed than Alternatives 1 through 3, it should cause a greater reduction in CWE potential.

Alternative 5

Summary of Alternative 5 Impacts

Water quality is generally good and will remain so except at few local areas where there may be slight degradation. This alternative has the greatest potential for local improved water quality of the five alternatives. There will remain areas of local soil erosion, bare soil, and sedimentation into surface water from campsites and trails. Of 60 streams found to be functional at-risk (151 evaluated), an estimated 58 percent could have improved condition, 0 percent could have a more degraded condition, and 42 percent should remain functional at-risk. Meadow hydrologic function has the highest potential for improvement, but still only 41 percent of the degraded meadows are expected to have improved conditions and 2 percent could still have a downward hydrologic function trend. There would be a minor reduction of bare, compacted soil and sedimentation into surface water from removal of commercial stock holding sites.

With removal of all commercial pack stock grazing, there would be the greatest certainty that meadows would experience beneficial effects to soil and hydrologic resources. Overall, there should be slightly less widespread adverse effects from trails, campsites, and meadow grazing.

Analysis

Alternative 5 would have the greatest reduction in soil and water resource impacts out of all alternatives. The removal of commercial pack stock grazing would likely cause the greatest difference between this alternative and the others. It would likely reduce the number of meadows with hydrologic function alteration, streams that are not properly functioning, and compacted soil and fragmented sod. Some meadows that are currently being or have recently been grazed by cattle would likely have no or minor improved condition under this alternative. Many currently grazed meadows are expected to have improved condition with removal of pack stock grazing.

Trails and campsites would likely show a less pronounced improvement in condition, because backpacker use would likely remain about the same as today. Because only 15 percent of all wilderness users access the wilderness by pack stock, the reduction in the number of campsites and the number of people on trails would be small. However, pack stock holding sites are generally much larger than backpacker campsites, and eventually, pack stock holding camps would likely be covered with duff and have reduced compaction. This would slightly decrease the area of compacted soil and likely reduce soil erosion and sedimentation into surface water near stock holding campsites. Wilderness-wide, the reduction in erosion and improvement in water quality would likely be too small to be measured, but the difference at local areas where there are many stock holding campsites could be measurable.

Meadows: In meadows where recent packs tock use appears to be having major contributions to meadow hydrologic function alteration, alteration of stream functional condition, or alteration of vegetation composition change, it is likely that removal of that use would allow recovery to begin. If a meadow is altered severely enough, removal of pack stock may not allow recovery. Meadow hydrologic function and stream geomorphic recovery may take decades because they depend on slow-acting geomorphic processes such as soil decompaction and stream aggradation.

Stream functional condition and vegetation vigor recovery will likely occur more quickly with removal of grazing because they depend mainly on the more short-term vegetative processes.

Under Alternative 5, commercial pack stock grazing or trailing through meadows would no longer occur. Private pack stock parties and production livestock will be allowed to graze as they have in the past. The total reduction in stock nights of grazing would be about 8,500 relative to the average grazing reported from 2001 through 2003. Non-commercial pack stock use is and will likely remain very low throughout the project area. There is current cattle grazing in the Ansel Adams West and the Western end of the Mono Creek/Rock Creek Geographic Unit, and will likely continue at current levels. Currently, 1,549 animal months (46,470 stock nights) are permitted within the project area. About 25 percent of all the 1,620 known meadows are within active cattle allotments, although not all of those have experienced recent cattle grazing. The meadows that would remain in active cattle allotments and would have continued grazing impacts are in the Ansel Adams West, Mono Creek/Rock Creek, Fish Creek/Convict/McGee, Florence/Bear, and John Muir Southwest Geographic Units. The Ansel Adams West Geographic Unit is the only one with greater than 25 percent of its area in an active cattle allotment.

In meadows where meadow hydrologic function alteration, alteration of stream functional condition, or alteration of vegetation composition appear to be predominantly caused by something other than recent commercial pack stock use, the effects of pack stock removal might not be as straightforward. If pack stock graze a meadow that has existing alteration of hydrologic and soil function, they can perpetuate the condition or even cause a downward trend in something that might otherwise begin to recover. Continued pack stock grazing likely prevents or retards recovery and in some cases continues the degradation, as was observed at Grassy and Jackson Meadows in the Silver Divide (SIL) Analysis Unit. Subsequent removal of pack stock could either allow recovery to begin, increase the rate of recovery, or slow the rate of degradation.

Meadow Hydrologic Function: There would likely be fewer meadows with hydrologic function alteration under Alternative 5 than under any other alternative (Figure 4.6, Table 4.65), and many meadows with current hydrologic function alteration would likely have at least minor improvement

Meadow hydrologic function alteration may begin to recover or completely recover within 20 years if the meadow's water source remains or if the water source has a potential to recover. In meadows with moderate or slight hydrologic function rather than severe, there is a greater chance that hydrologic function could show an upward trend with removal of grazing. The potential for some recovery without grazing is due to different productivity, water source, soil type, and existing impacts in the meadow.

Of the 230 meadows analyzed for hydrologic function alteration, 137 meadows were found to have no hydrologic function alteration. All of these meadows are all expected to remain in good hydrologic condition under Alternative 5. This expectation is based on the assumption that no new trails or campsites will be created through meadows.

Of the 93 meadows with at least slight hydrologic function alteration, about half would be expected to improve and about half would be expected to stay in their current condition with removal of commercial pack stock.

Of the 17 meadows with current severe hydrologic function alteration, we expect 13 to remain in their current condition with little or no recovery (Table 4.65). The other four may have potential for some minor recovery in hydrologic function. If these four meadows are grazed by non-commercial pack stock, they could show a static or downward trend in hydrologic function condition.

Of the 24 meadows found to have moderate hydrologic function alteration, about half (10) are expected to have at least minor recovery under Alternative 5, while the other half (13) are expected to have no change or a downward trend.

Of the 52 meadows with slight hydrologic function, about half are expected to have at least minor recovery and the other half are expected to remain in their current condition. One meadow is expected to have a downward trend depending on climate, because it appears to be responding to dry conditions, not recreational use.

None of the meadows with severe hydrologic function alteration within the Ansel Adams West Geographic Unit are expected to show hydrologic function recovery within the next 20 years. These meadows are all part of an active but vacant cattle grazing allotment, where grazing has not occurred for about 10 years. In these meadows, there appears to have been some vegetative vigor and composition improvement, but lack of hydrologic recovery to date. We assume that recovery will continue to occur at the same slow rate as it is today, and therefore expect little recovery for decades.

Stream Function Condition (PFC): With removal of commercial pack stock, Functioning Condition of streams should improve in more meadows than any other alternative (Figure 4.6, Table 4.66). Stream condition might improve in some areas that are currently Functional at-risk, and might remain static in others. In very few cases, stream functional condition could worsen, but only when the condition is due to drought, other natural causes, hiking trails, or cattle grazing. Stream functional condition has the potential to improve more rapidly than meadow hydrologic function condition because under the PFC protocol, stream functional condition depends partly on stream bank vegetation vigor and composition. Vegetation generally has the potential to regrow more quickly than stream morphology can return to its pre-disturbed state. Eventually, as vegetation grows on stream banks or on instream point bars, fine sediment can be trapped in the vegetation, slowly building new streambanks and narrowing channels (Beard 2004).

In many streams in the project area, rest from grazing would allow vegetation to grow quickly on stream banks and in-stream bars, improving stream functional condition quickly. This appears to be the case in Purple Meadow, where grazing was reduced from 438 stock nights in 2002 to 47 in 2003 and none in 2004. In 2001, two stream reaches in the meadow were rated Functional at-risk with a downward trend. In 2004, those same reaches had major vegetative recovery and were estimated to be functional at-risk with an upward trend. The soil near these stream reaches is wet and the meadow has high productivity. Further, the affected stream reaches are small, intermittent first order streams that receive little flow. In other areas, (likely those with lower fine sediment loads or lower productivity), vegetation does not quickly grow on stream banks or on point bars. For example, Fish Creek through Cascade Meadows is incised and has streambanks and raw point bars that have not vegetated substantially since they were exposed about 20 years ago. The affected reach of Fish Creek is a sixth order stream that receives much larger flows than the streams in Purple Meadow. Although we cannot predict exactly how stream

functional condition would react to removal of grazing, we attempted to use our observations of meadow productivity, stream size, vegetation type and vigor, and sediment loads to predict general trends.

Of the 151 streams in meadows where stream functional condition was analyzed, 91 (60 percent) are at PFC. These streams will likely remain at PFC as long as they do not receive increased private pack stock grazing use and no new trails with a major stream crossing are created. Of the remaining 60 stream segments, about 60 percent are expected to improve condition, while the remaining 40 percent are expected to remain in their current state.

Of the 16 stream segments where condition was rated functional at-risk with a downward trend, 11 are expected to have improvement in condition under Alternative 5, while 5 are expected to remain in their current condition. The five expected to continue in their current condition are experiencing effects that will not be altered by removal of commercial pack stock. While pack stock use could perpetuate altered stream functional condition, One will probably continue to be grazed by cattle (Graveyard Meadow), two are functional at-risk due mainly to trails that may continue to be used (Ram Meadow and Hilton 4 Camp Meadow), and two are functional at-risk due mainly to drought (Crater Meadow and Dorothy Outlet Meadow).

Martin's Meadow is an exception. In 2001, the lower reach in the meadow was rated functional at-risk with an upward trend. In 2004, the same reach was rated non-functional, due to rapidly advancing headcuts in and lateral to the stream. The erosive nature of the sandy soils and the severity of headcutting suggest that the nonfunctional rating will continue until active headcut repair work occurs.

Of the 29 stream segments where stream condition was rated functional at-risk with a non-apparent trend, 16 are expected to have some improvement, while 13 are expected to remain in their current condition. The 13 that are expected to remain in their current condition appear to be experiencing effects that will not be altered by removal of commercial pack stock, particularly cattle grazing and trails, or other unknown causes.

Of the meadow stream segments analyzed for stream functional condition, 15 were found to be functional at-risk with an upward trend. We expect about half to improve at least slightly from their current condition, and half to remain in their current functional at-risk state.

Grazing Water Quality Effects: Under Alternative 5, fine sedimentation into surface water from meadows would likely slowly decrease. Although water quality is thought to be good on a wilderness scale, there are some meadows where bank sloughing, stream incision, and soil erosion increases fine sediment in streams within and directly downstream of the meadows. These are generally the meadows with a stream functional condition rating of “functional at-risk”, or those with high levels of sod fragmentation. Those meadows where stream functional condition is expected to improve from its current state would likely have a decrease in streambank erosion and therefore a decrease in fine sedimentation into surface water. Sod fragmentation is expected to decrease in all meadows where there is currently sod fragmentation. About 30 percent of meadows analyzed have moderate to severe sod fragmentation, where sod fragmentation could be leading to soil erosion and subsequent fine sedimentation into surface water. However, much sod fragmentation is far from water, and any eroded soil from the fragmentation would not enter water. Therefore, the reduction in fine sedimentation due to reduced sod fragmentation should be small.

Because only a small fraction of the current pack stock use in the wilderness would occur under Alternative 5, the volume of manure entering surface water would greatly decrease. Because current water quality effects from manure are unknown, the degree of improvement to water quality from less manure is unknown. However, it is known that there would be a reduction of manure in the water, and likely a reduction of negative local water quality effects under Alternative 5.

Meadow Soil Effects: In the overall wilderness area, a small portion of soil was found to be impacted by current recreational use, estimated at less than 1 percent. Therefore, removal of commercial pack stock, which is only part of that recreational use, will likely have little effect on overall soil productivity wilderness wide or on the geographic-unit scale. Some analysis units and more local areas, such as individual meadows, could have increased soil productivity, reduced soil compaction, reduced bare soil, and reduced sod fragmentation.

Under Alternative 5, soil compaction in meadows will probably slowly be reduced, improving infiltration and water storage capacity of soils, and reducing peak flows in streams through increased infiltration. It is uncertain how long it will take compaction to fully recover in each meadow.

Out of the 13 meadows known to have severe soil compaction, 9 of them are in the Ansel Adams West Geographic Unit and are known to have been grazed by cattle until 10 to 15 years ago. None of these meadows have had more than light pack stock grazing reported in the past 3 years, so we assume that they have not received more than light grazing since cessation of cattle grazing. These meadows remain severely compacted, suggesting that severe compaction below the surface of the soil within the project area does not recover within 10 to 15 years. This finding is similar to others' findings, which suggest that surface soil recovery is fairly rapid, but compaction recovery may take decades at depths greater than 15 or 20 cm (Alexander and Poff 1985). We therefore assume that compaction would slowly recover in most compacted meadow areas under Alternative 5, but the extent and degree of recovery in any one meadow is uncertain.

Meadow sod fragmentation will likely decrease in all meadows where it is related to commercial pack stock use. Hoof trampling studies on the Inyo National Forest suggest that deep hoof punches persist for more than two years, but the longevity of hoof punches is unknown. However, shallow hoof punches and sod fragmentation will likely fill in with vegetation in most meadows because vegetation usually grows back soon after cessation of grazing. Generally, as elevation increases, meadow recovery rate decreases (Ratliff, 1985). The only exceptions might be meadows that have severely compacted, dry areas where it is difficult for vegetation to establish. Few areas such as these were observed, but they would include dusting areas and areas where stock congregate, such as holding areas. While some meadows have these features, they are relatively small compared to the meadow size overall, and sod fragmentation should have a much smaller extent under the No Action alternative.

Trails: Under Alternative 5, trail effects on soil and hydrologic condition will likely improve relative to Alternative 1. Without active repair, trails that are currently diverting surface water and eroding due to water running down the trail will continue to do so whether they are used by commercial pack stock or not. However, our assumption is that most of the trails causing noticeable sedimentation into surface water or diverting surface water will be gradually repaired over the next 20 years. Therefore, there would likely be a reduction in sediment into surface water and diversion of surface water.

Under this alternative, stock use would be greatly reduced on trails with termination of commercial pack stock use. Trails would likely stop widening but could continue to deepen and therefore divert more overland flow and stream flow even with removal of pack stock use. Without active rehabilitation of incised and widened trails, they are likely to remain in their current state or possibly experience slight upward or downward trend. The trails that are the most severely incised or widened, and those with the most erosion occurring are likely to be rehabilitated or have some maintenance over the next 20 years. Therefore, trail condition should improve overall, though hiker use could perpetuate incision, widening and multi-trailing on heavily used hiker trails.

Campsites: Hydrologic and soils effects from campsites should decrease over time as the Wilderness Plan is implemented and sites closer than 100 feet from water are closed and rehabilitated. This would continue to occur under all alternatives. Hikers will continue to use most campsites that remain open, and therefore the reduction in compacted area will likely be very small.

Beyond the reduction in campsites close to water prescribed in the 2001 Wilderness Plan, under Alternative 5, exclusively stock campsites will gradually decompact and revegetate. Campsites where pack stock are regularly held generally disturb a larger area than backpacker sites because additional area is used to tether animals (Cole 1990). With removal of commercial pack stock, sites would likely become smaller. Complete recovery may occur within decades on all but the most heavily used sites. Spildie and others (2000) found that within 5 years of closure, stock holding sites in the Selway-Bitterroot Wilderness in Idaho had a 46 percent decrease in bare soil area. If they continued to be used by campers, the former stock holding sites had a slightly smaller, but similar, decrease in bare soil area. Assuming that recovery rates would be similar in the project area, stock holding sites may reduce in size substantially over 20 years.

It is unknown what percent of the project area is covered by campsites. However, on the Inyo National Forest, inventories suggest that less than 0.5 percent of the area is campsites. Overall, this is already an area small enough to be inconsequential, although some areas with a high concentration of campsites likely have a cumulative effect that increases flow in nearby streams. The percent of area covered by campsites will likely slightly decrease. This will likely decrease local direct and indirect impacts to water quality and improve watershed function at these areas directly adjacent to campsites.

Cumulative Impacts

This alternative has been analyzed in terms of the effects of past, present and reasonably foreseeable future actions to soil and hydrologic processes.

Alternative 5 is likely to allow the quickest recovery of meadow hydrologic function alteration, stream functional condition, and soil productivity in more locations than any other alternative. However, on a wilderness-wide scale, removal of all commercial pack stock use might only allow minor improvements.

The greatest improvement to soil and hydrologic condition should come due to the cessation of commercial pack stock grazing in all meadows. This is because other than in a few Analysis Units in the Mono Creek/Rock Creek and Ansel Adams West Analysis Unit, the only other grazing is very little private pack stock use. It is possible that there would be a slightly increased incidence of private pack stock use when the wilderness areas are not accessible to commercial

pack stock operators. That could increase private pack stock grazing but it would still likely remain a small percentage of current commercial pack stock grazing levels.

In the Ansel Adams West and West Mono Creek/Rock Creek GUs, cattle grazing would likely continue, allowing continuation of soil compaction, stream functional condition alteration and sediment into water from stream bank erosion.

The soil and water impacts from trails and campsites should be slightly reduced with the removal of commercial pack stock. However, continuation of backpacker use and low levels of private pack stock use could maintain most trails in their degraded state and most campsites at their current size although there would be less potential for increased trail incision and widening with drastic reductions in pack stock travel.

Cumulative Watershed Effects

The overall potential for cumulative watershed effects (CWEs) should decrease under Alternative 5. None of the alternatives is likely to have any effect on the potential for CWEs in more than one watershed, the East Fish Creek Watershed. The existing area of disturbed soil, compacted soil, incised channels, streambank disturbance, and other watershed impacts is unknown. However, rough estimates suggest that less than 1 percent of the Wilderness area is disturbed by grazing, trails and campsites. The stream length with streambank disturbance is unknown.

We predict that every action alternative would slightly reduce the risk of CWEs within a few watersheds, but that none of the alternatives would be measurably difference from the current effect overall in most watersheds (Table 4.65). The East Fish Creek, Edison Reservoir, and North Fork San Joaquin River watersheds are the only three watersheds where there is currently disturbance estimated on over 1 percent of the watershed. Those are therefore the only watersheds where there might be a risk of overall CWEs. The Granite Creek and Hilton Creek watersheds are both near the 1 percent threshold, with at least 0.75 percent of their watershed area estimated to be disturbed. In the field, we observed that East Fish Creek, Edison Reservoir, North Fork San Joaquin River, and Granite Creek watersheds appear to actually have potential cumulative watershed effects. All of these watersheds were visited at least in part, and the watershed effects of portion of the watershed not visited was estimated to be the same as the areas visited. Although Hilton Creek watershed has a large amount of disturbed ground due to high levels of hiker and commercial pack stock use, Hilton Creek itself does not appear to be suffering CWEs.

Because potential CWEs are thought to be related to commercial pack stock use only in the East Fish Creek Watershed, it is the only watershed where a decreased CWE potential could occur. Alternative 5 could provide the most rapid improvement in watershed function in East Fish Creek, although recovery of the incised portions of Fish Creek may occur over decades or centuries.

Geographic Scale

Ansel Adams East – Alternative 1

Analysis

In the Ansel Adams East Geographic Unit, as wilderness-wide, soil and water resource conditions are unlikely to change from their current condition in most locations. The Ansel Adams East currently has relative high levels of pack stock use. Meadows are generally in fair to moderate hydrologic and soil condition, and would likely remain so. A high number of streams analyzed for stream functional condition are functional at-risk, and their condition is unlikely to change through most of the geographic units. Overall, trails and campsites should continue to have little effect on soil and water resources, but individual areas may have water quality degradation and hydrologic function alteration due to trails.

Meadows: Meadow condition is unlikely to change under Alternative 1, although condition could change if use changes. Alternative 1 is the only alternative where grazing could occur in any area except those four areas that are currently closed. There is no way to determine where future grazing might occur, but it is assumed that it should not change substantially from current locations.

Meadow Hydrologic Function: Almost 90 percent of meadows are expected to remain in their current hydrologic function condition, as shown in Figure 4.7. Four meadows could have minor degradation of hydrologic function, while two are expected to have improved hydrologic function. Of the 48 meadows visited in the field, almost 70 percent were found to have no hydrologic function alteration currently. The rest were found to have slight to moderate hydrologic function alteration. Most meadows should therefore remain without hydrologic function alteration. The difference between the projected hydrologic function effects under Alternative 1, 2, 3 and 4 are minor (Table 4.69).

Figure 4.7 A comparison of the effects of alternatives on meadow hydrologic function condition in the Ansel Adams East Geographic Unit

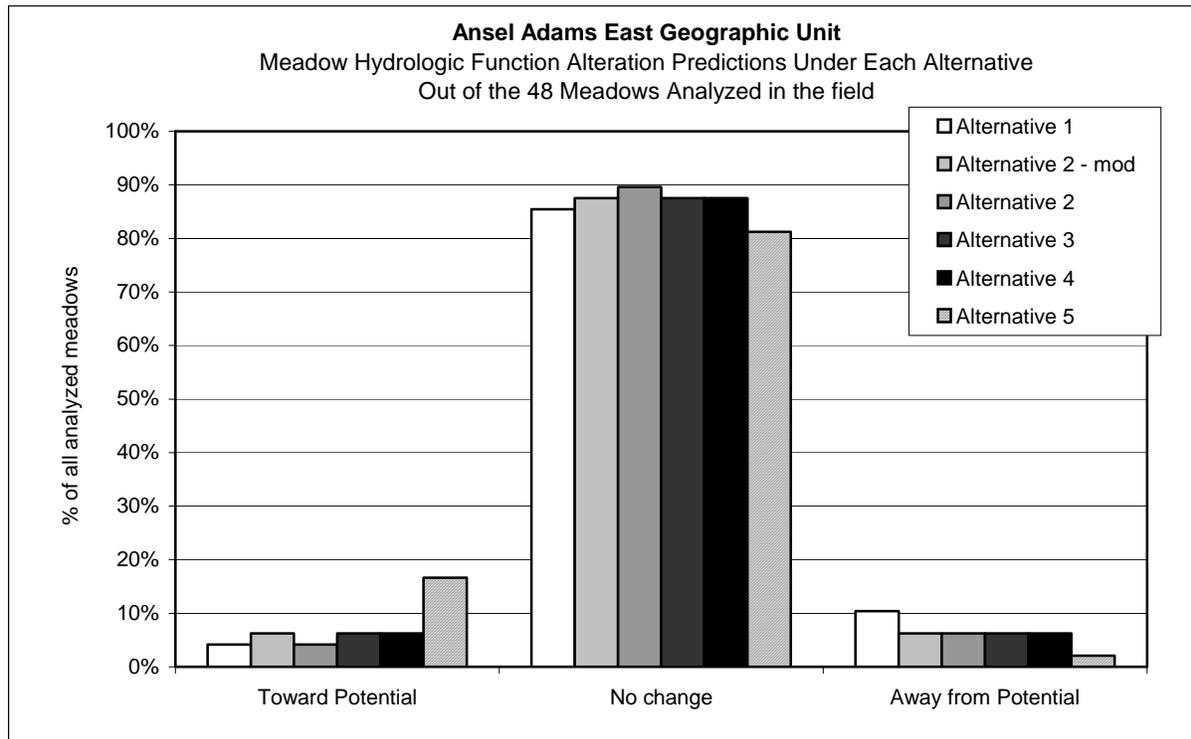

Table 4.69. Hydrologic Function Alteration Predictions for all meadows visited in the Ansel Adams East Geographic Unit. The number of meadows predicted to have each trend was estimated by the IDT, using the meadow’s characteristics such as soil moisture, stream bank stability, and meadow productivity. The predictions in this table assume that the some meadows would not receive their allocated stock nights, if they are in an area unlikely to received increased use. The prediction underestimates the worst possible effects, but is a more realistic estimation. The potential effects if all stock nights were used is included in the text.

Trends By Number of Meadows						
Current Meadow Hydrologic Function Condition (# of meadows with that condition)	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
No hydro alteration (32)

The five meadows that are expected have minor degradation of hydrologic function are Upper Deer Creek Meadow (ccd18a), Middle Deer Creek Meadow (ccd17), Lower Spooky Meadow (rus3), Garnet Lake Meadow (thi15) and the meadow on the Northwest Delta of Thousand Island Lake (thi12). Upper Deer Creek Meadow (ccd18a) would likely not be grazed, but the active headcut in the lower portion of the meadow appears that even without any grazing, it will keep progressing into the meadow, possibly expanding the area with a lowered water table. The other four meadows should only have worsened hydrologic function if they are grazed at or above current levels.

The two meadows expected to have minor improvements in hydrologic function alteration are the meadows between Garnet and Emerald Lakes (thi14) and Summit Meadow (ccd11). Improvement in hydrologic function at the meadow between Garnet and Emerald Lakes should occur when the trail through the meadow receives maintenance to reduce trail incision. If the trail and the headcuts propagating from the trail are repaired, the headcuts should revegetate and eventually aggrade. Although it is uncertain when this repair would occur, it is likely to occur within the next 20 years. Trail repair is a separate but related action that would be approved under a future decision, and is not guaranteed to occur under this action. Summit Meadow has some trampled and headcut areas that appear to have recent vegetation growth, and if the meadow continues to have no commercial grazing, that vegetation growth should continue to allow improved hydrologic function. The trail incision is currently causing headcuts to move into the meadow.

Meadow Stream Functional Condition (PFC): Similar to the entire wilderness, the Ansel Adams East Geographic Unit is unlikely to have much change in stream functional condition relative to current conditions under Alternative 1 (Figure 4.8). Of the 41 meadows analyzed for stream functional condition, almost 80 percent are expected to remain in their current condition. About 10 percent might have improved stream functional condition while the remaining 10 percent could develop poorer stream functional condition. Table 4.70 compares stream functional condition predictions among alternatives.

Figure 4.8 A comparison of predicted changes to stream functional condition (PFC) among alternatives for the streams where PFC was analyzed. A total of 41 meadows were analyzed for PFC, all within meadows or other grazed areas. This chart includes all streams analyzed, whether they are at proper functioning condition or whether they are currently functional at-risk.

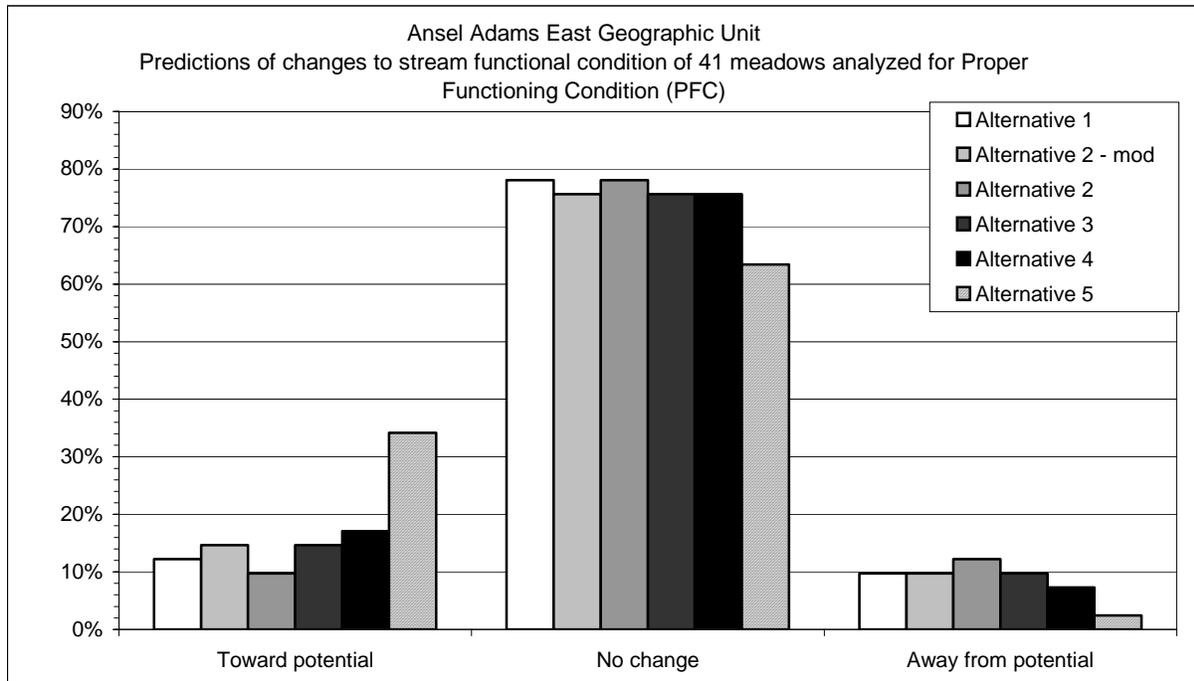

Table 4.70 Summary of all meadow stream functional condition predictions under all alternatives in the Ansel Adams East Geographic Unit. Stream functional condition was determined using the Proper Functioning Condition (PFC) protocol. The streams are separated by those that are currently properly functioning, those that are functional at-risk with an upward trend, those that are functional at-risk with a non apparent trend, and those that are functional at-risk with a downward trend. The predictions are based on assumptions that grazing will continue about as it has in the past in most areas, except in meadows that are closed to grazing and those nearby meadows where grazing might move to.

Current stream functional condition rating (# with each rating)	Number of Meadows expected to have each trend					
	Alternative 1	Alternative 2 - Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
Proper Functioning Condition (26)						
Toward potential	1	0	0	0	0	2
No change	23	22	22	22	23	23
Away from potential	2	4	4	4	3	1
Functional at-risk upward trend (2)						
Toward potential	1	1	1	1	1	1
No change	1	1	1	1	1	1
Away from potential	0	0	0	0	0	0

Current stream functional condition rating (# with each rating)	Number of Meadows expected to have each trend					
	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
Functional at-risk non apparent trend (8)						
Toward potential	1	1	1	1	2	7
No change	7	7	7	7	6	1
Away from potential	0	0	0	0	0	0
Functional at-risk downward (5)

No change	30	31	32	31	31	26
Away from potential	5	4	5	4	3	1

The six meadows expected to have improved stream functional condition are the John Muir Trail/Shadow Creek Junction Meadow, Upper Ediza Meadow, Northwest Thousand Island Lake Meadow behind the Moraine, the Garnet/Emerald Meadow Complex, Johnston Meadow, and an unnamed meadow in Deer Creek (ccd16). In all but Johnston Meadow and ccd16, the improvements are expected to occur only with trail repair. These meadows have streams that are functional at-risk mainly due to trail crossings, and the effects are over a small reach.

It is a foreseeable future action that the trail crossings would be repaired, although the repair may take up to 10 years due to budget constraints. Johnston Meadow is expected to have a minor improvement its current stream rating of functional at-risk with a downward trend. The meadow was grazed heavily as a pasture until the early 1990s, but is not expected to be grazed at those levels in the future. In the 10 years that the meadow has been closed, the stream has begun to grow vegetation on a few stream banks and point bars, while other remain unvegetated, and it is expected that there would be a minor increase in vegetative growth and therefore stream functional condition with continued light grazing in this large meadow.

The five meadows expected to have worse stream functional condition under Alternative 1 are Lower Spooky Meadow, Superior Lake Meadow, Garnet Lake Meadow, Northwest Delta Thousand Island Lake, and Upper Deer Creek Meadow (ccd18a). The first four would continue to have substantial grazing. Their stream banks are vulnerable due to past impacts or lack of armoring. Therefore, grazing pack stock could continue to trample stream banks, eat vegetation on the stream banks, and reduce stream functional condition. Upper Deer Creek Meadow (ccd18a) would likely not be grazed under Alternative 1 because it has not been grazed recently. It currently has active headcuts that are in the lower portion of the meadow and moving into the meadow. It is unknown why the headcuts occurred, but they do not appear to be related to recent

pack stock grazing. The meadow has low productivity and vegetation is unlikely to stabilize the headcuts under any alternative.

Soil Effects: There should be continued degradation of soil productivity in local meadows. Of the 39 meadows analyzed for compaction, four were found to have moderate or severe compaction. Under Alternative 1, all of these are open to grazing, and therefore have the potential for continued compaction. All have been grazed within the past three years, and therefore are predicted to have continued grazing and continued moderate compaction.

Trails: Under Alternative 1, there would be one system trail closed to commercial pack stock in the Ansel Adams East Geographic Unit, the Holcomb Meadow Trail. It is assumed that a reasonably foreseeable future action is that the 13 system trails with moderate to severe effects on soil and hydrologic resources would be repaired under all alternatives to reduce soil erosion, incision, and diversion of surface water. However, it is likely that repair will occur slowly and be less effective on some trails than under other alternatives.

Under all alternatives, trails with moderate to severe resource impacts would likely not recover without repair. There would be little difference in the recovery rate of these trails whether they were used by pack stock or not, because once trails incise or widen, water begins to flow down the trail and continues erosion, even with no use of any kind. However, heavy pack stock create more soil loss and trail erosion than hikers, and trails used by pack stock under Alternative 1 would likely need to be maintained more often to prevent soil loss.

Trail sanding would continue to be allowed on a case-by-case basis with Forest Service approval. No trails in this geographic unit are regularly sanded or expected to be requested in the future. Therefore, there are no predicted effects of sanding in this Geographic Unit under any alternative, and it will not be discussed under the other alternatives.

The Thousand Island and Shadow-Ediza Analysis Units both receive high levels of commercial pack stock and backpacker use, and would likely continue to receive high use. Both of these units have an unusually large number of trails leading to soil loss, surface water diversion, and local reduction in water quality. This alternative is the one most likely to have continued negative soil and water resource impacts because all trails would be open to commercial pack stock use. Under all other alternatives, more user and system trails would be closed to pack stock use and would therefore likely have slightly fewer impacts.

The Parker, Glacier Canyon, Gibbs, Bloody Canyon, River High and River Corridor AUs are likely to have very little change to soil and hydrologic resources from trails. The main pack stock use in these units is pass through use, with the main destination area at Badger Lake and some camping along the High Trail, the River trail and at Agnew Pass. There are no known negative effects of the use at the High Trail, River Trail and Agnew Pass use areas. The trails cause normal of bare soil and compacted soil, and the same effects should continue under all alternatives.

Campsites: The effects to campsites would be the same as predicted under the wilderness scale. However, the reduction in compacted, bare soil and sediment entry into water could be noticeable at Ediza Lake. The lake currently has a few campsites too close to water and contributing sediment into the lake. Associated trails appear to be causing more sediment input into the lake. This may be one area where a foreseeable future action is that sites are designated

for stock holding and client drop off due to the high use at the lake and likely water quality reduction due to campsites and trails.

The Rush Creek and Upper Rush Creek Analysis Units would be managed as they have been in recent years, with more site-specific intensive management than other analysis units. There should continue to be fewer resource impacts from stock holding sites than in other AUs, because they are designated. They should continue to meet BMPs.

Cumulative Impacts

This alternative has been analyzed in terms of the effects of past, present and reasonably foreseeable future actions to soil and hydrologic processes within the Ansel Adams East Geographic Unit. The effects under Alternative 1 should be the same as current cumulative impacts. Past actions, including commercial pack stock and private recreational use, have caused some local increases in soil erosion, sedimentation and stream function condition alteration. Past, present and future actions are the same as on the wilderness-wide scale except where described below.

Past actions particular to this Geographic Unit include the construction of two major dams at Waugh and Gem Lakes, fundamentally altering stream flow and many beneficial uses below the dams. These dams are near the edge of the wilderness, and do not affect upstream beneficial uses. The dams will remain into the future and will continue to alter stream flow downstream of the dams.

Alternative 1 would allow commercial pack stock use to continue in all areas currently open. In some local areas, the combination of past, present and future commercial pack stock grazing and other recreational use would allow continuation of slight water quality degradation, stream morphology alteration and soil productivity reduction. The largest contributor to cumulative soil and water effects appears to be trails, both used by commercial pack stock and by private pack stock and hikers.

In some areas, such as near Ediza and Thousand Island Lake, hiker use unrelated to commercial pack stock, has led to increased areas of soil compaction from campsites and user trails. These effects will not change under Alternative 1 because commercial pack stock and hiker use would likely remain about the same. Reasonably foreseeable future actions include trail repair on trails with moderate to severe soil and water resource impacts. This repair would reduce the extent of soil erosion, stream bank trampling, and sedimentation into surface water.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

In summary, the watersheds with at least some portion in the Ansel Adams East Geographic Unit were not found to currently have cumulative watershed effects, nor are they expected to have any increased potential for CWEs under Alternative 1. Some trails and meadow grazing practices have caused increased fine sediment input into surface water in the Upper Middle Fork San Joaquin River watershed (Shadow Ediza, Thousand Island, Minaret, River High and River Analysis Units). In this watershed, there is a relatively high percentage of stream segments that were found to be functional at-risk. However, the local effects of trails and grazing do not appear

to have transported downstream to cause potential CWEs within the watershed and are not likely to do so under Alternative 1 because all uses should remain about the same.

Ansel Adams East – Alternative 2 – Modified

Analysis

The Ansel Adams East is likely to have very little overall change in soil or hydrologic condition under Alternative 2 – Modified. Local changes might be substantial in a few locations where commercial pack stock management would have the largest changes, such as at Thousand Island Lake and the Shadow-Ediza area. The greatest changes to soil and hydrologic resource condition would likely be from closure or rest of meadows that currently have soil and hydrologic function alteration. There should be little overall change in campsite extent or condition, and therefore campsite management should have little effect on soil or hydrologic condition.

For site-specific areas not discussed below, but discussed under Alternative 1, the effects should be the same.

Meadows/Wetlands: Meadow condition should improve overall in this area, although the effects should be slight. There will be some meadows closed to grazing, which should reduce soil and hydrologic effects, but some would remain open that could have continued negative effects. The effects should be minor because all meadows would have stock nights allocated, and they were developed to meet the meadows' capacity.

It is possible that the Crater Creek Analysis Unit could see increased pack stock grazing under this alternative, as well as under Alternatives 2, 3, and 4. While destination quotas will allow for greatly increased use, it is unlikely that the entire allocations will be used because the area is not a desirable destination. Much of the area has soils vulnerable to erosion due to high ash content. If use does increase, especially grazing use, some meadows could have increased bare ground, stream trampling, vegetation removal and soil compaction that could lead to slightly decreased meadow hydrologic function and stream functional condition.

Meadow Hydrologic Function: Of the 48 meadows analyzed in the field for grazing suitability and condition, all were analyzed for hydrologic function alteration. Of these meadows, none were found to have severe hydrologic function alteration, and only four were found to have moderate hydrologic function alteration. Twelve have minor hydrologic function alteration and the remaining 32 were not found to have hydrologic function alteration.

Of the four meadows with moderate hydrologic function alteration, three are expected to remain in their current hydrologic condition under Alternative 2 – Modified, while one is expected to show minor improvement. (The *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under all Alternatives* table in the project record shows individual meadow predictions.) The three meadows expected to remain in their current condition are Summit Meadow (ccd11), an unnamed meadow in Deer Creek (ccd16) and Johnston Meadow (min11). Summit Meadow and the unnamed meadow both have stream incision and headcuts with an unknown cause and have not been recently grazed by commercial pack stock. Both meadows have low levels of grazing proposed. Because both meadows have stream incision and headcuts that appear to have little vegetation growth and therefore little potential for recovery, neither meadow would be expected to recover hydrologic function within 20 years, even with no grazing. All would have some grazing allowed. The grazing should not

cause hydrologic function to move away from its potential because the levels of pack stock grazing allowed were developed to prevent widespread streambank trampling and vegetation removal.

In Johnston Meadow, the cumulative effect of grazing over time has altered stream functional condition to a point that it is unlikely that the stream will aggrade within centuries. The meadow has not been heavily grazed since the mid 1990s, and banks continue to collapse, instream bars remain unvegetated, and few stream banks support vegetation. Grazing at the proposed 193 stock nights could cause some trampling and vegetation removal that would slow recovery of hydrologic function. Although past records of actual use were not available, we know that 19 AUMs (about 580 stock nights) were permitted. Therefore, the proposed use is less than was likely used in the past, but still substantial. It is possible that all 193 stock nights would be used in Johnston Meadow because it is a foreseeable future action that Agnew Meadow, closer to the pack station, will have grazing reduced from current levels.

Of the 12 meadows with slight hydrologic function alteration, eight are expected to remain in that condition, two are expected to have hydrologic function trend toward their potential, and two are expected to trend away from potential. The meadows expected to trend toward its potential hydrologic function are Garnet Lake Meadow (thi15) and the Northwest Delta Thousand Island Lake (thi12). The meadows would be closed to or rested from grazing and the fragmented sod and streams impacts could be reduced without pack stock use.

The eight meadows, with slight hydrologic function alteration, that are expected to remain so have different reasons for their lack of recovery. Four meadows would continue to be grazed. The levels of grazing proposed, and the vulnerability of soils and the stream, will likely continue with some stream bank trampling and vegetation removal preventing vegetation from growing back. Four meadows will not be grazed, but the low productivity could prevent vegetative recovery within the medium term.

The two meadows expected to have a trend away from their potential could have grazing, and are both in the Crate Creek Analysis Unit. However, it is unlikely that these stock nights will be used because it is close to the pack station that would use this operating area and stock may not be able to be easily held here.

Thirty-two of the 48 meadows analyzed in the field do not appear to have hydrologic function alteration currently. One is expected to have a downward trend in hydrologic function, Middle Deer Creek (ccd17), because grazing could be increased from none currently to 230 stock nights. The impacts would likely be minor, with some compaction or sod fragmentation where stock congregate. Twenty-one of these meadows would be grazed, but their productivity, stream bank stability, and lack of current impacts should prevent substantial stream bank alteration, compaction, vegetation removal, or trampling to lead to any change in hydrologic function alteration.

Stream Functional Condition (PFC): Alternatives 2 should have a similar number of meadow streams remain in their current condition as Alternative 1, although one more stream would be expected to have an improved condition instead of no change in condition (Figure 4.8).

Of the 41 meadow stream segments analyzed for PFC, 26 are currently in proper functioning condition. Four of those (Superior Lake, Upper Crater Creek, Middle Deer Creek and Upper Deer Creek) could trend away from potential stream condition under this alternative because

they might be grazed more heavily than they have been recently, and streambanks will likely see some trampling and vegetation removal. Moving away from potential stream condition does not necessarily mean that the streams are expected to move to functional at-risk. It only suggests that their condition may slightly worsen, away from the potential stream condition.

Because the streams are currently functioning properly, the stream banks are not critical areas, and can be grazed up to 40 percent utilization or 20 percent streambank trampling. Although this standard may be met, the stream could still trend away from proper functioning condition with annual local stream bank trampling and vegetation removal. All of the four meadows listed above have the potential to receive the full amount of grazing allocated.

Of the meadow stream segments analyzed for PFC, 15 were found to be functional at-risk. None of these should have a downward trend because all will either be closed to grazing or rested under Alternative 2 – Modified.

Six functional at-risk meadow stream segments (Upper Ediza, NW Thousand Island Lake, Thousand Island Lake behind the moraine, Johnston Meadow, Garnet Lake and Garnet/Emerald Complex Meadows) could have an upward trend toward proper functioning condition. Grazing would be prohibited or the meadow would be rested in all cases, and the stream banks retain enough water supply and the meadows are productive enough to allow for vegetative growth on stream banks to begin improving the stream functional condition.

Meadow Soil Effects: There should be a slight improvement in soil productivity over Alternative 1. Of the 39 meadows analyzed for compaction, four were found to have moderate or severe compaction. One of those could be grazed under Alternative 2 – Modified, and therefore has the potential for continued compaction. The Forest Service Soil Quality Standards (Forest Service Handbook 2509.18) require that soil porosity should be at least 90 percent of total porosity required under natural conditions. Soil porosity was not quantitatively measured, but meadows with moderate to severe compaction could have soil compaction exceeding standards.

The meadows will likely be grazed at their recommended capacity which is similar to the current grazing, and therefore compaction should continue at its current level and extent. The three meadows with moderate to severe compaction that would not be grazed could have reduced compaction over time, although it is uncertain how long it will take compaction to fully recover.

Trails: Under Alternative 2 – Modified, the reduction of trail effects on soil and hydrologic condition could be substantial relatively to Alternative 1. The Ansel Adams East Geographic Unit has one of the highest percentages of trails with a moderate to severe resource rating. Of the 12 trails with moderate or severe resource ratings, six would be prohibited for commercial pack stock use. One of these, the trail to Emily Lake, would be closed to commercial pack stock until it is fixed. All of the trails that have moderate to severe resource ratings would be high priorities for repair to reduce erosion. The repair would likely be long-lasting on the trails closed to commercial pack stock use because it would take the impact of heavy animals off the trail. Repairs would therefore take longer to dilapidate.

The other six trails with moderate or severe resource ratings would be left open for commercial pack stock use. These trails would also likely receive repairs to increase stability and reduce erosion, but would be more likely to have the repairs wear out quickly and therefore might be slightly more likely to cause erosion problems within a few decades.

Until trail repair occurs, all 12 trails will likely continue to erode and possibly increase sedimentation into surface bodies when the trails are near water. Soil loss and local slight decreases in water quality could result.

The Shadow/Ediza Analysis Unit should have one of the greatest reduction in soil loss, soil erosion, and sedimentation from trail repair out of all analysis units. Ediza Lake is one of the few lakes in the wilderness where a trail was seen directly depositing large amounts of sediment into surface water. While many stream crossings contribute some sediment into streams, Ediza has a delta built up without being washed away, and therefore it is very obvious how much sediment is carried into the lake by the trail. The use trail from Ediza to Iceberg Lakes is the cause of the sediment, and commercial pack stock will be prohibited on the trail. While removal of pack stock itself would not prevent the trail from continuing to deposit sediment into Ediza Lake, the removal will allow rehabilitation to occur and ensure that the repairs last longer than they would with commercial pack stock use.

Campsites: Hydrologic and soils effects from campsites should become slightly less than under Alternatives 1. There will likely be very little change in bare soil area, compacted soil, or erosion from campsites into surface water. As in every other alternative, campsites within 50 to 100 feet of water should eventually be obliterated and possibly rehabilitated. Stock holding campsites will be designated under this alternative within two years, and then all stock holding sites would meet BMPs. Non-stock holding sites could take longer to bring into compliance. Stock camp site designation would prevent large campsite proliferation and therefore prevent increases in bare soil and compacted ground.

The Rush Creek and Upper Rush Creek Analysis Units are two of the only analysis units in the wilderness that is used heavily by commercial pack stock now, but will show almost the same effects under Alternative 2 – Modified. The unit is already managed in much the same way as proposed. All commercial pack stock holding sites are already designated and meet BMPs.

Any new stock camp or expanded stock holding campsites would be designated over 100 feet from surface water and would increase the area of bare and compacted soil, but would not likely affect water quality or affect the watershed overall.

Cumulative Impacts

The past, present, and reasonably foreseeable future actions in the Ansel Adams East Geographic Unit are the same as wilderness-wide. Alternative 2 – Modified is not expected to contribute to adverse cumulative impacts on soil and water resources, and should slightly reduce the risk of cumulative impacts.

In Ansel Adams East, about 20 of the 50 meadows analyzed for grazing suitability were found to be unsuitable, protecting them from grazing impacts such as fragmented sod, trampled stream banks, and vegetation removal. The rest have stock nights allocated, likely at low enough levels to prevent vegetation utilization, stream bank trampling, and soil compaction from exceeding standards. In a few meadows, use of the entire allocated stock nights could cause a minor trend away from potential hydrologic function, and in a few, grazing management could allow meadow conditions to improve. In the unlikely case that there is a major increase in private pack stock use in the area, meadow hydrologic function could worsen in a greater number of meadows.

Designation of campsites and implementation of destination quotas should prevent future cumulative effects associated with commercial pack stock use. However, continuation of hiker use and private pack stock use on trails and at campsites will likely prevent most of those areas from experiencing reductions in soil and water resource impacts.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

The Ansel Adams East Geographic Unit currently does not contain watersheds that appear to have cumulative watershed effects. Because this alternative limits the extent of use, and limits the number of stock nights in meadows, commercial pack stock use should not increase the potential for cumulative watershed effects.

Ansel Adams East – Alternative 2

Analysis

The Ansel Adams East is likely to have very little overall change in soil or hydrologic condition under Alternative 2. The difference between this alternative and Alternative 2 – Modified should be negligible, because management is almost the same. Local changes relative to Alternative 1 might be substantial in a few locations where commercial pack stock management would have the largest changes, such as at Thousand Island Lake and the Shadow-Ediza area. The greatest changes to soil and hydrologic resource condition would likely be from elimination of grazing on meadows that currently have soil and hydrologic function alteration. There should be little overall change in campsite extent or condition, and therefore campsite management should have little effect on soil or hydrologic condition.

Meadows/Wetlands: Meadow condition should improve overall in this area relative to Alternative 1, although the effects should be slight. The effects should almost be the same as under Alternative 2 – Modified, because meadow management would be different in only two meadows, the Northwest Delta of Thousand Island Lake (thi12) and Johnston Meadow (min11). Both meadows would be rested from grazing under Alternative 2 – Modified, but would be open under this alternative.

Meadow Hydrologic Function: Of the 48 meadows analyzed in the field for grazing suitability and condition, all were analyzed for hydrologic function alteration. Of these meadows, only one, the Northwest Delta of Thousand Island Lake (thi12), should have different effects to meadow hydrologic function than Alternative 2 – Modified.

Two meadows the Northwest Delta of Thousand Island Lake and Johnston Meadow (min11) would be open to grazing under Alternative 2, and both could have over 100 stock nights annually. However, it is expected that the Northwest Delta of Thousand Island Lake could have a worsening hydrologic function condition with the proposed 106 stock nights of grazing. The stream in this meadow has little vegetative cover and areas that are vulnerable to increased stock trampling, compaction, and stream bank erosion. Johnston Meadow, on the other hand, has moderate hydrologic function alteration currently, and 193 stock nights in this 22 acre meadow is not expected to be enough to further degrade meadow hydrologic function. It is assumed that the

grazing use that helped lead the meadow to its current condition was much heavier use in the past, when the meadow was used as a pasture. However, it is likely that use of 193 stock nights could maintain the meadow in its current condition with moderate hydrologic function alteration.

Stream Functional Condition (PFC): Alternatives 2 should have a similar number of meadow streams remain in their current condition as Alternative 1, although one more stream would be expected to have worse condition (Figure 4.8). The difference between this alternative and Alternative 2 – Modified should be very slight, with a difference in future stream functional condition predicted only for two meadows.

Both Johnston Meadow and the Northwest Delta of Thousand Island Lake could have worse stream functional condition under Alternative 2 than they would as described under Alternative 2 – Modified. Both meadows contain streams that were rated functional at-risk with a downward trend, and both streams are vulnerable to further stream impacts from continued grazing. Johnston Meadow has extensive bare streambanks in the upper meadow, and it is predicted that there could be an increased trend away from potential with 193 stock nights under Alternative 2 (versus a prediction of a minor upward trend under Alternative 2 – Modified). The Northwest Delta Thousand Island Lake was predicted to have an improved stream functional condition change in its stream condition under Alternative 2 – Modified, but is expected to remain in its same condition with continued grazing under Alternative 2 – Modified.

Meadow Soil Effects: There should be a slight improvement in meadow soil productivity over Alternative 1, and the effects should be almost the same as under Alternative 2 – Modified. Of the 39 meadows analyzed for compaction, four were found to have moderate or severe compaction. Two of those could be grazed under Alternative 2, and therefore have the potential for continued compaction. The Forest Service Soil Quality Standards (Forest Service Handbook 2509.18) require that soil porosity should be at least 90 percent of total porosity required under natural conditions. Soil porosity was not quantitatively measured, but meadows with moderate to severe compaction could have soil compaction exceeding standards.

The meadows will likely be grazed at their recommended capacity which is similar to the current grazing, and therefore compaction should continue at its current level and extent. The two meadows that would not be grazed could have reduced compaction over time, although it is uncertain how long it will take compaction to fully recover.

Trails: Under Alternative 2, the reduction of trail effects on soil and hydrologic condition could be substantial relatively to Alternative 1, and almost the same as under Alternative 2 – Modified. However, the continued loss of soil from trails could be more widespread under Alternative 2 than 2 – Modified. The Ansel Adams East Geographic Unit has one of the highest percentages of trails with a moderate to severe resource rating. Of the 12 trails with moderate or severe resource ratings, three would be prohibited for commercial pack stock use. These trails would be a high priority for repair to reduce erosion and the repair would likely to be long-lasting because removal of pack stock use would take the impact of heavy animals off the trail. Repairs would therefore take longer to dilapidate.

The other nine trails with moderate or severe resource ratings would be left open for commercial pack stock use. These trails would also likely receive repairs to increase stability and reduce erosion, but would be more likely to have the repairs wear out quickly and therefore might be slightly more likely to cause erosion problems within a few decades. Until trail repair occurs, the

11 trails will likely continue to erode and possibly increase sedimentation into surface bodies when the trails are near water. Soil loss and local slight decreases in water quality could result.

Campsites: Hydrologic and soils effects from campsites should become slightly less than under Alternatives 1, and likely slightly less than Alternative 2 – Modified. There will likely be very little change in bare soil area, compacted soil, or erosion from campsites into surface water. As in every other alternative, campsites within 50 to 100 feet of water should eventually be obliterated and possibly rehabilitated. Stock holding campsites will be designated under this alternative within two years, and then all stock holding sites would meet BMPs. Non-stock holding sites could take longer to bring into compliance. Stock holding site designation would prevent large campsite proliferation and therefore prevent increases in bare soil and compacted ground.

Under Alternative 2, 17 stock camps would be designated. Under Alternative 2 – Modified, about 35 stock camps would be designated. These sites would be more likely to be large sites with bare soil and some soil loss off the site. Therefore, there could be slightly less extensive bare soil from stock camps under Alternative 2. However, there would likely be a similar number of spot/dunnage sites and backpacker sites, so the overall increase should be negligible.

The Rush Creek and Upper Rush Creek Analysis Units are two of the only analysis units in the wilderness that is used heavily by commercial pack stock now, but will show almost the same effects under Alternative 2. The unit is already managed in much the same way as proposed. All commercial pack stock holding sites are already designated and meet BMPs and only one more would be designated.

Any new stock holding campsites or expanded stock holding campsites would be designated over 100 feet from surface water and would increase the area of bare and compacted soil, but would not likely affect water quality or affect the watershed overall.

Cumulative Impacts

The past, present, and reasonably foreseeable future actions in the Ansel Adams East Geographic Unit are the same as wilderness-wide. Alternative 2 is not expected to contribute to adverse cumulative impacts on soil and water resources, and should slightly reduce the risk of cumulative impacts.

In Ansel Adams East, about 20 of the 50 meadows analyzed for grazing suitability were found to be unsuitable, protecting them from grazing impacts such as fragmented sod, trampled stream banks, and vegetation removal. The rest have stock nights allocated, likely at low enough levels to prevent vegetation utilization, stream bank trampling, and soil compaction from exceeding standards. In a few meadows, use of the entire allocated stock nights could cause a minor trend away from potential hydrologic function, and in a few, grazing management could allow meadow conditions to improve. In the unlikely case that there is a major increase in private pack stock use in the area, meadow hydrologic function could worsen in a greater number of meadows.

Designation of campsites and implementation of destination quotas should prevent future cumulative effects associated with commercial pack stock use. However, continuation of hiker use and private pack stock use on trails and at campsites will likely prevent most of those areas from experiencing reductions in soil and water resource impacts.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

The Ansel Adams East Geographic Unit currently does not contain watersheds that appear to have cumulative watershed effects. Because this alternative limits the extent of use, and limits the number of stock nights in meadows, commercial pack stock use should not increase the potential for cumulative watershed effects.

Ansel Adams East – Alternative 3

Analysis

Most of the Ansel Adams East Geographic Unit should have the same soil and hydrology effects as under Alternative 2. The exception could be the Deer Creek subwatershed (Crater Creek Analysis Unit), where use might migrate when Silver Divide is limited in grazing for commercial pack stock. The areas outside of Deer Creek should have similar use patterns as under Alternative 2, because the same campsites will be designated for stock holding, and the same destinations should be as popular and get the same amount of use. Grazing prohibitions would occur in almost the same locations, although one more meadow, Holcomb Meadow, would be open to grazing under Alternative 3. Therefore, grazing effects to soil and hydrologic resources should be similar as under Alternative 2.

Meadows/Wetlands: The effects on meadows should be the same as predicted under Alternative 2 – Modified, except possibly in the Crater Creek and Cargyle Analysis Units (Figure 4.6, Table 4.66). Over most of the area, grazing management is the same. The Crater Creek and Cargyle Analysis Units are adjacent to the Cascade Valley, Silver Divide and Upper Fish Creek Analysis Units. The grazing will be curtailed in those analysis units, as under Alternative 2 – Modified. There will be no limits to travel into the Deer Creek area as there were under Alternative 2 – Modified, and therefore it is possible that use will move there. If so, grazing could be used to near the maximum grazing allowed. In Alternative 2– Modified, predictions were made based on all the grazing capacity being used, with caveats that those predictions were likely overstated because it was likely that there would be little increase in grazing from recent use.

Meadow Hydrologic Function: Of the 48 meadows analyzed for hydrologic function alteration, three are expected to have improved hydrologic function and three are expected to have slightly more altered hydrologic function. The rest are expected to remain about the same, with most meadows having little to no hydrologic function alteration.

There is very little difference between predictions for Alternatives 1 through 4 in Ansel Adams East (Figure 4.7, Table 4.69). The predictions are the same for all meadows as described under Alternative 2 – Modified.

In Alternative 3, the same range of effects as under Alternative 2 could occur in almost all meadows. However, it is more likely that more meadows could have minor increases in hydrologic function alteration because they are more likely to be grazed at their full estimated capacities.

Meadow Stream Functional Condition (PFC): Alternative 3 should have the same effects to stream functional conditions as Alternative 2 – Modified in all meadows (Figure 4.7, Table 4.69). The effects should be the same because grazing allocations are the same in all meadows. It is possible that the Deer Creek area (Crater Creek Analysis Unit) would receive more grazing under Alternative 3 because there would be less control on traveling trips and packers might begin to take more trips into the Deer Creek Area. However, even if the grazing increases to the maximum allocated stock nights annually, the changes in effects to stream functional condition should be negligible.

Meadow Soil Effects: The effect to meadow soil compaction and productivity should be almost the same under Alternative 3 as predicted under Alternative 2, with the exceptions in the Crater Creek/Deer area described above. Three separate meadows in the Crater Creek/Deer Creek area could have enough grazing to increase compaction slightly. Those meadows are; Upper Deer Creek Meadow (ccd18b), Middle Deer Creek Meadows (ccd17) and Upper Crater Meadow (ccd2).

Trails: Under Alternative 3, the reduction of trail effects on soil and hydrologic condition could be substantial, and likely very similar to Alternative 2. Only two trails that will be prohibited for commercial pack stock use in Alternative 2 will be open under Alternative 3; the Marie Lakes Trail (#1-189) and a portion of the Spooky Meadow Trail (#1-142). These trails are not being closed for resource purposes under Alternative 2 and do not currently have more than slight soil erosion. They are not likely to have increased soil loss or incision under Alternative 3 that they have currently because they are not commonly used trails and use should not increase substantially. Other than those two trails, it is likely that trail use, trail maintenance, and therefore effects of trails on soil and hydrologic resources should be the same as under Alternative 2.

Campsites: The effect of campsites on soil and water resources should be the same as under Alternative 2. Most of the same stock holding campsites and access routes to campsites will be designated, and the same sites within 100 feet of water should be obliterated. It is possible that the number of non-stock holding campsites could increase as some destinations without destination quotas that would be in place under Alternative 2. However, the sites would not be stock holding sites and therefore would likely compact soil and remove vegetation over a small area. Any new sites would also be at least 50 to 100 feet from water, and therefore would likely have few impacts to water quality.

Cumulative Impacts

The cumulative impacts of commercial pack stock use under Alternative 3, when added to other past, present and reasonably foreseeable future actions, should be slightly beneficial relative to the current condition.

Designation of stock holding campsites and implementation of grazing suitability should prevent some future cumulative effects associated with commercial pack stock use. However, continued commercial pack stock use of trails, along with continued hiker use and private pack stock use, will allow for continued trail erosion, incision, and capture of surface water. Because some trails would be closed to commercial pack stock use under Alternative 3, the effects could be slightly reduced or at least would not be as negative as under Alternative 1.

There could be slightly more negative cumulative effects to soil and water resources under Alternative 3 than under Alternative 2, because destinations would not have quotas, there could be an unlimited number of traveling trips, and fewer trails would be closed to grazing. The continuation of hiker use and private pack stock use would likely continue a very similar area of bare soil area from campsite and trail use.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

The Ansel Adams East Geographic Unit currently does not contain watersheds that appear to have cumulative watershed effects. Because this alternative limits the extent of commercial pack stock, creates fewer stock holding sites near water, and prohibits grazing in meadows that are unsuitable, commercial pack stock use should not increase the potential for cumulative watershed effects and should slightly decrease the potential.

Ansel Adams East – Alternative 4

Analysis

The Ansel Adams East Geographic Unit could have substantial reductions in negative effects to soil and hydrologic resources in some areas, but is likely to have effects similar to Alternative 2, 2 – Modified and 3 in most of its area. The Analysis Units most likely to have reductions in negative soil and hydrologic effects are Shadow/Ediza and Thousand Island Analysis Units. At least five destinations in the Shadow/Ediza and Thousand Island Analysis Units would be closed to commercial pack stock access, and stock holding and stock supported camps will no longer occur in those areas. There could be minor reductions in area of soil compacted from a reduction in the number of campsites and stock tie-up areas. However, the reduction should only be minor in local areas, and is not likely to be measurably different than under Alternatives 2 and 3.

Meadows/Wetlands/Grazing: Ansel Adams East could have some differences in grazing practices between Alternatives 2 – Modified through 4. Four meadows; Holcomb Meadow (King Analysis Unit), the meadow at the Northwest Delta of Thousand Island Lake (Thousand Island Analysis Unit), Rodgers Lake Meadows (Upper Rush) and an unnamed meadow in Crater Creek (ccd16), would be closed in Alternative 4, but open in Alternative 2, 2 – Modified and/or 3. Another meadow, Summit Meadow, will only have 46 stock nights of grazing allowed under Alternative 4, with 61 under Alternatives 2 – Modified and 3. The different watershed effects from these actions should not be noticeable at a Geographic Unit scale, although there may be some local improvement in hydrologic and soil condition at the meadows that are being closed, with associated degradation of hydrologic and soil condition at any meadows where the grazing moves.

Meadow Hydrologic Function: Although grazing is curtailed in some meadows and may increase in others, there is unlikely to be more than a minor change in hydrologic function in any one meadow or grazing zone relative to Alternative 1.

The predictions of changes in hydrologic function in Table 4.69 are based on the likely number of stock nights used, not necessarily the full proposed stock nights in areas where use is expected

to be low. However, in the text, the possible ramifications of full utilization are discussed. In some meadows, more grazing might occur, depending on whether the packer chooses to graze in a meadow or not. In the text, it is described whether it is assumed that a meadow will be used to its full allocated grazing or not. In Table 4.69 and Figure 4.7, the predictions assume that the proposed allocation is used to its fullest only where it is likely to be used.

Of the 48 meadows analyzed for hydrologic function alteration, it is expected that three would have improved hydrologic function condition while three would have hydrologic function away from potential, the same as under Alternatives 2 – Modified and 3.

In the four meadows with current moderate hydrologic function alteration, the soil and water resources effects should be the same as under Alternative 3, with three meadows expected to show improved hydrologic function alteration. Of the 12 meadows with slight hydrologic function alteration, eight are expected to remain in their current condition, two are expected to trend toward their potential, and two are expected to trend away from potential, the same as under Alternative 2 – Modified.

Of the 32 meadows that do not appear to have current hydrologic function alteration, one could have a downward trend and the rest are expected to remain in their current condition. Middle Deer Creek Meadow (ccd17) could receive up to 230 stock nights of grazing, which could cause slight compaction, slight stream bank alteration, and slight sod fragmentation that could lead to slight short term increases in hydrologic function alteration. If the alteration appears that it is persisting year to year, or that it is becoming more than slight, grazing numbers would be reduced or the meadow would be closed to grazing. It is uncertain whether the meadow would be grazed to its full proposed stock nights, but it could be because Deer Creek is near the Fish Creek watershed, where grazing is being greatly reduced. Grazing therefore may move into the Deer Creek area.

Stream Functional Condition (PFC): There is likely to be little difference overall in stream functional condition in the Ansel Adams East Geographic Unit from Alternatives 1 through 3. There should be a slight improvement of some streams' condition, however, that were not likely to improve under Alternatives 2 and 3. The majority of streams analyzed, about 75 percent, should remain in their current condition under all alternatives other than Alternative 5.

Table 4.70 shows the predicted differences between effects to stream functional condition between all alternatives. As the table shows, there should be one stream that could have a downward trend under Alternatives 2, 2 – Modified and 3 that would likely continue without any change or have improved stream function condition under Alternative 4. This meadow, Marie Meadows, would have less grazing under Alternative 4. While the difference is between 93 and 70 stock nights, and the difference in stream effects might be minor, it could be few enough stock nights that vegetation could grow back annually and prevent any loss of stream functional condition.

Meadow Soil Effects: There should be a slight improvement in soil productivity over Alternatives 1 through 3. The difference, however, would be local and not substantial on a Geographic Unit scale. Of the 39 meadows analyzed for compaction, 22 would be open to grazing. Of the four meadows that currently have moderate or severe compaction, two could continue to be grazed while two would be closed to grazing, as under Alternatives 2 and 3. Of the 35 meadows that currently have little to no compaction, it is assumed that none will have measurably increased overall compaction under Alternative 4. Although 21 of those meadows

could be grazed, the meadows have low enough proposed grazing numbers that compaction should only occur in areas where stock congregates, such as dusting areas or trails through the meadow.

Sod fragmentation does not currently appear to play a large role in reducing soil productivity in this analysis unit, and the overall impact of sod fragmentation should not change substantially under Alternative 4. However, there could be a reduction in sod fragmentation in some meadows that could increase local soil productivity. Of the 15 meadows found to have a moderate to severe of sod fragmentation, six could be grazed. Only one of those meadows should have enough grazing to allow increased sod fragmentation. The others have grazing levels the same or less than recent levels, and therefore there is no reason that sod fragmentation should increase.

Thirty-one meadows were found to have little or no sod fragmentation. Of those meadows, 15 would be open to grazing. Only two or three of the 15 would have high enough stock numbers on soil vulnerable to sod fragmentation to increase sod fragmentation. The increased sod fragmentation would likely be minor in most cases, because grazing should not occur in wet “critical” areas where sod fragmentation is most likely to occur.

Trails: The effects to trails should be similar to Alternatives 2 – Modified through 3, because although a few more trails would be closed to commercial pack stock use, they would likely not have improved condition until repair occurs. However, the trails that are not used by pack stock would have a better chance of remaining stable once repair occurs.

Cumulative Impacts

The cumulative impacts from Alternative 4 would likely be the similar as under Alternatives 2, 2 – Modified and 3. While there would be slightly less pack stock use, the difference in the Ansel Adams East Geographic Unit would be small enough that cumulatively, the effects should be negligible.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

The Ansel Adams East Geographic Unit currently does not contain watersheds that appear to have cumulative watershed effects. This alternative further limits the extent of commercial pack stock use, creates fewer stock holding sites near water, and prohibits grazing in meadows that are unsuitable and those with current impacts. Commercial pack stock use should not increase the potential for cumulative watershed effects and could slightly decrease the potential by reducing the area of ground disturbance related to commercial pack stock use.

Ansel Adams East – Alternative 5

Analysis

The Ansel Adams East Geographic Unit would likely have local improvements to current soil and water condition, but little change overall. The northern portion of the unit in the Lee Vining Creek and Rush Creek watersheds does not have any commercial pack stock use currently, and therefore there will be no changes to soil or watershed condition in that area. The rest of the

geographic unit would likely have some reduction in stream bank trampling, bare soil, soil compaction, and meadow hydrologic function alteration.

Meadows: Only a few meadows in the Ansel Adams East Geographic Unit currently have hydrologic function alteration, and therefore removal of pack stock is unlikely to have Geographic Unit scale effects to meadow soil and hydrologic condition. However, a number of meadow streams are functional at-risk, and some of those should show recovery under Alternative 5.

Meadow Hydrologic Function: Alternative 5 would likely improve meadow hydrologic function more than any other alternative, but the difference would likely be minor (Figure 4.6, Table 4.66).

Only four meadows in this geographic unit currently have moderate to severe hydrologic function alteration. Therefore, removal of commercial pack stock would not likely have major effects on the overall meadow hydrologic function, although there could be some minor improvement in those 4 meadows.

There are 12 meadows with slight hydrologic function alteration, and six have reported commercial pack stock grazing from 2001 to 2003. Six of those would be expected to have improved hydrologic function under Alternative 5. Five others should remain in their current condition. The meadows not expected to have hydrologic function recovery have hydrologic function alteration due to something other than recent pack stock grazing, such as historical grazing, drought or a trail. The meadows with trail impacts might have improved hydrologic function alteration when the trail is repaired.

Four meadows currently have moderate hydrologic function alteration, and while all have the potential to recover their hydrologic function over decades or centuries, only two are expected to show considerable change over 20 years (Table 4.69). Twelve meadows currently have slight hydrologic function alteration, and about half are expected to remain in the same condition without commercial pack stock use.

Meadow Stream Functional Condition (PFC): There should be greater improvement in stream functional condition under Alternative 5 than any other alternative. About 1/3 of analyzed streams expected to have at least slightly improved hydrologic function condition (Figure 4.8, Table 4.70). In contrast, the alternative with the next highest number of streams expected to have improved functional condition in 20 percent of analyzed streams. The other 2/3 of streams are expected to remain in their current condition, while one could have a downward trend due to drying out of the meadow from an unknown cause.

Generally, the streams that are predicted to have improved functional condition are those where there are recent pack stock impacts. Removal of pack stock use is therefore expected to allow vegetation to grow on banks and allow some improvement in stream condition. However, two meadows, Summit Meadow (Cargyle Analysis Unit) and an unnamed meadow (ccd16) in Deer Creek (Crater Deer Creek Analysis Unit) have not had any recent pack stock use reported. These meadows appear to have functional at-risk streams due to drying out of the meadow from some unknown cause, possibly drought. Removal of all pack stock use should not affect their stream condition.

Meadow Soil Condition: Few meadows in this geographic unit were found to have more than slight soil compaction or sod fragmentation, and therefore removal of all commercial pack stock

would have little effect on overall soil productivity. Four meadows were found to have moderate to severe compaction, all at least partially due to recent commercial pack stock grazing. Removal of commercial pack stock should allow compaction to slowly recover, although the rate of recovery is unknown. Within 20 years, it is likely that there would be considerable reduction in compaction.

Trails: There are a high percentage of trails in Ansel Adams East that are causing moderate to severe soil and water resource impacts. Those trails with moderate to severe impacts would likely not show reduction in those impacts with removal of pack stock, although removal of pack stock might prevent future trail incision, trail widening and multi-trailing that causes soil erosion.

Campsites: Alternative 5 should have the greatest reduction in bare soil, soil compaction, and local water quality degradation of any alternative. The reduction from current campsite area, however, should be minor in most areas other than those most heavily used by commercial pack stock, such as Shadow Lake, Thousand Island Lake, and Ediza Lake.

Cumulative Impacts

Cumulative impacts to soil and water resources are expected to be reduced under Alternative 5. The major reduction in number of meadows grazed, trails used by any pack stock, and campsites used by stock holding parties suggests that impacts should be reduced from current levels. The reduction (or improvement) in cumulative impacts under Alternative 5 would be more than any other alternative. However, in Ansel Adams East, the reduction in negative cumulative impacts should not be as major as other Geographic Units. The area is heavily used by hikers, and therefore the impacts from campsites and trails should not have major beneficial effects. Grazing has caused some hydrologic and soil effects, but the effects are generally minor to moderate and over a small extent. The cessation of commercial pack stock grazing should reduce the extent of soil compaction, stream bank trampling, sod fragmentation, and meadow hydrologic function alteration.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

The Ansel Adams East Geographic Unit currently does not contain watersheds that appear to have cumulative watershed effects. This alternative would prohibit commercial pack stock use in the wilderness. Because the total area of ground disturbance should be slightly less under Alternative 5, especially in meadows, the potential for CWEs should decrease slightly.

Ansel Adams West – Alternative 1

Analysis

In the Ansel Adams West Geographic Unit, there are likely to be very few, if any, changes to soil and water resources relative to their current condition. Most of the adverse effects to soil and water resources can be related primarily to cattle grazing that continued until the 1990s. Commercial pack stock use currently has and should continue to have effects only in a few locations within the entire geographic unit.

Meadows/Wetlands: The overall impacts of grazing to meadow hydrologic function and stream functional condition is unlikely to change under Alternative 1 or under any other alternatives. Much of the area has soil and hydrologic impacts from recent cattle grazing and could continue its slow recovery under all alternatives. The area has low levels of commercial pack stock grazing in most areas, except around Sadler Lake and Joe Crane Lake and some at Anne Lake. Only near those three locations should there be any effect from commercial pack stock grazing under Alternative 1.

The Lake Catherine and Cargyle Analysis Units are different than most of the other analysis units in Ansel Adams West because they were not recently grazed by cattle. These areas appear to have fewer impacts to soil and hydrology, likely due to the less recent cattle grazing. Both areas receive low levels of commercial pack stock use, and are likely to continue to receive light use. Currently, there are no known substantial impacts to water or soil resources other than altered hydrologic function at Stairway Meadow in the Cargyle Analysis Unit. Stairway meadow is very dry and appears to have altered hydrologic function and vegetation composition, for unknown reasons. It is expected that the meadow should gradually have improved hydrologic function if there is a series of years with high precipitation. Use is concentrated in the Stevenson-Hemlock area, where some grazing occurs. If grazing increased moderately, soil and water resources would likely not have adverse impacts because there is ample grazing available and the meadows appear to be somewhat resistant to impacts.

Meadow Hydrologic Function: Alternative 1 is likely to have the greatest number of meadows with continued hydrologic function alteration, although the difference between alternatives should be very small (Figure 4.11). Of the 29 meadows analyzed, it is assumed that five might have minor improved condition while one is likely to have a slight trend away from potential hydrologic function (Table 4.71).

Figure 4.9 A comparison of the effects of alternatives on meadow hydrologic function condition in the Ansel Adams West Geographic Unit.

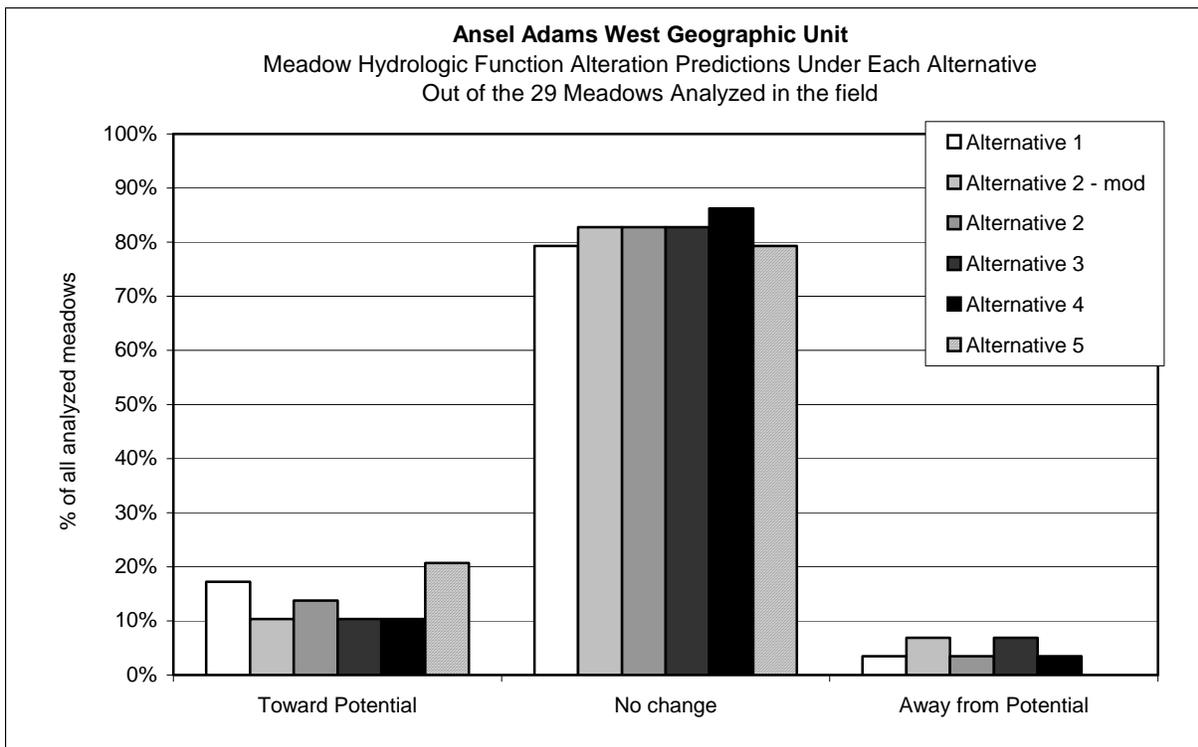

Table 4.71 Hydrologic Function Alteration Predictions for all meadows visited in the Ansel Adams West Geographic Unit. The number of meadows predicted to have each trend was estimated by the IDT, using the meadow’s characteristics such as soil moisture, stream bank stability, and meadow productivity. The predictions assume that the some meadows would not receive their allocated stock nights, if they are in an area not likely to received increased use. The prediction underestimates the worst possible effects, but is a more realistic estimation. The potential effects if all stock nights were used are included in the text.

Trends By Number of Meadows						
Current Meadow Hydrologic Function Condition (# of meadows with that condition)	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
No hydro alteration (12)

Away from Potential	1	2	1	2	1	0

It is assumed that only 2 of the 14 meadows with moderate to severe hydrologic function alteration have had enough pack stock use to have contributed to the alteration. The two meadows at Sadler Lake and between Sadler and McClure Lakes, would likely continue to be grazed at their current levels. Both have current hydrologic function alteration likely at least partially associated with recent commercial pack stock grazing. Both meadows have trampled stream banks, excessive bare soil, soil compaction, vegetation composition change and possibly lowered water tables. Continued use could increase the extent and severity of stream bank trampling and bare soil in the meadow between Sadler and McClure Lakes. That meadow has wet areas near springs that are vulnerable to increased trampling and a stream bank with little armoring from rocks or strong rooted vegetation. The meadow has upland vegetation encroachment possibly associated with a lowered water table, and with or without grazing, this would likely continue. However, the remaining wet portions of the meadow could have worse hydrologic function with continued grazing.

Four of the five meadows expected to have improved hydrologic function either have impacts from recent cattle grazing or trails. Because the cattle grazing will likely not occur in the future, these meadows are expected to have a gradual decrease in soil compaction and bare soil could reduce meadow hydrologic function. The other meadow, Stairway to Cargyle Meadow, appears to have compaction and bare soil from some unknown past disturbance. The meadow has moderate productivity and appears to be recovering. Recovery should continue if the meadow continues to receive no grazing use.

Meadow PFC: The changes in meadow stream functional condition are likely to be minor under Alternative 1, although there could be widespread minor improvement in the Ansel Adams West area under all alternatives. This alternative should have slightly fewer streams that show some improvement than the other alternatives (Figure 4.10). About 75 percent of analyzed streams are expected to remain in their current condition, while 20 percent are expected to have at least minor improvement and one is expected to move away from PFC.

Figure 4.10 A comparison of predicted changes to stream functional condition (PFC) among alternatives for the streams where PFC was analyzed in the Ansel Adams West Geographic Unit. A total of 20 streams were analyzed for PFC, all within meadows or other grazed areas. This chart includes all streams analyzed, whether they are at proper functioning condition or whether they are currently functional at-risk.

Most streams that are currently at Proper Functioning Condition should remain at Proper Functioning Condition, and most that are functional at-risk should remain so (Table 4.72). Changes in functional condition should be minor because use should not drastically increase or decrease in any area. Over time, some recovery could occur in streams that are functional at-risk, but the recovery is likely to be gradual.

Table 4.72 Summary of all meadow stream functional condition predictions for Ansel Adams West Geographic Unit under all alternatives. Stream functional condition was determined using the Proper Functioning Condition (PFC) protocol. The streams are separated by those that are currently properly functioning, those that are functional at-risk with an upward trend, those that are functional at-risk with a non apparent trend, and those that are functional at-risk with a downward trend. The predictions are based on assumptions that grazing will continue about as it has in the past in most areas, except in meadows that are closed to grazing and those nearby meadows where grazing might move to.

Current stream functional condition rating (# with each rating)	Number of Meadows expected to have each trend					
	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
Proper Functioning Condition (6)						
Toward potential	1	1	1	1	1	1
No change	5	4	5	4	4	5

Current stream functional condition rating (# with each rating)	Number of Meadows expected to have each trend					
	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
Away from potential	0	1	0	1	1	0
Functional at-risk upward trend (5)						
Toward potential	1	1	1	1	1	1
No change	4	4	4	4	4	4
Away from potential	0	0	0	0	0	0

Toward potential	2	4	4	4	4	4
No change	5	4	4	4	4	4
Away from potential	1	0	0	0	0	0
Functional at-risk downward (1)						
Toward potential	0	0	0	0	0	0
No change	1	1	1	1	1	1
Away from potential	0	0	0	0	0	0
Total Ansel Adams West (20)						
Toward potential	4	6	6	6	6	6
No change	15	13	14	13	13	14
Away from potential	1	1	0	1	1	0

The one stream that may have a trend away from PFC is in Sadler to McClure meadow, for the same reasons as discussed under the previous meadow hydrologic function section. The four streams expected to have improved functional condition are all streams that appear to have stream alteration due to past uses, and not recent pack stock grazing. They appear to be slowly growing vegetation on raw stream banks and are likely to continue this slow recovery.

Trails: The effect of trails on soil and hydrologic resources is not substantial in the Ansel Adams West Geographic Unit. The trails that do have moderate to severe water and soil effects are likely to remain in their current condition under Alternative 1. The major differences between Alternative 1 and the other alternatives is that commercial pack stock would be allowed to use almost all system trails in Alternative 1. Therefore, some trails that currently have few impacts could have increased impacts with increased commercial pack stock use. However, it is unlikely that use would change, and therefore it is assumed that the effects on soil and hydrology would be the same as currently. It is a foreseeable future action that trails with moderate to severe resource impacts would be repaired over time under all alternatives. In this Geographic Unit, only the Anne Lake, McClure Lake and Timber Creek Trails have moderate or severe resource impacts, and therefore are the trails mostly likely to receive repair. Even if these trails are repaired within 20 years, it is unlikely to make a difference to soil and water resources on a Geographic Unit scale.

The user trail into Staniford Lake from the Lillian Lakes trail is on a steep slope and is poorly defined. Therefore, multiple trails are eroding due partially to pack stock use. A campsite accessed by commercial pack stock from this trail is within 100 feet of water and is contributing slight amounts of sediment to the lake. Use of the trail and campsite would likely continue. The trail is likely to become wider and possibly more incised with continued use, although the hillside is rocky and the rocks should prevent deep incision. Over time, the erosion from the trail may enter the lake and slightly increase fine sedimentation into the lake.

Campsites: Campsites generally do not cause unacceptable impacts to soil and water resources currently in this geographic unit. They are not expected to do so under Alternative 1 because management should not change from currently management. The only areas with more than occasional commercial pack stock use are Sadler Lake and Joe Crane Lake. One major stock holding campsite at Sadler Lake is within 10 feet of an intermittent stream, and is allowing increased sedimentation into that stream. It is a foreseeable future action that the campsite would be closed, because the Wilderness Plan requires that there should be no campsites within 50 feet of water. However, until the site is obliterated, it will continue to prevent infiltration due to compacted soil and therefore allow increased runoff to carry sediment into water. Other than at Sadler Lake, few campsites would have an effect to soil or water resources beyond their immediate footprint.

A spot/dunnage campsite on the west side at Staniford Lake might be obliterated over time because it does not meet Best Management Practices (BMPs). Until obliteration, it will continue to have bare compacted soil that facilitates erosion and small amounts of sediment entering the Lake. There does not appear to be increased sediment in this lake, and do not appear to be affecting beneficial uses, nor should they under Alternative 1.

Cumulative Impacts

This alternative has been analyzed in terms of the effects of past, present and reasonably foreseeable future actions to soil and hydrologic processes in the Ansel Adams West Geographic Unit. Past actions in this geographic unit are slightly different than other Geographic Units. It is one of the few areas where widespread cattle grazing continued in the area until the mid 1990s, causing soil compaction, stream incision, stream bank trampling, vegetation composition change, and lowering of water tables in some meadows. Dams were also built in the 1930s to extend the season of fishing downstream at Lillian, Rutherford and McClure Lakes. The dams may be slightly altering stream flow downstream, but there is little evidence of impacts to stream morphology or riparian vegetation.

This Geographic Unit has some of the most widespread soil compaction, stream function condition alteration, meadow hydrologic function alteration, and general alteration of hydrologic function. This is likely mainly due to cattle grazing that continued in the area until the 1990s. There are few impacts from commercial pack stock, focused near Sadler and Joe Crane Lakes. Alternative 1 would not add to cumulative impacts, and cumulative impacts in this area would likely be the same under all alternatives. Therefore, soil and water resource impacts would continue their slow recovery from past cattle grazing, and the effects would likely continue for the next few decades or centuries in meadows with gully erosion and stream incision.

Because there is little commercial pack stock use in the area currently, outside of the Sadler and Joe Crane Lake areas, actions related to pack stock management should not affect cumulative

impacts. In those areas, recent stock grazing and trailing appears to have contributed to soil compaction, soil erosion, and alteration of meadow and stream hydrologic function. There was likely cattle grazing here within the past 15 years, and the combination of past cattle grazing combined with recent pack stock grazing and trailing has led to these impacts.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

One of the three watersheds in the Ansel Adams and John Muir Wildernesses that is known to have potential Cumulative Watershed Effects (CWEs), Granite Creek, is in the Ansel Adams West Geographic Unit.

In the Granite Creek Watershed, there would likely be no difference in CWE potential under this alternative from the current condition because commercial pack stock use is currently not widespread. Meadows that were grazed by cattle in the past and suffered soil compaction, stream bank collapse and stream incision will likely continue their slow recovery of hydrologic function and stream functional condition, and soil compaction and bare soil will begin to recover. The area has not been grazed by cattle in over 10 years, and is not likely to be grazed by cattle in the future. The recovery process will likely take decades or centuries in most of the meadows, and will show only slight improvement in 20 years. It is possible that commercial pack stock use could increase in some areas, but if so, they would likely decrease in other areas within the watershed, because there are no nearby areas with commercial pack stock use that might move to this watershed. Therefore, the effects would likely not be different watershed-wide.

In the other five watersheds (North Fork San Joaquin River, Strawberry Creek, Middle Fork, Hoffman Creek, and Four Forks), there are no known cumulative watershed effects and none are expected under Alternative 1. Commercial pack stock use should not change from its current patterns and therefore should not cause positive or negative cumulative effects to other watersheds.

Ansel Adams West – Alternative 2 – Modified

Analysis

There should be very little change in effects to soil and hydrologic function relative to current conditions. There could, however, be a slow, steady upward trend in soil and hydrologic condition as effects of recent cattle grazing continue recovering. Most of the meadows appear to have had some vegetative vigor and composition improvement, but lack of hydrologic recovery to date. Ansel Adams West would continue to receive little recreational or commercial pack stock use under Alternative 2 – Modified. Therefore, most of the meadows with hydrologic function alteration, stream function alteration, and incised trails would be allowed to continue their slow recovery.

Meadows/Wetlands: Many meadows that were visited in the field in the Ansel Adams West Geographic Unit have hydrologic and soil alteration. Although few are expected to show more than minor recovery within the next 20 years, there are two meadows near Sadler Lake where hydrologic and soils improvements might occur with changes in pack stock management.

Meadow Hydrologic Function: The Ansel Adams West Geographic Unit has the highest percentage of visited meadows with hydrologic function alteration, and few of those meadows should have more than gradual, minor improvements in hydrologic function. Over 65 percent showed moderate to severe hydrologic function alteration. Because most of the impacts observed appear to be related to recent and historic cattle grazing, there should be little effect from any action regarding commercial pack stock use. Therefore, there should be little difference between the meadow hydrologic function effects of Alternative 2 – Modified and all of the other alternatives (Figure 4.9, Table 4.71).

It is assumed that only 2 of the 12 meadows with moderate to severe hydrologic function alteration have enough pack stock use to have contributed to the alteration. One of these meadows, the meadow between Sadler and McClure Lakes (sad13), will have grazing for one trip, estimated to be 12 stock for 3 nights, or 36 stock nights. Even with this grazing reduced from a high of 127 stock nights, the hydrologic function alteration is not likely to recover fully throughout the meadow because the water table appears to have dropped and non-meadow vegetation is encroaching. These processes may not be recoverable. However, meadow compaction, stream bank trampling, sod fragmentation, and spring head trampling should decrease over time, slightly improving meadow hydrologic function.

Sadler Lake Meadows (sad12) should show improvement in meadow hydrologic function with a gradual reduction in compaction and bare soil. Grazing will still be allowed near the current levels, but will be moved to the opposite side of the lake from current grazing, and access to campsites will be designated to allow some recovery of meadow and stream hydrologic function. Moving grazing to the north side of the lake may increase local trampling, hoof punching and loss of vegetative vigor, but 53 stock nights should not be enough to cause more than slight, local impacts in this good condition meadow which should not affect meadow hydrologic function.

The meadows that appear to have hydrologic function alteration due to past cattle grazing might slowly recover their hydrologic function, but will likely show only minor trends toward potential within 20 years. Many of the meadows have lowered water tables, compacted soil, and stream bank collapse; conditions which may take decades or centuries to recover. However, up to six of these meadows appear to have hydrologic function alteration that is beginning to recover and should continue to recover in the future.

In the Cora Analysis Unit, many of the most impacted meadows may have low levels of grazing under Alternative 2 – Modified. However, the levels are low enough that they are not likely to greatly affect meadow recovery. The incision and water table lowering is so widespread in Detachment, Knoblock and Chetwood Cabin Meadows that it is unlikely they will recovery their hydrologic function within many decades. While continuation of grazing may remove stream channel stabilizing vegetation and remove some vegetation, the proposed grazing was allocated at low enough levels to allow some vegetation to slowly grow on stream banks at a similar slow speed that it occurs today.

Meadow PFC: Under Alternative 2 – Modified, most meadow streams should remain in their current condition. The difference from all other alternatives should be minimal, although there could be slightly more streams with improved functional condition under Alternative 2 – Modified than under Alternative 1 (Figure 4.10, Table 4.72). About 1/3 of the meadows could show a slight, slow improvement in stream functional condition.

Of the 20 meadow streams analyzed for stream functional condition, six are expected to show some improvement. This prediction assumes that grazing would not be as high as allowed because the area is not heavily used by commercial pack stock anywhere except near Sadler Lake. If all of the proposed grazing is used, up to four fewer meadows would likely have improved stream functional condition. Two of the six streams that could have improved condition are in Sadler to McClure Meadow and Sadler Lake Meadow. Both of the areas are currently grazed, but under Alternative 2 – Modified, grazing would be prohibited or moved to another portion of the meadow. In Sadler to McClure Meadow, areas of the meadow have high enough productivity to allow vegetation to grow on stream banks and improve stream functional condition. At Sadler Lake, grazing would be moved to the opposite side of the lake from the current grazing, and over time, there could be slight reduction in bare stream banks as vegetation grows along denuded banks.

One meadow, Stevenson Meadow (Iac1), could have a minor trend away from potential stream functional condition (PFC). The meadow had no grazing reported in the past, but could have up to 175 stock nights under Alternative 2 – Modified. While the meadow is large and was found to be able to support 175 nights of grazing within the suitable portions of the meadow, it is possible that stock would congregate in some areas along streams. If so, they could increase stream bank trampling, reduce vegetative cover on the stream bank, and cause some increased stream erosion. However, because the stock nights were calculated so that utilization would not exceed standards, and because wet areas are considered unsuitable, it is likely that the increased impacts would be minor and only local, not leading to a functional at-risk stream rating.

Many meadows in this Geographic Area have functional at-risk streams associated with recent cattle grazing. Although many of these meadows would be open to a low level of commercial pack stock grazing under Alternative 2 – Modified, it is unlikely to substantially affect their stream functional condition in most meadows. The levels of grazing proposed are low, and streams in these large meadows are expected to have vegetative growth even with light pack stock grazing.

Meadow Soil Compaction: Many meadows in this area are currently compacted, with about half of the 28 analyzed showing moderate to severe compaction. There should be a slow reduction in compaction in most of these meadows, because it is mostly related to recent cattle grazing that will not occur in the future. Of the 13 meadows known to have moderate to severe compaction, 11 could be grazed under Alternative 2. However, only five of those are likely to have substantial grazing. These five could remain compacted, but are not likely to have increased compaction because the grazing allocations are very low relative to the recent cattle grazing that caused the compaction.

In meadows that currently have little to no compaction, there could be increased grazing in a few meadows, including the Sadler Pond Meadow and Stairway Meadow. There could be slight compaction in these meadows, especially in areas where pack stock might concentrate, such as dusting areas or near stream banks. The compaction should not exceed soil quality standards overall, because grazing will be limited to the number though to retain or improve meadow condition.

Trails: There should be few changes in trail effects to soil and water under this alternative because trails are not a large portion of the effects in this Geographic Unit. Only three trails, McClure Lake, Timber Creek, and Anne Lake trails, are known to have soil and hydrologic

resource effects currently. The effects on all three trails are no greater than moderate overall with few severe areas of erosion. The trail to McClure Lake has the most severe observed effects to soil productivity because it is eroded deeply in a few steep sections, and at one spot, the sediment from the trail has covered a small portion of a meadow. This trail could continue to be used by commercial pack stock under this alternative, and the steep, eroded trail segments would be a priority for stabilization. Until the stabilization occurred, the trail would likely continue to deepen, widen, and deposit sediment on the meadow, regardless of pack stock use levels, resulting in a loss of soil on the trail itself and a loss of soil productivity on the portion of the meadow buried by the sediment. On a watershed scale, trails are cumulatively a very small portion of the watershed effects, which are overwhelmingly meadow loss of hydrologic function attributable to past cattle grazing. However, where trails encounter sensitive areas such as streams and meadow, there is often impacts to soil and water primarily due to lack of long term maintenance and in some cases poor location.

Many of the trails in this geographic unit were not visited in the field due to the lack of commercial pack stock use throughout much of the unit. The effects of the non-visited trails on hydrologic and soil resources should not change under this alternative because they will continue to receive little or no commercial pack stock use with destination quotas in place.

Campsites: Campsite effects to soil and hydrologic processes should be the same as in the wilderness scale. As in the rest of the wilderness, the largest campsites, stock holding sites, would be designated at existing sites, and contained so they would likely not grow much larger. There would be no new stock holding sites, and therefore the area of bare soil from stock holding sites would either remain static or decrease. As in all alternatives, all campsites, whether used by stock or not, would be obliterated if they are within 50 feet of water, and in some cases those within 100 feet of water would be obliterated. This would have the effect of reducing campsite area near water where the bare, compacted soil can more easily erode into surface water and locally reduce water quality. This is expected to result in slightly, possibly immeasurably small improved water quality as the number of sites near water is reduced.

Cumulative Impacts

The cumulative impacts in the Ansel Adams West Geographic Unit should be the same under Alternative 2 as under Alternative 1. Although there would be more commercial pack stock grazing restrictions and controls on the number of destinations used, most of the current cumulative soil and water resource impacts are due to recent cattle grazing, and cannot be affected by controlling commercial pack stock use.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

The Ansel Adams West Geographic Unit contains two of the three watersheds that have over 1 percent ground disturbance currently, and therefore have a potential for CWEs (Edison Reservoir and Granite Creek watersheds). These watersheds were visited in the field, and the lack of evidence of downstream effects suggests that the watersheds have not experienced CWEs. However, the relatively high percentage of meadows with moderate-to-severe hydrologic function alteration contribute to CWE potential. Alternative 2, which pertains only to

commercial pack stock use, would likely have little to no effect on CWE potential, because most of the meadow hydrologic function alteration can be attributed to recent cattle grazing. Management under Alternative 2 – Modified could allow for increased commercial pack stock grazing in meadows where grazing is suitable, but grazing levels would be controlled and would be far less than past cattle grazing. Therefore, the potential for CWEs should gradually be reduced over time as meadows recover their hydrologic function, but the differences between Alternatives 1 through 4 should be negligible.

Ansel Adams West – Alternative 2

Analysis

There should be very little change in effects to soil and hydrologic function relative to current conditions. In the Ansel Adams West Geographic Unit, there should be very little, if any difference between the effects of Alternative 2 and Alternative 2 – Modified. There could be a slow, steady upward trend in soil and hydrologic condition as effects of recent cattle grazing continue recovery. Most of the meadows appear to have had some vegetative vigor and composition improvement, but lack of hydrologic recovery to date. Ansel Adams West would continue to receive little recreational or commercial pack stock use under Alternative 2 – Modified, about the same as under Alternative 2. Therefore, most of the meadows with hydrologic function alteration, stream function alteration, and incised trails would be allowed to continue their slow recovery.

Meadows/Wetlands: Many meadows that were visited in the field in the Ansel Adams West Geographic Unit have hydrologic and soil alteration. Although few are expected to show more than minor recovery within the next 20 years, there are two meadows near Sadler Lake where hydrologic and soils improvements might occur with changes in pack stock management.

Meadow Hydrologic Function: Because most of the impacts observed appear to be related to recent and historic cattle grazing, there should be little effect from any action regarding commercial pack stock use. Therefore, there should be little difference between the meadow hydrologic function effects of Alternative 2 – Modified and all of the other alternatives (Figure 4.9, Table 4.71).

The only difference in meadow management under Alternative 2 relative to Alternative 2 – Modified is that the meadow between Sadler and McClure Lakes (sad13) would be open to one trip a year for grazing. This should be between 30 and 40 stock nights. This level of grazing should be low enough that the current severe hydrologic function alteration in the meadow should remain about the same, with a possible very slight upward trend in the wet areas. The wet areas and stream banks would have less hoof punching and less compaction, and therefore could have a negligible improvement in hydrologic function. However, much of the meadow area where lupine and lodgepole are invading into the meadow would likely stay in the same condition, with what appears to be altered hydrologic function from unknown past uses possibly combined with current grazing.

Meadows in the rest of the geographic unit should have the same effects as under Alternative 2 – Modified, because stock camp management, destination quotas, grazing management, and number of stock using the area annually should be almost the same.

Meadow Stream PFC: Under Alternative 2, most meadow streams should remain in their current condition. The difference from all other alternatives should be minimal, although there could be slightly more streams with improved functional condition under Alternative 2 than under Alternative 1 (Figure 4.10, Table 4.72). The effects should be the same as under Alternative 2 – Modified because there is only different management in one meadow, where the increase in stock nights should be small enough to make no difference in stream functional condition.

Meadow Soil Compaction: The effects would be the same as under Alternative 2 – Modified, because meadow management in the same in all but one meadow, where there could be up to 40 more stock nights of grazing, and only once per year. This grazing should occur seldom enough and be at low enough levels that compaction should not be affected.

There should be a slow reduction in compaction in most currently compacted meadows, because it is mostly related to recent cattle grazing that will not occur in the future. Of the 13 meadows known to have moderate to severe compaction, 12 could be grazed under Alternative 2. However, only five of those are likely to have substantial grazing. These five could remain compacted, but are not likely to have increased compaction because the grazing allocations are very low relative to the recent cattle grazing that caused the compaction.

Trails: There should be few changes in trail effects to soil and water under this alternative because trails are not a large portion of the effects in this Geographic Unit. The effects should be the same as under Alternative 2 – Modified because trail management and overall levels of commercial pack stock use would be almost the same. The only difference in trail management is that the Chittendon Lake Trail could not be used by commercial pack stock under Alternative 2, and it could under Alternative 2 – Modified. The trail currently does not cause soil or water resource degradation, and continuing the current use should therefore not increase soil or water resource degradation. Therefore, the effects should be the same as under Alternative 2 – Modified.

Campsites: Campsite effects to soil and hydrologic processes should be the same as in the Wilderness scale. As in the rest of the wilderness, the largest campsites, stock holding sites, would be designated at existing sites, and contained so they would likely not grow much larger. There would be no new stock holding sites, and therefore the area of bare soil from stock holding sites would either remain static or decrease. As in all alternatives, all campsites, whether used by stock or not, would be obliterated if they are within 50 feet of water, and in some cases those within 100 feet of water would be obliterated. This would have the effect of reducing campsite area near water where the bare, compacted soil can more easily erode into surface water and locally reduce water quality. This is expected to result in slightly, possibly immeasurably small improved water quality as the number of sites near water is reduced.

Cumulative Impacts

The cumulative impacts in the Ansel Adams West Geographic Unit should be the same under Alternative 2 as under Alternative 2 – Modified and Alternative 1. Although there would be more commercial pack stock grazing restrictions and controls on the number of destinations used, most of the current cumulative soil and water resource impacts are due to recent cattle grazing, and cannot be affected by controlling commercial pack stock use.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

The Ansel Adams West Geographic Unit contains two of the three watersheds that have over 1 percent ground disturbance currently, and therefore have a potential for CWEs (Edison Reservoir and Granite Creek watersheds). These watersheds were visited in the field, and the lack of evidence of downstream effects suggests that the watersheds have not experienced CWEs. However, the relatively high percentage of meadows with moderate to severe hydrologic function alteration contribute to CWE potential. Alternative 2, which pertains only to commercial pack stock use, would likely have little to no effect on CWE potential, because most of the meadow hydrologic function alteration can be attributed to recent cattle grazing. Management under Alternative 2 could allow for increased commercial pack stock grazing in meadows where grazing is suitable, but grazing levels would be controlled and would be far less than past cattle grazing. Therefore, the potential for CWEs should gradually be reduced over time as meadows recover their hydrologic function, but the differences between Alternatives 1 through 4 should be negligible.

Ansel Adams West – Alternative 3

Analysis

The effects to soil and hydrologic resources should be almost the same as under Alternative 2 – Modified, except grazing effects could be different at about three meadows due to different grazing management. The Ansel Adams West Geographic Unit only has a few areas of high commercial pack stock use, such as Sadler Lake. There are also no major areas within or near the geographic unit where use is going to be curtailed enough to move use into Ansel Adams West.

Meadows: Of the 38 meadows with proposed grazing actions, only three have different actions proposed under Alternative 3 than Alternative 2. The other meadows will likely have the same soil and hydrologic effects as predicted under Alternative 2.

The main difference between Alternative 2 and 3 is that it is possible that there could be more traveling trips under Alternative 3. Traveling trips would not be specifically restricted to a certain number. Therefore, more meadows would receive their full grazing allocation. The effects would be minimal because many of the meadows within this geographic unit already have hydrologic function alteration or streams that are functional at-risk due to past cattle grazing. While full use of proposed grazing could slow recovery of these meadows, the use is so much less than recent cattle grazing that recovery should continue in most cases.

Meadow Hydrologic Function: Overall, meadow hydrologic function effects are likely to be the same as under Alternative 2 – Modified (Figure 4.9, Table 4.71). Management would be the same in all meadows, and therefore the effects should be the same.

PFC: Stream functional condition is likely to have the same effects under Alternative 3 as it would under Alternative 2 – Modified (Figure 4.10, Table 4.72). Grazing actions are the same in all meadows, and trail use will be managed the same on all but two trails that should not affect stream functional condition.

Cumulative Impacts

The past, present and reasonably foreseeable future actions are slightly different than other Geographic Units because there have been cattle grazing in Ansel Adams West within the past 15 years. These cumulative impacts would be the same as under Alternative 2 – Modified because they are dominated by recent cattle grazing and different pack stock management would have substantial enough to effects to alter cumulative impacts.

Cumulative Watershed Effects

CWE potential would be the same under Alternative 3 as under Alternative 2 – Modified, because management would be similar enough to preclude difference in area of soil disturbance.

Ansel Adams West – Alternative 4

Analysis

Alternative 4 should have very few differences between soil and hydrologic effects than the current condition or Alternatives 1 through 3. Differences could occur with different management of pastures in this unit, but otherwise, commercial pack stock use and effects to soil and hydrologic resources should remain low.

Meadows/Wetlands: Although the meadows would be managed slightly different under Alternatives 4, in fact the use would likely be the same as Alternative 2 – Modified in most portions of this Geographic Unit. The effects to soil and hydrologic conditions should therefore be about the same.

Meadow Hydrologic Function: The effects to meadow hydrologic function under Alternative 4 should be similar to Alternative 2 – Modified and slightly better than Alternative 1 (Figure 4.9, Table 4.71). For individual meadow predictions, see the table *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under All Alternatives* in the project record. Of the 24 meadows found to be suitable under Alternative 2 – Modified, five would have stock nights level reduced by 25 percent, and two would be closed to grazing. These management changes should not make a difference to meadow hydrologic function. While a 25 percent reduction in grazing could be enough to slightly reduce vegetation utilization and stream bank trampling, the reduction should not be sufficient to change hydrologic function effects. The two additional meadows that would be closed to grazing currently have severe hydrologic function alteration. Although prohibition of grazing in these meadows could help vegetation regrow on stream banks slightly faster or allow compaction to recover slightly faster, it is assumed that the meadows would not show significant hydrologic function recovery even without grazing.

In summary, of the 29 meadows analyzed for hydrologic function, three are expected to have a trend toward potential, 25 are expected to remain in their current condition, and one could expected to have a minor trend away from its potential. The one meadow expected to have a trend away from potential, the meadow between Stairway and Cargyle Meadow, currently has no hydrologic function alteration, and therefore a slight alteration would not be expected to make the meadow functional at-risk.

Stream Functional Condition (PFC): Stream functional condition is unlikely to be different under Alternative 4 than Alternative 2 – Modified in any meadow. In the two meadows that

would be closed to grazing under Alternative 4 and not under Alternative 2 – Modified, the streams have raw banks and lowered water tables. It does not appear that vegetation has begun to stabilize banks and improve their functional condition within 10 to 15 years without cattle grazing, and it appears unlikely that vegetation will begin to grow within decades. There could be some vegetative growth on point bars if it can get established between high flows, but it appears that the process of revegetation will take a long time.

Of the 20 meadows analyzed for stream functional condition (PFC), six are expected to have a trend toward potential, thirteen are expected to remain in their current condition, and one is expected to have a minor trend away from potential. The one stream expected to have a trend away from potential (in the meadow between Stairway and Cargyle) would likely only have minor negative effects. The grazing allocated was developed to prevent impacts to vegetation, soils, and hydrologic function, and is expected to do so.

Trails: The effects of trails to soil and water resources under Alternative 4 should be about the same as under Alternative 2. Effects from trails are not a large portion of watershed effects in this GU geographic unit, and trail management would not be substantially different under Alternative 4. Only two user trails would be closed to commercial pack stock under Alternative 4 that would not be closed under Alternative 1 through 3. The trails are currently not contributing to negative soil or water resource impacts, and therefore their closure should not affect soil or water resources.

Campsites: Campsites should have a slightly reduced negative effect on soil and water quality than under Alternative 2 – Modified. All campsites would be designated within two years under Alternative 4, including spot and dunnage sites as well as stock holding sites. All sites used by commercial pack stock would therefore meet BMPs within two years. There would be reduced compacted, bare area, especially near water. The difference would be negligible on a Geographic Unit scale because only four sites were found to be allowing substances to enter water.

Cumulative Impacts

The effect of Alternative 4 on cumulative impacts should be the same as under Alternatives 1 through 3. Commercial pack stock use patterns in the Ansel Adams West are that could affect soil and water resources would likely not change under Alternative 4. Most cumulative effects appear to have a much larger contribution from recent cattle grazing than commercial pack stock use, and therefore the changes to commercial pack stock use proposed in Alternative 4 would not likely affect cumulative impacts.

Cumulative Watershed Effects (CWE)

The potential for CWEs would be the same as under Alternative 1. This is because the main contribution to CWE potential in this watershed is cattle grazed meadows, and no Alternative would affect that impact. Although only suitable meadows would be grazed under this alternative, and a few trails would be closed to commercial pack stock use, the difference in disturbed ground would be negligible in the Ansel Adams West Geographic Unit.

Ansel Adams West – Alternative 5

Analysis

The Ansel Adams West Geographic Unit is one of the GUs least likely to show a change in current condition under Alternative 5. There are low levels of commercial pack stock use in most of the analysis unit, and therefore their exclusion should not have a large effect except in the few higher use areas such as Sadler Lake. This area has the highest percentage of analyzed meadows with hydrologic function alteration, attributable mainly to recent cattle grazing. Removal of pack stock would likely not have much positive impact on those meadows.

Meadows: The effects to meadow hydrologic function and stream functional condition should be almost the same as under Alternative 4 (Figure 4.9 and Figure 4.10, Table 4.71 and Table 4.72). That is because the only two meadows with impacts attributable to commercial pack stock grazing would be closed to grazing under Alternative 4. The other meadows appear to have hydrologic function alteration and stream function alteration due to recent cattle grazing. Therefore, removal of pack stock should not have a major effect on the meadows' condition. It is likely that removal of all commercial pack stock use could allow faster recovery than if there was even low levels of pack stock grazing because stream bank vegetation would not be eaten and stream banks would not be trampled at all. This would allow maximum potential for vegetation to stabilize stream banks and the meadow surface.

Trails: The effect to trails should be the same as at the wilderness-wide scale. There are few trail impacts in this geographic unit currently, and the removal of all pack stock would reduce the potential for future impacts to soil and water resources.

Campsites: While the effect of campsites on soil productivity and water quality is slight in the Ansel Adams West Geographic Unit, Alternative 5 could allow a greater reduction in those effects over time than any other alternative. The greatest difference would likely occur at Sadler Lake, where there are currently two major and numerous minor stock holding campsites. Under the other alternatives, the existing stock sites would not be used any more, but new sites might have to be created to allow stock holding at the lake. Under Alternative 5, the sites would no longer be used and no new sites would need to be created. If left alone, the sites would likely slowly decompact and revegetate, but would likely not be covered with duff because there are few trees at Sadler Lake. It might take decades, but the sites would eventually decompact and cease erosion.

Cumulative Impacts

Cumulative impacts to soil and water resources are expected to be slightly reduced under Alternative 5 in the Ansel Adams West Geographic Unit. There are only a few meadows that are currently grazed where removal of commercial pack stock could allow some recovery of hydrologic function. Because only a few trails are used by commercial pack stock, removal of commercial pack stock from those trails should only slightly reduce erosion levels or prevent future erosion. However, the slight reduction in campsites size and trail tread width and depth could cause local reduction in negative cumulative impacts. The greater beneficial effect would be from the continued rest from cattle grazing.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

There could be a slightly reduced risk for CWE potential under Alternative 5, because the area of disturbed ground from campsites and meadows would be slightly less than under the other alternatives with removal of all commercial pack stock use. However, only two meadows; Sadler Lake Meadow and Sadler to McClure Meadow, have hydrologic function alteration attributable to recent commercial pack stock grazing. These two meadows, along with the others with cattle grazing effects, would likely take decades to recover hydrologic function. While removal of commercial pack stock grazing might hasten recovery, the differences in time of recovery would likely be slight everywhere except near Sadler Lake. The reduction in campsite area disturbed would likely be too small to affect CWEs because most campsites would continue to be used by hikers or private pack stock parties.

Fish Creek/Convict/McGee – Alternative 1

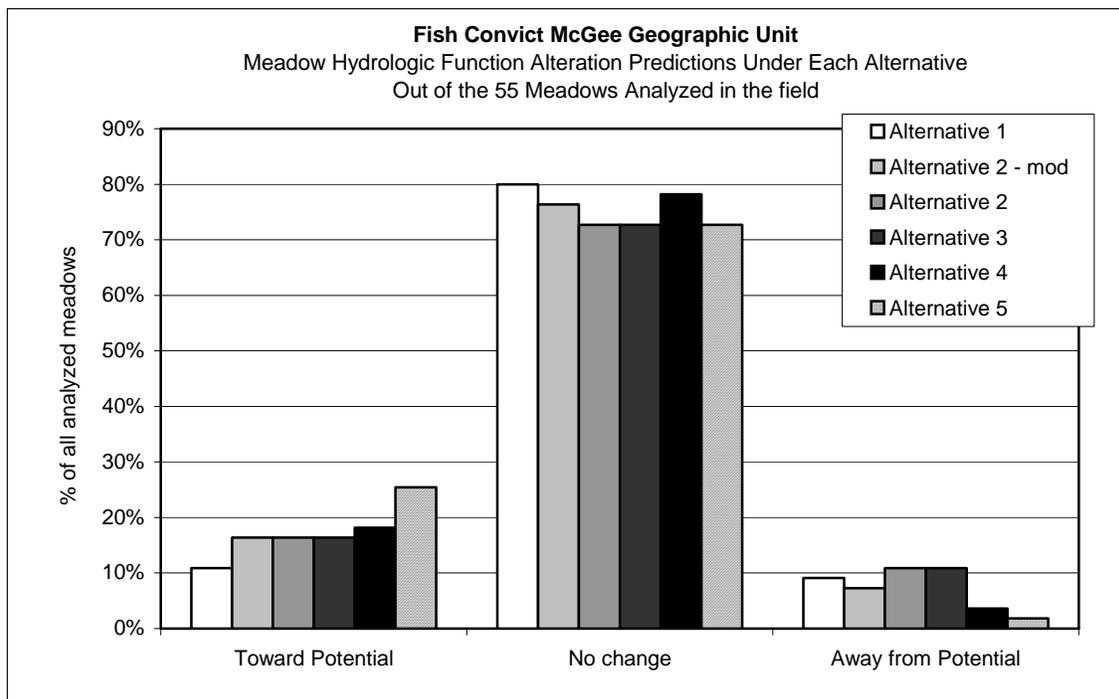

Analysis

The Fish Creek/Convict/McGee is the Geographic Unit is the area that shows the most widespread soil and hydrologic impacts at least partially attributable to recent commercial pack stock use. It contains one of the few watersheds, East Fish Creek, suspected of having cumulative watershed effects due at least partially to recent commercial pack stock use. This geographic unit is the most likely to continue to have continued widespread impacts from commercial pack stock use. It is also the most likely to show local changes in hydrologic and soil resources under all other alternatives. However, there are few existing impacts in the Convict, McGee and Margaret Lakes portions of the Geographic Unit, and they are expected to remain with little alteration of soil and water resources.

Meadows: Meadow condition is not likely to change from current condition in many locations under Alternative 1. The meadows in the Fish Creek portion of the Fish Creek/Convict/McGee Geographic Unit are the areas most likely to have differences between effects of Alternative 1 and the other alternatives because they currently has the greatest extent of negative effects due at least partially to commercial pack stock use. The action alternatives address only commercial pack stock use, and therefore are most likely to change soil and water resource conditions in the Fish Creek area. Alternative 1 is likely to have noticeably fewer meadows with improved hydrologic function.

Meadow Hydrologic Function: The Fish Creek/Convict/McGee Geographic Unit has the highest percentage of meadows found to have hydrologic function alteration of any geographic unit. That is expected to continue under Alternative 1. In all other alternatives, there is expected to be more recovery and fewer meadows trending away from potential hydrologic function condition (Figure 4.11).

Figure 4.11 A comparison of the effects of alternatives on meadow hydrologic function condition. The percent refers to the percent of all meadows that are expected to have a trend toward potential, away from potential, or remain in their existing condition.

Of the 55 meadows analyzed for hydrologic function, most are expected to remain in their current condition. About 10 percent are expected to have improved condition while 10 percent are expected to trend away from their potential hydrologic function (Table 4.73).

Table 4.73 Hydrologic Function Alteration Predictions for all meadows visited in the Fish/ Convict/McGee Analysis Unit, under all alternatives. The number of meadows predicted to have each trend was estimated by the IDT, using the meadow’s characteristics such as soil moisture, stream bank stability, and meadow productivity.

Trends By Number of Meadows						
Current Meadow Hydrologic Function Condition (# of meadows with that condition)	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5

Away from Potential	5	4	6	6	2	1

Six meadows are predicted to have improved hydrologic function condition under Alternative 1 (see *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under All Alternatives* table in project record). These are all meadows where trails are incised and diverting water out of the adjacent meadow, or historical trailing has caused headcuts to propagate into the meadow. Without trail repair, the improvement in hydrologic function would probably not occur because the incised trails will continue to capture water, and flowing water causes further incision. It is a reasonably foreseeable future action that some of these six trails, if not all, would be repaired within 20 years. If the trails are repaired, they could aggrade to a shallower trail, allowing the adjacent water table to rise up to the level of the trail. Further, trail repair would also likely include repair of headcuts propagating from the trail. With these repairs, meadow hydrologic function could improve in these meadows.

The five meadows where hydrologic function condition is expected to move away from potential all have at least slight hydrologic function alteration. They also have areas of saturated soils, stream banks with little armoring, or other areas vulnerable to hoof punching, chiseling, and compaction. All are currently grazed by commercial pack stock and are expected to be grazed in the future.

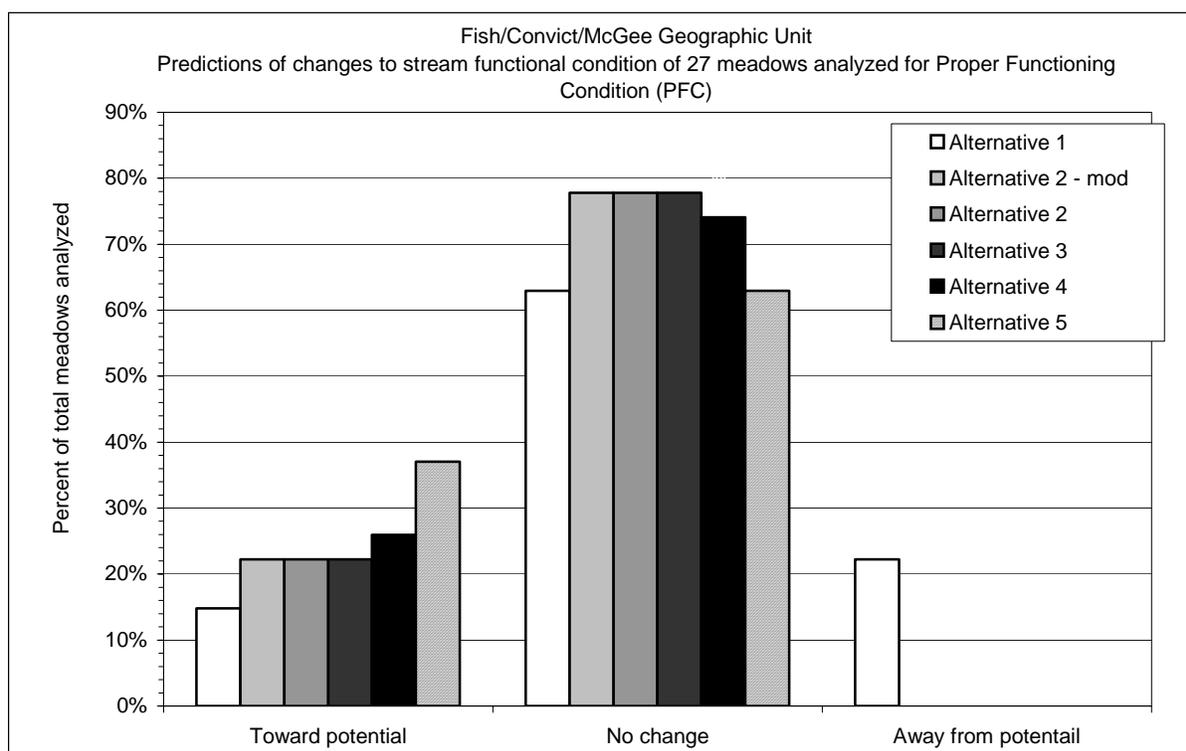

Two of these meadows, Jackson Meadow and Grassy Meadow, have the potential to have areas of permanent meadow loss if they continue to be used at the same levels as today. The upper portion of Jackson Meadow has reaches of deeply incised channels with active headcuts propagating laterally from those channels into the meadow. As the headcuts grow, the gullies below them capture water from the adjacent meadow and groundwater, and lower the water table. This process is currently occurring in Jackson Meadow, and continued grazing in the current location at recent levels would not allow vegetation to grow on the headcuts or stream banks to begin stabilizing them. Even without grazing, however, it is uncertain whether the headcuts would be stabilized by vegetation in the short-term. Active restoration of the headcuts could help prevent further propagation, but with continued grazing near the restored areas, they would be more likely to fail due to trampling and vegetation removal at the restoration sites.

Portions of Jackson Meadow are in good condition with high productivity, and continued grazing should only cause minor increases in sod fragmentation and stream bank trampling.

Grassy Meadow has incised and widened channels, and appears to have an increased sediment load in the streams above and below Grassy Lake. The meadow also has compacted soils and excessive bare soil. These effects are likely to continue and possibly worsen with continued grazing at current levels, because the streams cannot grow vegetation on their banks and begin to narrow and aggrade.

Meadow Stream Functional Condition (PFC): Stream functional condition is likely to move farther from potential in some meadows. Like meadow hydrologic function, Alternative 1 would be likely to have the most streams in poorer functional condition than any other alternative (Figure 4.12).

Figure 4.12. A comparison of predicted changes to stream functional condition (PFC) among alternatives for the streams where PFC was analyzed in the Fish Creek/Convict/McGee Geographic Unit. A total of 28 streams were analyzed for PFC, all within meadows or other grazed areas. This chart includes all streams analyzed, whether they are currently at proper functioning condition or functional at-risk.

Out of the 27 meadow streams analyzed for stream functional condition (PFC), about 60 percent of are projected to remain in their current condition. About 15 percent are expected to have improved condition and about 25 percent could move away from their potential stream condition.

The McGee Creek drainage was closed to commercial pack stock grazing from 2001 to 2003, and re-opening meadows could lead to some increased use. The one meadow expected to receive moderate levels of use is Martin's Meadow, which was grazed heavily until the mid 1990s. The meadow has streams that were functional at-risk with an upward trend in 2001, but non-functional in 2005, after a large storm in summer 2003. The stream has headcuts over four feet

tall advancing up the stream and laterally into the meadow, along trails and natural swales. Grazing could slightly increase the rate of advance of the headcuts, because streams could not grow vegetation on their banks. Due to the erosive nature of the meadow and size of the headcuts, they will likely continue to advance, increasing the length of stream with a non-functional rating, whether the meadow is grazed or not.

Four meadow streams are expected to have improved functional condition (Table 4.74). Three of those meadows are not expected to be grazed substantially by commercial pack stock under Alternative 1, because three have had little or no reported recent grazing, and the other, Second Crossing, would continue to be closed to grazing.

Table 4.74 Summary of all meadow stream functional condition predictions for the Fish/Convict/ McGee Geographic Unit under all alternatives. Stream functional condition was determined using the Proper Functioning Condition (PFC) protocol. The streams are separated by those that are currently properly functioning, those that are functional at-risk with an upward trend, those that are functional at-risk with a non-apparent trend, and those that are functional at-risk with a downward trend. The predictions are based on assumptions that grazing will continue about as it has in the past in most areas, except in meadows that are closed to grazing and those nearby meadows where grazing might move to.

Current stream functional condition rating (# with each rating)	Number of Meadows expected to have each trend					
	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
Proper Functioning Condition (15)						
Toward potential	0	0	0	0	0	3
No change	12	15	15	15	15	12
Away from potential	3	0	0	0	0	0
Functional at-risk upward trend (3)						
Toward potential	1	1	1	1	1	1
No change	2	2	2	2	2	2
Away from potential	0	0	0	0	0	0
Functional at-risk non apparent trend (4)						
Toward potential	2	2	2	2	2	2
No change	2	2	2	2	2	2
Away from potential	0	0	0	0	0	0
Functional at-risk downward (5)						
Toward potential	1	3	3	3	4	4
No change	1	2	2	2	1	1
Away from potential	3	0	0	0	0	0
Total Fish Creek/Convict/McGee (27)						
Toward potential	4	6	6	6	7	10
No change	17	21	21	21	20	17
Away from potential	6	0	0	0	0	0

Six meadow streams would be expected to trend away from their potential functional condition. All but one (Martin's Meadow) are in the Fish Creek watershed, and about half are currently functional at-risk with a downward trend. These meadows would be expected to have continued moderate to heavy levels of commercial pack stock grazing. They either have non-armored stream banks or previously disturbed stream banks that are vulnerable to pack stock grazing. Grazing at current or increased levels could prevent the stream banks from recovering, and, over time, become extensive enough to reduce the streams' ability to withstand high flows.

Trails: Trails within the Fish Creek/Convict/McGee Geographic unit are some of the most heavily used by commercial pack stock, and also have some of the most widespread severe impacts to soil and hydrologic resources. These impacts include covering 1/3 of Baldwin/Scheelore Meadow with sediment eroded from a trail, possibly lowering the water table at Peter Pande Meadow, and diversion of spring channels at Duck Lake. These impacts are likely to continue and possibly worsen until the trails are repaired. Many of the trails causing soil and water resource impacts are in meadows where the soil is saturated at least part of the year. The trails are undesirable for pack stock and hikers to walk in, and they often leave the trail and form new trails that are in the drier adjacent meadow. This activity is likely to continue as long as the trails are in the wet meadows, and therefore the loss of soil and water diversion is likely to become worse until trail repair occurs. Continued use by commercial pack stock at levels similar as recently, along with continued hiker and private pack stock use, should slowly further degrade the trails if there is extensive pack stock use, or prevent recovery.

One trail, the Baldwin Canyon Trail above Baldwin/Sheelore meadow in McGee Canyon, is a high priority for repair. It eroded during large rainstorms in 2003, and sediment from the trail covered about 15 percent of the meadow. If the trail is not repaired soon, more sedimentation into the meadow could occur and the meadow could decrease in size, reducing soil productivity and water holding capacity in the area.

Repair of the McGee and Lee/Cecil Trails is a reasonably foreseeable future action, and is proposed for the next five years. All trails within the Tully Hole, Tully Lake, Lee/Cecil Lakes and McGee Canyon would likely have major reductions in their effects to soil and water resources. This would occur under all alternatives, and the effects are only slightly dependent on commercial pack stock use.

Campsites: Campsites would likely continue their current minor impacts to soil compaction and bare soil area and slight increases in sediment into water bodies. At least 13 spot/dunnage and stock holding sites were found to be out of compliance with BMPs. Over time, those sites would be obliterated, slightly reducing substance entry into water, regardless of the levels of commercial pack stock use.

Around Jackson Meadow, the area of bare soil due to campsites has grown in recent years, and it may continue to grow. The packers would be free to hold stock at any campsite, and therefore could increase bare soil area anywhere over 100 feet from surface water.

The Convict Analysis Unit currently receives little overnight commercial stock use, and is unlikely to receive more in the future. Therefore, most commercial pack stock impacts should be to trails and to spot/dunnage campsites. These impacts are not currently major in any location and should not be so in the future.

Cumulative Impacts

This geographic unit has one of the highest levels of commercial pack stock use. It also has the highest percentage of meadows with hydrologic function alteration at least partially attributable to commercial pack stock use. Further, this area, along with most of the AA/JM Wilderness, was grazed by sheep and cattle until the early to mid 1900s. Although the geographic unit remains with less than 1 percent of its land area disturbed and likely overall good water quality, it is one of the wilderness areas most impacted by commercial pack stock use. The only other use in the area is a minor amount of private pack stock use and a high level of backpacker and day hiker use. These uses would all continue, and the commercial pack stock use would likely continue to have disproportionately high impacts for the number of people accessing the wilderness. In this area, meadows grazed by commercial pack stock appear to have the largest impact to soil and water resources, more than campsites or trails. However, trails also contributed to meadow hydrologic function alteration and to local increases in fine sediment in surface water. Trails are used by backpackers and commercial and private pack stock, and it is impossible to determine which has the greater impact. The numbers of hikers are likely far greater than the number of pack stock, but each mule or horse likely has a greater effect on trails, loosening and removing more soil than each hiker.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis, in the project record.

The Fish Creek/Convict/McGee Geographic Unit contains the only watershed that may have Cumulative Watershed Effects due at least partially to commercial pack stock use. Fish Creek is incised and widened through most of its length, the result of a flood in 1982. It is uncertain whether the creek would have incised and widened if the watershed was not heavily used by commercial pack stock. It is possible, although not certain, that long-term meadow grazing impacts (from cattle and sheep as well as commercial pack stock) or general trail degradation from pack stock and hikers exacerbated the storms' effects and allowed the creek to incise and widen.

There is less commercial pack stock use currently in the Upper Fish Creek Watershed than there was in the 1960s and 1970s, and no sheep or cattle grazing, and it is likely that there is reduced potential for cumulative watershed effects from the past. However, continued grazing of meadows allows for continued soil compaction, stream bank trampling, vegetation removal and sod fragmentation that continues stream incision and excessive erosion. These effects may not increase the potential for cumulative watershed effects, but are likely to slow or prevent recovery.

Beyond commercial pack stock use, continued use by hikers and non-commercial pack stock would continue to retain disturbed soil to campsites and trails. This use should be the same under all alternatives.

Fish Creek/Convict/McGee – Alternative 2 – Modified

Analysis

The Fish Creek/Convict/McGee Geographic Unit has the second highest percent of analyzed meadows with hydrologic function alteration, and a high percentage of trails that affect soil and hydrologic function. The greatest impacts are in the upper Fish Creek watershed (Upper Fish Creek, Silver Divide, Cascade Valley and Purple Bench Analysis Units), and therefore the greatest resource improvement due to pack stock management change are likely to occur there under all action alternatives. In fact, out of the entire wilderness area, the Upper Fish Creek watershed is the area likely to see the greatest improvement in soil and hydrologic resource condition under Alternative 2 – Modified.

Meadows: The highest commercial pack stock grazing densities are in this Geographic Unit, and the largest reductions in grazing densities would be here. It is one of the few areas where the total maximum number of grazing nights would be reduced under Alternative 2 – Modified. The area currently has some of the most widespread hydrologic function and stream function alteration of all GUs. This geographic unit does not have as severe or widespread alteration of soil and hydrologic function as those that are grazed by cattle, however. It therefore has a greater chance of improvement under this action which applies only to commercial pack stock use.

Under Alternative 2 – Modified, there would be a one night stay limit for each traveling trip through the Silver Divide Analysis Unit. It is unknown whether this will reduce the demand for grazing enough that grazing allocations would not be fully used in some meadows. If the demand is greater than the available allocation, it will be difficult for the packers to find grazing nearby, and feed may need to be packed in.

Meadow Hydrologic Function: Meadow hydrologic function should improve more than under Alternative 1 overall (Figure 4.11, Table 4.73). Meadows within the Fish Creek/Convict/McGee Geographic Unit have different causes for their hydrologic function alteration, and therefore have different degrees of recovery estimated. For example, Cascade Valley Meadow is unlikely to show hydrologic function improvement even with very little grazing because the alteration is due to Fish Creek being incised throughout the valley. Aggradation of Fish Creek may never occur or may occur over centuries. Fish Creek incised in 1982 during a large flood, and appears to continue to widen. Point bars within the creek have little vegetation growing on them yet, and we assume there will not be much more recovery in the next 20 years. Grassy Meadow, on the other hand, has extensive areas with incised channels, but the water source for the meadow appears to largely be springs, and therefore even with an incised channel, the meadow should get enough water to quickly grow vegetation on stream banks and in the meadow with removal of grazing.

Of the 23 meadows found to have no hydrologic function alteration, all but one is expected to remain in their current condition. The Canyon West of Olive Lake (sil15) could have increases in grazing from none to 114 stock nights if the packers choose to graze their stock there. The meadow is suitable for grazing, but due to low productivity, any hoof punching, stream bank trampling, or vegetation removal may persist from year to year and eventually lead to slight alteration of meadow hydrologic function. If this begins to occur, the meadows will likely have grazing reduced or prohibited. In the long term, the meadow should only have very slight or no hydrologic function alteration.

Of the 23 meadows with slight hydrologic function alteration, 15 are expected to remain in their current condition, six are expected to have some trend toward potential, and two could have a trend away from potential.

Of the four meadows with moderate hydrologic function alteration, two are expected to have no change, while one each is expected to move toward and away from potential.

Of the five meadows found to have severe hydrologic function alteration, three are expected to remain in their current condition, and two may have a trend toward potential hydrologic function.

The six meadows that are expected to have a trend away from their potential could all receive more or the same levels of commercial pack stock grazing as they have recently. They also all have low to moderate productivity or some saturated soil areas that make the meadow vulnerable to sod fragmentation, stream bank trampling, and bare soil creation. Because grazing stock nights were developed considering meadow capacity, these effects should be minor and within standards.

No grazing will occur in the Convict Analysis Unit, and only 14 grazing nights were used from 2001 to 2003. Therefore, there should continue to be few to no effects to meadow soil or hydrologic resource from grazing.

Meadow Stream Functional Condition (PFC): Stream functional condition would be expected to improve in almost ¼ of analyzed meadows, more than under Alternative 1 (Figure 4.12). Currently, 15 of the analyzed stream segments are properly functioning, while 12 are functional at-risk.

Of the 15 streams rated at PFC, all are expected to remain in their current condition (Table 4.74). Of the 12 streams rated functional at-risk, six are expected to remain in their current condition, six could have a trend toward their potential, and none should trend away from their potential.

Those stream segments expected to have a trend toward their potential will either have grazing removed, reduced, or remain about the same as recent reported use. These meadows all have their water source intact over most of the meadow and have moderate to high productivity. Therefore, vegetation can grow back on stream banks relatively quickly and improve the ability of the stream to withstand high flows. No meadows where streams were rated for PFC should have a trend away from potential. However, two stream segments with a current unknown rating could have a trend away from their potential (Box Canyon above Grassy and Olive Lake West) could have grazing increased from 2001 to 2003 use, and have low to moderate productivity. If the packers keep their stock away from vulnerable streambanks, the streams will likely either remain in their current state or move closer to their potential, as vegetation will have a chance to slowly grow on the streambanks. If the commercial pack station operators cannot avoid further trampling sensitive streambanks, it is a foreseeable future action that these meadows would be closed or the recommended stock nights would be reduced. In Martin's Meadow, as discussed under Alternative 1, the stream is likely to have an increased length of non-functional stream whether it is grazed or not.

For individual meadow predictions under all alternatives, see the table *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under All Alternatives* in the project record.

Meadow Soil Effects: Of the 14 meadows that currently have moderate to severe compaction, six could be grazed under Alternative 2 – Modified. The grazing would only be over 40 stock

nights at Tully Hole Meadow and Horse Heaven. The allotted grazing is not likely enough to increase compaction beyond its current state, because it is lower than past reported grazing, which is assumed to have caused the compaction.

Trails: The contribution from trails to soil erosion and local water quality degradation should be less than currently and under Alternative 1 and 3, but greater than Alternatives 4 and 5. Under this Alternative, five of the 14 trails with a moderate to severe resource rating would not be used by commercial pack stock. While removal of commercial pack stock alone will not usually allow a trail to stop eroding, the removal of stock will allow for more easily constructed, longer term repair that should reduce erosion once it is completed. Coupled with trail repair, removal of pack stock could reduce erosion and subsequent sedimentation into surface water.

Campsites: This geographic unit should not have substantially different effects to campsites than any other geographic unit or Alternatives 3 through 5. As in other Geographic Units, stock holding sites will be designated and there should be about the same number or fewer than today. All campsites less than 50 feet from water and some less than 100 feet of water would eventually stop being used and possibly be rehabilitated over time, reducing the chance of water quality degradation and soil erosion. All stock holding or spot/dunnage sites would be designated, and would be designed to meet BMPs. Within 2 years, all commercial pack stock-related campsites would meet BMPs. Therefore, there could be a slight reduction of sediment and manure entering water from campsites.

Cumulative Impacts

The Fish Creek/Convict/McGee Geographic Unit contains some of the areas most likely to have reduced soil and water resource impacts. It is the area with the second highest incidence of meadow hydrologic function alteration and stream functional condition (PFC) alteration.

The reduction in negative cumulative impacts is most likely within the Fish Creek Watershed, including the Silver Divide, Upper Fish Creek, Purple Bench and Cascade Valley Analysis Units. In this area, the current impacts, including stream incision, meadow hydrologic function alteration, and local increased sedimentation into surface water, are likely at least partially attributable to recent commercial pack stock use, particularly grazing and trail use. Past uses including commercial pack stock grazing, possibly livestock grazing, and recreational use, and concurrent uses including private pack stock use and hiker use, likely also contributed to the soil and water resource conditions. Because the Fish Creek Watershed is one of the areas with the greatest impacts related to recent commercial pack stock use, it is one of the areas where more stringent management proposed in Alternative 2 – Modified has the potential to reduce negative impacts.

Although other uses, such as private pack stock use and hiker use, would continue to occur, commercial pack stock use is relatively heavy within the Fish Creek Watershed, and reduction of that use would likely help reduce impacts. Within Fish Creek, there would be a one night stay for traveling commercial pack stock trips, 29 of the 55 meadows analyzed would be closed to grazing, and campsites would be designated. These actions would help reduce the extent of pack stock use, the duration of grazing, and would likely allow improved meadow condition, improved stream condition, and a slight reduction in bare soil from campsites.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis* in the project record.

In summary, the Fish Creek Watershed within the Fish Creek/Convict/McGee Geographic Unit is the only watershed that may have cumulative watershed effects at least partially related to commercial pack stock use of trails and grazing of meadows. Although it is uncertain whether the cause was natural or related to heavy use of the area, Fish Creek incised and widened during a storm in 1982 along much of its length. It is possible that the reduced water holding capacity in meadows upstream, tributary incision, or incision at trail crossings contributed to the incision of the main Fish Creek channel. The Fish Creek Watershed has some of the highest levels of commercial pack stock use and commercial pack stock grazing. It is also used by the greatest number of separate commercial pack stations. Under Alternative 2 – Modified, reductions in grazing stock nights, a reduction in the number of traveling trips through the area, and a reduction in the number of pack stations allowed to use the area would all likely result in less commercial pack stock use and fewer soil and water impacts associated with that use. Therefore, the potential for cumulative watershed effects should slightly decrease in the long-term.

Fish Creek/Convict/McGee – Alternative 2

Analysis

The Fish Creek/Convict/McGee Geographic Unit has the second highest percent of analyzed meadows with hydrologic function alteration, and a high percentage of trails that affect soil and hydrologic function. The greatest impacts are in the upper Fish Creek watershed (Upper Fish Creek, Silver Divide, Cascade Valley and Purple Bench Analysis Units), and therefore the greatest resource improvement due to pack stock management change are likely to occur there under all action alternatives. In fact, out of the entire Wilderness area, the Upper Fish Creek watershed is the area most likely to see the improvement in soil and hydrologic resource condition under Alternative 2.

Meadows: The highest current commercial pack stock grazing densities are in this Geographic Unit, and the largest reductions in grazing densities under Alternative 2 would be here. It is one of the few areas where the total number of grazing nights would be reduced under Alternative 2. The effects would be very similar as under Alternative 2 – Modified because there would be substantially different management in only 3 meadows, and other management, such as a one-night stay in the geographic unit, designated stock holding campsites, and destination quotas, would be the same.

Meadow Hydrologic Function: Meadow hydrologic function should be the same overall as under Alternative 2 – Modified, except in two meadows (Figure 4.11, Table 4.73).

The two meadows where hydrologic function predictions are different are The Box Canyon above Grassy (sil2) and Rainbow to Margaret (mar4). The Box Canyon above Grassy would not be grazed under Alternative 2 – Modified, but would be grazed under this alternative. Because the area has relatively low productivity and is vulnerable to compaction, it is possible that the increase in stock nights from none to 67 could cause a slight downward shift in hydrologic function. In the meadow between Rainbow and Margaret Lakes, there is an old trail that is

locally affecting the meadow's hydrologic function by diverting groundwater into the trail that is incised about three feet. Allowing up to 127 stock nights in this meadow, as proposed under Alternative 2, could cause a slight downward shift in meadow hydrologic function as the area around the trail is hoof punched and vegetation is removed. Under Alternative 2 – Modified, it was predicted that there would be no change in the meadow's current slight hydrologic function. Under this alternative, it is unlikely that 127 stock nights would be used in this meadow, as only 4 were reported in the past, and there are no nearby areas being closed to grazing. Therefore, the differences between the alternatives in this meadow could be negligible.

Meadow Stream Functional Condition (PFC): Stream functional condition would be expected to improve in up to ¼ of analyzed meadows, the same as under Alternative 2 – Modified (Figure 4.12). Management would be different in six meadows in the Fish Creek/Convict/McGee Geographic Unit, but the difference to stream functional condition would be negligible because the difference in management is not substantial in any meadow where stream functional condition is known. It is possible that the Box Canyon above Grassy (sil2) could have a trend away from potential stream functional condition under Alternative 2, although current stream condition as defined using the PFC protocol is unknown. It is known that the access trail to the meadow is in a stream for a short distance, and use of this trail to access the grazing area could increase hoof punching, stream bank disturbance, and nickpoints within the stream.

For individual meadow predictions under all alternatives, see the table *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under All Alternatives* in the project record.

Meadow Soil Effects: Of the 14 meadows that currently have moderate to severe compaction, 6 could be grazed under Alternative 2. The grazing would only be substantial numbers at Tully Hole Meadow and Horse Heaven. The allotted grazing is not likely enough to increase compaction beyond its current state, because it is lower than past reported grazing, which is assumed to have caused the compaction. Compaction overall is likely to be about the same as under Alternatives 2 – Modified, 3 and 4, slightly less than under Alternative 1, and more than under Alternative 5.

Trails: The contribution from trails to soil erosion and local water quality degradation should be almost the same as under Alternative 2 – Modified. Under this Alternative, 6 of the 14 trails with a moderate to severe resource rating would not be used by commercial pack stock. While removal of commercial pack stock alone will not usually allow a trail to stop eroding, the removal of stock will allow for more easily constructed, longer term repair that should reduce erosion once it is completed. Coupled with trail repair, removal of pack stock could reduce erosion and subsequent sedimentation into surface water.

Campsites: This geographic unit should not have substantially different effects to campsites than any other geographic unit or Alternatives 3 through 5. As in other geographic units, stock holding sites will be designated and there should be about the same number or slightly fewer than today. All campsites less than 50 feet from water and some less than 100 feet of water would eventually stop being used and possibly be rehabilitated over time, reducing the chance of water quality degradation and soil erosion. All stock holding or spot/dunnage sites would be designated, and would be designed to meet BMPs. Within two years, all commercial pack stock-related campsites would meet BMPs. Therefore, there could be a slight reduction of sediment and manure entering water from campsites.

Cumulative Impacts

The Fish Creek/Convict/McGee Geographic Unit contains some of the areas most likely to have reduced soil and water resource impacts. It is the area with the second highest incidence of meadow hydrologic function alteration and stream functional condition (PFC) alteration.

The reduction in negative cumulative impacts is most likely within the Fish Creek Watershed, including the Silver Divide, Upper Fish Creek, Purple Bench and Cascade Valley Analysis Units. In this area, the current impacts, including stream incision, meadow hydrologic function alteration, and local increased sedimentation into surface water, are likely at least partially attributable to recent commercial pack stock use, particularly grazing and trail use. Past uses including commercial pack stock grazing, possibly livestock grazing, and recreational use, and concurrent uses including private pack stock use and hiker use, likely also contributed to the soil and water resource conditions. Because the Fish Creek Watershed is one of the areas with the greatest impacts related to recent commercial pack stock use, it is one of the areas where more stringent management proposed in Alternative 2 has the potential to reduce negative impacts.

Although other uses, such as private pack stock use and hiker use, would continue to occur, commercial pack stock use is relatively heavy within the Fish Creek Watershed, and reduction of that use would likely help reduce impacts. Within Fish Creek, there would be a one night stay for traveling commercial pack stock trips, 17 of the 28 meadows analyzed would be closed to grazing, and campsites would be designated. These actions would help reduce the extent of pack stock use, the duration of grazing, and would likely allow improved meadow condition, improved stream condition, and a slight reduction in bare soil from campsites.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial pack stock use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis* in the project record.

In summary, the Fish Creek Watershed within the Fish Creek/Convict/McGee Geographic Unit is the only watershed that may have cumulative watershed effects at least partially related to commercial pack stock use of trails and grazing of meadows. Although it is uncertain whether the cause was natural or related to heavy use of the area, Fish Creek incised and widened during a storm in 1982 along much of its length. It is possible that the reduced water holding capacity in meadows upstream, tributary incision, or incision at trail crossings contributed to the incision of the main Fish Creek channel. The Fish Creek Watershed has some of the highest levels of commercial pack stock use and commercial pack stock grazing. It is also used by the greatest number of separate commercial pack stations. Under Alternative 2, reductions in grazing stock nights, a reduction in the number of traveling trips through the area, and a reduction in the number of pack stations allowed to use the area would all likely result in less commercial pack stock use and fewer soil and water impacts associated with that use. Therefore, the potential for cumulative watershed effects should slightly decrease in the long-term.

Fish Creek/Convict/McGee – Alternative 3

Analysis

The effect to soil and hydrologic resources should be the same under Alternative 3 as they are under Alternative 2 – Modified. There could potentially be more traveling trips to the area in Alternative 3, as in the other Geographic Units. The only substantial difference in effects to soil and hydrologic resources should be the lack of a one night stay under Alternative 3 in the Upper Fish Creek, Cascade Valley, Purple and Silver Divide Analysis Units. Therefore, traveling trips might be more likely to remain longer in those areas, possibly creating larger campsites as stock could be brought in and out of camp more times per year, creating more social trails and general bare area due to increased stock movement. However, because grazing would still be limited under Alternative 3, traveling trips might not use this area as heavily as they have in the past if the packers decide not to pack in feed, and they may not create larger campsites or more bare area.

Meadows/Grazing: Grazing would be managed the same as Alternative 2 in all meadows, and therefore there should be no specific grazing area with different effects.

However, in some portions of the Fish Creek/Convict/McGee Geographic Unit, mainly in the Margaret Analysis Unit, Alternative 3 would allow for less predictability for meadow effects. Throughout the Margaret Analysis Unit, few meadows are currently grazed, and under Alternatives 1, 2 – Modified, and 2, hundreds of stock nights of grazing would be allocated. However, under Alternatives 2, quotas would allow only minor increases in spot/dunnage trips or traveling trips, and the increased use would be spread across the analysis unit. Under this alternative, there would be no quotas on traveling trips or spot/dunnage trips. Therefore, if a packer wished to increase use in one area and use all of the allocated stock nights of grazing, it is possible that meadows could see greatly increased use. The predictions for meadow hydrologic function and stream functional condition changes would be the same as under Alternative 2, however, because the differences in the effects of partial and full utilization of stock nights is not well understood, and the worst effects were assumed in this case.

Trails: There are about six trails where commercial pack stock will be allowed to travel under Alternative 3 where they would not be allowed to travel under Alternative 2. All the trails could have a slightly increased potential for erosion under Alternative 3, but none are heavily used now nor would they be likely to be heavily used in the future. Therefore, the erosion potential is not likely to be measurably larger. There are two trails that would provide access to destinations that would not be accessible under Alternative 2. The destinations are Sharktooth Lake and Ram Lake. There could be slightly more bare ground due to dunnage campsites at these locations under Alternative 3 and therefore slightly reduced infiltration and possibly increased soil loss. However, the designated sites would be over 100 feet from water and therefore there should not be increased sediment delivery to water or other effects on water quality.

Cumulative Impacts

The cumulative effects should be the same as under Alternative 2, because past, present, and reasonably foreseeable future actions are the same, and management is similar enough that the difference in cumulative effects should be negligible.

Fish Creek/Convict/McGee – Alternative 4

Analysis

As under Alternatives 2, 2 – Modified and 3, the Fish Creek/Convict/McGee is the Geographic Unit that is most likely to have changes from the current condition. The area has been used heavily by commercial pack stock recently, and has soil and water resource effects likely attributable to recent commercial pack stock use. The greatest reduction in soil and water resource effects is likely to be from reduction of grazing in this area. However, reduction of use on trails and campsites could also reduce soil compaction and erosion, and local water quality degradation and alteration of stream morphology.

Meadows: Portions of this geographic unit should see the greatest reductions in commercial pack stock grazing compared to other Geographic Units. From 2001 to 2003, the largest number of stock nights of grazing reported in this Geographic Unit was 2002, with over 2,100 stock nights reported. Roughly the same number of stock nights may be expected annually under Alternative 1. Under Alternatives 2 and 3, about 1,600 stock nights is the recommended high. Under this alternative, the recommended high stock nights of grazing are less than 800 annually. It is unknown how much grazing would be use by private stock.

The reductions in pack stock grazing are likely to lead to improvement of meadow soil and hydrologic function conditions over time. The improvement should be especially noticeable in the Silver Divide, Upper Fish Creek, Cascade Valley, and Purple Bench Analysis Units because they currently show negative soil and hydrologic effects from pack stock. In those analysis units combined, the largest number of stock nights of grazing reported was in 2002, at about 1,350 stock nights. Roughly the same number of stock nights could be expected annually under Alternative 1. Under Alternatives 2, 2 – Modified and 3, about 900 stock nights of grazing is the recommended high. Under this alternative, the recommended high stock nights of grazing is about 270 annually, or less than 1/3 of the recent reported use. It is unknown how much grazing would be use by private stock.

Decreased grazing in this geographic unit could lead to increased grazing in other nearby Geographic Units, especially Ansel Adams East, which is easily accessed from the Fish Creek area. Under Alternative 4, however, grazing would also be limited in other geographic units, and each meadow or grazing zone will have an allocation that would not cap grazing. The effects of increases in other areas are discussed in their geographic unit section.

Meadow Hydrologic Function: Of the 55 meadows analyzed for hydrologic function, it is expected that 43 would remain in their current condition, while 10 could show some improvement in hydrologic function and two could show downward trend in hydrologic function.

The number of meadows with hydrologic function alteration under Alternative 4 should be less than Alternative 1 and similar as under Alternatives 2 and 3, although there should be slightly fewer meadows with hydrologic function alteration (Table 4.73, Figure 4.11). Four meadows that would be open under Alternative 2 – Modified would be closed to commercial pack stock grazing under Alternative 4. Three of the four meadows that would be closed under Alternative 4 were predicted to have slightly worsened hydrologic function under Alternative 2 – Modified and should have static condition under Alternative 4. Six other meadows would have decreased

grazing allocations, and one, the meadow between Rainbow and Margaret Lakes (mar4) may have reduced hydrologic function alteration under Alternative 4.

Meadow PFC: The number of streams with a trend toward proper functioning should be similar under Alternative 4 as under Alternative 2 – Modified (Figure 4.12, Table 4.74). There are only 2 streams out of the 28 analyzed for PFC that are expected to have any noticeable difference in stream functional condition under the two alternatives. Olive Lake West would be closed to grazing under Alternative 4, and therefore should have static, good stream condition. Jackson Meadow (sil8) contains the stream most likely to show some change from current condition. Under Alternative 4, the meadow would have no commercial pack stock grazing, where the recent high was 318 stock nights. Although the very upper portion of the meadow has low productivity and streams are not likely to show improved condition, the streams in the middle portion of the meadow could have some vegetation grow on banks because the productivity is higher in that portion of the meadow.

Trails: There could be slight reduction in soil and water resource impacts from trails under Alternative 4. Under this alternative, 7 out of 51 system trails would be closed to commercial pack stock use that would not be closed under Alternatives 1 through 3. The greatest effect is likely the reduction of use at the destinations accessed by those seven trails. Beyond a reduction in system trail use, there would also be the associated reduction in campsite use and user trail use. There could be a subsequent gradual reduction in area of compacted and bare soil, and some local reduction of sedimentation into surface water. Geographic Unit wide, the difference is likely to be minimal.

Campsites: There could be a slight reduction in bare soil and compacted soil under Alternative 4. All stock holding and spot/dunnage sites would be designated. While backpackers would still use most sites, stock holding and spot/dunnage sites at popular commercial pack stock areas, such as those at Jackson and Grassy Meadows, could be reduced in numbers. While the sites would likely take decades to decompact and grow vegetation, duff would likely cover the sites after a few years and lessen the volume of soil lost through erosion.

Cumulative Impacts

Negative cumulative impacts are expected to be slightly reduced under Alternative 4. The overall reduction in number of meadows grazed, the reduced stock nights, and fewer trails approved for commercial pack stock use suggests the potential for a cumulative impact is unlikely when compared to the existing condition. The reduction (or improvement) in cumulative impacts under Alternative 4 is less than Alternatives 1 through 3 and greater than alternative 5. Current effects from hikers and non-commercial pack stock would remain the same, and therefore most campsites and trails would remain in their current condition, because most campsites and trails are used by non-commercial users.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis* in the project record.

Cumulative Watershed Effects should be similar as under Alternative 2 – Modified, although there could be a greater reduction in CWE potential. The only watershed in the area with

suspected potential CWEs is the East Fish Creek Watershed. Grazing would be reduced in this watershed from a reported high of 1,340 stock nights to about 270, while it was about 900 under Alternative 2. Therefore, although the number of campsites and trail condition should be the same as under Alternative 2 – Modified, the reduced grazing should reduce the overall area of disturbed ground and hydrologic function alteration over the long-term.

Fish Creek/Convict/McGee – Alternative 5

Analysis

The Fish Creek/Convict/McGee Geographic Unit is likely to have the largest improvement to soil and water resource condition out of any geographic unit. Alternative 5 would likely have the least negative impacts of any alternatives. This geographic unit is likely the only one that contains a watershed that could have a noticeable reduction in cumulative watershed effects under Alternative 5. The improvement should be the greatest in the Fish Creek Watershed, in the Silver Divide, Upper Fish Creek, Cascade Valley and Purple Analysis Units. Those areas receive some of the highest levels of commercial pack stock use in the Ansel Adams and John Muir Wilderness areas, and therefore should have the largest change to resource impacts with removal of all commercial pack stock. The greatest improvement should be with removal of grazing, which could lead to improvement in stream functional condition, meadow hydrologic function, and soil productivity.

Meadows: Alternative 5 is likely to allow more meadows to have improved hydrologic function condition than any other alternative (Figure 4.11, Table 4.73). The difference between meadow conditions under Alternative 1 and Alternative 5 could be substantial. This area has some of the most severe and widespread impacts to meadow hydrologic function at least partially attributable to recent pack stock grazing, and removal of pack stock grazing could therefore have the greatest positive effect.

Meadow Hydrologic Function: Alternative 5 should have the least negative effect to meadow hydrologic function out of any alternative, although the difference between Alternatives 4 and 5 should be slight (Figure 4.11). Of the 55 meadows analyzed, about 27 percent are expected to show improved hydrologic function condition. Under Alternative 4, about 20 percent of meadows are expected to show improved hydrologic function condition.

Of the 32 meadows that currently have at least slight hydrologic function alteration; about half are likely to remain in their current condition. Almost all of these meadows, other than Tully Hole, have hydrologic function alteration mostly due to other uses than recent commercial pack stock grazing, such as an historical trail or incisement of Fish Creek. Therefore, removal of pack stock use is not likely to allow any recovery of hydrologic function. In the case of Tully Hole, its moderate hydrologic function alteration is likely related to commercial pack stock grazing. However, the alteration includes hummocks and a slightly incised stream channel, which could both take decades or centuries to return to a more natural condition.

Meadow Stream Functional Condition (PFC): Alternative 5 is likely to have the most streams with improved stream functional condition out of all alternatives, and the most widespread improvement from current conditions (Figure 4.12, Table 4.74). The difference in this geographic unit could be larger than any other geographic unit.

Of the 27 meadow streams analyzed for PFC, it is projected that 37 percent could have improved functional condition under Alternative 5. In contrast, only 15 percent are expected to have improved condition under Alternative 1. The difference is because all meadows would be closed to commercial pack stock grazing, and many meadows of these meadows have been grazed heavily by commercial pack stock in the recent past. The recent heavy pack stock grazing appears to be at least partially responsible for the reduction of stream functional condition, and removal of all grazing should allow maximum recovery.

Trails: The effects to soil and water resources should be the same as under the wilderness scale. It is a foreseeable future action that trails in the McGee, Silver Divide and Upper Fish Creek Analysis Units would have major repair. The trail project is proposed for implementation before 2010. If the project receives funding, the most impactful trails would be stabilized and could have reduced soil loss and reduced diversion of surface water in those analysis units.

Campsites: The effects to soil and water resources should be the same as under the wilderness scale. The greatest reduction in the extent of bare and compacted soil from campsites should be in the Silver Divide, Upper Fish Creek, Cascade Valley and Purple Bench Analysis Units. The area should continue to be a popular destination for backpackers, however, so campsite extent would not be drastically reduced overall with the cessation of use only in stock holding and spot/dunnage sites.

Cumulative Impacts

Cumulative impacts to soil and water resources are expected to be reduced under Alternative 5. The reduction in number of meadows grazed, trails used by any pack stock, and campsites used by stock holding parties suggests that impacts should be reduced from current levels. The reduction (or improvement) in cumulative impacts under Alternative 5 would be more than any other alternative. In the Fish Creek/Convict/McGee Geographic Unit, many of the negative effects to soil and water resources, such as trail incision, meadow hydrologic function alteration, and stream hydrologic condition alteration (PFC) can be at least partially attributable to commercial pack stock use. Therefore, removal of that use could cause improved conditions. However, continuation of private pack stock use and hiker use could sustain most of the local effects from campsites and trails.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis* in the project record.

There should be a long-term reduction in potential for CWEs with removal of all commercial pack stock. The main difference between the effects of Alternative 5 and the other alternatives would be the difference in grazing effects. Because no meadows would be grazed by commercial pack stock, there would be a large reduction in grazing, especially in the East Fish Creek Watershed. This reduction in grazing, along with less pack stock on trails, would reduce the area of ground disturbance to below 1 percent of the total land area, reducing cumulative effects. The improvements to meadow hydrologic function good take decades, so the improved watershed condition should be long-term.

Mono Creek/Rock Creek – Alternative 1

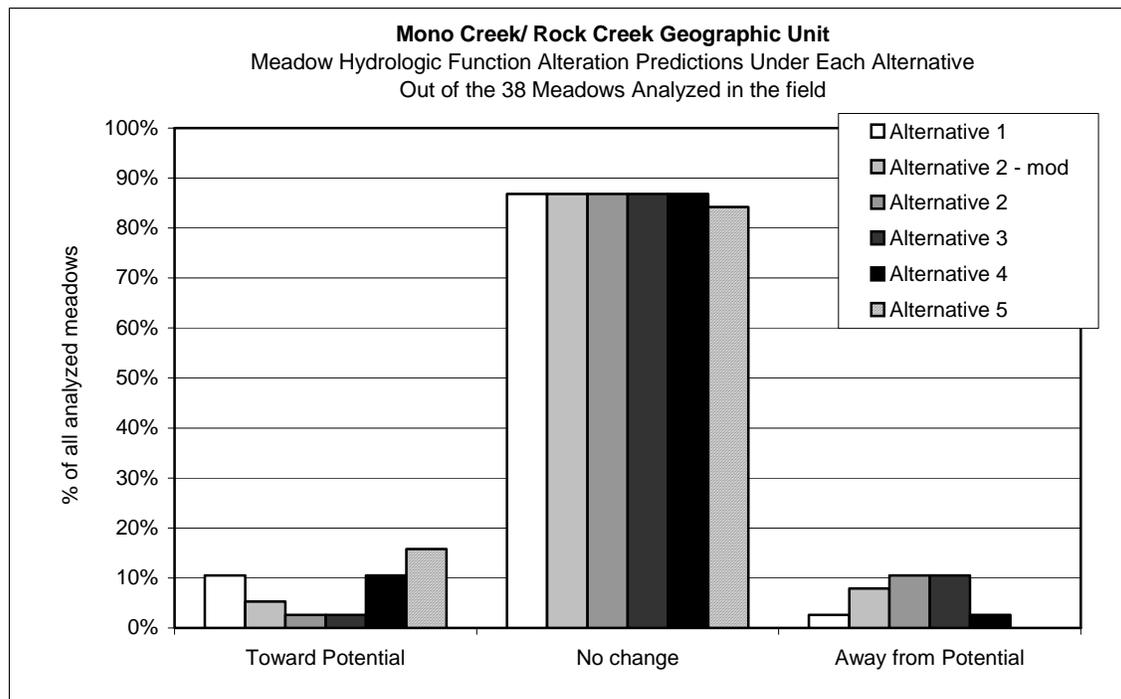

Analysis

The Mono Creek/Rock Creek Geographic Unit should not show a change to soil and hydrologic resources under Alternative 1 relative to its current condition. The current condition includes a few trails and meadows causing severe soil and hydrologic alteration locally, but as the rest of the wilderness, good condition overall. Portions of the area currently receive heavy pack stock use, and many traveling trips with overnight stock use and grazing. Continued current use under Alternative 1 could cause a minor downward trend in soil and hydrologic function in some locations over time. A portion of the Graveyard Analysis Unit continues to be grazed by cattle and cattle grazing effect will continue regardless of pack stock management.

Meadow: The Rock Creek/ Mono Creek Geographic Unit is varied in the type of commercial pack stock use and other uses. In the Little Lakes Valley Analysis Unit, there is heavy day hiker and backpacker use, with little commercial pack stock use and no overnight commercial pack stock use. Therefore, the meadows have soil compaction, sod fragmentation and stream bank trampling mainly from hikers and anglers and not pack stock. Although some of the hikers and anglers are brought to the area by commercial pack stock, the vast majority of the use is non-pack stock users. In the Graveyard Analysis Unit at the west end of the Mono Creek/Rock Creek area, there is an active cattle allotment. The lower elevation meadows in the Graveyard Analysis Units have moderate to severe soil and hydrologic resource impacts attributable to cattle grazing. There is almost no overnight commercial pack stock use in the area, suggesting that the commercial pack stock use would continue to be a negligible effect. In the Mono Creek watershed, including the Laurel, Hopkins, Second Recess, Fourth Recess, Pioneer, and Silver Pass Analysis Units, there is regular overnight commercial pack stock grazing and related meadow compaction, stream bank trampling, stream incision, and sod fragmentation. Under Alternative 1, soil and water resource alteration related to commercial pack stock would likely continue to be most prominent in the Mono Creek Watershed area.

Meadow Hydrologic Function: Most of the 38 meadows analyzed for hydrologic function should remain in their current condition under Alternative 1. It is predicted that hydrologic function could improve in two more meadows under Alternative 1 than under Alternatives 2 and 3 (Figure 4.13). The differences between alternatives would likely be minor in the Mono Creek/Rock Creek Geographic Unit.

Figure 4.13 A comparison of the effects of alternatives on meadow hydrologic function condition.

Four of the 38 meadows analyzed would be expected to have improved hydrologic function and one would be expected to have worse hydrologic function under Alternative 1. The other 33 would be expected to remain in their current condition. Currently, about 2/3 of the meadows analyzed have no hydrologic function alteration, and the remaining 1/3 have at least slight alteration.

Table 4.75 Hydrologic Function Alteration Predictions for all meadows visited in the Mono Creek/Rock Creek Geographic Unit. The predictions are given as number of meadow expected to have a trend toward potential, away from potential, or remain in their current condition with no change. The number of meadows predicted to have each trend was estimated by the IDT, using the meadow’s characteristics such as soil moisture, stream bank stability, and meadow productivity.

Trends By Number of Meadows						
Current Meadow Hydrologic Function Condition (# of meadows with that condition)	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
No hydro alteration (25)						
Toward Potential	0	0	0	0	0	0
No change	24	24	24	24	24	25
Away from Potential	1	1	1	1	1	0
Slight hydro alteration (5)						
Toward Potential	1	0	0	0	1	2
No change	4	4	4	4	4	3
Away from Potential	0	1	1	1	0	0

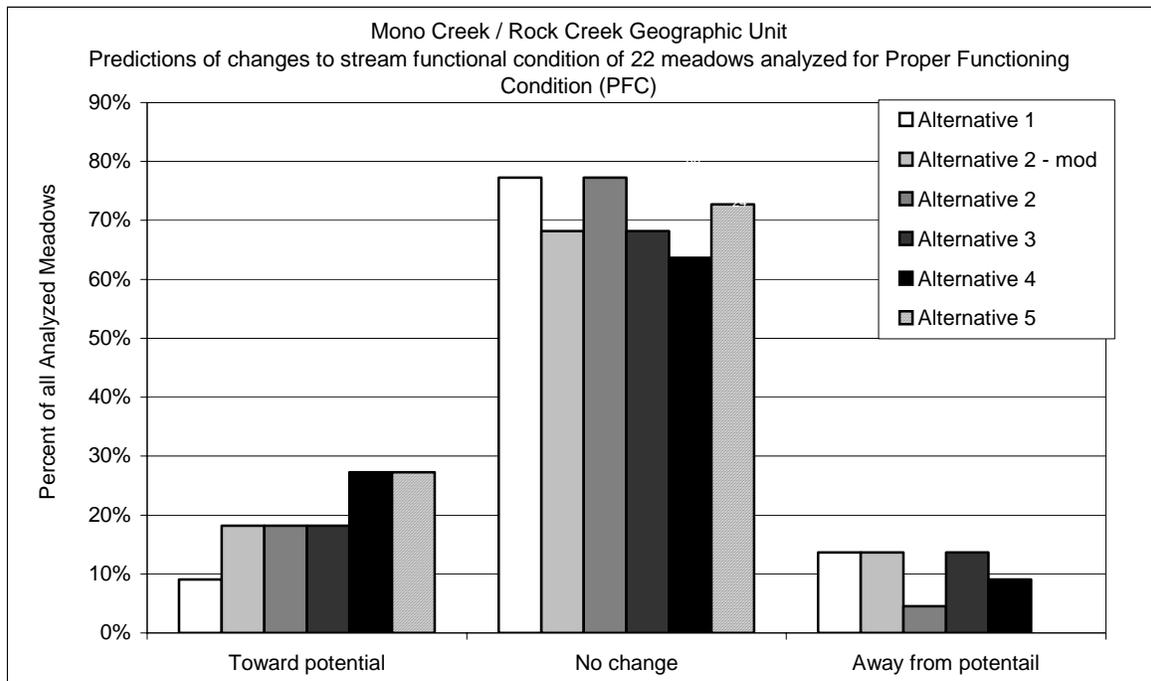

Trends By Number of Meadows						
Current Meadow Hydrologic Function Condition (# of meadows with that condition)	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
Mod hydro alteration (5)						
Toward Potential	2	2	1	1	2	3
No change	3	2	2	2	3	2
Away from Potential	0	1	2	2	0	0
Severe hydro alteration (3)						
Toward Potential	1	0	0	0	1	1
No change	2	3	3	3	2	2
Away from Potential	0	0	0	0	0	0
All Meadows Analyzed (38)						
Toward Potential	4	2	1	1	4	6
No change	33	33	33	33	33	32
Away from Potential	1	3	4	4	1	0

The four meadows that could have improved hydrologic function have all been grazed by cattle within the past decade and are all within the Graveyard Analysis Unit. None have had reported commercial pack stock grazing since 2001 and are not expected to be grazed by commercial pack stock in the future. None of these meadows has been grazed by cattle within the past few years, and it is expected that cattle will not graze the meadows in the future. Therefore, these moderate to high productivity meadows are likely to have gradual reduced compaction, vegetation growing on stream banks, and revegetation of bare soil that should help improve the meadows' hydrologic function.

The one meadow that could have worse hydrologic function under Alternative 1, North of Mono Rock (for1) is currently grazed and has little current hydrologic function alteration. However, the meadow received variable grazing between 2001 and 2004, and show signs of the beginnings of hydrologic function alteration, such as sod fragmentation, stream bank trampling, and vegetation removal. If grazing continues at the highest levels used in the past few years, these impacts could persist year-to-year and begin accumulating over time, eventually reducing the ability of the meadow sod to prevent erosion from surface runoff over the meadow.

Meadow Stream Functional Condition (PFC): About 75 percent of meadow streams are expected to remain in their current functional condition, with slightly more than 10 percent expected to both have improved and worsened conditions. Alternative 1 and Alternative 3 share the lowest expected number of streams to move closer to potential functional condition (Figure 4.14). Currently, about 2/3 of the streams analyzed are at proper functioning condition, while the other 1/3 are functional at-risk.

Figure 4.15 A comparison of predicted changes to stream functional condition (PFC) among alternatives for the streams where PFC was analyzed in the Rock/Mono Creek Geographic Unit. A total of 23 streams were analyzed for PFC, all within meadows or other grazed areas. This chart includes all streams analyzed, whether they are at proper functioning condition or whether they are currently functional at-risk.

Of the 17 meadow streams analyzed for functional condition using the PFC protocol, two are expected to have improved stream condition while three could move away from potential (Table 4.76). The two streams expected to move toward functional condition are in the meadows expected to have improved hydrologic function condition. The three expected to trend away from potential are the meadow near the camp North of Mono Rock (for1), Third Recess Meadow complex (for4) and the Hopkins/Bench Camp Meadow (for8). These meadows are all regularly grazed by commercial pack stock and have poorly armored stream banks and saturated soil areas that are easily chiseled by pack stock. All currently have low levels of hoof punching and stream trampling, below stream bank trampling standards of 20 percent annually. Only one, the stream in Hopkins/Bench Camp Meadow, was rated functional at-risk. However, all of these streams are vulnerable to trampling and erosion, and if use continues to be high in repeated years, it is possible that the sod fragmentation and stream bank trampling would accumulate enough to begin causing a reduction in stream function.

In the Silver Peak Analysis Unit, Silver Pass Meadow currently has severe hydrologic function alteration and has a stream that is functional at-risk with a downward trend. Continued pack stock use could propagate compaction, continue stream bank trampling, and prevent any vegetation from growing on stream banks. The water table in Silver Pass Meadow is already lowered, but continued use at current levels could allow high flows to further incise and widen the channel, lowering the water table further and possibly eventually allowing permanent vegetation alteration in the drier 2/3 of the meadow.

Table 4.76 Summary of all meadow stream functional condition predictions for the Mono Creek/Rock Creek Geographic Unit under all alternatives. Stream functional condition was determined using the Proper Functioning Condition (PFC) protocol. The streams are separated by those that are currently properly functioning, those that are functional at-risk with an upward trend, those that are functional at-risk with a non-apparent trend, and those that are functional at-risk with a downward trend. The predictions are based on assumptions that grazing will continue about as it has in the past in most areas, except in meadows that are closed to grazing and those nearby meadows where grazing might move to.

Current stream functional condition rating (# with each rating)	Number of Meadows expected to have each trend					
	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
Proper Functioning Condition (14)						
Toward potential	0	0	1	0	1	1
No change	12	11	12	11	11	13
Away from potential	2	3	1	3	2	0
Functional at-risk upward trend (2)						
Toward potential	1	1	1	1	2	2
No change	0	1	1	1	0	0
Away from potential	1	0	0	0	0	0
Functional at-risk non apparent trend (1)						
Toward potential	0	0	0	0	0	0
No change	1	1	1	1	1	1
Away from potential	0	0	0	0	0	0
Functional at-risk downward (5)						
Toward potential	1	3	2	3	3	3
No change	4	2	3	2	2	2
Away from potential	0	0	0	0	0	0
Total Mono Creek/Rock Creek (22)						
Toward potential	2	4	4	4	6	6
No change	17	15	17	15	14	16
Away from potential	3	3	1	3	2	0

Meadow Soil Effects: Twenty-nine meadows were analyzed for soil compaction in the Mono Creek/Rock Creek Geographic Unit. Of those, about 30 percent (8 meadows) were found to have moderate to severe compaction. Only three of those appear to have compaction from recent pack stock use. Another one, Graveyard Meadow, is currently grazed by cattle. Those four meadows are likely to continue to receive similar use in the future and the compaction is likely to remain. The other four meadows either had past cattle or pack stock grazing that no longer occurs. Therefore, the compaction in those meadows is expected to slowly decrease over time through soil freezing and thawing, rodent activity in the soil, and vegetation growth.

There is moderate sod fragmentation extent in about 1/3 of the meadows analyzed. Most of these meadows are currently grazed by commercial pack stock or cattle, although some, such as those in Hilton Creek, likely received past commercial pack stock grazing and currently may have pack stock traveling over them but little grazing. Most of these meadows would likely not see much reduction in sod fragmentation under Alternative 1, although the meadows in Hilton Creek may show some reduction because they are no longer grazed.

Trails: Within the Mono Creek watershed, user and system trails are causing local soil loss, surface water diversion, and possibly slight increased sedimentation into surface water. These trails would likely remain in similar condition under Alternative 1 and all other alternatives. Reduction of trail impacts to soil and water resources likely depends more on trail maintenance and repair than whether they are used by commercial pack stock or not. However, increased trail erosion, trail widening and multi-trailing is more likely with pack stock use because pack stock are heavier and less likely to remain within the trail tread, and therefore more likely to remove soil or widen the trail. If use remains as it is, there should be few changes to trails other than a gradual increase in erosion and multi-trailing on heavily used trails. If pack stock use shifts to new areas, especially in the recesses tributary to Mono Creek, there could be increased trail incision, widening and multi-trailing because those trails often go through meadows where the area adjacent to the trail is non-hardened and easily chiseled by hooves.

As in all other alternatives, a reasonably foreseeable future action is that trails with severe resource impacts will eventually be repaired. In this geographic unit, nine trails have moderate to severe impacts to soil and water resources. If we assume those trails would be repaired within 20 years, it is likely that the local impacts would decrease on those nine trails, even with continued commercial pack stock use.

Campsites: Campsites are generally causing excessive bare, compacted soil and possible local water quality effects only in the Hilton Lakes Analysis Unit and along the Mono Creek Corridor (A map of all BMP site locations is in the project record). In these areas, there is a high concentration of campsites, both those used by commercial pack stock and those used by backpackers. It is a foreseeable future action that campsites too close to water, such as the two stock holding camps near the confluence of Mono and Hopkins Creeks, would be closed in a gradual and piecemeal fashion. Therefore, there would be a gradual reduction in sedimentation into surface water from campsites.

The Hilton Analysis Unit receives heavy commercial pack stock use, but little to no overnight commercial pack stock use has been reported. Under Alternative 1, the same use patterns should continue. There would likely be a continuation of dense campsites at Davis Lakes, where there is excessive compacted soil. Continued use could lead to gradual enlargement of campsites, which could eventually increase sedimentation into surface water.

Cumulative Impacts

This alternative has been analyzed in terms of the effects of past, present and reasonably foreseeable future actions to soil and hydrologic processes in the Mono Creek/Rock Creek Geographic Unit. Past, present and reasonably foreseeable future actions are the same as at the wilderness scale. Present and recent past actions differ from the general wilderness only in the Graveyard Analysis Unit, where cattle grazing continues today. Past and present actions have caused some local increases in compacted soil, stream bank trampling, stream incision and

increased sedimentation into surface water. However, other than in the Graveyard Analysis Unit, these effects are generally dispersed and minor enough to prevent widespread cumulative impacts.

Alternative 1 would allow commercial pack stock use to continue in all areas that are currently not closed to use. Therefore, the local compacted soil, stream bank trampling, stream incision and increased sedimentation into surface water due to campsites, commercial pack stock grazing, and trails should continue.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

Of the five watersheds within the Mono Creek/Rock Creek watershed, one may have Cumulative Watershed Effects that have moved downstream from upstream land uses. Along Cold Creek, recent cattle grazing appears to have caused stream incision, increased fine sedimentation into streams, soil compaction, and lowering of water tables in the meadows. It is uncertain whether these effects are due to grazing only in the meadows where the stream impacts occur, or whether they are cumulative watershed effects that have been transported downstream from grazing in the higher portions of the watershed. Either way, the effects do not appear to be related to commercial pack stock use. While cumulative watershed effects could continue with continued cattle grazing, Alternative 1 will cause little to no change in cumulative watershed effects.

Mono Creek/Rock Creek – Alternative 2 – Modified

Analysis

The Rock Creek and Mono Creek Geographic Unit has variable hydrologic processes, geomorphology, meadow types, and use patterns. Therefore, Alternative 2 – Modified will likely have different effects on different portions of the unit. Improvements in soil and water condition are expected to occur in some specific areas. For example, in Hilton Creek, use would be reduced overall and the impacts to soil and hydrologic resources would likely decrease in extent over time. In contrast, in some areas (e.g. Little Lakes Valley) there should not be a substantial change in commercial pack stock use, and soil and hydrologic resource effects would be unchanged.

Other local areas could degrade slightly relative to the existing condition. In the Mono Creek watershed, use would be moved from areas that currently have concentrated use and local severe stream and meadow condition alteration, and moved to areas that currently have few impacts. This could cause an increase in extent of soil and hydrologic alteration, but a decrease in the severity because locations where use would be shifted to are more suitable for the use.

Water quality should meet nondegradation standards as required in the Water Quality Control Plans, because commercial use would be curtailed to areas where it is suitable, stock camp would be designated and would meet BMPs, and trails contributing to water quality degradation would be prioritized for repair.

Meadows: The management changes proposed in Alternative 2 – Modified are likely to cause changes in the soil and hydrologic processes of only a few local meadows. There could be a

rapid improvement to negative soil and hydrologic effects from commercial pack stock use in some meadows, and an increase in negative soil and hydrologic effects in others. While this alternative closes the most vulnerable and altered meadows to grazing, it allows for an increase in grazing from current levels in many meadows that could have a slight degradation in stream functional condition, increases in sod fragmentation, and possibly a slight trend away from potential meadow hydrologic function.

The number of traveling trips would be reduced in the Mono Creek Corridor from 35 trips to 16 trips, reducing grazing demand by about half. Even with this reduction in demand, the reduction in grazing in the Fourth Recess Analysis Unit would possibly cause grazing to increase in another nearby analysis unit, likely Hopkins Creek or Second Recess.

Predictions for individual meadow condition under all alternatives can be found in the table, *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under All Alternatives* in the project record.

Meadow Hydrologic Function: There is little change predicted for meadow hydrologic function under Alternative 2 – Modified. Overall, Alternatives 2 – Modified, 2 and 3 could have the fewest meadows moving toward their potential hydrologic function and the most moving away from it out of any of the alternatives, although the differences should be minor (Figure 4.13, Table 4.75).

Of the 38 meadows analyzed for hydrologic function alteration, 8 currently have moderate to severe hydrologic function alteration. Only two of those meadows appear to have a contribution to hydrologic function alteration from recent commercial pack stock use. Those meadows are Silver Pass Meadow (sip6) and Hopkins/Mono Creek confluence (for8). Under Alternative 2 – Modified, Silver Pass Meadow would be rested from grazing and Hopkins/Mono Creek Confluence meadow would be limited to 19 stock nights. Silver Pass Meadow would likely show little improvement in hydrologic function in the short or medium-term, because the meadow has an incised channel and actively collapsing stream banks that are not likely to begin growing vegetation and aggrading for decades. Hopkins/Mono Creek Confluence could show some improvement in stream functional condition and decrease in sod fragmentation with grazing limitations, and is the only impacted meadow predicted to have improved hydrologic function.

One meadow (Second recess) without current hydrologic function alteration would be expected to move away from its potential. It has 278 stock nights proposed and 23 is the highest use reported. The increased allowable use is limited to the carrying capacity assumed for the meadow, and not likely to have a major negative impact to hydrologic function. However, there could be slightly increased compaction, bare sod, sod fragmentation, and stream bank trampling. All of these could contribute to slight downward trends in hydrologic function.

PFC: As with hydrologic function alteration, stream functional condition (PFC) is likely to have the greatest number move away from their potential and the lowest number move toward their potential under Alternatives 2 – Modified, 2 and 3 (Figure 4.14, Table 4.76). The difference would likely be minor, however.

Of all 22 meadow streams analyzed, about 68 percent are expected to remain with their current condition, about 18 percent are expected to trend toward proper stream functional condition, and 4 percent are expected to move away from their potential.

Of the five meadow stream segments rated functional at-risk with a downward trend, two are expected to have no change and three are expected to move closer to their potential.

The one meadow rated functional at-risk with a non-apparent trend (Pocket Meadow in the Silver Pass Analysis Unit) is expected to remain in its current condition under all alternatives, because the incised stream banks and raw point bars do not appear to have substantial revegetation and would likely continue to have slow revegetation.

The two meadows that were rated functional at-risk with an upward trend (Middle Graveyard Meadow and Mono/Hopkins Meadow) could either remain in their current upward trend, or have slight changes in either direction. Mono/Hopkins Meadow (for8) could be grazed under Alternative 2 – Modified, but at the relatively low level of 19 stock nights. The stream banks in both of these meadows are already trampled and lack vegetation in some areas, making them susceptible to further trampling and unable to withstand high flows. These trampled stream banks are critical areas that should not receive any trampling under this alternative, but if stock cannot be managed to avoid stream banks, stream functional condition could move away from potential. Middle Graveyard Meadow would not be grazed under this alternative, but there should only be a minor improvement in stream functional condition without grazing, because the stream is already deeply incised.

Soil Effects: Soil compaction will likely remain about the same overall, with some meadows having the potential for increased compaction and some with the potential for reduced compaction. Eight meadows in this geographic unit currently have moderate to severe compaction. Five of those have some grazing allocated to them under Alternative 2 – Modified. Four of them have enough grazing allocated to them that compaction could continue its current severity and extent, although only four will likely receive all of their allocated grazing regularly. Of the meadows that currently do not have any compaction observed, four or five could have enough grazing to increase compaction locally where the pack stock congregate. However, only one or two of these meadows will likely receive anywhere near their full allotted grazing, mainly near the Mono Creek corridor in Hopkins Creek and in the Second Recess analysis units.

One meadow, Turk Meadow in the Hilton Analysis Unit, is currently not grazed but has moderate compaction and slight hydrologic function alteration. The meadow covers 57 acres, and even if most of the 243 stock nights allocated are used, compaction and hydrologic function alteration should only increase in local areas where stock congregate, if the stock is managed to use different portions of the meadow each year or throughout each season.

Trails: Trail contribution to resource effects should be slightly reduced under this alternative, but only if trail repairs are completed. There is a high percentage of system and user trails in this geographic unit known to be causing soil erosion, diversion of water, and sedimentation into surface water, especially within the Analysis Units along Mono Creek. Because many of these trails are high use trails, they are high priorities for repair. Six of the fourteen system trails with moderate to severe resource ratings would be designated not suitable for commercial stock, one would be reopened after repair. The others would likely need repair more often to prevent future erosion because pack stock are heavier and are more likely to displace trail structures and chisel soil along trails.

Commercial pack stock will be prohibited from using many of the user trails in the Pioneer Basin, which will eventually decrease soil erosion, especially when the trails are repaired.

Campsites: The area of bare and compacted soil due to campsites should be slightly reduced under Alternative 2 – Modified, although not as much as under Alternatives 4 and 5. The reductions should be especially large near Davis Lakes, in the Hilton Creek Analysis Unit where the concentration of sites is currently high. The designation of fewer stock holding sites than currently exists should eventually reduce the area of bare soil once they are covered with litter or actively rehabilitated.

In the Little Lakes Analysis Unit, there would be some reduction in commercial pack stock use at Gem Lakes, which should help reduce lake shore compaction and bare soil creation near the lake and campsites. This could help reduce soil loss and lakeshore morphology alteration through time.

The one major stock holding campsite causing sedimentation into Mono Creek is at the confluence of Hopkins and Mono Creeks. This camp is within 10 feet of a stream, and commercial pack stock use will no longer be allowed at this camp. This should reduce local sedimentation into Mono Creek but would be a negligible contribution to overall sediment reduction in Mono Creek.

Cumulative Impacts

The past, present, and reasonably foreseeable future actions under Alternative 2 – Modified are the same in the Mono Creek/Rock Creek Geographic Unit as they are at the wilderness scale.

The area currently has some local cumulative effects to soil and water resources along trails, in meadows, and at campsites. In some areas, such as along Mono Creek, these effects appear to be attributable to past and recent commercial pack stock use as well as hiker use of trails and campsites. In other areas, such as in the Graveyard Analysis Unit, recent and continuing cattle grazing has compacted meadows, caused channel incision, and altered meadow hydrologic function, with little to no contribution from commercial pack stock users. In the areas such as the Mono Creek Corridor, where commercial pack stock use appears to have contributed to soil and water resource degradation, Alternative 2 – Modified would likely reduce negative cumulative effects. Improvement is likely because Alternative 2 – Modified closes meadows to commercial pack stock use that are unsuitable for grazing, designates stock holding campsites to reduce the number of sites being used, and limits grazing on other meadows that are suitable for grazing. Overall, this alternative should reduce the area of bare soil, improve stream functional condition, and reduce erosion and sedimentation into surface water.

However, even in areas where commercial pack stock management would change, this action would not affect private pack stock users or backpackers. Therefore, it is possible that the number of campsites would remain about the same, although grazing would still be reduced in areas sensitive to grazing impacts.

In areas such as the Graveyard Analysis Unit, where commercial pack stock use does not appear to be contributing to the existing local cumulative soil and water resource effects, Alternative 2 – Modified would likely cause no change.

Because much of the area has high levels of backpacker and/or day hiker use, water quality from human waste will continue at levels the same as today. Although the extent of current water quality effects are unknown, water quality should not degrade, because grazing use is curtailed, stock holding campsites would be designated to meet BMPs, and non-commercial use should remain about the same.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document, *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis* in the project record.

This area appears to have potential cumulative watershed effects only within the Graveyard Analysis Unit, which is in the Edison Reservoir watershed. The Cold Creek portion of the Edison Reservoir Watershed appears to have an increased potential for cumulative watershed effects due to recent and continuous cattle grazing. Under Alternative 2 – Modified, increased commercial pack stock grazing would be permitted in the upper portions of the watershed, in the Middle Graveyard Creek and Upper Cold Creek Complex. It is unlikely that the full allocated grazing would be used in this area, because there has not been more than twenty stock nights of grazing in the entire Cold Creek Watershed in recent years. It is possible that grazing could move to this area from nearby areas closed to grazing. However, even with the full use of allocated stock nights, there should not be an increase in potential for cumulative watershed effects although it could slow or prevent improvement.

Mono Creek/Rock Creek – Alternative 2

Analysis

The Rock Creek and Mono Creek Geographic Unit has variable hydrologic processes, geomorphology, meadow types, and use patterns. Therefore, Alternative 2 will likely have different effects on different portions of the unit. The effects should be very similar to Alternative 2 – Modified, although there could be slightly improved soil and water resource conditions compared to Alternative 2. Improvements in soil and water condition relative to Alternative 1 are expected to occur in some specific areas.

The similar effects expected under Alternatives 2 and 2 – Modified are due to the similar management proposed. Both alternatives have destination quotas, limits on traveling trips through Mono Creek, they limit grazing only to suitable meadows with almost the same meadows open to grazing, and they allow stock camps only at designated sites that would meet BMPs. The differences are that Alternative 2 has fewer destinations and stock camps, and therefore use would be concentrated to a smaller area.

Meadows: The management changes proposed in Alternative 2 are almost the same as under Alternative 2 – Modified. Three meadows, Middle Graveyard Meadow (gra2), Silver Pass Lake Meadow (sip7) and Upper Graveyard Meadow (gra11) would be open to grazing under Alternative 2, but were rested or closed under Alternative 2 – Modified. This could lead to greater negative impacts in these two meadows, although the differences would likely be slight

Predictions for individual meadow condition under all alternatives can be found in the table, *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under All Alternatives* (available in the project record).

Meadow Hydrologic Function: There is little change predicted for meadow hydrologic function under Alternative 2. Overall, meadow hydrologic function should have the same changes as predicted under Alternative 2 – Modified in all but two meadows. (Figure 4.13, Table 4.75).

The one meadows where meadow hydrologic function is expected to be different than as described under Alternative 2 – Modified is Middle Graveyard Meadow. Under Alternative 2, the meadow could receive up to 41 stock nights. With that grazing, there could be slightly increased compaction, bare sod, sod fragmentation, and stream bank trampling. All of these could contribute to slight downward trends in hydrologic function. Under Alternative 2 – Modified, the meadow would be rested and it was expected that the rest could allow a slight upward trend in meadow hydrologic function.

The other two meadows with different management, Silver Pass Lake Meadow (sip7) and Upper Graveyard Meadow (gra11), should not have differences in hydrologic function due to this management. Upper Graveyard Meadow should remain in the same condition whether it is grazed or not, due to the severe stream incision and headcuts that could continue for decades. Silver Pass Lake Meadow is large and resilient to stock impacts due to its lack of wet areas and well-armored stream channels.

Stream Functional Condition (PFC): As with hydrologic function alteration, stream functional condition (PFC) is likely to be very similar as predicted under Alternative 2 – Modified (Figure 4.14, Table 4.76).

Under Alternative 2, two more meadow streams would be expected to have a trend away from potential that were expected to remain in the same condition under Alternative 2 – Modified. Those meadows are Upper Graveyard Meadow (gra11) and Silver Pass Lake Meadow (sip7).

Soil Effects: Soil compaction will likely be about the same as under Alternative 2 – Modified, because management proposed would be the same in all but three meadows. None of those three meadows currently have compaction, and neither alternative should increase compaction because stock night densities are low enough (less than 12 stock nights per acre) to prevent more than local compaction at sites of concentration.

Trails: Trail contribution to resource effects should be slightly reduced under this alternative, but only if trail repairs are completed. There is a high percentage of system and user trails in this geographic unit known to be causing soil erosion, diversion of water, and sedimentation into surface water, especially within the analysis units along Mono Creek. Because many of these trails are high use trails, they are high priorities for repair. However, only two of the 14 system trails with moderate to severe resource ratings would be designated not suitable for commercial stock. The others would likely need repair more often to prevent future erosion because pack stock are heavier and are more likely to displace trail structures and chisel soil along trails.

Commercial pack stock will be prohibited from using many of the user trails in the Pioneer Basin, which will eventually decrease soil erosion, especially when the trails are repaired.

Campsites: The area of bare and compacted soil due to campsites should be slightly reduced under Alternative 2, slightly more than under Alternative 2 – Modified. The reductions should be especially large near Davis Lakes, in the Hilton Creek analysis unit, where the concentration of sites is currently high. The designation of fewer stock holding sites than currently exists should eventually reduce the area of bare soil once they are covered with litter or actively rehabilitated.

The one major stock holding campsite causing sedimentation into Mono Creek is at the confluence of Hopkins and Mono Creeks. This camp is within 10 feet of a stream, and commercial pack stock use will no longer be allowed at this camp. This should reduce local

sedimentation into Mono Creek and be a negligible contribution to overall sediment reduction in Mono Creek.

Cumulative Impacts

The past, present, and reasonably foreseeable future actions are the same in the Mono Creek/Rock Creek Geographic Unit as they are at the wilderness scale.

The area currently has some local cumulative effects to soil and water resources along trails, in meadows, and at campsites. In some areas, such as along Mono Creek, these effects appear to be attributable to past and recent commercial pack stock use as well as hiker use of trails and campsites. In other areas, such as in the Graveyard Analysis Unit, recent and continuing cattle grazing has compacted meadows, caused channel incision, and altered meadow hydrologic function, with little to no contribution from commercial pack stock users. In the areas such as the Mono Creek Corridor, where commercial pack stock use appears to have contributed to soil and water resource degradation, Alternative 2 would likely reduce negative cumulative effects. Improvement is likely because Alternative 2 closes meadows to commercial pack stock use that are unsuitable for grazing, designates stock holding campsites to reduce the number of sites being used, and limits grazing on other meadows that are suitable for grazing. Overall, this alternative should reduce the area of bare soil, improve stream functional condition, and reduce erosion and sedimentation into surface water.

However, even in areas where commercial pack stock management would change, this action would not affect private pack stock users or backpackers. Therefore, it is possible that the number of campsites would remain about the same, although grazing would still be reduced in areas sensitive to grazing impacts.

In areas such as the Graveyard Analysis Unit, where commercial pack stock use does not appear to be contributing to the existing local cumulative soil and water resource effects, Alternative 2 would likely cause no change.

Because much of the area has high levels of backpacker and/or day hiker use, water quality from human waste will continue at levels the same as today. Although the extent of current water quality effects are unknown, water quality should not degrade, because grazing use is curtailed, stock holding campsites would be designated to meet BMPs, and non-commercial use should remain about the same.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document, *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis* in the project record.

This area appears to have potential cumulative watershed effects only within the Graveyard Analysis Unit, which is in the Edison Reservoir watershed. The Cold Creek portion of the Edison Reservoir Watershed appears to have an increased potential for cumulative watershed effects due to recent and continuous cattle grazing. Under Alternative 2, increased commercial pack stock grazing would be permitted in the upper portions of the watershed, in the Middle Graveyard Creek and Upper Cold Creek Complex. It is unlikely that the full allocated grazing would be used in this area, because there has not been more than twenty stock nights of grazing in the entire Cold Creek Watershed in recent years. It is possible that grazing could move to this area

from nearby areas closed to grazing. However, even with the full use of allocated stock nights, there should not be an increase in potential for cumulative watershed effects although it could slow or prevent improvement.

Mono Creek/Rock Creek – Alternative 3

Analysis

In the Mono and Rock Creek Geographic Unit, there is potential for improvement in soil and hydrologic resources under Alternative 3. The effects should be similar to Alternative 2 – Modified in most of the Geographic Unit other than the Silver Pass and Graveyard Analysis Units. In those analysis units, there could be an increase in commercial pack stock grazing that could slightly worsen meadow or stream hydrologic function condition.

Uses other than grazing, including campsites and trails, will likely have the same effects on soil and hydrologic resources as under Alternative 2 – Modified. Campsite and trails management would be almost the same, and therefore their effects will be discussed only briefly under Alternative 3.

Meadows: Conditions in meadows could be slightly worse under Alternative 3 than under Alternative 2 – Modified, although the effects should be the same in most locations. The impacts should be less widespread and severe than under Alternative 1 (Figures 4.13 and 4.14, Tables 4.75 and 4.76). Under Alternative 2 – Modified, a range of effects was predicted in the Silver Pass and Graveyard Analysis Units. Worsening conditions would only occur in a few locations if grazing use increased to the proposed allowable use levels. Under Alternative 2 – Modified, the limitations on traveling trips would likely prevent any substantial local increases in grazing. Under Alternative 3, there are no specific limits on the number of traveling trips that could occur. The number of traveling trips is only limited by the number of stock at each pack station and trailhead quotas. The same nearby grazing areas would be closed to use, and therefore there is a good chance that some or all of the five meadows with increased grazing could have slight downward trends in stream and/or meadow hydrologic function.

The effects to meadows would be very similar as Alternative 2 – Modified, because the management proposed for meadows would be almost the same. The only difference is that one meadow, Middle Graveyard Meadow, would be expected to have a minor trend away from natural hydrologic function under Alternative 3, where it was expected to have a minor trend toward natural hydrologic function under Alternative 2 – Modified. The difference is that under Alternative 3, the meadow could be grazed to 41 stock nights.

Trails: The effects to soil and water resources from trails are likely to be the same as under Alternative 2 – Modified. There are only about two more trail miles open to stock under Alternative 3 than under Alternative 2 – Modified. There could be more pack stock traffic on those trails, causing slightly more trail erosion and soil loss. The effect should be negligible, as the difference is only about 2 percent of the total trail miles in the Mono Creek/Rock Creek Geographic Unit.

Campsites: Alternative 3 should have the same campsite effects as Alternative 2 in the Mono Creek/Rock Creek Geographic Unit. That is because under both alternatives, the same 17 campsites would be designated.

Cumulative Impacts

The cumulative impacts in the Mono Creek Rock Creek Geographic Unit should be similar to Alternative 2, and there should not be detrimental cumulative effects. Alternative 3 should reduce negative cumulative effects to soil and water resources relative to Alternative 1. The difference to soil and water effects between Alternatives 2 – Modified and 3 is that under Alternative 3, more traveling trips would be allowed, and therefore more grazing might occur. The grazing effects would likely be the same as predicted under Alternative 2 – Modified, but negative effects would be more likely to occur, while under Alternative 2, it would be expected that the predicted negative effects would be less likely to occur.

As under all alternatives, hiker and backpacker use would remain about the same, contributing to slight water quality degradation through human waste disposal, trail use, use of soaps, waste water disposal, and trail use.

Mono Creek/Rock Creek – Alternative 4

Analysis

There could be fewer negative effects to soil and water resources under Alternative 4 than under Alternatives 1 through 3, especially in the Hilton and Graveyard Analysis Units. In other areas, such as the Little Lakes Valley Analysis Unit, the effects should be the same as under Alternatives 1 through 3. As under all alternatives other than Alternative 5, there should be only an overall slight improvement for soil and water resources. Grazing would be allowed in fewer meadows and access to some destinations that are used by commercial pack stock currently would no longer be allowed. While these actions would occur across the wilderness, the percent of areas with reduced use in this Geographic Unit is larger than in others. The reduced use should have the effect of decreasing the number of meadows with the potential for hydrologic function alteration, decrease the number of streams that are not properly functioning, and decrease the amount of bare soil because of the reduced number of stock holding campsites. The improvements should be slight in most locations.

Meadows/wetlands: Meadow condition should improve from current conditions in most areas with altered meadow condition. There should also be fewer negative soil and hydrologic effects to meadows than under Alternatives 2 – Modified, 2 and 3. However, there should be a greater extent of negative effects than under Alternative 5.

Meadow Hydrologic Function: Under Alternative 4, there should be fewer meadows that trend away from their potential hydrologic function and more meadows that trend toward their hydrologic function than under Alternatives 1 through 3 (Figure 4.13, Table 4.75). As under all alternatives, most meadows should remain with their current hydrologic function.

Out of the 38 meadows analyzed for hydrologic function alteration, 33 are expected to remain in their current condition. Four are expected to trend toward their potential and none should trend away from their potential. The four meadows that are expected to trend toward their potential are Hopkins/Mono Creek Confluence Meadow, (for8), Hilton Creek/Turk Meadow (hil8), Upper Graveyard Meadow (gra11), and Middle Graveyard Meadow (gra2). Grazing will be eliminated or substantially reduced from current grazing on these meadows under Alternative 4. Hilton Creek/Turk Meadow, Middle Graveyard and Upper Graveyard Meadow have not been grazed recently by commercial pack stock. They all appear to have hydrologic function alteration due to

past grazing, from commercial pack stock at Hilton Creek/Turk Meadow and cattle at Middle and Upper Graveyard Meadow. The meadows are predicted to have improved hydrologic function because they would likely continue to recover from past grazing. Soil should slowly decompact, vegetation should increase vigor, and stream banks should slowly have vegetation begin to cover the banks. Upper Graveyard Meadow has severe hydrologic function alteration currently, but the stream banks appear to be revegetating and the meadow appears to have retained much of its water source from springs. The meadow is currently compacted, but as it decompacts, the spring water may allow the meadow to recover some of its hydrologic function even though the stream is unlikely to aggrade. The recovery, if it occurs, should be minor within 20 years. Hilton Creek/Turk Meadow has only minor hydrologic function, which should be able to show recovery within 20 years without grazing.

Hopkins/Mono Creek Confluence Meadow would likely show some recovery under Alternative 4 because grazing would be reduced to only 13 to 20 stock-nights per year. The meadow was reported to have 134 stock nights in 2003 and 118 in 2002. Also, the trail to the campsite near the meadow runs through the meadow and is incised and contributing to meadow hydrologic function alteration. Under Alternative 4, there would be no campsite at the meadow. The removal of the campsite, as well as reduction of grazing nights to only 13 stock nights, should allow this moderate productivity meadow to revegetate and decompact, thus reducing hydrologic function alteration.

The one meadow that is likely to have hydrologic function trending away from potential is Second Recess Meadows (sec14), as described under Alternative 2. This would only occur if the meadow were used to near its full proposed allocation of 278 stock nights.

Stream Functional Condition (PFC): Alternative 4 would likely have fewer stream channels move away from PFC and more move toward PFC than under Alternative 2 – Modified, although the difference would be minor and not likely to be noticeable on a Geographic Unit scale (Figure 4.14, Table 4.76). Overall, it is predicted that out of the 22 streams analyzed for PFC, 14 would remain in their current condition. Six might have a trend toward their potential, while two could have a trend away from their potential.

The two meadows that could trend away from their stream functional condition potential would have many more stock nights allocated than have been recently used. Both meadows, Silver Pass Lake Meadow and Second Recess Meadow, could see drastically increased grazing because nearby grazing would be curtailed and the packers might begin grazing new meadows. The stock night allocations correspond with carrying capacity, and therefore the effects should be minor. Volcanic Knob Meadow is not likely to be grazed to anywhere near its full capacity because there is very little commercial pack stock use reported in the area, and it is assumed that it is not a destination that packers are likely to move to. If they do move to Volcanic Knob Meadow, the effects would likely be no more than a slight, local move away from potential stream functional condition that should not move the stream to a functional at-risk condition.

The six meadows that could trend toward their potential would be the same meadows described in the hydrologic function section above, plus two more; Silver Pass Meadow (sip6) and Middle Graveyard Meadow (gra2). Neither meadow would be grazed under Alternative 4. These meadows both have severe hydrologic function alteration currently that does not appear to be able to show any recovery within 20 years due to severe stream incision that has altered most of the meadows' water source. However, the stream condition is more easily recoverable than

hydrologic function alteration, and there may be enough productivity in these meadows to allow vegetation to grow on stream banks and point bars. Vegetation growth could help streams withstand high flows without eroding and therefore could improve the streams' functional condition.

Meadow Soils: Soil compaction will likely have little change overall, although a few meadows may have potential for increased compaction and others have potential for reduced compaction. Eight meadows currently have moderate to severe compaction. Five of those have some grazing allocated to them under Alternative 4. Four of them have enough grazing allocated to them that compaction could continue its current severity and extent, although only three likely will receive their full proposed grazing level. Of the meadows that currently do not have any observed compaction, four or five could have enough grazing to locally increase compaction where the pack stock congregate. They would be the same four or five meadows as under Alternative 2 – Modified.

Trails: The Mono Creek/Rock Creek Geographic Unit is one of the units likely to have a slight reduction in soil and water resource impacts from trails under Alternative 4, although the reduction would likely be slight and local. Under Alternative 4, 12 system trails (out of 50 in the Geographic Unit) would be closed to commercial pack stock that would be open under Alternatives 1 through 3. Closure of the trails to commercial pack stock would likely not reduce the trail impacts to soil and water resources, but would help prevent further trail incision, soil loss, and stream crossing trampling and stream bank erosion. It is a foreseeable future action under all alternatives that the trails with moderate to severe resource impacts would be repaired within 20 years. Without pack stock use on these trails, they would be more likely to remain stable without soil erosion, incision or widening.

Campsites: The area of bare and compacted soils due to campsites should be slightly reduced under Alternative 4, likely more than under Alternatives 1 through 3, but less than under Alternative 5. All stock holding and spot/dunnage sites would be designated, limiting expansion of sites and therefore increases in bare and compacted soil. While Alternative 2 would have about 17 stock holding sites, Alternative 4 would have 12. Most sites in the geographic unit are used by backpackers and not commercial pack stock clients. Therefore, the effects of reduction in pack stock holding sites and spot/dunnage campsites would likely be small on a geographic unit scale. Locally, however, where the stock holding sites were no longer used, rehabilitation could reduce the area of bare soil, compacted soil and reduce erosion into surface water. The improvement should be largest along the Mono Creek corridor in the Fourth Recess and Second Recess Analysis Units, although unlikely to affect overall water quality in Mono Creek.

Cumulative Impacts

The cumulative impacts under Alternative 4 would likely be similar to Alternative – Modified, 2 and 3. Five more meadows would be closed to commercial pack stock grazing than under Alternative 3 and six more meadows would be closed than under Alternative 4. However, these meadow closures would not likely have effects on overall cumulative impacts. The meadows closed are mainly those that do not currently have soil or water resource impacts, and therefore their closure would not reduce cumulative impacts beyond Alternatives 2 – Modified, 2 and 3. This alternative would slightly reduce cumulative impacts relative to Alternative 1.

Cumulative Watershed Effects

The cumulative watershed effects (CWEs) observed in the Graveyard Analysis Unit (Edison Watershed) would likely remain about the same under Alternative 4. The effects appear to be due mainly to recent cattle grazing, and restrictions on commercial pack stock use would not likely alter conditions.

Mono Creek/Rock Creek – Alternative 5

Analysis

The Mono Creek/Rock Creek Geographic Unit is one of the areas that would likely have the greatest reduction in negative impacts to soil and water resources under Alternative 5. This area receives a high level of commercial pack stock use, and therefore removal of pack stock is likely to make a noticeable difference to resource effects.

Meadows: Alternative 5 is likely to allow the greatest number of meadows to have improved soil and hydrologic conditions of any alternative, and the only one where no meadows could have increased negative soil or hydrologic impacts related to commercial pack stock use. The predicted difference between the alternatives is minor on a geographic unit scale, but should be substantial in popular destinations and grazing areas.

Meadow Hydrologic Function: As with all other alternatives, meadow hydrologic function is unlikely to change in most meadows. However, under Alternative 5, the greatest percentage of meadows should have improved hydrologic function condition and, unlike all other alternatives, none should have a trend away from potential hydrologic function (Figure 4.13, Table 4.75).

Of the 38 meadows analyzed for hydrologic function in the field, 85 percent would be expected to remain in their current condition and the other 15 percent would be expected to have an improved trend. Six of the thirteen meadows that are currently known to have hydrologic function alteration would likely have an improved trend, because their altered hydrologic function is at least partially attributable to commercial pack stock use. See table, *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under All Alternatives* in the project record for individual meadow comparisons. The other seven meadows would not likely have improvement in hydrologic function alteration. These meadows would likely remain in their current condition for one of various reasons. Some of the meadows, such as Graveyard Meadow (Graveyard Analysis Unit) and Pocket Meadow (Silver Peak Analysis Unit), have impacts that are not related to recent commercial pack stock grazing. The hydrologic function is severely altered in those meadows and is unlikely to change with removal of light pack stock grazing. Other meadows, such as Silver Pass Meadow (Silver Peak Analysis Unit), appear to have hydrologic function alteration due at least partially to recent commercial pack stock use. The hydrologic function is severely altered in the meadow, and is unlikely to show recovery over decades or centuries, if ever, until the stream can aggrade and the water table can begin to return to its previous height nearer the surface of the meadow.

Meadow Stream Function Condition (PFC): Under Alternative 5, there would likely be fewer streams made to have worse functional condition than under any other alternative (Figure 4.14, Table 4.76). The difference should not be major, however. Of 22 meadow streams analyzed, about 75 percent would be expected to remain in their current condition and about 25 percent would be expected to have improved condition. In comparison, Alternative 1, with the

least improvement expected in stream condition, could also have about 75 percent of streams with no change in condition, but about 13 percent could have degraded condition while the other 13 percent could have improved condition.

No meadows would be expected to have a trend away from potential under Alternative 5 because none would be grazed and none are known to have other factors that could cause a downward trend. Three of the eight streams that were found to be currently functional at-risk would be likely to remain in their current condition. These three streams have impacts that do not appear to be related to recent pack stock grazing. Therefore, removal of the light or non-existent pack stock grazing that was occurring in the meadows is unlikely to change their stream functional condition.

Trails: Alternative 5 is most likely to prevent future soil and water resource impacts from trails, but is unlikely to reduce current impacts. Some trails in this geographic unit, such as those in the Hilton Creek Watershed, in the Mono Creek Corridor and in Third Recess and Hilton Creeks, receive heavy pack stock use. Removal of pack stock use from those trails may prevent increased erosion and trail incision because less soil is thought to be removed by hikers than pack stock. However, these trails are not likely to aggrade or narrow without maintenance or repair. It is a foreseeable future action that the trails with moderate to severe resource impacts would be repaired, and removal of pack stock could allow those repairs to last longer without the trail beginning to erode and incise again.

Campsites: The difference between campsite effects to soil and water resources would likely be small between alternatives. However, within the Mono Creek Corridor and within the Hilton Creek Analysis Unit, where there is a high density of campsites, the reduction in use at stock holding sites and spot/dunnage sites could allow for some reduction in bare and compacted soil and reduction in sedimentation into surface water. The reduction in campsite area would likely be minor because backpackers would probably continue to use the same number of campsites as they are currently and they use the majority of the campsites in the Mono Creek/Rock Creek area.

Cumulative Impacts

Cumulative impacts to soil and water resources are expected to be reduced under Alternative 5. The major reduction in number of meadows grazed, trails used by any pack stock, and campsites used by stock related parties suggests that impacts should be reduced from current levels. The reduction (or improvement) in cumulative impacts under Alternative 5 would be more than any other Alternative. In the Mono Creek/Rock Creek Geographic Unit, many of the negative effects to soil and water resources, such as trail incision, meadow hydrologic function alteration, and stream hydrologic condition alteration (PFC) can be at least partially attributable to commercial pack stock use. Therefore, removal of that use could cause improved conditions. However, continuation of private pack stock use and hiker use could sustain most of the local water quality and geomorphology effects from campsites and trails.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see the document, *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis* in the project record.

This area appears to have potential cumulative watershed effects only within the Graveyard Analysis Unit, which is in the Edison Reservoir watershed. Alternative 5 should cause no changes to CWE potential. The effects would be similar to the current condition, because cattle grazing would continue, there would continue to be little pack stock grazing, and campsites and trails would likely continue to be used by backpackers. However, under this alternative, there would be no commercial pack stock in the area. Therefore, the meadows in the upper Cold Creek sub-watershed would not be grazed by pack stock, and would likely continue a slow recovery as cattle did not begin to graze the area again. There might be an eventual slight reduction in campsite area and trail length, because there could be less overall use at Graveyard Lakes. However, backpackers would still visit Graveyard Lakes and would likely continue use of most existing campsites.

Bishop/Humphreys – Alternative 1

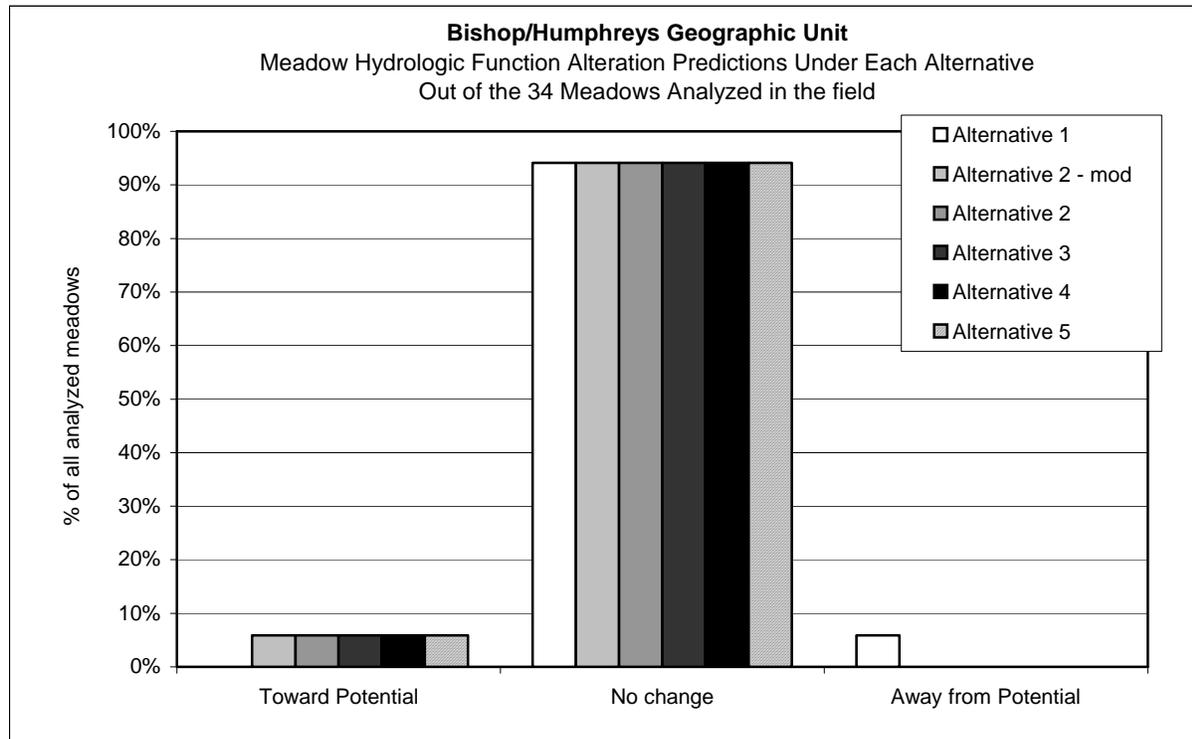

Analysis

There should be few changes to soil and hydrologic condition under Alternative 1, because there should be few changes in commercial pack stock use patterns in the Bishop/Humphreys area. Unlike most other geographic units, trails and campsites in the geographic unit are the largest known contributor to soil and water resource impacts, and are likely to continue to be so in the future. There is little grazing in this geographic unit, mostly concentrated in French Canyon, and there are only a few grazed meadows with soil and water resource impacts. Unless use patterns change, the area should remain with few soil and water resource impacts.

Meadows: Most meadows in the Bishop Humphreys Geographic Unit generally have few impacts to soil and water resources. The only meadow that is currently known to have more than slight hydrologic function alteration is Hutchinson Meadow, which has severe compaction over a small area and stream bank trampling. A few other meadows also have stream functional condition alteration. Depending on use patterns, meadows within French Canyon could see some increased soil and water resource degradation, but overall, the meadows in this geographic unit should remain in relatively good condition overall.

Meadow Hydrologic Function: There are few meadows with hydrologic function alteration in the Bishop/Humphreys area, and only one is expected to have any change under Alternative 1. Therefore, meadow hydrologic function should remain good in almost all of this geographic unit. There are also few expected differences between alternatives, as shown in Figure 4.15.

Figure 4.15 A comparison of the effects of alternatives on meadow hydrologic function condition in the Bishop Humphreys Geographic Unit. The y-axis represents the percent of the 34 meadows that are in each trend category.

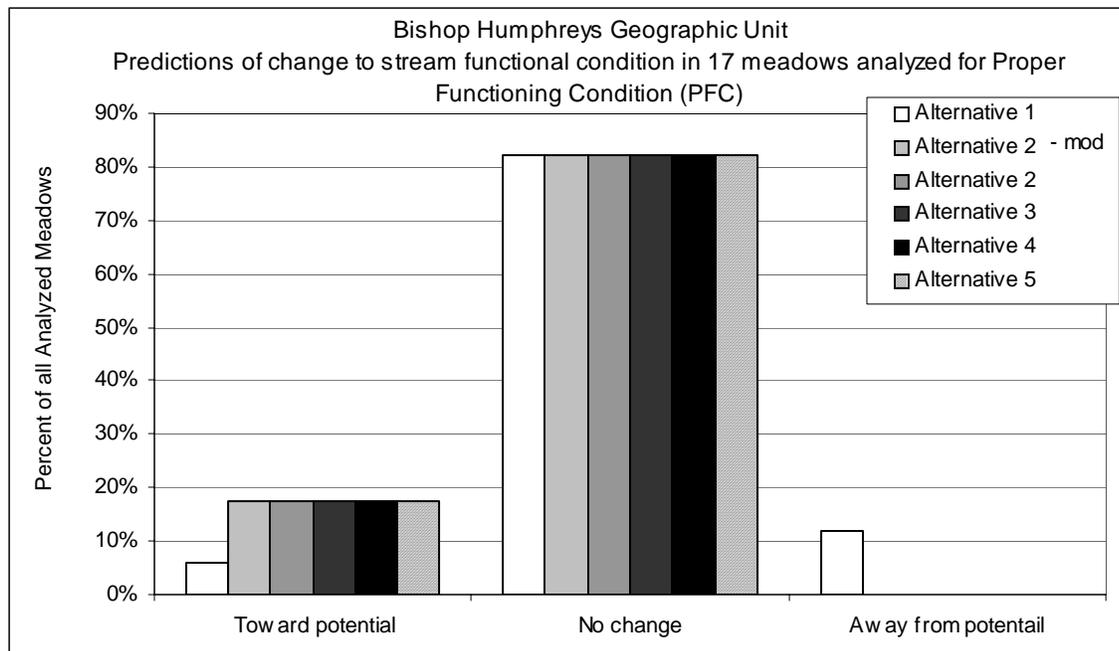

Out of 34 meadows analyzed for hydrologic function, only two are expected to have any change under Alternative 1 (Table 4.77). Those meadows are the wet meadow adjacent to Waterfall Camp and the meadow at the confluence of Merriam Creek and French Canyon. Both of these meadows are very wet. The wet meadow Adjacent to Waterfall Camp is likely a fen, and does not currently receive grazing. Stock traveling through the fen to get from Waterfall Camp to graze on the other side of the fen have caused deep hoof punches that appear to have begun small rills. If the fen continues to be trampled, more rills may develop and they could begin to incise and grow larger during overland flow. Fens can be lost over time if they are exposed to oxygen through sod fragmentation (Cooper et al., 2004a) and the current use of the area could be irreparably harming the fen. If stock is kept out of the fen, it would likely recovery very quickly, as the water table and spring flows appear to be intact. The meadow at the confluence of Merriam Creek and French Canyon had reported grazing only in 2003, and previously had few impacts. The meadow has wet soils year-round and most of the meadow never reaches range readiness. If the meadow continues to be grazed as heavily as it was in 2003, it is likely that there would be increased sod fragmentation, bare soil, and soil displacement, possibly leading to hummocking or soil loss from the meadow.

Table 4.77 Hydrologic Function Alteration predictions for all meadows visited in the Bishop Humphreys Geographic Unit, under all alternatives. The number of meadows predicted to have each trend was estimated by the IDT, using the meadow's characteristics such as soil moisture, stream bank stability, and meadow productivity.

Current Meadow Hydrologic Function Condition (# of meadows with that condition)	Trends By Number of Meadows					
	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
No hydro alteration (30)						
Toward Potential	0	0	0	0	0	0

All Meadows Analyzed (34)						
Toward Potential	0	2	2	2	2	2
No change	32	32	32	32	32	32
Away from Potential	2	0	0	0	0	0

Meadow Stream Functional Condition (PFC): Few meadow streams in the Bishop/Humphreys Geographic Unit are known to have hydrologic function alteration, and few are likely to have changes in condition under Alternative 1. Fewer streams should show improved condition under Alternative 1 than any other alternative, but the difference would likely be minor (Figure 4.16).

Figure 4.16 A comparison of predicted changes to stream functional condition (PFC) among alternatives for the streams where PFC was analyzed in the Bishop/Humphreys Geographic Unit. A total of 17 streams were analyzed for PFC, all within meadows or other grazed areas. This chart includes all streams analyzed, whether they are at proper functioning condition or whether they are currently functional at-risk.

Of the 17 streams analyzed for stream functional condition, four are known to be functional at-risk. One of those stream segments is expected to have an improved trend, while one is expected to have a worsened condition (Table 4.78).

Table 4.78 Summary of all meadow stream functional condition predictions for the Bishop Humphreys Geographic Unit under all alternatives. Stream functional condition was determined using the Proper Functioning Condition (PFC) protocol. The streams are separated by those that are currently properly functioning, those that are functional at-risk with an upward trend, those that are functional at-risk with a non-apparent trend, and those that are functional at-risk with a downward trend. The predictions are based on assumptions that grazing will continue about as it has in the past in most areas, except in meadows that are closed to grazing and those nearby meadows where grazing might move to.

Current stream functional condition rating (# with each rating)	Number of Meadows expected to have each trend					
	Alternative 1	Alternative 2 –modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
Proper Functioning Condition (13)						
Toward potential	0	0	0	0	0	0
No change	12	13	13	13	13	13

Away from potential	0	0	0	0	0	0
Functional at-risk downward (1)						
Toward potential	0	1	1	1	1	1
No change	0	0	0	0	0	0
Away from potential	1	0	0	0	0	0
Total Bishop Humphreys (17)						
Toward potential	1	3	3	3	3	3
No change	15	14	14	14	14	14
Away from potential	1	0	0	0	0	0

The stream segments expected to move away from its potential condition is in the same meadow that is expected to have a downward trend in hydrologic function, at the French Canyon Merriam Creek Confluence (fre14). The one stream segment expected to have improved condition is at the Upper Pine Lake Inlet. The trail was near the stream and it appears that stock were watering in the area, or just walking around from the nearby stock holding camp. The stream crossing also widened the stream beyond normal at a stream crossing. The stream banks are chiseled and there appears to be minor stream widening. The crossing is scheduled for repair in 2005, to confine the use to a narrower crossing and stabilize the channel. Therefore, it is expected that the stream functional condition would improve as stock are less likely to walk on the stream banks.

Trails: Incised trails are leading to surface water diversion in various areas of this geographic unit, and would likely continue in the same locations under Alternative 1. The main system trail through French Canyon is incised and there are multi-trails in many areas. Although the multi-trail have often been blocked with branches and rocks from further use, the trails still do not have erosion control structures and continue to be a pathway for surface water. The water flowing down the trails appears to be further incising them, or at least not allowing vegetation to grow in and begin to capture sediment. The situation is similar on the trail to Elba and Moon Lakes and on many trails near Golden Trout Lakes where a network of system and non-system trails is contributing sediment into adjacent lakes and streams.

The Gable, Pine Creek, Granite Park, Horton, Humphreys, Lamarck, and North Piute Analysis Units are all only used for pass through on trails and for some spot and dunnage trips. None of these analysis units have widespread hydrologic or soil resource impacts, and none are expected to have a change in condition under Alternative 1. All of these units have some trail incision leading to soil loss and slight water diversion. The trail incision is likely due to a combination of commercial pack stock use, hiker use, and private pack stock use, and would not change under

any alternative because changes only in commercial pack stock management is not likely to affect the trails.

As with other alternatives, there is the potential for increased trail incision and widening with continued pack stock use, but there would likely be little to no recovery without active restoration. Therefore, the trails currently causing water diversion and soil loss will likely continue to do so until they are repaired, regardless of commercial pack stock use.

Campsites: Campsite extent and effects to water quality should remain about the same under Alternative 1, with some reduction in sites near water in the long-term. There are many campsites and associated social trails around Piute Lake in the Piute Analysis Unit and Golden Trout Lakes in the Glacier Analysis Units. The campsites themselves are usually over 100 feet from the lake, but they are causing excessive bare, compacted soil. The Piute Lake area is heavily used by backpackers and stock supported parties, but there is no stock holding at the lake. Therefore, it is unlikely that the density and size of sites would change under any alternative, because the action regards only commercial pack stock use. The campsite at Waterfall Camp in French Canyon is currently not meeting BMPs for campsites, as it is less than 50 feet from water and there is manure and sediment from the site entering ephemeral streams. Ephemeral streams do not flow year-round, but usually only during snowmelt and right after rainfall. Sediment and manure built up during summer can reach the nearby creek when it flows. It is a reasonably foreseeable future action under all alternatives that this site would be contained over time, reducing its potential for water quality degradation. Until containment occurs, there could be continued small volumes of sediment entering intermittent streams.

Cumulative Impacts

Alternative 1 has been analyzed in terms of the effects of past, present and reasonably foreseeable future actions to soil and hydrologic processes. Past, present and reasonably foreseeable future actions in the Bishop Humphreys Geographic Unit are the same as in the general Ansel Adams and John Muir Wildernesses. However, there may have been more concentrated historical sheep grazing because Piute Pass was an entry point for shepherds.

Generally, this geographic unit has few soil or water resource impacts outside of the French Canyon Corridor and Golden Trout Lakes in Piute Canyon. In those areas, some incised trails, and meadows with headcuts and bare soil. Many of these impacts appear to be historical or cumulative effects from a combination of historical sheep grazing, historical and current recreational use, and historical and recent commercial pack stock use. Impacts in most of the meadows appear to be recovering and should continue recovery under Alternative 1. Trail impacts are likely to remain the same as today, causing some water diversion and soil erosion. It is a foreseeable future action that the trails causing the most severe water diversions and dewatering of meadows would be repaired within 20 years. If the trails are repaired, many soil and water resource impacts in this geographic unit would cease.

Bishop/Humphreys – Alternative 2 – Modified

Analysis

The Bishop/Humphreys Geographic Unit is currently has meadow hydrologic function, stream functional condition, and soil condition near potential over most of its area, with some exceptions in heavily used meadow areas and adjacent to trails. Because Alternative 2 –

Modified would not change commercial pack stock use much in this area, it is assumed that there will be few changes in the current hydrologic and soil conditions.

Meadows/wetlands: There are a few meadows within the Bishop/Humphreys area that have some hydrologic function alteration due to trailing or grazing. However, most of the heavily used areas are used mainly for spot/dunnage trips, and grazing occurs regularly in only a few areas. Therefore, the grazing impacts are substantial only in a few locations, and changes in management should change meadow conditions only locally.

Grazing levels reported for the entire French Canyon have been about the same as the proposed grazing, but it is uncertain where the grazing occurred and therefore uncertain whether the proposed grazing will have different effects. If grazing occurs mainly where it has in the past within French Canyon, there should be no change in the generally good condition of meadows in the Canyon. The one exception will be the Merriam Confluence, where 126 stock nights of grazing were reported in 2003. This area would be prohibited for grazing, and therefore the packers would need to disperse their grazing nights in other portions of the canyon. The sod fragmentation and trampling at Merriam Confluence should then decrease.

Meadow Hydrologic Function Alteration: There should be improved hydrologic function in a few meadows in this area, although the vast majority is likely to remain in their current condition (Figure 4.15). The effects should be slightly improved hydrologic function in more meadows than under Alternative 1, but the same as all other alternatives.

Thirty-four meadows in this geographic unit were visited in the field and analyzed for grazing suitability and current condition. Of the 34 analyzed, only four were determined to have any hydrologic function alteration. Two of the meadows with hydrologic function alteration are expected to remain in the same condition under this alternative, because grazing management should not change in those meadows and they are not vulnerable to further impacts (Table 4.77). For individual meadow comparisons, see the table, *Projected Changes to Meadow Stream Functional Condition and Meadow Hydrologic Function under All Alternatives* in the project record.

Two meadows are predicted to have a trend toward hydrologic function potential. These meadows, the meadow adjacent to Waterfall Camp (fre3) and Hutchinson Meadow (gla12), have very different conditions and expected changes. The meadow Adjacent to Waterfall Camp does not currently have grazing, but stock travel through the wet meadow to access grazing. Under Alternative 2 – Modified, this practice would be prohibited, and the packers would be required to prevent use of the area. Because the meadow is wet, the many hoof punches and rills currently in the meadow should revegetated quickly and improve hydrologic function condition. Hutchinson Meadow is regularly grazed currently, with a high concentration of grazing (up to 290 stock nights reported) in an area of the meadow less than 3 acres. Grazing would be reduced to about 70 stock nights, possibly allowing for some reduced sod fragmentation, reduced stream bank trampling, and increased vegetative vigor that could allow hydrologic function to improve.

Meadow Stream Functional Condition: Stream functional condition could change in a few meadows in this Geographic Unit, but should remain about the same overall. The effects should be similar under all action alternatives, though slightly more streams should have improved condition than under Alternative 1 (Figure 4.16).

Seventeen stream segments were analyzed for stream functional condition (PFC) and 13 were found to be properly functioning. None of the properly functioning stream segments are predicted to change from their current condition (Table 4.78).

In the meadow streams with a functional at-risk rating, one is predicted to remain in its current condition and three are expected to move toward their potential. One meadow with a functional at-risk downward trend is likely to improve completely within a few years. The fen next to Waterfall Camp (French Canyon Analysis Unit) would be prohibited to grazing or any trailing. The meadow is a fen, which is very wet, and it is expected that the hoof punches and small headcuts throughout the meadow should grow in with vegetation within a few years, reducing the chance for high flows to cause erosion of the wet meadow. Another meadow expected to have an improved stream condition is at the Upper Pine Lake Inlet (in the Pine Creek Analysis Unit), where trail repair already completed should eventually allow the stream crossing to have fewer hoof punches and increased vegetative growth on stream banks. Hutchinson Meadow (in the Glacier Analysis Unit) would have reduced grazing under Alternative 2 – Modified, likely allowing more vegetation to grow on stream banks and reducing the annual stream bank trampling.

Trails: There will likely be a gradual reduction of trail impacts to water quality and soil loss, as trails are gradually repaired. Some of the extensive user trails around Golden Trout Lake should slowly recover as they are made off-limits to commercial pack stock, although the recovery might not occur without active rehabilitation. If the trails revegetate, their potential to contribute sediment to surface water should be reduced. Along French Canyon, the system trail is multi-trailed and incised along much of its length, possibly diverting surface water from areas directly adjacent to the trail. It is unlikely that the entire extent of the trail will receive the heavy maintenance necessary within the next few decades, and therefore the trail will likely continue its slight alteration of surface water flow. The most severely eroded trail known in this Geographic Unit, the trail to Elba and Moon Lakes, will be a priority for repair. Until then, it will continue to divert stream flow, overland flow, and lower the water table in meadows adjacent to the trail. After it is repaired, stream flow and surface flow will likely recover natural patterns.

Campsites: Under this alternative, the Bishop/Humphreys Geographic Unit should have the same effects from campsite designation and closures as in other Geographic Units and wilderness-wide. There should be a slight reduction in bare area and impermeable soil near water. The site with the greatest potential for reduction in bare soil and erosion is Waterfall Camp. The camp is currently about four acres of bare, dusty soil that is easily eroded and appears to be contributing sediment and manure to nearby intermittent streams. The site will eventually be contained to a smaller size further from surface water, and erosion from the site into creeks should be reduced.

Cumulative Impacts

The past, present and reasonably foreseeable future actions are the same in this geographic unit as in the wilderness-wide area. Some of the areas within the Bishop Humphreys area receive relatively heavy commercial pack stock and other recreational use, more than some other portions of the wilderness.

Alternative 2 – Modified is unlikely to change current cumulative impacts. Those current impacts include some erosion from trails used by commercial pack stock and other recreational

users, particularly in French Canyon and near Golden Trout Lakes. Although Alternative 2 – Modified will cap use to these areas, it would not likely reduce the use enough to reduce the cumulative effects. These effects are local and do not cause cumulative watershed effects.

Bishop/Humphreys – Alternative 2

Analysis

The effects under Alternative 2 should be the same as described under Alternative 2 – Modified in the Bishop/Humphreys Geographic Unit. This geographic unit has very little difference in proposed management under the two alternatives, and the effects should therefore be the same. Two more system trails would be open to commercial pack stock under Alternative 2, but the difference to soil and water resources would not be noticeable. The trails would continue to be used by others users and neither trail currently has more than slight erosion or diversion of surface water, so the use of these trails by commercial pack stock should not alter their current condition.

Meadows/wetlands: The effects to meadow soil and hydrologic function should be the same as under Alternative 2 – Modified. Management would be the same in all meadows, and about the same number of stock would be expected to be held overnight under both alternatives due to similar destination quotas and traveling trip quotas.

Trails: There will likely be a gradual reduction of trail impacts to water quality and soil loss, as trails are gradually repaired, the same as under Alternative 2 – Modified. Two trails, the trail to Ruwau Lake and the trail to Lamarck Col, would be closed to commercial pack stock use under Alternative 2 – Modified, but open under this alternative. Lamarck Col trail gets little pack stock use currently, and the continuation of that use should not affect the trail condition related to soil and water resources. The Ruwau Lake trail closure should not affect the trail condition, since it is used by many hikers. However, the closure would prevent access to Ruwau Lake by commercial pack stock, which could help reduce the extent of camps at the lake and possibly reduce the number of people camping at the lake. This could help reduce lakeshore compaction.

Campsites: Under this alternative, the Bishop/Humphreys Geographic Unit should have the same effects from campsite designation and closures as in other geographic units and wilderness-wide. There should be a slight reduction in bare area and impermeable soil near water. The site with the greatest potential for reduction in bare soil and erosion is Waterfall Camp. The camp is currently about four acres of bare, dusty soil that is easily eroded and appears to be contributing sediment and manure to nearby intermittent streams. The site will eventually be contained to a smaller size further from surface water, and erosion from the site into creeks should be reduced.

Cumulative Impacts

The past, present and reasonably foreseeable future actions are the same in this geographic unit as in the wilderness-wide area. Some of the areas within the Bishop Humphreys area receive relatively heavy commercial pack stock and other recreational use, more than some other portions of the wilderness.

Alternative 2 is unlikely to change current cumulative impacts. Those current impacts include some erosion from trails used by commercial pack stock and other recreational users, particularly in French Canyon and near Golden Trout Lakes. Although Alternative 2 will cap use to these

areas, it would not likely reduce the use enough to reduce the cumulative effects. These effects are local and do not cause cumulative watershed effects.

Bishop/Humphreys – Alternative 3

Analysis

The effects to soil and water resources under Alternative 3 should be similar to Alternative 2 – Modified, although there could be local slight differences due to different grazing practices. The proposed meadow management would be the same in this geographic unit, and therefore the effects have the potential to be the same. However, because traveling trips are not specifically restricted as much under Alternative 3, there is likely to be more use in the areas farther than one day from the trailhead. In this Geographic Unit, French Canyon is likely the only place where use would be different under the two alternatives. That is because it is the only area where the proposed grazing is larger than the past reported grazing, and there is potential for increased use. The meadows in the French Analysis Unit could therefore receive increased stream bank disturbance, sod fragmentation, soil compaction, and bare soil creation. The change in this area is not likely, however, because the trailhead quotas do not reduce use from current use in Pine Creek, the main trailhead for this area. There is no motivation for packers to have more overnight stock-holding trips in the backcountry, as in some geographic units where trailhead quotas might restrict entry and encourage the packers to keep their stock in the wilderness more nights.

Trail and campsites would be managed almost the same under Alternative 3 as under Alternative 2 – Modified. Only one more mile of trail would be open to commercial pack stock, and one more stock holding campsite would be designated. The difference in effects should therefore be negligible.

Cumulative Impacts

Because the direct and indirect effects are only negligibly different from under Alternative 2, the cumulative impacts are the same as under Alternative 2.

Bishop/Humphreys – Alternative 4

Analysis

There should be very little difference in impacts to soil and hydrology under the action alternatives. Access to destinations is slightly different, with up to 10 destinations not accessible to commercial pack stock under Alternative 4 that were open under Alternative 2 – Modified.

Meadows: Meadow management is proposed to be the same other than a 25 percent reduction of grazing nights in Hutchinson Meadow (Glacier Analysis Unit). The small reduction in grazing should not make a difference in the degree of hydrologic function alteration or stream functional condition.

Trails: As with other alternatives and other Geographic Units, improvement in trail condition is unlikely under this action, even with removal of commercial pack stock from six system trails and at least eight user trails that would be open under Alternatives 1 through 3. This could limit further trail erosion, widening, soil loss and surface water diversion from trails such as the Merriam Lake Trail (French Analysis Unit), Saddlerock Lake Trail (Glacier Analysis Unit), and Chocolate-Ruwau Loop Trail (Bishop Analysis Unit). However, the erosion and water diversion

that is occurring on trails throughout the Bishop/Humphreys area would likely not be reduced without trail repair and maintenance. It is a reasonably foreseeable future action that the nine trails with moderate to severe resource effects would be repaired within 20 years. If so, the effects to soil and water resources should be reduced, but until then, they should remain about the same as currently under all Alternatives.

Campsites : The reduction in overall commercial pack stock use, and designation of all stock holding and drop sites, could lead to a reduction in the number of campsites needed. Some campsites could eventually be obliterated or naturally have reduced soil compaction and bare soil. The difference should be minimal, however, because backpacker use should remain about the same, and backpackers would be able to camp wherever they wished. There would likely be some reduction in bare, compacted soil over time with fewer stock holding campsites, but it would occur slowly unless the sites were actively restored.

Cumulative Impacts

Negative cumulative impacts are expected to be slightly reduced under Alternative 4. The overall reduction in number of meadows grazed, the reduced stock nights, and less number of trails approved for commercial pack stock use suggests the potential for a cumulative impact is unlikely when compared to the existing condition. The reduction (or improvement) in cumulative impacts under Alternative 4 is less than Alternatives 1 through 3 and greater than Alternative 5.

The majority of use would continue to be from hikers and backpackers, and their small negative effects to water quality and stream morphology would continue.

Bishop/Humphreys – Alternative 5

Analysis

The Bishop/Humphreys Geographic Unit could have a slight reduction in impacts to soil and water resources under Alternative 5, but the difference from the other alternatives would be minor. The areas that would be most likely to have improved condition would be the French Canyon Corridor and the area around Golden Trout Lakes, which are the most heavily used areas by commercial pack stock. The local impacts to soil and water resource condition are due mainly to trails, however, and simply removing commercial pack stock from the trails is not likely to improve their condition, until the trails are repaired.

Meadows: There is unlikely to be a major difference in meadow condition under Alternative 5 than under Alternatives 1 through 4. That is because few meadows in this area currently have moderate or severe soil and resource effects currently, and therefore changes in grazing management should not make much difference in meadow condition overall.

Meadow Hydrologic Function: The same meadows are likely to have improved hydrologic function under Alternative 5 as under Alternatives 4 (Figure 4.15, Table 4.77). Only two meadows are expected to have improved hydrologic function alteration while 32 are expected to remain in their current condition. The two meadows that have altered hydrologic function related to commercial pack stock, Hutchinson Meadow and Adjacent to Waterfall Camp would not be grazed under Alternative 5 (or Alternative 4). They should have reduced compaction, stream bank trampling, and sod fragmentation for improved hydrologic function.

Meadow Stream Functional Condition (PFC): There is likely to be improved stream functional condition in the same streams as under Alternative 4 (Figure 4.16, Table 4.78). Three streams that currently have hydrologic function alteration would be expected to have improved condition, while one would be expected to remain in its current condition. The stream expected to remain in its current condition with no commercial pack stock grazing is in Elba Lake Meadow (French Canyon Analysis Unit). A small stream segment appears to have been incised due to historical grazing or trail use. The incision does not appear to be able to lessen naturally without some restoration.

Trails: The effect to soil and water resources from trails is likely to be the same as wilderness-wide. There could be a reduction in the extent of user trails near Golden Trout Lakes, however. The user trails around the lakes are generally not deeply incised, and over time, they could revegetate and have reduced erosion. The area is used for by many spot/dunnage parties and not overnight by commercial pack stock, but might have reduced number of campers overall with reduction of spot/dunnage trips. The number of user trails could be reduced with an overall reduction in campers to the area.

Campsites: The effect to soil and water resources from campsites is likely to be the same as wilderness-wide, with a possible slight reduction in the extent of bare, compacted soil. There could be a measurable reduction in the extent of bare soil due to campsites near Golden Trout Lakes. The Golden Trout Lakes area contains many sites used for spot/dunnage trips. Without commercial pack stock use, there could be a slight decrease in the total number of campsites needed at this heavily used area.

Cumulative Impacts

Cumulative impacts to soil and water resources are expected to be slightly reduced under Alternative 5. The major reduction in trails used by pack stock, and campsites used by stock holding parties suggests that impacts should be reduced from current levels. The reduction (or improvement) in cumulative impacts under Alternative 5 would be more than any other Alternative. The areas most likely to show improvement are in and around Hutchinson Meadow, and near Golden Trout Lakes, because that is the area with the greatest soil and water resource impacts from commercial pack stock use. Many of the negative effects to soil and water resources, such as trail incision, meadow hydrologic function alteration, and stream hydrologic condition alteration (PFC) can be at least partially attributable to commercial pack stock use. Therefore, removal of that use could cause improved conditions. However, continuation of private pack stock use and hiker use could sustain most of the local effects from campsites and trails.

Florence/Bear – Alternative 1

Analysis

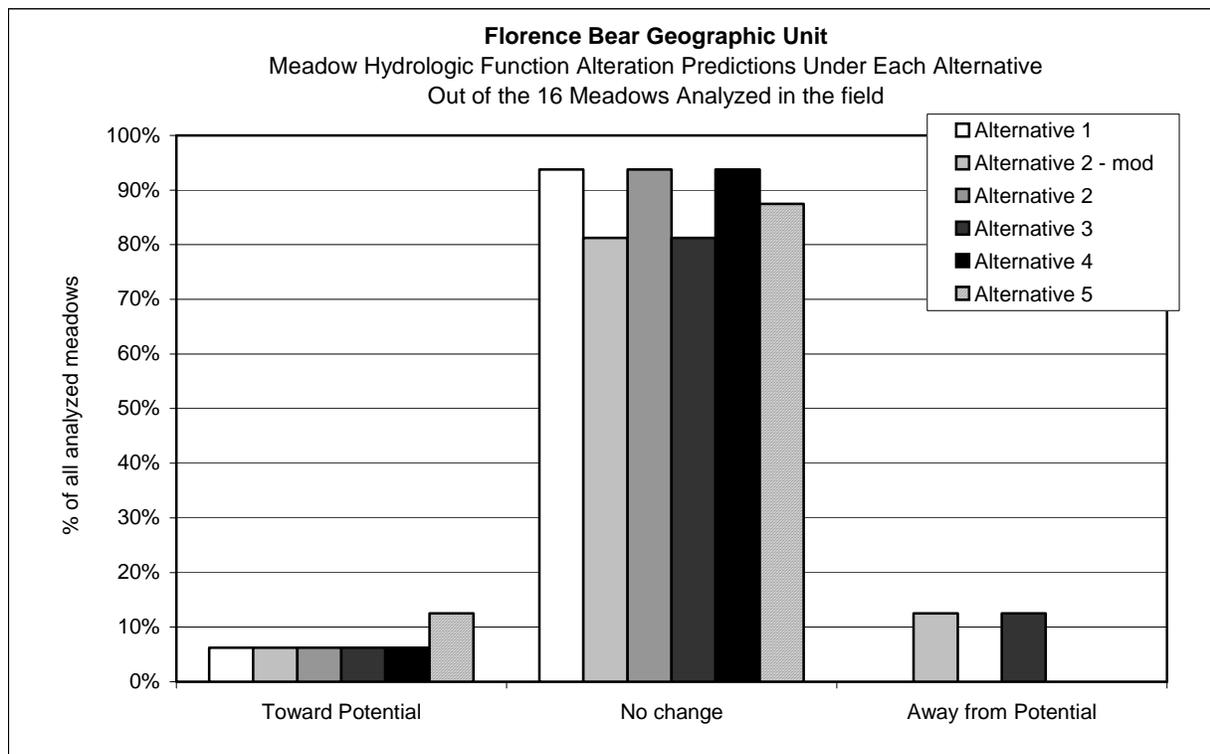

There should be few changes in soil and hydrologic resource condition relative to current condition because there should be few changes in commercial pack stock use-patterns. The largest impact to soil and hydrologic condition related to pack stock is likely grazing, although it occurs only in a few locations. There are few known impacts to soil and hydrology in this Geographic Unit, and it will likely remain that way.

The Bear Lakes, East Florence, Ward Mountain, Bolsillo, Ershim, Dutch, Dutch/Boulder and Apollo Analysis Units are not known to have major or widespread impacts to soil and water resources. They have little to no commercial pack stock use and are not expected to have increased use in the future under Alternative 1 or other alternatives. Therefore, there is not expected to be any change in impacts to soil and water resources under any alternative and will not be discussed further.

Meadows: The Florence/Bear Geographic Unit generally has few effects outside of its five pastures (Blayney, Double, Jackass, Hellhole, and Poison Meadows). This area contains the only pack stock pastures within the Ansel Adams and John Muir Wildernesses. Some of the pastures, such as Double Meadow, show few hydrologic or soils effects, with only slight vegetation composition change and vegetation removal. Others, such as Lower Blayney Meadow, have streams with altered condition and some hydrologic function alteration. Jackass, Hellhole, and Poison meadows are located below Florence dam, which also alters hydrologic function. It is likely that these meadows would remain in their degraded state, and that meadows in good condition would remain in good condition.

Meadow Hydrologic Function: Meadow hydrologic function is likely to change in only one meadow, and there should be very little difference between alternatives (Figure 4.17). That is because this area receives little commercial pack stock use and the actions in all alternatives apply only to commercial pack stock.

Figure 4.17 A comparison of the effects of alternatives on meadow hydrologic function condition in the Florence/Bear Geographic Unit.

Seven of the 16 meadows analyzed for hydrologic function currently have at least slight hydrologic function alteration. Of those, only one meadow is likely to show improved hydrologic

function condition (Table 4.79). That meadow, Rosemarie Meadow, appears to be recovering from past impacts. Although the meadow remains grazed at low levels, (the highest reported use was 38 stock nights in this 11-acre meadow), incised channels have revegetated and bare soil appears to be filling in. If the meadow continues to be grazed at low levels, it is likely that the recovery would continue.

The Sallie Keyes Analysis Unit has two areas with concentrated commercial pack stock use. These areas are near Sallie Keyes Lakes and near Blayney Meadows. Near Sallie Keyes Lakes, there is some evidence of historical grazing impacts from an unknown user, which appears to be recovering over the dry areas of the meadow and should continue its recovery. However, the wet portions of the meadow have severe sod fragmentation and hoof punching, which would likely continue under Alternative 1. This could lead to soil loss and loss of soil productivity. Blayney Meadow, which is used as a pasture, is partially on private land and partially on Forest Service Land. The meadow has moderate hydrologic function alteration due to commercial pack stock grazing, and this would likely continue in its current condition under Alternative 1. It is possible that the meadow could have increased compaction, sod fragmentation and stream trampling impacts with continued use, but the productivity likely would allow some recovery every year, keeping the meadow in an overall static condition.

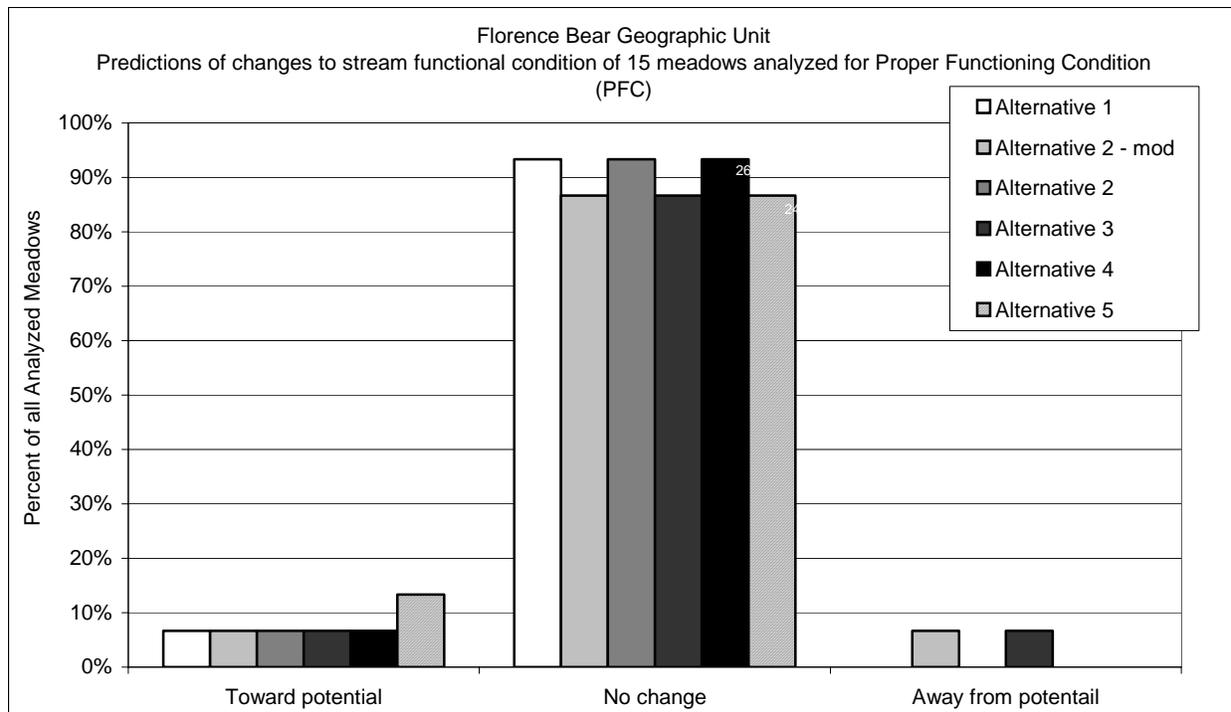

Table 4.79 Hydrologic Function Alteration Predictions for all meadows visited in the Florence/Bear Geographic Unit. The number of meadows predicted to have each trend was estimated by the IDT, using the meadow's characteristics such as soil moisture, stream bank stability, and meadow productivity. The predictions assume that the some meadows would not receive their allocated stock nights, if they are in an area not likely to received increased use. The prediction underestimates the worst possible effects, but is a more realistic estimation. The potential effects if all stock nights were used are included in the text.

Current Meadow Hydrologic Function Condition (# of meadows with that condition)	Trends By Number of Meadows					
	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
No hydro alteration (9)

Away from Potential	0	2	0	2	0	0

Meadow Stream Functional Condition (PFC): There is likely to be very little change to stream functional condition under Alternative 1, because use should be about the same. Currently, few streams are known to be functional at-risk, except those downstream from Florence Dam. There should also be very few differences between Alternative 1 and any other alternative (Figure 4.18).

Figure 4.18 A comparison of predicted changes to stream functional condition (PFC) among alternatives for the streams where PFC was analyzed in the Florence/Bear Geographic Unit. Sixteen streams were analyzed for PFC, all within meadows or other grazed areas. The percent on the y-axis is the percent of the 16 meadows predicted to have each trend. This chart includes all streams analyzed, whether they are at proper functioning condition or functional at-risk.

Fifteen streams were analyzed for stream functional condition, and four were found to be functional at-risk. Those streams are in Hilgard, Hellhole, Jackass and Rosemarie Meadows.

Hilgard and Rosemarie both have stream bank chiseling, streambank vegetation removal, incised streams, and collapsing banks at least partially due to current and historical commercial pack stock use. Only one of those, the stream in Rosemarie Meadow, is likely to have a change in condition (Table 4.80). The stream is likely to have continued recovery from what appears to be past stream incision, widening, and gullyng.

Hilgard Meadow has been grazed in recent years by commercial pack stock, and has compacted soils, vegetation composition change, and a widened stream through the meadow. The use in the meadow should continue at recent levels, and the impacts to the stream and meadow should remain the same.

Table 4.80 Summary of all meadow stream functional condition predictions for the Florence/Bear Geographic Unit under all alternatives. Stream functional condition was determined using the Proper Functioning Condition (PFC) protocol. The streams are separated by those that are currently properly functioning, those that are functional at-risk with an upward trend, those that are functional at-risk with a non-apparent trend, and those that are functional at-risk with a downward trend. The predictions are based on assumptions that grazing will continue about as it has in the past in most areas, except in meadows that are closed to grazing and those nearby meadows where grazing might move to.

Current stream functional condition rating (# with each rating)	Number of Meadows expected to have each trend					
	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
Proper Functioning Condition (11)						
Toward potential	0	0	0	0	0	0
No change	11	11	11	11	11	11

No change	14	13	14	13	14	13
Away from potential	0	1	0	1	0	0

Meadow Soil Effects: Soil compaction does not appear to be substantial in the overall Florence/Bear Geographic Unit. Three meadows out of the eleven analyzed for soil compaction have slight to moderate compaction. All meadows, Rosemarie Meadow in the Seldon Analysis Unit, Boot Meadow in the Sallie Keyes Analysis Unit, and Hilgard Meadow in the Italy Analysis Unit, currently have some pack stock grazing and have likely had grazing for many years. All of them would likely continue to be grazed. Boot Meadow and Rosemarie Meadow may have slow compaction recovery because they are not grazed regularly, but Hilgard Meadow is unlikely to show much recovery in compaction because it is grazed every year. It is likely that the pastures Jackass Meadow, Hell Hole Meadow, Poison Meadow, Double Meadow and Lower Blayney Meadow also have some compaction, but the extent or severity is unknown. If they are compacted, they are likely to remain so under Alternative 1.

Trails: There are currently few soil or water resource impacts from trails, with only the Italy Pass trail known to have moderate or severe water or soil resource concerns. There is unlikely to be increased or decreased impacts with continuation of the current use patterns.

Campsites: There are currently few known soil or water resource impacts from campsites. There is unlikely to be a change in the extent of bare, compacted soil or water quality under Alternative 1 if use remains as it is today. Under Alternative 1, packers could begin using any campsite as a stock holding site, as long as it was over 50 to 100 feet from water. There could then be an increase in bare and compacted soil extent. However, there is no indication that use would change and therefore there would be more stock holding sites under Alternative 1.

Cumulative Impacts

The past, present and reasonably foreseeable future actions in the Florence/Bear Geographic Unit are the same as the wilderness in general, although the impacts from the dam at Florence are unique. The Florence Lake Dam alters stream flow and stream morphology downstream, including in the wilderness pastures at Jackass, Poison and Hellhole Meadows.

Under Alternative 1, there would likely be no change to cumulative impacts, because the current uses of commercial pack stock, private pack stock users, and hikers should remain the same. Further, the most severe single impact in the geographic unit, Florence Lake Dam, would continue to alter stream flow, water quality, riparian vegetation and meadow/wetland hydrologic function. The dam is going through Federal Energy Regulatory Commission (FERC) relicensing, and flows could improve meadow condition. Most of the remaining area has few known soil or water resource impacts.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis*, in the project record.

In summary, none of the watersheds within the Florence/Bear Geographic Unit was found to have existing cumulative watershed effects. Further, none of the watersheds is expected to have increased potential for cumulative watershed effects under Alternative 1 because there would continue to be low use through most of the area.

Florence/Bear – Alternative 2 – Modified

The soil and hydrologic effects under all action alternatives should be almost the same because most campsite, trail, and grazing management would be the same. The only difference would be local and due to different grazing allocations at the pastures Jackass, Double and Lower Blayney Meadows.

Meadows: Under Alternative 2 – Modified, meadow hydrologic function should improve in one meadow and move away from potential in two meadows (Jackass Meadow and Lower Blayney Meadow). Sixteen meadows were analyzed for hydrologic function.

Meadow stream functional condition was analyzed in 15 meadows, and one is expected to have improved condition while another (Jackass Meadow) is expected to move away from potential stream functional condition.

Jackass Meadow, in the East Florence Analysis Unit, is currently managed as a pasture. The entire complex is about 135 acres, and only about 10 percent is within wilderness. Currently, 400 stock nights annually are permitted for this meadow complex. It is unknown whether they are all normally used. The meadow currently has severe hydrologic function alteration over less than 1/3 of the meadow due to flow alterations from Florence Dam. The South Fork San Joaquin River is regulated here by the dam, and therefore the flow volumes, flow timing, water temperature, sediment load and stream morphology are altered. Cessation of commercial pack stock grazing could only cause slight to moderate improvement to the meadow's hydrologic function, because the dam effects will remain. Under Alternative 2 – Modified, grazing could be increased from about 400 stock nights per year to 2,025 overall. This could increase stream bank trampling, vegetation removal, and meadow compaction. There could therefore be a slight downward trend overall in meadow hydrologic function and stream functional condition. However, it is unlikely that 2,025 stock nights will be used in this meadow by commercial pack stock, as only 400 have been permitted and used in the past and there is likely not a need for 2,025 stock nights

It is possible that the packers would graze more in the area around Sallie Keyes Lake under Alternative 2 – Modified than they do currently. That would, however, require a shift in recent use patterns that is not likely to occur. There is no nearby use being curtailed or other reason that the packer would begin taking more trips into the Sallie Keyes area.

In the East Florence Analysis Unit, Double Meadow is likely the only area where there could be changes in soil or hydrologic condition under Alternative 2 – Modified. Although the pack stations did not report use in Double Meadow using the standard reporting system, they verbally communicated that they usually graze the meadow with 15 to 30 head for about 5 weeks, using the meadow as a pasture for non-working stock in the off-season (Smith 2004). This could be anything up to about 1000 stock nights for the 60-acre meadow. Under Alternative 2 – Modified, the meadow could continue to be used as a pasture and could have up to 1,250 stock nights. There would also likely be no hydrologic function alteration and the meadow would continue to be near potential hydrologic function. The meadow currently has no hydrologic function alteration, and little to no compaction, stream bank disturbance, sod fragmentation, or bare sod. Therefore, the small increase in stock nights from the recent high of up to 1000 should not alter meadow hydrologic function, because the moderate-high productivity and stream bank stability should be able to prevent hydrologic or soil alteration from these stocking rates.

In the Sallie Keyes Analysis Unit, Lower Blayney Meadow has a proposed 544 stock nights of grazing could lead to a slight downward trend of meadow hydrologic function. The meadow currently has slight to moderate hydrologic function alteration over more than 1/3 of the meadow. Sixty stock nights of commercial grazing was reported in 2001, and none in 2002 or 2003. The meadow is also used by recreational pack stock, but grazing levels are unknown. It is possible that with commercial pack stock grazing of 544 stock nights, stream incision and headcuts could worsen because of increased stream bank trampling, meadow compaction, and vegetation removal that could reduce stream bank stability and encourage further incision.

Cumulative Impacts

The past, present, and reasonably foreseeable future actions are the same over most of this geographic unit than as they are in the wilderness and in other geographic units, although the impacts from the dam at Florence are unique. The Florence Lake Dam alters stream flow and stream morphology downstream, including in the wilderness pastures at Jackass, Poison and Hellhole Meadows.

The construction of the dam affected flow the South Fork San Joaquin River through the wilderness area. The alteration from the dam, along with grazing, appears to have caused local cumulative effects in Jackass Meadow. Under Alternative 2 – Modified, Jackass Meadow could have more grazing than is currently permitted. Therefore, it is possible that the stream banks already altered by past grazing and dam operations could show increased disturbance. It is more likely, however, that grazing would remain about the same and the cumulative impacts of commercial pack stock grazing and flow alterations from Florence Dam would continue the functional at-risk condition of the stream.

Other than in Jackass Meadow, the Cumulative Impacts in the Florence/Bear Geographic Unit should be the same as under Alternative 1. The use proposed in the area limits further expansion to new areas, but would not likely alter pack stock use from its current pattern.

Florence/Bear – Alternative 2

Analysis

Most of the Florence/Bear Geographic Unit should have little change to its current local and mainly minor impacts to soil and hydrologic resources. Much of the area was not visited in the field due to low levels of reported or requested pack stock use, but due to low levels of reported use of any kind, it is assumed that there are few impacts in the unvisited areas.

Meadows: Meadow conditions are unlikely to change because grazing management proposed in Alternative 2 is similar to the existing condition.

Meadow Hydrologic Function: Only one meadow out of the sixteen analyzed for hydrologic function is likely to show changed hydrologic function condition under Alternative 2 (Table 4.79). That meadow, Rosemarie Meadow, could gradually have improved hydrologic function condition as past compaction and stream bank trampling slowly recovers. There should be no difference between Alternative 2 and Alternative 1 because there should be little actual change in use under Alternative 2 (Figure 4.17).

Meadow Stream Functional Condition (PFC): Under Alternative 2, only one out of the 15 streams analyzed for PFC should have improved hydrologic function condition (Table 4.80).

With controls on the levels of grazing in Rosemarie Meadow, the stream banks could continue to have increased vegetative cover that stabilizes the banks and makes the stream move toward PFC. The other meadows would likely remain in their current condition, which is generally good. There should be no difference between Alternative 2 and Alternative 1 (Figure 4.18), because Alternative 2 does not proposed substantial changes to current management.

Cumulative Impacts

The Cumulative Impacts in the Florence/Bear Geographic Unit should be the same as under Alternative 1. The use proposed in the area limits further expansion to new areas, but would not likely alter pack stock use from its current pattern.

Florence/Bear – Alternative 3

Analysis

The soil and hydrologic effects under Alternative 3 should be almost the same as under Alternative 2 – Modified because campsite, trail, and grazing management would be the same. The only difference could be from the lack of destination quotas, which would allow expansion or relocation of overnight or spot/dunnage use to areas that might not be suitable for increased use.

Meadows: The effects to meadow soil and hydrologic function would be the same as described under Alternative 2 – Modified in almost all meadows.

It is possible that the packers would graze more in the area around Sallie Keyes under Alternative 3 than under Alternative 2. That would, however, require a shift in recent use patterns that is not likely to occur. There is no nearby use being curtailed or other reason that the packer would begin taking more trips into the Sallie Keyes area. The effects should not be different in that area than under Alternative 2.

Cumulative Impacts

The cumulative impacts should be the same as under Alternative 2 – Modified because management that affects soil and water resource impacts is the same.

Florence/Bear – Alternative 4

Analysis

There should be little difference between effects to soil and water resources under Alternative 4 and Alternative 2 over most of the Geographic Unit. However, there could be a noticeable improvement in meadow condition at the pastures Hellhole, Poison and Jackass Meadows in the Hooper and East Florence Analysis Unit. Otherwise, the relatively low levels of commercial pack stock use in this area should remain about the same, and therefore the effects to soil and water resources should be about the same as currently and under Alternative 2.

Meadows: Grazing would have substantially different management recommendations relative to Alternative 2 in only three pastures near the wilderness boundary; Hellhole (Hooper Analysis Unit), Poison (Hooper Analysis Unit), and Jackass Meadows (East Florence Analysis Unit). These meadows are currently managed as pastures, with 200, 200 and 400 annual stock nights

allocated, respectively. Under Alternative 4, the meadows would not be permitted as pastures. All grazing use would be required to be associated with pack trips. Because pack trips do not use these locations as destinations, nor are they likely to do so in the future, it is likely that these meadows receive only recreational and administrative pack stock use. Therefore, the amount of vegetation removal, soil compaction, sod fragmentation and stream bank trampling should be reduced under Alternative 4 relative to current conditions and the effects predicted under Alternative 2. These pastures could have some recreational pack stock grazing and Forest Service Administrative pack stock grazing under Alternative 4, but the level of grazing they would receive, and whether it would affect hydrologic resources, is unknown.

Meadow Hydrologic Function: Even in the pastures, where little grazing is likely to occur under Alternative 4, there should not be any substantial changes in meadow hydrologic function relative to Alternative 1. Two of the three pastures have severe hydrologic function because they have alterations of flow from operations of Florence Reservoir. Although pack stock grazing might be able to make the hydrologic function of the meadows worse, removal of grazing by itself is not expected to improve the meadows' hydrologic function. However, current hydropower licensing efforts may change flow conditions below Florence Dam, which combined with a reduction in grazing is expected to synergistically result in improved hydrologic and riparian conditions in Jackass Meadow.

The third pasture, Poison Meadow, has slight hydrologic function alteration now, evident in non-meadow vegetation encroachment and vegetation composition change and stream incision and headcuts. It is assumed that the vegetation change could be due to stream incision related to longer-term pack stock grazing in the pasture. Meadow hydrologic function will likely remain slightly altered under Alternative 4.

Meadow Stream Functional Condition (PFC): As with meadow hydrologic function, stream functional condition in meadows is unlikely to be different from under Alternative 2, for the same reasons described above in the Meadow Hydrologic Function section

Meadow Soil Effects: There would likely be little change in compaction due to changes in commercial pack stock grazing other than in the three pastures; Jackass Meadow, Hell Hole Meadow, and Poison Meadow. All three meadows have been grazed relatively heavily by commercial pack stock in recent years, and none should receive commercial grazing under Alternative 4. Therefore, the meadows can begin to decompact from vegetation growth, rodent activity and freeze-thaw action in the soil. It is unknown how long it would take soil to show substantial reduction in compaction, but the change would likely be minor within 20 years.

Sod fragmentation should show similar patterns to soil compaction, with differences between Alternative 2 – Modified and 4 only in the pastures. None of the pastures has more than minor sod fragmentation currently, and removal of grazing should allow that sod fragmentation to recover.

Trails: The hydrologic and soil effects from trails should be negligibly different under Alternatives 2 through 4. Under Alternative 4, two system trails, the Hell Hole Trail and the Hooper Diversion Trail would be prohibited for commercial pack stock use. These trails have no known resource effects, and therefore closing the trails to pack stock would probably have little direct effect on soil or water resources. Closure of the Hell Hole Trail would prohibit access to the Hell Hole areas, which would have little direct effect because the area is closed to grazing

under this alternative, and the grazing is the only known negative effect on soil and hydrologic processes.

Cumulative Impacts

Cumulative impacts are expected to be slightly and locally reduced under Alternative 4. The overall reduction in number of meadows grazed, the reduced stock nights, and less number of trails approved for commercial pack stock use suggests the potential for a cumulative impact is unlikely when compared to the existing condition. Further, current hydroelectric licensing efforts may have a future impact of changing the flow regime in Jackass Meadow, thereby improving hydrologic and riparian conditions. The reduction (or improvement) in cumulative impacts under Alternative 4 is less than Alternatives 1 through 3 and greater than Alternative 5.

Cumulative Watershed Effects

For a full discussion of cumulative watershed effects, see *Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses: Cumulative Watershed Effects Analysis* in the project record.

In summary, none of the watersheds within the Florence/Bear Geographic Unit was found to have existing cumulative watershed effects. Further, none of the watersheds are expected to have increased potential for CWEs under Alternative 4, because use should stay about the same in most areas of the geographic unit. The only changes would be reduction in grazing use on meadows that currently have some hydrologic function alteration, and therefore, there could be a slight, local reduction in CWE potential.

Florence/Bear – Alternative 5

Analysis

The Florence/Bear Geographic Unit should have very little change to soil and hydrologic resource condition under Alternative 5 relative to current condition and the other alternatives. There is little pack stock use currently in the area, other than pass through use. The exception is the pastures in the Hooper, East Florence, and Sallie Keyes Analysis Units, where there is heavy commercial pack stock grazing. The effects should be similar to Alternative 4, although there should be slightly less bare, compacted soil and soil loss due to an eventual reduction in the number of stock holding campsites.

Meadows: The effects to meadows should be almost the same as under Alternative 4. The meadows that currently have resource impacts, including the pastures at Jackass, Hellhole, Poison, Double, and Lower Blayney Meadows, would not be used as pastures under Alternative 4 or 5. The only other meadow with major resource concerns, Hilgard Meadow (Italy Analysis Unit), would likely only have minor improvement in condition under Alternative 5, and no change in condition under Alternative 4. The overall difference in meadow soil and hydrologic condition would likely be minor.

Meadow Hydrologic Function: Meadow hydrologic function effects should be the same as under Alternative 4 (Table 4.79, Figure 4.17). The only meadow with current hydrologic function alteration that would have different grazing management would be Hilgard Meadow, which would be open to grazing under Alternative 4. However, its hydrologic function alteration

is due mainly to the incised, widened stream through the meadow. The aggradation and narrowing of the channel would likely take decades or centuries, and should therefore the meadow hydrologic function should improve only very slowly under Alternative 5.

Meadow Stream Functional Condition (PFC): There could be slightly more meadows with improved stream condition under Alternative 5 than under any other alternative (Table 4.80, Figure 4.18). Under Alternative 5, two streams are expected to have improved condition, while under the other alternatives, one stream is expected to improve condition. The one different meadow is Hilgard Meadow, where it is expected that removal of commercial pack stock grazing could allow vegetation to grow on stream banks and allow some sinuosity to return to the apparently widened and straightened stream.

Trails: The water and soil resource effects from trails should be the same in Florence/Bear as under the wilderness scale. Trails are currently causing a few local instances of soil erosion and sedimentation into water, and should continue to cause few local issues.

Campsites: The overall number of campsites, and therefore the impacts from campsites, would be slightly reduced. While the number of hiker camps would remain the same, stock camps would no longer be used by commercial pack stock, and therefore the bare ground area from those sites would be reduced or eliminated over time. Because there are few campsites known to be causing water quality or erosion impacts in this geographic unit, the positive effect should be minor and local.

Cumulative Impacts

Cumulative impacts to soil and water resources are expected to be reduced under Alternative 5. The main reduction in impacts would be due to all closure of grazing. The reduction (or improvement) in cumulative impacts under Alternative 5 would be more than any other Alternative. In the Florence/Bear Geographic Unit, most of the negative effects to soil and water resources are in pastures and can be partially attributable to commercial pack stock use. Therefore, removal of that use could cause improved conditions. However, continuation of private pack stock use and hiker use could sustain most of the local effects from campsites and trails.

John Muir Southeast – Alternative 1

Analysis

Under Alternative 1, there is unlikely to be any changes from current soil and water resource conditions. There is little use in this area other than pass-through trips to Sequoia Kings Canyon National park and dunnage trips in the North Fork of Big Pine Creek and Cottonwood Lakes. There could be an increase of use into the South Fork of Big Pine Creek from current conditions because the trail would be opened to pack stock. However, this is likely to have only a local, slight increase in erosion and sedimentation into streams and mainly upstream of Willow Lake where the trail is not well armored. The area currently receives moderate hiker use and pack stock use of the trail would likely only cause minor increased trail width, trail incision, and sedimentation into surface water.

Despite the lack of substantial impacts currently, and the lack of overnight stock holding in the area, Alternative 1 could have more negative effects to soil and water resources from trails than

the other alternatives. Under the other alternatives, some or all of the trails would be closed to commercial pack stock use. The trails are generally in good condition and effects would not change much with removal of pack stock use. However, if pack stock use decreased on the trails, there would likely be less erosion and incision in the future because only hikers would be using the trails and they generally remove less soil from trails.

Cumulative Impacts

There are no observed cumulative impacts to soil and water resources from past and present actions, and there are not expected to be cumulative impacts under Alternative 1. Use of this area is by commercial pack stock users, recreational pack stock users, and hikers. Most of these users pass through the area to access the Sequoia-Kings Canyon National Park. Therefore, effects are mainly slight erosion of trails. Under Alternative 1, the uses are all expected to remain about the same, and therefore impacts should remain about the same and minimal overall.

John Muir Southeast – Alternative 2 – Modified

Analysis

There should be very few changes in the currently minor soil and hydrologic effects within this Geographic Unit. Use is currently mainly trail use to get from the Inyo National Forest to Sequoia Kings Canyon National Park, except in the North Fork of Big Pine Creek and in the Cottonwood Lakes area. Almost all-overnight use is spot/dunnage, and so there are very few large campsites or grazed meadows. This action would impose few changes on commercial pack stock use, other than closure of some trails. Therefore, the effects will not be discussed in detail.

The North Fork Big Pine Analysis Unit is one of only two Analysis Units in the John Muir Southeast Geographic Unit where spot/dunnage trips are supported by commercial pack stock. These trips generally drop off parties near lakes and the pack stock remains mainly on system trails. The system trails are generally stable and built to withstand heavy use, and are not eroding or contributing sedimentation into surface water. Campsites serviced by pack stock were sometimes larger than the many backpacker campsites in this area, but none were found to have major water quality or soil erosion effects.

Cumulative Impacts

Cumulative impact to this area are minor, and do not constitute Cumulative Watershed Effects. While many of the watersheds in this area have a major trail and some backpacker campsites, the use does not appear to be causing alterations to water quality, stream morphology, meadow hydrologic function, or other hydrologic or soil processes other than a few local areas without commercial pack stock use. Most of the major streams are diverted into the Los Angeles aqueduct outside of the wilderness area. These diversions have occurred since the 1920s and will continue into the near future. Alternative 2 – Modified does not affect water flow and therefore does not contribute to the flow effects downstream of the diversions.

John Muir Southeast – Alternative 2

Analysis

The direct, indirect and cumulative effects to soil and water resources should be the same as under Alternative 2 – Modified. The only difference in management is that the uppermost 0.4 miles of trail to Birch Lake in the Birch Analysis Unit would be closed to commercial stock. While this could prevent future increases in impacts to soil erosion from the trail, it should not make a difference relative to Alternative 1 because the trail is rarely used by commercial pack stock.

John Muir Southeast – Alternative 3

Analysis

The effects to soil and water resources should be the same under Alternative 3 as they would be under Alternative 2. The same system trails would be closed to commercial stock use, keeping the more erosive stock off the trails and therefore preventing increased erosion. No grazing would be allowed anywhere in both alternatives, and therefore, meadows should not show any different effects.

John Muir Southeast – Alternative 4

Analysis

The effects to soil and hydrologic resources in this geographic unit should be the same as under Alternative 2 – Modified within National Forest Land. The effects on Sequoia/Kings Canyon National Park could be substantial, although the degree of the effects is unknown.

At least three major trails would be closed to commercial pack stock under Alternative 4 that would be open under Alternative 2. These trails are the South Fork of Big Pine Creek, Taboose Pass Trail, and Sawmill Pass Trail. The South Fork of Big Pine Creek Trail is currently closed to pack stock, and therefore there would likely be no change to use or soil and hydrologic effects under Alternative 4. There could be less bare soil due to campsites and less trail erosion than under Alternative 2, however. The other trails, Taboose Pass and Sawmill Pass Trails, are well maintained due to their popularity for backpacker and commercial pack stock use. They do not currently have known effects to soil and hydrologic resources and with removal of pack stock, their condition should not change substantially.

Cumulative Impacts

Sequoia/Kings Canyon National Park would likely receive less commercial pack stock use accessing the park from the John Muir Southeast Area. Sawmill Pass and Taboose Pass, two major entry points into the National Park, would be closed to commercial pack stock. Although the commercial packers might move their use to another entry point, such as Kearsarge Pass, trailhead quotas would likely prevent much increase on other trails. While the effects on the trails themselves should be minimal, reducing the number of stock entering the National Park could reduce the amount of grazing. There could therefore be a reduction of bare soil, soil compaction, sod fragmentation, stream bank trampling, and other effects to meadows in the National Park. The degree of these reductions is unknown.

The closure of the South Fork Big Pine Creek, Taboose Pass, and Sawmill Pass Trails to pack stock should not affect cumulative watershed impacts. The trails would continue to be used relatively heavily by backpackers, keeping the trail free of vegetation and compacted. The removal of commercial pack stock use might prevent the trails from eroding and incising as quickly as they would with commercial pack stock use.

John Muir Southeast – Alternative 5

Analysis

There would likely be little difference to soil and hydrologic resource affects under Alternative 5 than under any other alternative. The only analysis units that regularly receive more than pass through use, the North Fork of Big Pine Creek and Cottonwood, could see a reduction in overall overnight use by campers. However, both areas are popular for backpacker use, and would likely remain so. The reduction in pack stock users would only reduce the use by a small percentage in these areas, and therefore there should be little difference. No analysis unit in John Muir Southeast regularly receives overnight commercial pack stock use. Therefore, there are no large stock holding sites or grazing areas. The reduction in bare and compacted soil due to campsites should be minimal.

Cumulative Impacts

Cumulative affects to soil and water resources are expected to be reduced under Alternative 5, although the differences would be slight and mainly concentrated along trails. The reduction in trails used by any pack stock suggests that the potential for future impacts should be reduced. However, continuation of private pack stock use and hiker use could sustain most of the local effects from campsites and trails.

John Muir Southwest – Alternative 1

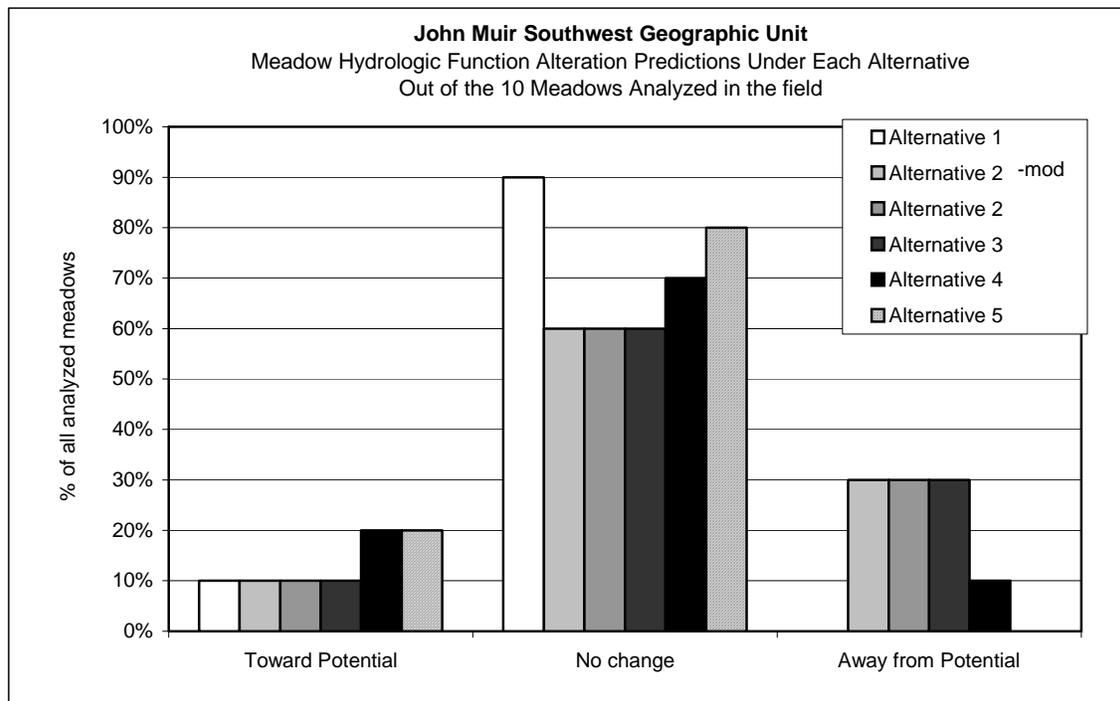

Analysis

There are likely to be few or no changes in effects to soil and water resource condition in the John Muir Southwest Geographic Unit. The area currently receives light commercial pack stock use, and is unlikely to begin receiving more. The trail and meadow impacts to soil and water resources are likely to remain, as they are today, dispersed but sometimes severe.

Meadows: Most meadows in John Muir Southwest are used sporadically by commercial pack stock, receiving grazing from one or two trips a year. Sod fragmentation, vegetation removal and stream bank trampling therefore can recover between grazing. In the future, as long as use remains about the same, meadows are likely to have little change in their generally good condition.

Meadow Hydrologic Function: Of the ten meadows analyzed for hydrologic function, only one is expected to have any change under Alternative 1 (Table 4.81). Further, there is only expected to be a difference in one meadow's hydrologic function between Alternative 1 and all other alternatives (Figure 4.19).

Figure 4.19 A comparison of estimated effects of all Alternatives to meadow hydrologic function. The chart shows the percent of the 10 meadows analyzed that are predicted to have trend toward potential, a trend away from potential, or no change in hydrologic function trend.

The one meadow that may have improved hydrologic function is Big Maxson Meadow, although the potential for change in the meadow is uncertain. In recent years, private pack stock has grazed the area, contributing to moderate hydrologic function alteration. If that use does not continue, the meadow would likely show improved hydrologic function through vegetation growth and reduction in compaction. However, that use could continue, and could perpetuate the meadow’s moderate hydrologic function alteration.

Table 4.81 Hydrologic Function Alteration Predictions for all meadows visited in the John Muir Southwest Geographic Unit. The number of meadows predicted to have each trend was estimated by the IDT, using the meadow’s characteristics such as soil moisture, stream bank stability, and meadow productivity. The predictions assume that the some meadows would not receive their allocated stock nights, if they are in an area not likely to received increased use. The prediction underestimates the worst possible effects, but is a more realistic estimation. The potential effects if all stock nights were used are included in the text.

Current Meadow Hydrologic Function Condition (# of meadows with that condition)	Trends By Number of Meadows					
	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5

Away from Potential	0	3	3	3	1	0

Meadow Stream Functional Condition (PFC): The same ten meadows were analyzed for their stream functional condition as were analyzed for meadow hydrologic function. The same results are expected, with only Big Maxson Meadow projected to have recovery of stream functional condition under Alternative 1 (Figure 4.20, Table 4.82). Because most use in the meadow is from private pack stock, commercial pack stock management should not affect the rate or degree of meadow recovery.

Alternative 1 is likely to have the same effect to stream functional condition as the other alternatives in all but Big Maxson meadow.

Figure 4.20 A comparison of predicted changes to stream functional condition (PFC) among alternatives for the streams where PFC was analyzed in the John Muir Southwest Geographic Unit. Fifteen streams were analyzed for PFC, all within meadows or other grazed areas. This chart includes all streams analyzed, whether they are at proper functioning condition or whether they are currently functional at-risk.

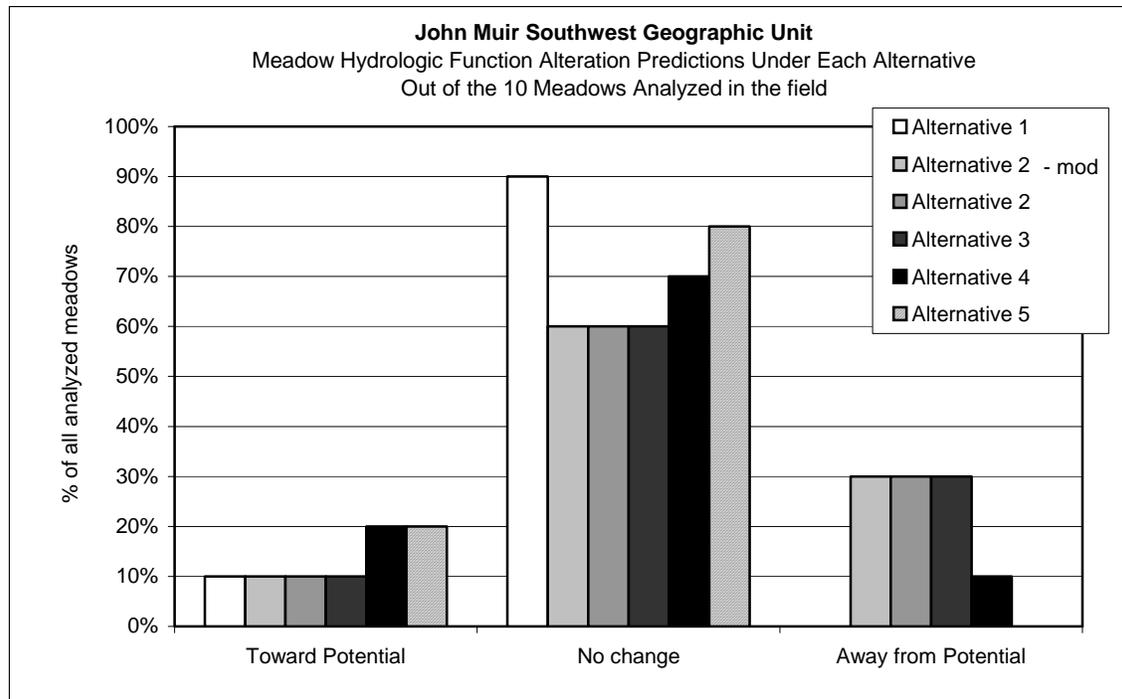

Table 4.82 Summary of all meadow stream functional condition predictions for the John Muir Southwest Geographic Unit under all alternatives. Stream functional condition was determined using the Proper Functioning Condition (PFC) protocol. The streams are separated by those that are currently properly functioning, those that are functional at-risk with an upward trend, those that are functional at-risk with a non-apparent trend, and those that are functional at-risk with a downward trend. The predictions are based on assumptions that grazing will continue about as it has in the past in most areas, except in meadows that are closed to grazing and those nearby meadows where grazing might move to.

Current stream functional condition rating (# with each rating)	Number of Meadows expected to have each trend					
	Alternative 1	Alternative 2 – Modified	Alternative 2	Alternative 3	Alternative 4	Alternative 5
Proper Functioning Condition (6)						
Toward potential	0	0	0	0	0	0

Toward potential	1	1	1	1	1	2
No change	9	9	9	9	9	8
Away from potential	0	0	0	0	0	0

Trails: Trails in the John Muir Southwest Geographic Unit are often directly adjacent to a stream and therefore have the potential to contribute fine sediment into the stream, locally altering water quality. This is unlikely to change under Alternative 1. In some areas, trails causing resource impacts would be repaired, but John Muir Southwest is not likely a high priority area for repair due to low use levels. Although some trails are incised and widened, and possibly contributing to slight sediment increases in local areas of streams, they are unlikely to be affecting the overall good water quality or soil productivity of this area.

Campsites: Campsites are currently not known to be causing excessive soil erosion or sedimentation into surface water. Because use should not change, it is unlikely that there will be any noticeable effect to soil and water resources from campsites under Alternative 1.

Cumulative Impacts

The past, present, and reasonably foreseeable future actions within the John Muir Southwest Geographic Unit are similar to the Ansel Adams and John Muir Wildernesses in general. The difference is that there is little commercial pack stock use in this area, and therefore few impacts can be related to commercial pack stock use. Continuation of low levels of commercial pack stock use should not change current condition and should not increase the potential for cumulative soil or water resource effects or cumulative watershed effects.

John Muir Southwest – Alternative 2 – Modified

Analysis

There should be little to no difference to soil and water resource impacts between Alternative 2 – Modified and Alternative 1 from grazing, trails or campsites. There is little commercial pack stock use in the area currently, and although there is allowance for increased use into the area

under Alternative 2, there is unlikely to be major increases in use. If use unexpectedly increased in the area, overall effects to soil and water resources would likely be too small to be noticed. The area has highly productive meadows and few areas affected now, and increased use would likely allow soil and water conditions to remain within standards.

Meadows: There is unlikely to be a difference between grazing effects to meadow hydrologic function or stream condition between Alternatives 1 and Alternative 2 – Modified in any location (Figure 4.19, Figure 4.20). However, if grazing is used to its full allocation, three meadows could have a trend away from potential hydrologic function where they were likely to remain in their same condition under Alternative 1.

Meadowbrook (bim5), Above Fleming Lake (fle21) and Above Lower Indian Lake (fle12) could all have substantially increased grazing relative to Alternative 1. Under current management, the meadows are grazed lightly or not at all and should show static hydrologic function and stream condition under Alternative 1. Under Alternative 2 – Modified, grazing would be allowed over 75 stock nights in all three meadows. It is possible that the hydrologic function and stream condition could move slightly away from their natural potential.

Trails: Under Alternative 2 – Modified, there are no substantial changes to trail management from current condition, and therefore the effects to soil and hydrologic resources should be the same as under Alternative 1.

Campsites: Campsites have minor and local impacts to water quality or soil productivity in this Geographic Unit, and that should remain the same under Alternative 2 – Modified. The difference between Alternative 2 – Modified and Alternative 1 is that stock holding sites would be designated under Alternative 2 – Modified. Therefore, the potential future increase in bare, compacted soil could be less under Alternative 2 – Modified.

Cumulative Impacts

The past, present and reasonably foreseeable future actions are the same as on the wilderness-wide scale, although this area has less extensive commercial pack stock use and other recreational use than most other geographic units.

Alternative 2 – Modified would allow for increased use in this area. It is unlikely that use would increase dramatically, however, and conditions should not change. Currently, there are local trail impacts to water quality where trails closely parallel streams. There are also a few meadows with what appear to be historical alteration of hydrologic function. If commercial pack stock use remains about the same as currently, there would likely be no increase in water and soil impacts. If use increases, there could be slightly increased meadow sod fragmentation, meadow stream bank trampling, and increases in bare soil due to increasing size of campsites as they are used more frequently.

There are currently no known cumulative watershed effects and there should be no increased potential for CWEs under Alternative 2 – Modified.

John Muir Southwest – Alternative 2

Analysis

There should be little to no difference to soil and water resource impacts between Alternative 2 and Alternative 2 – Modified from grazing, trails or campsites. Management should be about the same under these alternatives, except that there would be 14 fewer destinations available under Alternative 2.

Meadows: There is unlikely to be a difference between grazing effects to meadow hydrologic function or stream condition between Alternatives 2 and Alternative 2 – Modified. The grazing management is the same in all meadows, and therefore the effects should be the same.

Trails: Under Alternative 2, there are no substantial changes to trail management from current condition, and therefore the effects to soil and hydrologic resources should be the same as under Alternative 1.

Campsites: Campsites have minor and local impacts to water quality or soil productivity in this Geographic Unit, and that should remain the same under Alternative 2. The difference between Alternative 2 and Alternative 2 – Modified is that about 14 more stock holding sites would be designated. Therefore, there could be barer, compacted soil from campsites than under Alternative 2. The difference should be negligible on the geographic-unit scale.

Cumulative Impacts

The past, present and reasonably foreseeable future actions are the same as on the wilderness-wide scale, although this area has less extensive commercial pack stock use and other recreational use than most other geographic units.

Alternative 2 would allow for increased use in this area. It is unlikely that use would increase dramatically, however, and conditions should not change. Currently, there are local trail impacts to water quality where trails closely parallel streams. There are also a few meadows with what appear to be historical alteration of hydrologic function. If commercial pack stock use remains about the same as currently, there would likely be no increase in water and soil impacts. If use increases, there could be slightly increased meadow sod fragmentation, meadow stream bank trampling, and increases in bare soil due to increasing size of campsites as they are used more frequently.

There are currently no known cumulative watershed effects and there should be no increased potential for CWEs under Alternative 2.

John Muir Southwest – Alternative 3

Analysis

Effects to soil and water resources should be the same under Alternative 3 as they are under Alternative 2 – Modified. The grazing proposal is identical to Alternative 2 – Modified, and there is only one system trail that will be open to commercial pack stock use under Alternative 3 that would not be open under Alternative 2 – Modified. There is no reason for use to increase in this area unless client demand changes. Some increased use in the area would be allowed under Alternative 2 – Modified as well, and therefore there should not be any difference between the use and therefore the effects under Alternative 3.

John Muir Southwest – Alternative 4

Analysis

The effects to soil and water resources should be same as under Alternative 4 as under Alternative 2 – Modified. At least five destinations would be prohibited to pack stock use that are open under Alternatives 1 through 3, and one additional meadow would be prohibited to grazing. However, these destinations do not receive substantial use on a regular basis, and the meadow closed to grazing, the meadow Above Fleming Lake (Fleming Analysis Unit), has not had any grazing recently reported. Therefore, the changes in management should not actually change effects to soil and water resources on the ground.

Under Alternative 4, there would be a reduction in the potential for future soil and water resource impacts with the few destination closures and the one meadow closure. It is not expected that use in this area would rise dramatically, however, because of limited demand for use here. If use does increase, the meadow at Meadowbrook could have increased sod fragmentation in critical areas, but only if the stock are not managed to avoid critical areas. In the large meadow, it is likely that stock could be managed to avoid critical fen areas through use of electric fencing or other means.

Cumulative Impacts

Cumulative impacts are expected to remain the same under Alternative 4. Although there could be an increased amount of commercial pack stock grazing in this area, it is unlikely that there would be increased use due to low customer demand for trips here. The overall fewer number of trails approved for commercial pack stock use suggests the potential for a cumulative impact is unlikely when compared to the existing condition.

John Muir Southwest – Alternative 5

Analysis

There should be little difference to soil and water resource condition under Alternative 5 compared to any other alternative. There are low levels of commercial pack stock use and grazing in the area, and therefore removal of that use would not likely cause any but local change in condition. The main difference would be that the few meadows currently grazed could have slight reductions in sod fragmentation, stream bank trampling, and vegetation removal. The differences from current condition and the other alternatives would likely be immeasurable.

Cumulative Impacts

Cumulative affects to soil and water resources are expected to be reduced under Alternative 5, although the improvement would likely be minor at only a few locations. The small reduction in number of meadows grazed, trails used by any pack stock, and campsites used by stock holding parties suggests that impacts should be reduced from current levels. The reduction (or improvement) in cumulative impacts under Alternative 5 would be more than any other alternative. However, the low current commercial pack stock use suggests that the cumulative impacts would be only slightly improved from current conditions. Continuation of private pack stock use and hiker use could sustain most of the local effects from campsites and trails.

4.3 Biological Environment

4.3.1 Wildlife

Methodology

Context. The context of an impact considers whether the impact would be localized or widespread across the analysis area. This aspect concerns the scale over which the impacts would occur. For instance, an impact that reduces the capability of habitat over broad areas has the potential to adversely affect habitat connectivity and corridor maintenance at the landscape level. This could have a more profound effect on wildlife species/species group fitness and survivability that would be more likely to affect the species viability. In contrast, a more contained localized impact may be important locally but is relatively minor at a landscape level.

Intensity. The intensity of an impact considers whether the impact would be non-substantive, substantive, or significant. Minor impacts are effects that would be detectable but would not be expected to substantively affect habitat structure and function for a specific species/species group. The direct effects to the species/species group would not be substantive enough to change the species/species group ability to utilize available habitat, or affect the species/species group survivability in that habitat. Substantive impacts would modify habitat structure and function and would have an effect on the habitat suitability for an individual species/species group. A significant impact would have a substantial effect on the sustainability of a habitat for an individual species or group, and potentially significantly affect the species use of the habitat or its survivability in that habitat.

Duration. The duration of an impact considers whether impact would occur in the short-term or continue and/or persist over a longer term. A short-term impact would be temporary in duration (such as a human disturbance event that may not be repeated on a sustained basis) and could be associated with activities such as infrequent camping or trail use that may not regularly continue through time. A longer-term impact could have a continuous, persistent effect or consequence on wildlife habitats or populations; such as loss of wet meadow and wetland habitats, abandonment of habitats, or a decline in a sustained population through time.

Type of Impact. The type of impact considers whether the impact would be beneficial or adverse to biological resources. A beneficial impact would result if an action contributes to improved habitat suitability for a species/species group, or an improvement in individual animal or population fitness and survivability. An adverse impact would result in opposite effects.

Wilderness Scale

Introduction

The prediction of direct, indirect, and cumulative effects on Threatened, Endangered, Sensitive and Management Indicator wilderness wildlife species identified in Chapter 3 is a difficult prospect for a number of reasons. First, there is an overwhelming lack of research, administrative studies, surveys, and monitoring of most of these wildlife species and habitat conditions in the AA/JM Wildernesses. This includes a lack of peer-reviewed scientific studies that have examined the effects of recreational use, specifically the effects of commercial pack stock activities (such as meadow grazing, trail use, and camps) on wildlife populations and habitat.

Knight and Gutzwiller (1995) stated in their book “Wildlife and Recreationists” that “recreation activities disturb wildlife [are] well appreciated but poorly understood. Most popular forms of recreation in wildlands have yet to receive even one detailed study.” They further state that the understanding of effects of recreation on wildlife is rudimentary.

Gaines et al (2003) attempted to develop models to illustrate the cumulative effects of motorized and non-motorized linear recreation routes on wildlife habitats on the Okanogan and Wenatchee National Forests. Their work included a thorough review of all scientific studies on the effects of non-motorized trail use in wilderness on wildlife populations and wildlife habitats.. The conclusion of the modeling effort was that there were a few studies that looked at effects of non-motorized trail use. The authors stated: “Relatively reliable information was available for many focal species concerning the immediate spatial effect, or zone of influence of a particular road or trail associated factor. Less information was available relating to the intensity of human use.” They also concluded that because quantitative evaluation of cumulative effects was not possible owing to data limitations for many species, it was necessary to develop a qualitative ranking scheme.

The study noted information gaps in the scientific literature that hindered understanding wildlife and recreation trail interactions, including:

1. The lack of information on the interactions between wildlife and non-motorized trails for many wildlife species, especially for species with small home ranges and limited mobility.
2. The interactions between wildlife and the intensity of human use on recreation trails (such as trail density or number of hikers per unit time).
3. The interactions between wildlife habitat use and the spatial extent (such as the proportion of a species home range, or a watershed) of recreational activity.
4. The relation of recreation trail and wildlife interactions to the demography of a particular species of management interest.

The study results demonstrate the difficulty in attempting to analyze the effects of specific activities that occur on trail systems on wildlife populations, especially given that activities such as commercial pack stock operations are but one user group in a multitude of users in the wilderness using the same trails, destinations and camping areas. Commercial pack stock use has been estimated in this EIS to amount to approximately 11 to 13 percent of all users in the AA/JM Wildernesses. The timing and locations of use, including trail use and destinations, is highly variable from one year to the next based on client demand.

Similar problems are found in the assessment of pack stock grazing effects on wildlife populations and wildlife habitat. In 1999, researchers published “Sierra Nevada Ecosystems in the Presence of Livestock”, a scientific review of what is known about the impacts of livestock grazing on multiple resources including wildlife populations and wildlife habitats in the Sierra Nevada (Diaz et al.1999). The report completely lacked information concerning the specific effects of pack stock grazing on wildlife and wildlife habitat.

The assessment is useful in the extrapolation of its findings to pack stock grazing use; however, it must be recognized that pack stock will graze somewhat differently than cattle or sheep. For example, pack stock do not utilize riparian shrubs like cattle might, and there are substantially fewer number of pack stock at one time (usually a few to up to 25) in any given meadow. Pack

stock may only be present in a meadow for a few days per summer, or they may graze intermittently throughout the summer, as well as in highly variable use patterns from one year to the next, unlike livestock allotments. Controlled scientific studies that document the effects of commercial pack stock use on wildlife and wildlife habitats are absent.

The “Science Review” acknowledges that the available literature is replete with statements about the probable effects of grazing, many of them observational or anecdotal, but rarely is there controlled studies from which to accurately assess different levels of grazing. Most studies refer to heavy grazing without actual forage use quantification by cattle or sheep, and do not examine moderate grazing intensities that are proposed in this EIS. The “Review” notes:

Many studies have focused on documentation of the effects of abusive (or heavy) grazing on ecosystem structure and function. The scientific foundation for understanding the response to abusive grazing is clear: plant cover is destroyed, soil erodes, water quality is degraded, individual wildlife species and their habitats are destroyed, biodiversity declines, invasive plants take hold. Conversely, ample studies have shown removal of domestic animals generally results in increases in plant cover, biomass, and diversity to some point. Water quality, stream bank stability, wildlife and fish habitat improve. Again the changes in ecosystem recovery response vary by ecosystem. Arid and semi-arid systems are generally slow to respond while riparian systems and areas with sufficient water are the most resilient in general, and improve the fastest. These studies are sufficient if the goal is to remove livestock grazing. However, if the goal is to maintain use of the public lands in the Sierra Nevada, then many more studies quantifying effects at different grazing intensities, frequencies, and seasons of use must be conducted.

Studies on the effects of pack stock grazing in high mountain meadows are also needed. The “Science Review” concluded that based on the available literature that livestock grazing in the Sierra Nevada generally negatively impacts wildlife.

Some assumptions and limitations exist for this effects analysis related to the effects of commercial pack station operations and the trail system alternatives on wildlife species and wildlife habitats. System and user trail use, as well as use of campsites and destinations by wilderness users (including commercial pack stock operators and clients) can result in variable levels of displacement and avoidance by some species of wildlife of areas immediately adjacent to these human use areas. These types of impacts may occur at critical times important to the completion of essential life activities by wildlife such as breeding, nesting and fawning, young rearing, and foraging (Gaines et al. 2003). The magnitude and extent of the disturbance and avoidance effect is highly variable by species and individuals within a species, based on such factors as previous encounters, activity at the time of the encounter, condition of the animal, and time of year of the disturbance. Some species of wildlife can habituate to predictable patterns of human disturbance resulting in lessened impacts on the species. The scientific understanding of how such impacts affect wildlife populations, their viability, and habitat use is poorly understood (Gaines et al 2003, Knight and Gutzwiller 1995).

The trail system alternatives propose trail management levels, system and use trail determinations, and use criteria (such as not suitable for commercial stock). The effects of such actions on wildlife habitat and wildlife use of trail corridors are minor based on the trail proposal assumptions stated in the trails section of this EIS. No trails will be closed to all users, eliminated, or re-routed under any of the alternatives. The factors that affect wildlife habitat, such as human disturbance along the trail corridor and poor trail location through key wildlife habitats, will not change significantly under any alternative. The change in trail management

level desired condition and trail suitability for commercial stock are unlikely to substantially change trail resource condition ratings, and subsequently wildlife habitat, over the next 20 years or longer. Site specific trail proposals outside the scope of this analysis will likely continue to occur to modify trail locations to restore or enhance key wildlife habitat.

The effects of commercial pack stock grazing on riparian wildlife habitats are similar enough to cattle grazing effects described in the scientific literature under similar levels of forage utilization and timing to extrapolate effects from livestock grazing studies. Many wilderness meadow habitats have been adversely affected, with a smaller subset of these meadows exhibiting substantial losses of wetland and wet meadow habitats from historical overgrazing practices. Analyzing the effects of commercial pack stock grazing on wildlife habitats in these meadows is very difficult where hydrologic conditions are already substantially degraded and meadow recovery remains uncertain as a result of continued hydrologic instability.

Commercial pack stock grazing at moderate forage utilization levels of 30 and 40 percent use can impact some riparian-dependent and associated wilderness wildlife species and their habitats that are found under relatively pristine wilderness conditions. The site specific and overall wilderness grazing impacts affect habitat suitability; modify some species numbers, individual vigor and survival ability; and alter use patterns of habitat. There is no research or monitoring evidence at this time, however, to suggest that this grazing is leading to a loss of viability for any wildlife species within the planning area. The effect is more of an unknown qualitative change in the habitat suitability from grazing induced changes in habitat structure, and direct animal disturbance interactions.

Alternative 2 through 4 display stock night capacity guidelines for individual meadows. Alternative 1 implements range readiness standards with no utilization standards until future action analyses appropriate utilization levels based on 2001 Wilderness Plan direction. Actual grazing use would be highly variable under implementation of any of these alternatives, and is likely to be considerably less than capacity in many meadows based on analysis of reported stock nights grazed from 2001 through 2003. The actual use reported is difficult to interpret in many meadows because use has been reported as a total for a watershed, or group of meadows, and not a single meadow. As a result there is a dichotomy in the analysis between the effects that would occur if available stock nights were fully utilized to meet the allowable stock nights and utilization levels, versus what is more likely to occur. Many meadows may not receive any use in some years. The highly popular destinations such as the Silver Divide, Mono Creek, and the Thousand Island, Rush, and Alger Creeks areas are more likely to receive sustained annual grazing use. Consequently, it is difficult to model the effects of actual grazing use effects on meadow wildlife habitat.

The discussion below focuses on Threatened, Endangered, Sensitive, and Management Indicator Species at the Wilderness Scale. The wildlife Geographic Scale section will further analyze differences of the proposed alternatives beyond the Wilderness Scale analysis to identify specific localized areas for the Yosemite toad and the Management Indicator Species and species groups where the effects by alternative are known to be substantive. Cumulative effects are described at the Wilderness Scale. Alternative 5 is sufficiently described at the Wilderness Scale for all wildlife species.

Summary of Alternatives 1-5 Impacts

Wildlife Biological Evaluation/Assessment determinations common to all alternatives:

Threatened and Endangered Species: Implementation of any Alternatives would not affect the bald eagle and Paiute cutthroat trout or their habitat found within the analysis area.

Implementation of Alternatives 1 through 4 may affect but would not adversely affect the Sierra Nevada bighorn sheep. Alternative 5 would not affect the Sierra Nevada bighorn sheep or its habitat.

Forest Service Region 5 Sensitive Species: Implementation of Alternatives 1 through 4 may affect individuals of the following species but would not contribute to a trend toward federal listing of any of these species, or lead to a loss of their viability in the planning (analysis) area: Yosemite toad, mountain yellow-legged frog, willow flycatcher, great gray owl, American marten, Pacific fisher, California wolverine, Sierra Nevada red fox, California spotted owl, Townsends big-eared bat, and the pallid bat. Implementation of Alternative 5 would not affect any of these species.

Management Indicator Species or Species Group: Implementation of any Alternative would not result in the loss of viability of any other MIS (i.e., Not on the federal threatened, endangered or proposed species list or Forest Service Region 5 sensitive species list) found within the planning (analysis) area.

No other federally listed threatened, endangered, proposed, or Forest Service Region 5 sensitive species or their habitat would be affected by implementation of any of the alternatives.

Effects Summary by Alternative

Wildlife – Alternative 1

The majority of 267 Yosemite toad occupied breeding meadows within the AA/JM Wildernesses would likely be unaffected by commercial pack stock use if grazing patterns continue as reported and observed from 2001 through 2004. Eighty-seven of the 267 occupied breeding meadows would be more likely to have commercial pack stock grazing overlap where impacts to Yosemite toad breeding habitats may occur.

Actual grazing use overlap and subsequent impacts would be highly variable based on past use with many meadows likely to receive very light to no use, and therefore a high probability of non-substantive impacts to toad breeding habitat. A small percentage of the 87 occupied breeding meadows (likely < 10 percent) would likely have substantive trampling and chiseling impacts from commercial pack stock grazing in Yosemite toad breeding sites. The 20 percent ground disturbance standard would be implemented to limit the amount of disturbance in critical breeding areas such as stream banks and lakes and ponds where toads may be found. Impacts in Yosemite toad breeding sites could substantively increase if meadows are grazed at maximum forage utilization levels allowed in the John Muir, Ansel Adams and Dinkey lakes Wilderness Plan.

Gradual implementation of range unsuitable meadow determinations as reasonably foreseeable action per Wilderness Plan direction may reduce the total number of Yosemite toad occupied breeding meadows where grazing impacts would likely occur.

Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be impacted if meadows are grazed to maximum allowable forage utilization levels.

The alternative allows for the highest level of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it has the least restrictive management control over campsite use, destination impacts such as access and social trails, grazing impacts, and approved system and use trails. All meadows are open to commercial pack stock grazing. Two hundred forty six meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. Four meadows would be closed to grazing. Sixty one meadows with hydrologic functioning problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates. Habitat structural characteristics could be impacted if meadows are grazed to maximum allowable forage utilization levels

Mountain yellow-legged frog stream habitat could be potentially impacted at two meadows approved for commercial pack stock grazing.

There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on approximately 7 miles of system trail closed to commercial stock as a result of resource concerns, and 102 miles on 94 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if sections with resource impacts begin to re-vegetate, and narrow in width such as where trails course through meadows, and at stream and spring crossing areas.

Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.

Wildlife – Alternative 2 - Modified

Alternative 2 – Modified manages for an increased level of protection for Yosemite toad meadow breeding habitats since grazing would be managed to avoid Yosemite toad occupied breeding habitats. Fifty two meadows approved for commercial packer stock grazing overlap with Yosemite toad breeding areas. Thirty four meadows that are approved for grazing in Alternative 1 are either unsuitable (28) for grazing or rested from grazing (6) in this alternative and would have full protection for the breeding habitats. One hundred ninety seven occupied Yosemite toad breeding meadows outside of grazing zones would be fully protected since grazing would be prohibited. Suitable/unsuitable determinations would be implemented immediately.

The alternative allows for some level of control of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it designates overnight stock holding camps, implements destination quotas that would limit destination impacts such as access and social trails, grazing impacts. All meadows outside of grazing zones are closed to commercial pack stock grazing. One hundred forty three meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. A subset of 110 meadows would be closed to grazing as a result of unsuitable for grazing determinations. Thirty four meadows with hydrologic functioning

problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates.

Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be impacted if meadows are grazed to maximum allowable use levels.

Mountain yellow-legged frog stream habitat could be potentially impacted at one meadow approved for commercial pack stock grazing.

There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on 73 miles of system trail not suitable for commercial stock, and 80 miles on 82 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if impacted sections narrow in width such as where trails course through meadows, and at stream and spring crossing areas.

Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.

Wildlife – Alternative 2

Alternative 2 manages for an increased level of protection for occupied Yosemite toad meadow breeding habitats. Fifty-six meadows approved for commercial packer stock grazing overlap with Yosemite toad breeding areas. Thirty meadows that are approved for grazing in Alternative 1 are unsuitable for grazing in this alternative and would have full protection for the breeding habitats. A 5 percent critical area maximum allowable disturbance standard would be implemented in all other Yosemite toad breeding habitat areas where commercial pack stock grazing would be approved to minimize trampling and chiseling effects to the breeding habitats, and minimize the potential for stock trampling of metamorph toads. Suitable/unsuitable determinations would be implemented immediately.

The alternative allows for some level of control of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it designates overnight stock holding camps, implements destination quotas that would limit destination impacts such as access and social trails, grazing impacts. All meadows outside of grazing zones are closed to commercial pack stock grazing. One hundred thirty nine meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. A subset of 108 meadows would be closed to grazing as a result of unsuitable for grazing determinations. Forty one meadows with hydrologic functioning problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates.

Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be impacted if meadows are grazed to maximum allowable use levels.

Mountain yellow-legged frog stream habitat could be potentially impacted at one meadow approved for commercial pack stock grazing.

There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on 73 miles of system trail not suitable for commercial stock, and 80 miles on 82

use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if impacted sections narrow in width such as where trails course through meadows, and at stream and spring crossing areas.

Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.

Wildlife – Alternative 3

Alternative 3 manages for an increased level of protection for Yosemite toad meadow breeding habitats. Fifty-three meadows approved for commercial packer stock grazing overlap with Yosemite toad breeding areas. Thirty three meadows that are approved for grazing in Alternative 1 are either unsuitable (32) for grazing or rested from grazing (1) in this alternative and would have full protection for the breeding habitats. A 5 percent critical area maximum allowable disturbance standard would be implemented in all other Yosemite toad breeding habitat areas where commercial pack stock grazing would be approved to minimize trampling and chiseling effects to the breeding habitats, and minimize the potential for stock trampling of metamorph toads. Suitable/unsuitable determinations would be implemented immediately.

The alternative allows for some level of control of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it designates overnight stock holding camps, implements destination quotas that would limit destination impacts such as access and social trails, grazing impacts. All meadows outside of grazing zones are closed to commercial pack stock grazing. One hundred forty three meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. A subset of 110 meadows would be closed to grazing as a result of unsuitable for grazing determinations. Thirty four meadows with hydrologic functioning problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates.

Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be impacted if meadows are grazed to maximum allowable use levels.

Mountain yellow-legged frog stream habitat could be potentially impacted at one meadow approved for commercial pack stock grazing.

There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on 63 miles of system trail not suitable for commercial stock, and 87 miles on 87 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if impacted sections narrow in width such as where trails course through meadows, and at stream and spring crossing areas.

Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.

Wildlife – Alternative 4

Alternative 4 manages for an increased level of protection for Yosemite toad meadow breeding habitats. Fifty-six meadows approved for commercial packer stock grazing overlap with Yosemite toad breeding areas. Thirty meadows that are approved for grazing in Alternative 1 are unsuitable for grazing in this alternative and would have full protection for the breeding habitats. A 5 percent critical area maximum allowable disturbance standard would be implemented in all other Yosemite toad breeding habitat areas where commercial pack stock grazing would be approved to minimize trampling and chiseling effects to the breeding habitats, and minimize the potential for stock trampling of metamorph toads. Suitable/unsuitable determinations would be implemented immediately.

The alternative allows for some level of control of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it designates overnight stock holding camps, implements destination quotas that would limit destination impacts such as access and social trails, grazing impacts. All meadows outside of grazing zones are closed to commercial pack stock grazing. One hundred twenty meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. A subset of 138 meadows would be closed to grazing at an unknown future date as a result of unsuitable for grazing determinations. Twenty seven meadows with hydrologic functioning problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates.

Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be impacted if meadows are grazed to maximum allowable use levels.

Mountain yellow-legged frog stream habitat would not be impacted since all three meadows would be closed to grazing.

There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on 173 miles of system trail not suitable for commercial stock, and 165 miles on 153 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if impacted sections narrow in width such as where trails course through meadows, and at stream and spring crossing areas.

Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.

Wildlife – Alternative 5

There would be no commercial pack stock grazing that would overlap with Yosemite toad occupied breeding habitats, or willow Flycatcher and great gray owl meadow suitable unoccupied habitats. Elimination of human and pack stock disturbance on trails, camps, and grazing areas associated with commercial pack stock operations would improve MIS mule deer, yellow warbler, meadow and meadow edge bird guild species habitats, as well as use of these habitats by these species.

Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas

Threatened and Endangered Species

Sierra Nevada Bighorn Sheep – Alternatives 1 through 4

Analysis

No substantive difference exists in effects to the Sierra Nevada bighorn sheep or its habitat with implementation of any of these alternatives. Pack stock, including llamas and burros (unlike domestic sheep and goats), cannot transmit disease to bighorn sheep and therefore do not pose a threat to the species. The continuation of light commercial pack stock use on trail systems and destinations on the Inyo National Forest in key bighorn habitats within the Mt. Langley, Mt. Williamson, Mt. Baxter, Wheeler Ridge, and Mt. Gibbs herd ranges would result in infrequent, benign encounters where bighorn observe from high alpine habitats the commercial pack stock operations. These encounters are most likely at thoroughfare mountain passes, and limited lower elevation destinations on the Inyo National Forest such as at Upper Cottonwood Basin-New Army Pass, Shepherd Pass, Sawmill Pass, Kearsarge Pass, Morgan Pass area, Upper Tamarack Basin below Wheeler Ridge, and Mono Pass. No effect would take place to bighorn sheep in the Baxter Pass area since the trail has not been used in recent years by commercial pack stock operators, and all alternatives would designate this system trail not suitable for commercial stock.

Camp and destination use by commercial pack stock operations would be unlikely to have any substantive effects to bighorn sheep that would cause sheep to modify or abandon habitat use areas. Camps and destination use generally occur at lower elevation forested areas outside of bighorn sheep herd habitat use areas. Commercial pack stock operators do occasionally drop clients off in locations such as Upper Cottonwood Basin or Upper Tamarack Basin where clients may hike into bighorn range to reach peaks. This type of activity would not occur within the California Bighorn Sheep Zoological Area since a Forest Order closure is in place to restrict all camping and off-trail hiking to areas outside key sheep habitat use areas. Commercial pack service to mountaineers and peak hikers is a very small part of the overall pack stock clientele and usually occurs in areas outside of key Sierra Nevada bighorn sheep high elevation habitats. Implementation of any of the alternative trail transportation system and management level designations, and commercial pack stock system and use trail suitability determinations would have no adverse effects on the Sierra Nevada bighorn sheep since trails have not been determined to be adversely affecting the species use of available key habitat areas in any of the herd ranges.

The Biological Assessment prepared for this EIS has determined that implementing alternatives 1 through 4 may affect, but will not likely adversely affect, the Sierra Nevada bighorn sheep. A previous informal consultation with the Ventura Field Office of the U.S. Fish and Wildlife Service was conducted by the Inyo National Forest in January, 2001 as part of Section 7 requirements of the Endangered Species Act. The consultation was conducted for the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses Management Plan EIS Record of Decision. It included an analysis of commercial pack stock operations as part of the general wilderness use that could overlap with Sierra Nevada bighorn sheep habitats. It was similar to this analysis in

many respects since it addressed trail use, camping, and destination use for all wilderness user groups. The U.S. Fish and Wildlife Service concurred with the same determination as this analysis, namely that it may affect but will not likely adversely affect the Sierra Nevada bighorn sheep. There is no critical habitat designated for this species, therefore, the implementation of these alternatives will not affect any critical habitat.

Cumulative Impacts

The species was originally listed in 2000 as endangered by the U. S. Fish and Wildlife Service because of the dramatic population decline in the late 1990s attributable to predation by mountain lions, failure of sheep to utilize low elevation favorable winter range habitat related to mountain lion presence, and the threat of large-scale mortality that could occur if domestic sheep transmitted disease to a bighorn population. The inability of existing regulatory mechanisms to deal with the issues of lion predation and disease transmission was also noted as a major reason for the listing of the species. The minor disturbance effects of commercial pack stock operations within or adjacent to Sierra Nevada bighorn sheep habitat would be insignificant to the cumulative effects operating on this species and its habitat.

Key cumulative affecters on the species that have been reduced since the species was listed as endangered in 2000 are predation of sheep by mountain lions, and the threat of disease transmission to bighorn sheep by domestic sheep. The population has increased substantially since listing to over 300 animals in response to the control of mountain lion predation and the return of bighorn sheep to low elevation winter ranges. The domestic sheep disease transmission issue has been substantially ameliorated by closure of domestic sheep allotments adjacent to bighorn habitats. Inyo National Forest Orders prohibit domestic goats within suitable bighorn habitat to prevent possible disease transmission, and dogs must be kept under immediate verbal or physical control at all times by their owners to prevent potential harassment to bighorns. The human use restrictions put into place in the Mt. Williamson and Mt. Baxter California Bighorn Sheep Zoological Areas created in 1977 continue to be in force by Forest Order. In addition, transplant of bighorn sheep to supplement existing marginal populations continues to improve the overall distribution of sheep and viability prospects.

Non-commercial pack stock recreation, backpackers, mountain climbers, and hikers will continue to go into or near bighorn habitat. These activities will continue to have minor effects on bighorn sheep from disturbance encounters that result in bighorn flight responses and the associated minor changes in bighorn use of habitat, especially with off-trail hikers and peak climbers that come into direct contact with bighorn.

Sierra Nevada Bighorn Sheep – Alternative 5

Analysis

The endangered Sierra Nevada bighorn sheep and its habitat will be largely unaffected by cessation of all commercial pack stock activities since the vast majority of the summer range habitat of the species is outside of the commercial use areas of operation. Commercial pack stock operations represent only 3 to 5 percent of all users in the key bighorn habitat areas in Sawmill, Shepherd, Kearsarge, Cottonwood, and Tamarack Analysis Units with much of this commercial pack stock use in the first 3 areas traveling to destinations in Sequoia-Kings Canyon National Park. As a result, commercial pack stock use is not considered a substantive affecter of bighorn

sheep habitat or the species use of the habitat. In addition, bighorn have the ability to habituate to non-threatening, predictable uses of adjacent areas of human recreation use, particularly when use does not overlap with critical habitat areas such as lambing habitat (Wehausen 2000).

The U. S. Fish and Wildlife Service listing proposed rule of January 3, 2000 (USDI Fish and Wildlife Service 2000) identified recreation as a minor affector of the species that did not contribute to the listing of the species. Recreational use within bighorn range, including commercial pack stock operations, was not considered a contributor to population decline of the species that warranted the listing of the species as endangered. The elimination of low existing use that occurs by commercial pack stock along trails in the upper Sawmill, Shepherd Pass, Morgan Pass, Upper Tamarack Basin, Mono Pass, and New Army Pass-Upper Cottonwood Basin areas where sheep may encounter limited overlap of their range with pack stock operations would likely have no effect on the way bighorn currently use the habitat. The determination of the Biological Assessment prepared for this EIS is that implementation of this alternative would not affect the Sierra Nevada bighorn sheep or its habitat.

Cumulative Impacts

The cessation of all commercial pack stock use within bighorn habitat will constitute no substantive change in the cumulative effects identified for Alternatives 1 through 4 of land uses and environmental factors affecting the bighorn sheep.

Paiute Cutthroat Trout – All Alternatives

Analysis and Cumulative Impacts

The Biological Assessment prepared for this EIS has determined that implementation of any of the alternatives would not affect the Paiute cutthroat trout (PCT). There is no critical habitat designated for this species therefore the implementation of these alternatives would not affect any critical habitat.

Commercial pack stock use is currently very limited on two trails that might access the PCT populations. There are no designated stock camps or pack stock grazing areas within 1 mile of either PCT populations being proposed under any Alternative. No actions are being proposed that would indirectly affect the species through reductions in the quality of habitat.

Implementation of the any of the alternative trail transportation system and management level designations, and commercial pack stock system and use trail suitability determinations would have no effect on the Paiute cutthroat trout since trails have not been determined to be adversely affecting the use of this species' occupied habitat.

Bald Eagle – All Alternatives

Analysis and Cumulative Impacts

The Biological Assessment has determined that implementation of any alternative would not affect the bald eagle since commercial pack stock operations do not substantively overlap with any known bald eagle nest territories or key foraging habitats. Known nest sites are found outside of wilderness. There is always the possibility that additional bald eagle nests may occur in wilderness forests around the major reservoirs, but none are known at this time.

Wilderness use around these reservoirs by commercial pack stock operations includes system trail use and minor amounts of grazing in meadows habitats. The one nest outside but adjacent to the wilderness is at Edison Reservoir, which is within viewing distance of the system trail that commercial pack stock operators use to access wilderness. No evidence exists that system trail use, by any user group, is having any adverse effect on nesting territory use by bald eagles. Implementation of any of the alternative trail transportation system and management level designations, and commercial pack stock system and use trail suitability determinations would have no effect on the bald eagle since trails have not been determined to be adversely affecting bald eagle use of available habitat.

Cumulative effects of timber harvesting, recreation use, and contaminants in the food chain (such as DDT insecticide residue) would likely continue to act on the species outside of wilderness, although there has been a significant reduction of these affecters since the listing of the species. As a result, the species has recovered to the point where the U. S. Fish and Wildlife Service has published in the July 6, 1999 Federal Register (USDI Fish and Wildlife Service 1999) a proposal to remove the eagle from the Endangered Species List. Implementation of any of the alternatives would not affect the bald eagle. There is no critical habitat designated for this species, therefore the implementation of any alternative would not affect any critical habitat.

Forest Service Sensitive Species

Yosemite toad

The Biological Evaluation has determined that implementation of Alternatives 1 through 4 may affect individual Yosemite toads but would not likely contribute to a trend toward federal listing or loss of viability of the species. Implementation of Alternative 5 would not affect Yosemite toads.

There is a degree of uncertainty associated with the determination for Alternative 1, however, since it does not immediately implement forage utilization grazing standards, or trampling and chiseling standards in meadows per direction in the 2004 SNFPA Record of Decision. Implementation of these standards has been identified as a reasonably foreseeable action with no associated time-table. Alternative 1 also does not implement a 5 percent disturbance standard in critical areas such as Yosemite toad breeding habitats.

The John Muir, Ansel Adams and Dinkey Lakes Wilderness Plan of 2001 adopted management direction for the Yosemite toad that was part of the 2001 Sierra Nevada Forest Plan Amendment Record of Decision. That direction excluded livestock, including pack stock, from standing water and saturated soils in wet meadows and associated streams and springs occupied by the Yosemite toad during the breeding and rearing season. Since then the 2004 FSEIS Record of Decision has modified that direction including the removal of the applicability of that direction to pack stock grazing. It deferred the development of management direction for pack stock grazing to site specific analyses such as this EIS. The effects analysis for Alternative 1 has a higher level of potential impact to the breeding areas than all other alternatives since it does not incorporate specific protective measures for Yosemite toad habitats. As a result, it has a higher degree of uncertainty as to what the potential impacts may be over the short and long-term to Yosemite toads and their habitat, given the complete lack of research on the effects of grazing on this species and its habitat.

The implementation of a regional adaptive management study to assess the effects of grazing on Yosemite toads and their habitat is set to begin in 2005 and will help to validate the determination for Alternatives 1 through 4. Study results will not be available for several years. Anecdotal and observational evidence indicates Yosemite toads continue to breed and occupy a few hundred meadows throughout the Sierra Nevada that are grazed by cattle and/or pack stock. Implementation of a 5 percent critical area disturbance standard under Alternatives 2 through 4 in grazed meadows would provide a higher degree of protection to minimize pack stock use and subsequent effects in Yosemite toad breeding areas of meadows.

Yosemite toad – Alternative 1

Analysis

No published research exists on the effects of wilderness land uses on Yosemite toads and their habitat. Much of the assessment of the effects of pack stock grazing in Yosemite toad habitat is based on subjective analysis of anecdotal observations, unpublished data, personal communications from a researcher, and extrapolation and inference from published studies on the effects of livestock grazing on riparian habitats in the Sierra Nevada and other landscapes.

A monitoring study summarized in the Biological Evaluation in the Planning Record (Inyo National Forest, unpublished report on file 2004) conducted in the summer of 2004 as part of this analysis attempted to assess the extent and magnitude of impacts of pack stock grazing on a sample of occupied Yosemite toad breeding habitats in the Ansel Adams and John Muir Wildernesses. The principal study objective was to determine the extent of pack stock use that directly overlapped with Yosemite toad breeding habitats. It was not designed to assess the effects of the use overlap on Yosemite toads and their habitat, though subjective evaluation of the effects is part of this analysis.

The effects of recreation such as hiking and camping, and trails in toad habitat are similarly extrapolated from limited field observations and studies on the effects of these activities to riparian meadows.

Grazing would likely continue to occur in at least 34 (13 percent) meadows out of 267 meadows in the AA/JM Wildernesses tallied by geographic unit in Table 4.83 where Yosemite toads breed based on reported grazing use from 2001 through 2003. An additional 53 (20 percent) other meadows with toad breeding populations were identified by commercial packers as meadows they may graze, but have not reported grazing use.

It is probable that the majority of the 34 meadows where use is traditionally reported would have light overlapping trampling and chiseling and grazing impacts at Yosemite toad breeding sites, with a smaller subset where impacts would be more substantive. This subset would likely be in the Upper Fish Creek area and the Thousand Island/Rush Creek areas. The other 53 meadows would likely have light to no overlapping impacts in most years. The two categories amount to 87 (33 percent) meadows out of 267 meadows in the AA/JM Wildernesses that are known breeding sites for Yosemite toads.

Upper Graveyard, Gra11; Grassy, Sil22; Martin's, Mcg4, Round, Mcg8; and Baldwin-Scheelore, Mcg10 meadows are in the group of 34 meadows where some level of grazing may occur. They have historical and current severe hydrologic functioning and sedimentation problems that are compromising the stability of the wet meadow portions where toads breed. Commercial pack

stock grazing may contribute to the perpetuation of the problem in the first two meadows; while poor trail conditions are severely affecting Baldwin-Scheelore, Round, and Martins meadows. In the first meadow, massive sediment deposition from the old mining road (now system trail) erosion gullies is covering over portions of the toad breeding pools. Martins meadow has a severe headcut in the lower meadow at the trail crossing that is eroding out this portion of the meadow and depositing sediment in the next meadow down (Round Meadow Mcg8) and also covering over a portion of the Yosemite toad breeding pool. Martin's Meadow is currently ungrazed. The severe trail impacts in these two meadows could be compounded by pack stock trampling and grazing impacts at the breeding sites if grazing were to occur at moderate forage utilization levels.

Other meadows where light to moderate grazing and/or trail impacts were observed in one or more years from all monitoring efforts from 2001 through 2004 in toad habitats include Second Meadow above Martin's Mcg9 (stock trailing), Peter Pande Tarn Sil7,(grazing), Red Slate Meadow, Sil24 (trail), and Crater Meadow, Ccd1 (trail).

The effect of grazing, and trail use, and potential overlapping pack stock use on the persistence of toad populations in any of the meadows is unknown. Effects may be minor in the majority of cases and would result in reduced habitat suitability and less than optimal habitat conditions. The effect may be more problematic in meadows such as Martins, Round, Baldwin-Scheelore and Grassy where loss of meadow hydrologic functioning and excessive sedimentation is threatening the long-term persistence of suitable breeding sites. The lack of research in this area of toad ecology makes it difficult to predict more. Long-term habitat monitoring, toad presence-absence data, and population demographic monitoring in grazed and ungrazed meadows would be needed.

Grazing is likely to be highly variable from year to year and there is a possibility of higher levels of impact from one year to the next, especially since the majority of the 267 meadows with toad populations are potentially available for some level of pack stock grazing under Alternative 1. Upper Rush, Thousand Island, McGee Creek, Upper Fish Creek, and Silver Divide meadows are most likely to continue to have overlapping impacts of pack stock grazing and trailing in Yosemite toad breeding sites.

McGee Creek, Convict Creek, Pine Creek and Crater Creek on the Inyo National Forest are designated Critical Aquatic Refuges (CARs) for the Yosemite toad. Forest Plan management direction for CARs may further restrict grazing use in the future in these refuges. Adaptive management efforts would likely continue under Alternative 1 based on additional monitoring efforts. Actions may be implemented to minimize impacts to specific toad breeding sites of concern through the annual operating plan process. The fact that approximately 66 percent of the breeding meadows have not been identified for grazing and are not likely to see commercial pack stock use and another 20 percent have been identified with no grazing use observed from 2001 through 2004 provides a high degree of confidence that breeding populations would persist and maintain areas of relatively undisturbed habitats well distributed across the AA/JM Wilderness landscapes. This likely allows for suitable population connectivity and the ability of the animals to disperse and supplement, or re-colonize areas where toad populations may be subject to adverse effects of disturbance events.

Table 4.83: Distribution of known occupied Yosemite toad breeding meadows in the Ansel Adams and John Muir Wildernesses and overlap with identified grazing areas (grazing observed/reported + requested) in Alternative 1 by geographic unit

Geo Unit	Breeding Meadows with observed grazing or reported grazing use	Other Breeding Meadows requested for grazing (No reported use)	Not requested	Total Breeding Meadows
AA East	13	2	19	34
AA West	1	2	17	20
Fish Creek/Convict/McGee	11	10	23	44
Mono Creek/Rock Creeks		9	12	21
Florence/Bear	4	10	41	55
John Muir Southwest	3	7	57	67
Bishop Humphreys	2	13	11	26
Totals	34	53	180	267

Alternative 1 does not immediately implement forage utilization grazing, or trampling and chiseling standards and could result in trampling of an unknown number of individual toads, particularly newly metamorphosed young throughout the summer months from early July through early September. This is likely to occur wherever pack stock use of trails and grazing overlaps with Yosemite toad breeding pool habitats in meadows. The most likely locations where this would occur is in the 34 meadows where grazing has been reported on a fairly regular basis.

Research is needed to examine the magnitude and significance of this probable effect. Metamorph toads are about one centimeter (3/8 inch), dark black in color, blend in with the color of the mudflat and are very poor hoppers immediately after metamorphosis from the tadpole stage. They congregate in the mudflats oftentimes on the perimeter of the breeding pool where it adjoins the moist/wet meadow interface. In these situations they may be highly vulnerable to trampling where pack stock graze the pool edges and walk through the shallow moist mudflat vegetated zones. Trampled metamorphs would be near impossible to see since they would likely be pushed into the mud without a trace.

Field observations from 2001 through 2004 only documented one dead trampled metamorph on the system trail above Honeymoon Lake in Pine Creek in 2002 where pack stock had moved through a drying breeding pool, as well as five metamorphs trampled by hikers in a trail tread in Granite Park in Upper Pine Creek in 2003. The trail was relocated above Honeymoon Lake to remove the trail overlap with the first breeding site.

It may be that incidental trampling of metamorphs (likely the most vulnerable life stage) by pack stock or hikers, while undesirable, has a minor effect on Yosemite toad population dynamics and maintenance. There is significant mortality of tadpoles, for instance, because of natural premature drying of pools before metamorphosis occurs. An adaptive management livestock grazing study to investigate the effects of grazing on the Yosemite toad is scheduled to begin at the

Regional level on multiple forests in 2005, and will hopefully provide further insight into the effects of this type of impact.

Wildlife photo #1 Photo on left of pack stock trampling of mudflat breeding pool zone where tadpoles occur in shallow pool margins and metamorphs develop and congregate after metamorphosis. Metamorph on right

Direct modification of the breeding site structural habitat characteristics would also likely occur; such as annual removal of vegetative cover used by all age classes of toads, and multiple year cumulative vegetative cover reductions where pack stock chisels have sliced through the vegetative sod of sedge, rush and mosses to expose bare ground.

The above photo shows a heavily trampled and chiseled Yosemite toad breeding pool habitat (foreground and middleground impact area) from pack stock use of a wet meadow. Undisturbed breeding pool area at very top center and right of photo shows contrast of what foreground pool should look like in an untrampled and unchiseled state.

These chisel areas of vegetative sod disruption have varying rates of re-vegetation and it may likely be numerous years for some chiseled areas to return to a pre-chiseled vegetative state if the chisels are punched through shallow, weakly rooted spikerushes, grasses, and mosses. This type of effect has been poorly studied but has been partly validated by the work of Cole et al. (2004) where their study noted declines in vegetative cover and productivity, changes in species composition, and increases in bare soil with repeated annual pack stock grazing over five years in the tufted hairgrass vegetation type in Yosemite National Park.

At current levels of grazing reported from 2001 through 2003 these effects are probably light enough at the landscape level and in most grazing areas, and infrequent enough to allow for breeding site maintenance and minimal toad trampling mortality events that might affect population dynamics. The implementation of Wilderness Plan range readiness delayed on dates for grazing may help to delay grazing until after metamorph dispersal away from the breeding areas has occurred in some meadows. However, field observations have documented considerable variation in metamorphosis dates and dispersal patterns making such prediction impossible with the current state of knowledge.

Most Yosemite toad breeding area microsites within an overall range-ready meadow do not reach range readiness criteria throughout the summer months, leaving them vulnerable to wet sod trampling and chiseling breeding pool habitat impacts (See above photo). In addition, range readiness dates can be adjusted from one year to the next, adding another variable to the assessment. Local problem areas of concern under this alternative may be managed through the pack station annual operating plan to develop management strategies to steer stock away from breeding pools where excessive trampling impacts are observed.

If all 86 Yosemite toad meadows tallied in Table 4.83 are grazed to moderate forage use standards as defined by the 2001 Wilderness Plan, including the wet meadow sections of the meadow where toad breeding sites are found, impacts may increase substantially since Alternative 1 does not require that pack stock be managed to avoid Yosemite toad breeding sites. This scenario is unlikely based on current grazing use levels and patterns. Impacts to long-term maintenance of Yosemite toad breeding sites and toad numbers in these meadows are unknown. Enough field evidence exists to reasonably hypothesize that breeding sites may be maintained under light to moderate grazing levels and continue to be occupied over the long-term by Yosemite toads because high numbers of existing sites overlap with commercial livestock allotments outside of Wilderness as well as the meadows grazed by commercial pack stock.

Furthermore, trampling and entrapment of toads may occur when pack stock collapse rodent burrows with their hooves where Yosemite toads are utilizing the burrows for underground cover. This potential effect remains uninvestigated and is extremely difficult to assess. Metamorph toads congregate in rodent burrows as the summer advances. They have been observed emerging from these burrows in early late spring where they used them as hibernacula through the winter months. Sherman (1980) found that Yosemite toad metamorphs often hibernate in burrows immediately adjacent to the breeding pools from which they emerged in the summer.

Implementation of the Alternative 1 trail transportation system, trail management levels, and system and user trails suitability determinations would likely continue the existing level of effects to Yosemite toad breeding areas in meadows listed in Table 4.84. Additional Yosemite toad breeding meadow areas may exist within the two Wildernesses and would be addressed as

inventory work and incidental monitoring identifies them, and any resource issues associated with wilderness uses. Other breeding area meadows may have trail problems (such as excessive sediment delivery from the trail, water diversion, trail incising, and parallel trailing); however, the problems have not been observed to directly affect breeding habitats. Annual trail maintenance projects, special trail improvement project opportunities, and the Capital Investment Program have been utilized to correct two of the trail areas at Martin's Meadow and the meadow above Honeymoon Lake (listed in Table 4.84), which have directly-affected breeding habitats. A limited number of projects would likely continue in the future.

Table 4.84. Observed trail problem overlap areas with Yosemite toad breeding sites

Geo Unit	Analysis Unit	Meadow Name and Number	Problem	Risk
AA East	Crater Creek	Lower Crater (Ccd1)	PCT trail headcut in trail crossing of meadow stream	Headcut at lower end of meadow puts meadow at risk to erosion
		Upper Crater Meadow (Ccd2)	System trail within 20 feet of breeding pool	Sediment spillage into breeding pool area
Fish Creek/Convict/McGee	McGee	Baldwin Scheelore (Mcg10)	Massive washout of system trail into meadow	Sediment covering breeding areas
		Round Meadow (Mcg8)	Upstream headcut erosion from system trail at Martin's Meadow delivering sediment into meadow	Sediment partially covering breeding pool
		Martin's Meadow (Mcg4)	System trail erosion at lower Meadow and system trail through breeding pool	System trail has been re-routed in 2004 out of breeding area but trail erosion at lower end is affecting Round Meadow
		Second Meadow above Martin's (Mcg9)	System trail is within 5 feet of breeding pool	Pack stock veer of trail and trail through breeding areas, sediment delivery into breeding pool
	Upper Fish Creek	Red Slate Meadow (Ufc3)	System trail causing erosion near breeding pool habitat	Meadow erosion will eliminate some portion of breeding habitat
Mono Creek/Rock Creek	Little Lakes Valley	Above Long Lake (Llv16)	User trail passes along edge of breeding pool	Minor impact on habitat, metamorph trampling potential
Bishop Humphreys	Pine Creek	Upper Pine Lake Outlet (Pin2)	System trail passes along edge of breeding area, poor trail design	Pack stock veer of trail and trail through breeding areas, metamorph trampling potential
		Italy Pass Trail	System trail passes	Observed metamorph

Geo Unit	Analysis Unit	Meadow Name and Number	Problem	Risk
		Meadows2 (Grp3)	along edge of breeding area	trampling from hikers
		West Of Honeymoon Lake (Pin4)	System trail passes along edge of breeding area	Observed metamorph trampling, trail re-routed in 2002 to fix problem
	Piute	Between Piute and Lock Leven (Piu1)	System trail passes along edge of breeding area	Potential for sediment delivery into breeding pool, water diversion and metamorph trampling potential
		Ponds east of Piute Pass (Piu4)	Old eroded multiple system trails above breeding pools	Potential for sediment delivery into breeding pool, water diversion

Baldwin Scheelore
Yosemite toad breeding habitat meadow where trail erosion (foreground) has deposited large sediment flow into breeding pools (middleground)

No substantive impacts have been observed in Yosemite toad breeding areas from commercial pack stock camps and destination use. The continuation of these existing uses is unlikely to have substantive adverse effects to Yosemite toad breeding habitats. There is always the possibility of inadvertent mortality to toads from pack stock clients stepping on them, particularly the metamorph age class, as they walk through meadows. This type of impact can occur from all wilderness user groups and is probably very low since most hikers avoid the wetter areas of meadows where Yosemite toad breeding pools are located.

Cumulative Impacts

Commercial livestock grazing on the Sierra, Stanislaus, Plumas and Eldorado National Forests, in and out of wilderness, as well as commercial and recreational pack stock grazing on these forests and in Yosemite and Kings Canyon National Parks may be affecting an unknown number of Yosemite toad breeding populations and habitat as described above. The extent and magnitude of effects are unknown at this time and remain largely uninvestigated. The 2004 SNFPA standards and guidelines for Yosemite toad management in other livestock grazing areas, such as commercial cattle allotments on the Sierra National Forest and other National Forests, are likely to promote long-term conservation of the species and its habitat and possibly decrease the cumulative grazing impacts described in the U. S. Fish and Wildlife Service 12-Month Finding for a Petition to List the Yosemite Toad (USFWS 2002).

Under Alternative 1, a subset of Yosemite toad breeding meadows identified in Alternatives 2 through 4 as unsuitable for grazing may be closed as a reasonably foreseeable future action as suitability determinations are implemented per direction in the Wilderness Plan. Alternative 1 may also implement as a reasonably foreseeable action SNFPA forage utilization grazing standards, and trampling and chiseling standards identified in the 2001 Ansel Adams, John Muir, and Dinkey Lakes Wildernesses Management Plan.

There is an unknown level of recreational pack stock grazing that also occurs and would likely continue in the AA/JM Wildernesses. The level of use is likely very limited and would have a very minor effect in Yosemite toad habitats since field observations by several survey crews and this Wilderness EIS interdisciplinary Team did not detect this type of grazing use from 2000 through 2004 overlapping in Yosemite toad habitats.

Other factors identified in the USFWS 12-month finding, such as UV radiation, disease, and air pollution and pesticide drift into the wilderness, remain poorly investigated as to their effects on the Yosemite toad. The species and its habitat are also affected at an unknown level when breeding population habitats overlap high use recreation areas close to roads (such as at Tioga Pass) where heavy human use and dog use occur in and along the margins of the breeding sites. There is potential in such areas for toads to be trampled or disturbed, as well as for vegetative cover at the breeding sites and breeding pool mudflats structure to be modified from trampling and chiseling impacts. Also, a limited amount of toad mortality has been observed to occur in such areas from capture of toads by people for bait or other purposes. A long-term research study at Tioga Pass meadow may have inadvertently contributed to the decline of the species there from unintentional stress-induced mortality and disease spread. The cumulative effects on species viability at the landscape level are unknown.

High elevation dams in and outside wilderness areas such as Gem Lake, Waugh Lake, Tioga Lake and Saddlebag Lake may have inundated suitable Yosemite toad breeding habitats, reducing habitat and marginalizing population connectivity and dispersal corridors.

Yosemite toad breeding meadows have a long history of overlap with heavy livestock grazing events of the early and mid 1900s. Numerous meadows still show the evidence of such events such as stream incision, main-stream and lateral side channel headcuts, and loss of wet meadow and wetland habitats. Some toad breeding sites may likely have been lost when stream incision events occurred. Poor trail and road locations and alignments have resulted in similar meadow degrading events as is evidenced today at Baldwin-Scheelore and Martin's Meadows in McGee Creek. The old mining road and the system trail have discharged large amounts of sediment into

the adjacent wet meadow Yosemite toad breeding pool areas and adversely affected the meadow hydrologic functioning.

Surveys mandated under the Sierra Nevada Forest Plan Amendment Record of Decision continue to find new populations of Yosemite toads in the Sierra Nevada and confirm current occupancy at many mid to high elevation historical locations. The Final Supplemental EIS for the Sierra Nevada Forest Plan Amendment (USDA Forest Service 2004) noted that 292 sites are known throughout the toads' historic range, 229 of which have been confirmed occupied since 1990. The number has increased substantially since the January 2004 publication of that document based on the results of the 2004 surveys.

On the Sierra National Forest inventory surveys in 2002, 2003, and 2004 approximately 313 (+/- 9) sites have been identified as occupied with Yosemite toad, 194 of which are within the AA/JM Wildernesses analysis area. Populations of Yosemite toad have been found as far south as Garlic Meadow near Monarch Wilderness at least 260 miles south of the original distribution described for the species at Kaiser Pass Meadow.

The AA/JM Wilderness, as of this writing, has 267 meadows where toads have been found breeding from 2001 through 2004. One hundred and ninety four of these sites are found on the Sierra National Forest. The Inyo National Forest has the remaining 73 breeding meadow sites in the AA/JM Wildernesses. Eight sites on the Inyo are outside of wilderness and two others are inside the Hoover Wilderness on the Forest.

The 2004 Final SEIS notes that it is impossible to fully assess the extent and magnitude of any decline in Yosemite toad populations in the Sierra Nevada because of the small amount of baseline data pertaining to the number and size of historic populations. Three separate monitoring studies noted that over 50 percent of locations visited in the mid 1990s showed toads were absent from historically occupied sites, particularly at the lower elevations of the toads range. These results indicate that there are substantially more populations of the Yosemite toad than what were considered even a year ago. This trend may likely continue as survey efforts continue and prompts questions as to just how prevalent the decline may be.

Numerous years of monitoring and research are needed to develop a full picture of the status of the Yosemite toad population throughout its range. The Sierra Nevada mountains are a changing landscape in just the last 100 years. The influence of long-term climate change in the Sierra and subsequent reduced snow packs and summer water flows may have a profound effect on the biogeography of the species. Toads may disappear from meadows that experience more rapid drying through the summer and associated reduction in available ephemeral pools where toads can breed. This factor by itself may have implications on the maintenance of lower elevation populations and habitat.

Yosemite toad – Alternative 2 - Modified

Alternative 2 - Modified would likely substantively reduce any potential for commercial pack stock trampling, chiseling, and grazing impacts in occupied Yosemite toad breeding habitats within a subset of 36 meadows (listed in Chapter 2, Table 2.30 and tallied in Table 4.85) that have been determined to be suitable for grazing by commercial pack stock.

Table. 4.85 Number of meadows in the AA/JM Wildernesses in Table 2.4 with occupied Yosemite toad breeding habitat by alternative and grazing suitability

Alternative	Suitable for Grazing	Unsuitable/Prohibited	Rest from Grazing
1	All meadows except Mudd Lake	1 Mudd Lake (Pioneer Basin Grazing Closure)	
2	40/16*	30	0
Modified - 2	36/16*	28	6
3	37/16*	32	1
4	30/16*	39	1

*These 16 meadows are in the John Muir SW Geographic Area. They have not been field analyzed but are available for commercial pack stock grazing within the grazing zones.

Minor effects would potentially occur to breeding pool habitat structure, and/or the vegetative cover zone surrounding the pool where Yosemite toad metamorphs congregate after metamorphosis within the 36 meadows determined to be suitable because stock could drift into the breeding areas on occasion, even under close management. The potential for trampling mortality of the metamorphs would be substantively reduced. There is always the relatively low probability that a Yosemite toad metamorph or other life stage could still be trampled within the suitable grazed meadow outside of the breeding habitat area as well, similar to Alternative 1.

Some level of vegetative improvement in meadow condition around breeding sites is likely at Upper Deer Creek, NW Thousand Island behind the Moraine, Alger Creek Terraces, Grassy, Peter Pande Tarn, Red Slate, Upper Graveyard, and NW Delta of Thousand Island Lake Meadows with implementation of Alternative 2 – Modified.

Commercial pack stock use would be managed to avoid Yosemite toad breeding habitats within these meadows. Only four of these meadows have had recent substantive grazing use that has overlapped with Yosemite toad breeding areas from the period of 2001 through 2003. Twenty eight meadows would be managed as unsuitable for grazing, and six meadows would be rested from grazing. These meadows, along with another 197 meadows with occupied Yosemite toad breeding habitats in the AA/JM Wildernesses, would not be affected by commercial pack stock grazing operations since grazing would not occur. The six rested meadows may be redesignated suitable for grazing at some future date when resource conditions have met recovery objectives. At that time grazing would be managed to avoid the critical breeding areas for Yosemite toads. Table 4.86 lists the occupied Yosemite toad breeding meadows by alternative where grazing proposals differ between Alternatives 2 -Modified through 4.

Table 4.86: Yosemite toad breeding meadows from Table 2.4 Alternatives 2 – Modified, 2, 3 and 4 determined to be unsuitable for grazing, prohibited from grazing, or rested from grazing by alternative

Geo unit	Analysis Unit	Meadow Name	Alt 2- Modified/Alt2/Alt3/Alt4 Determinations #=Stock Nights, U = unsuitable, P = Prohibited, R = Rest from grazing	Observed Impacts on Toad Habitat

The effects of implementation of Alternative 2 - Modified destination use regulating system for commercial pack stock operations would likely have no substantive effects on Yosemite toads and their breeding habitats, similar to Alternative 1. No commercial pack stock impacts have been observed in Yosemite toad habitats as a result of commercial pack stock use of campsite destinations, stock holding areas, and drop points for dunnage or spot camps. Commercial pack stock use of destinations would likely shift somewhat under Alternative 2 – Modified since destination quotas would limit the number of trips to these areas, and users may seek other destinations as quotas are filled. Some meadows that have Yosemite toad breeding populations may experience higher levels of associated grazing and others less if destination use patterns shift; however, there should be no substantive change in effects to Yosemite toad habitats.

Implementation of Alternative 2 – Modified trail transportation system, and trail management levels would not substantively change the existing trail effects to Yosemite toad breeding habitats (identified in Table 4.84 in Alternative 1) since the management level designation simply conveys a trail class and trail suitability and does not implement specific actions to re-route or repair problem trail areas. The disapproval of user trails to commercial stock would not have substantive effects to Yosemite toad habitats. The NSCS system trail designations in Pioneer Basin, Upper Pine Creek (Granite Park), and Baldwin-Scheelore may have localized benefits to meadows in a few locations where trails come close to Yosemite toad breeding habitats. In certain situations, such as at Baldwin-Scheelore, there may be a decreased risk of

trail degradation that would result in a higher degree of protection than Alternative 1 for Yosemite toad breeding areas and other meadow use areas.

Cumulative Impacts

The implementation of critical area protection at Yosemite toad breeding sites within grazed meadows, as well as the stock night guidelines, would improve the long-term management at Yosemite toad breeding meadows. Unsuitable for grazing meadow determinations would also remove any potential impacts to the Yosemite toad breeding sites in those meadows. These actions, along with the identification and re-location of system and use trails that have the potential to adversely affect the long-term maintenance of toad breeding sites, contribute to positive conservation measures in the management of the species. Otherwise, cumulative effects would continue to operate on the species as in Alternative 1.

Yosemite toad – Alternatives 2 and 3

Analysis

Alternative 2 and Alternative 3 have the potential for similar reductions in commercial pack stock grazing effects to Yosemite toad breeding areas as in Alternative 2 – Modified. Alternatives 2 and 3 would provide this protection with the implementation of unsuitable for grazing meadow determinations and a maximum 5 percent disturbance standard in all critical Yosemite toad breeding areas within meadows suitable for commercial pack stock grazing.

The allowance of up to 5 percent disturbance in critical areas within 40 meadows in Alternative 2 and 37 meadows under Alternative 3 identified as suitable for commercial pack stock grazing in Table 2.30 where Yosemite toads breed will likely result in some minor level of trampling and chiseling impacts in Yosemite toad breeding pool habitats and the adjacent meadow perimeter where Yosemite toad young congregate. Only eight of the meadows suitable for continued grazing have shown grazing use during the period of 2001 through 2003 amounting to forage use levels from light to moderate. The most consistently grazed meadows are in the Thousand Island, Rush and Upper Rush Analysis Units. Observations in light use areas suggest a minor annual incremental loss of vegetative cover in some of the pools and meadow pool perimeters. Implementation of the 5 percent standard would likely maintain breeding pool habitats without adverse effects to the hydrologic character of these pools.

The effects of implementation of Alternatives 2 or 3 destination use regulating systems for commercial pack stock operations areas would likely have no substantive effect on Yosemite toad habitats and impacts to the species in comparison to Alternative 1. No commercial pack stock impacts have been observed in Yosemite toad habitats as a result of commercial pack stock use of campsite destinations. Commercial pack stock use would likely shift under the different alternatives where trailhead quotas are applied versus destination quotas, as well as designated overnight stock holding camps. Grazing would likely shift in locations as a result. Some meadows that have Yosemite toad breeding populations may experience higher levels of grazing use and others less use if destination use patterns shift.

Implementation of Alternative 2 trail management actions differs slightly in potential effects from Alternative 2 – Modified since Pioneer Basin Trail and the Baldwin-Scheelore Trail would be open to commercial stock. This would increase the potential for stock use to contribute to the

already unstable trail areas that route near Yosemite toad breeding pools. Alternative 3 would allow only the Pioneer Basin trail to be open to commercial pack stock.

Cumulative Impacts

The implementation of critical area use standards at Yosemite toad breeding sites, as well as the stock night guidelines would improve the long-term management at Yosemite toad breeding meadows. Unsuitable for grazing meadow determinations would also remove any potential impacts to the Yosemite toad breeding sites in those meadows. These actions, along with the identification and re-location of system and use trails that have the potential to adversely affect the long-term maintenance of toad breeding sites, contribute to positive conservation measures in the management of the species. Otherwise, cumulative effects would continue to operate on the species as in Alternative 1.

Yosemite toad – Alternative 4

Analysis

The effects would be similar to Alternative 2 – Modified, except that two additional meadows would become unsuitable for commercial pack stock grazing. The potential for commercial pack stock trampling effects in the breeding pools at Rodgers Lakes Meadows (Uru5), and Chief Lake Meadow (Sil9) would be eliminated.

A traditional packer camp would be moved at Round Meadow in McGee Creek that is within 50 feet of a toad breeding site. The camp re-location would likely remove the probability of clients walking through the meadow where the metamorph toads are emerging from the breeding pools. This may provide some slight additional long-term protection for the breeding site from potential trampling impacts to the vegetative cover or the toads since clients would not be as likely to walk into the meadow at this particular location. This is the only site observed where a camp is in such close proximity to the breeding site.

Alternative 4 use levels and controls is noted to limit the area and extent of future commercial pack stock operations, and there would be a 20 percent overall reduction in service day wilderness use by commercial pack stock operations. These controls, as well as designated camps and designated drop sites, probably would not change potential impacts to Yosemite toad breeding sites unless there was a corresponding reduction of commercial pack stock grazing at a breeding site that cannot be determined at this time.

The Fish Creek area may see improved wilderness character in areas that overlap with Yosemite toad breeding areas at Tully Lake, Red and White Lake and Peter Pande Lake areas. Tully Lake Meadow (Ufc4) does show grazing use would be allowed so it is not clear how the improved wilderness character would affect the potential grazing that may occur there. Many of the Yosemite toad breeding meadows in Fish Creek and adjacent Silver Divide have been identified as unsuitable under this alternative and Alternatives 2-Modified, 2, and 3 that already provide protection regardless of pack stock operation use patterns.

The suitability for grazing determinations and the maximum 5 percent allowable disturbance at all Yosemite toad breeding critical areas are the main determinants of impacts to these meadows. Many of these meadows are along system trails where the alternative is not likely to substantially change use patterns.

Implementation of Alternative 4 trail transportation system and trail management levels would not likely have substantive effects over Alternatives 2 – Modified, 2, and 3 other than what is described above. Some Yosemite toad breeding meadows may have a higher level of protection where commercial pack stock operation use is lowered and system NSCS and use trail closures are implemented. This change on the landscape could only be confirmed through a field monitoring program. The effect is not thought to be substantive. These shifts across the landscape are difficult to assess since so many variables come into play in the way commercial pack stock operations would choose to adjust their use, as well as how even under lowered use stock would still be allowed to graze in suitable meadow areas, and utilize forage to maximum allowable standards.

Cumulative Impacts

Cumulative effects are similar to Alternative 2 and 3.

Yosemite toad – Alternative 5

Analysis

The elimination of commercial pack stock use would remove any potential for further impacts to Yosemite toad breeding meadows from this user group. Grazing use would cease in the 87 meadows that have Yosemite toad breeding areas and have been identified by commercial pack stations as desirable or currently used for pack stock grazing and would be fully protected. Yosemite toad breeding site areas within meadows where grazing, trampling, and chiseling impacts have been observed would rehabilitate to undisturbed conditions. Table 4.83 shows the breakdown of breeding meadows by geographic unit.

Cumulative Impacts

The elimination of all commercial pack stock operations would have a long-term beneficial effect on the Yosemite toad breeding habitats, and likely the species as well. However, the extent and magnitude of this effect is unknown in terms of how it would actually affect toad use of breeding meadows and population dynamics and viability. The most significant improvement would be the maintenance of breeding sites, including pool morphology and vegetative cover, in a relatively undisturbed state in meadows that have been traditionally grazed, or trailed through by commercial pack stock. The probability of trampling impacts and other factors, such as rodent burrow collapse associated with pack stock, would cease. There would also likely be less potential for sediment from trails to enter the breeding sites in meadows since trail width would likely decrease, trails would increase in stability with less maintenance requirements, and widened spring and stream channels, and associated headcuts and trampling and chiseling impacts would decrease. Some level of impacts would continue from recreational pack stock use and hiker and backpacker use of these areas; however, it would likely be very small in comparison, unless this user group increased as commercial operations ceased.

These actions, along with the identification and re-location of system and use trails that have the potential to adversely affect the long-term maintenance of toad breeding sites, contribute to positive conservation measures in the management of the species. All other cumulative effects would continue to operate on the species as in Alternative 1.

Mountain yellow-legged frog – Alternative 1

Analysis and Cumulative Impacts

The Biological Evaluation has determined that implementation of Alternatives 1 through 4 may affect individual mountain yellow-legged frogs but would not likely contribute to a trend toward federal listing or loss of viability of the species. Implementation of Alternative 5 would not affect the frog.

The continuation of the existing commercial pack stock use areas under Alternative 1 including destinations, camps, and grazing sites would likely have very minor effects on the existing mountain yellow-legged frog populations and habitats. Three specific areas are likely to continue to have localized habitat impacts under this alternative that are not desirable, but are also probably not substantially affecting the species' use of the areas.

Donahue Camp (Uru8) crossing in Upper Rush Creek would likely continue to have a localized 100 foot stream bank collapse where stock cross over to the camp, until the stock crossing is re-located. Frog habitat is being impacted to some degree at this crossing since the undercut stream banks the frogs use for cover have been collapsing as a result of the crossing erosion point. The main system trail the stock use to access this area also routes directly along a frog pond; however, no adverse effects have been observed.

One mountain yellow-legged frog was observed in a grazed meadow at North of Mono Rock Meadow (For1) in the upper Mono Creek watershed. The spring channel the frog was in had areas of pack stock trampling and chiseling impacts that would likely continue under this alternative unless specific mitigation measures were employed through the annual operations instructions. The population of frogs in this meadow needs further assessment to determine exactly where frog use overlaps with stock use.

Commercial pack stock grazing would also continue along the west meadows of Thousand Island Lake (Thi16) where mountain yellow-legged frogs have been observed using small inlet stream habitat. There are localized areas of widened stream channel and stream bank collapse where stock cross the streams and graze that would likely continue under this alternative unless specific mitigation is developed in the annual operations plan. The effect on mountain yellow-legged frog use of the meadow habitats is unknown but may be undesirable from a management viewpoint. However, the effects may not be substantive enough to adversely affect continued frog use of the meadow habitat.

The continuation of pack stock grazing at Rodgers Lakes Meadows (Uru5) in Upper Rush Creek is unlikely to have substantive adverse effects to the frog population that uses the ponds. The outlet stream habitat may be subject to trampling and chiseling effects from pack stock grazing. Pack stock have only been grazing the area for a few years. Monitoring of this stream habitat would need to be conducted with implementation of Alternative 1 to validate that it is not resulting in unacceptable impacts to the frogs' habitat. This would be part of an adaptive management strategy. Implementation of forage utilization standards, and trampling and chiseling disturbance standards identified in the 2001 Ansel Adams, John Muir and Dinkey Lakes Wildernesses Management Plan may be implemented as a reasonably foreseeable action. These standards would provide additional mitigation to limit areas of stream bank trampling and chiseling impacts from pack stock in mountain yellow-legged frog habitat.

The commercial pack stock user trail from Emerald Lakes to Garnet Lake passes along the margin of a mountain yellow-legged frog pond at Meadow Thi14. This alternative would allow continued use of the trail by commercial pack stock. There is likely a minor amount of sediment and runoff that enter the frog pond habitat. The adverse affects of this type of use on the frog population is unknown; however, moving the trail away from the pond area would be more desirable from a management standpoint. This type of action may be implemented as part of a long-term trail improvement project as funding becomes available. Backpackers and recreational pack stock users may also use the trail but the dominant use would continue to be from commercial pack stock.

No other specific grazing, trail, destination and pack stock camp adverse effects to mountain yellow-legged frog habitats or populations have been identified. The vast majority of the known populations described in Chapter 3 are unaffected by commercial pack stock operations.

Currently, commercial pack station operators and fishermen are promoting and advocating high lake fish populations to provide fishing opportunities for clients and themselves. The perpetuation of fish populations is an important factor affecting the viability and distribution of mountain yellow-legged frog populations range-wide in the High Sierra including Yosemite and Sequoia-Kings National Parks. The decision to perpetuate fish populations in high lakes and subsequent impacts to frog populations and viability are largely within the jurisdiction of the California Department of Fish and Game. The Department is currently reviewing the high lakes fish stocking program, developing watershed plans to implement management changes over the long-term, and conducting site specific fish removals and frog re-introductions to assist in the recovery of the species.

Implementation of the trail transportation system and management level designations, and commercial pack stock system and use trail suitability determinations other than what has already been stated above would have no adverse effects on the mountain yellow-legged frog since no other trails are known to be affecting the species use of occupied habitats.

The impact of disease, pesticide drift into high lakes, UV radiation, and pollution effects such as acid rain continue to be long-term management concerns range-wide in the recovery of the species in the AA/JM Wildernesses. Research continues in an attempt to understand how these effectors are impacting the viability of the mountain yellow-legged frog population.

Mountain yellow-legged frog – Alternatives 2 – Modified, 2, 3, and 4

Analysis and Cumulative Impacts

The elimination of grazing at the Meadow North of Mono Rock (For1) as a result of the unsuitable determination would likely have a beneficial effect to the spring channel habitat the mountain yellow-legged frog was observed using since trampling and chiseling impacts would cease. The elimination of commercial pack stock grazing along the southwest end of Thousand Island Lake would likely eliminate any disturbance to stream banks the frogs utilize and provide a higher level of protective maintenance for the stream habitats. The elimination of grazing at Rodgers Lakes Meadows under Alternative 4 probably would not change the mountain yellow-legged frog habitat to any extent since the frogs occupy pond habitat in that meadow that does not appear to be affected by current grazing use. Also, eliminating grazing could improve habitat if surveys showed the frogs using stream outlet channel habitat, but that is currently unknown.

All other habitats are not expected to experience substantive changes from implementation of the proposed trail alternatives or use regulating mechanisms. Cumulative effects would be nearly the same as Alternative 1, except for the lower impacts associated with these alternatives.

Mountain yellow-legged frog – Alternative 5

Analysis and Cumulative Impacts

The Donahue Camp pack stock crossing in Upper Rush Creek would likely rehabilitate over the long-term as commercial stock use ceases. This should improve mountain yellow-legged frog habitat along the stream reach below the crossing. Otherwise, the cessation of all commercial pack stock use in the AA/JM Wildernesses would not substantively change the effects described under Alternatives 2 through 4. Most yellow-legged frog populations are associated with lakes or meadows where commercial pack stock do not go.

Willow flycatcher

The Biological Evaluation prepared for this EIS has determined that implementation of Alternatives 1 through 4 may affect individual willow flycatcher but would not contribute to a trend toward federal listing for this species, or loss of viability within the planning area. Implementation of Alternative 5 would not affect the willow flycatcher.

Willow flycatcher – Alternative 1

Analysis

Commercial pack stock grazing in all suitable unoccupied willow flycatcher meadow habitats in Chapter 3, Tables 3.24 and 3.25, and meadows likely to be used in Table 4.87, would likely result in some level of annual reduction of herbaceous cover, and productivity that over the long-term has the potential to lower overall meadow productivity, basal vegetative cover, basal litter cover, relative graminoid cover, increase bare soil, and alter meadow species composition according to a study conducted by Cole et al. (2003) in montane brewers reedgrass, and tufted hairgrass plant communities. The magnitude of this effect would be highly variable since no grazing standards would exist under this alternative except for range readiness. These plant communities can be common components of the willow flycatcher suitable habitat meadows identified in Table 4.87. There is likely to be some effect on willow shrubs from stem breakage as pack stock push into willows to graze available forage at the base of the shrubs and in the interspaces. This could reduce shrub foliage cover and have some decrease in habitat suitability. The effects on meadow herbaceous species composition, density and productivity, and willow foliage reduction from stem breakage have not been studied sufficiently in the Sierra habitats to determine how they may affect the potential occupancy and use of suitable willow flycatcher meadows.

Vegetative productivity losses along stream bank riparian areas in particular could affect the stability of streams over time, with increased risk of headcut development, stream incision, and stream widening if meadows are grazed at moderately high utilization levels. One hypothesis advanced in the Sierra Nevada Forest Plan Amendment EIS effects analysis (USDA Forest Service 2001) for livestock grazing in willow flycatcher habitat is the potential to lose riparian habitat that can adversely affect insect production, the key food base of the willow flycatcher.

There is an uncertainty and a risk to the maintenance of high quality suitable willow flycatcher habitat based on the impacts described above when meadows are grazed at maximum allowable forage utilization levels during the summer months of July and August; however, it is unknown how this change could affect potential willow flycatcher occupancy.

The Willow Flycatcher Conservation Assessment (Green et al. 2003) noted the difficulty in assessing grazing impacts such as might occur under this alternative and stated that the influence of managed grazing on willow flycatcher status in high quality, good ecological condition habitat was unknown at this time. The most critical management concern is the effect of grazing implementation on the maintenance of wet meadow and wetland habitat components that provide the most suitable willow flycatcher foraging habitats.

Poison, Hellhole, Jackass, Double and Blayney Meadows listed in 4.87 under the Florence/Bear GU do not exhibit substantive loss of these habitats, nor do the willow communities appear to be adversely affected based on a Sierra NF Grazing Suitability Assessment dated December 14, 2004 (unpublished report on file). They are the most likely to be grazed near full utilization levels under Alternative 1 since they are used as lower elevation stock holding pastures.

Management of the willow flycatcher habitat in Lower and Upper Blayney Meadows is complicated by the fact that the lower meadow is approximately 50 percent private inholdings, and the upper meadow is 80 percent private land where grazing management is not under Wilderness Plan standards. Jackass Meadow is 90 percent in non-wilderness and will be analyzed further as part of a separate non-wilderness analysis process.

Chetwood, Detachment, Knoblock, and Graveyard meadows in AA West GU are degraded meadows where historical stream channel incision and the loss of the perched meadow water table may have resulted in loss of suitable willow flycatcher habitat. No records are available to assess willow flycatcher habitat historical condition. Pack stock grazing will be allowed in these meadows. The meadows have not had any substantive pack stock grazing in them for several years so it is difficult to evaluate at this time how grazing would affect any potential meadow recovery. The first three meadows are predicted to have a slight upward trend in meadow hydrologic condition with implementation of this alternative. Graveyard Meadow is not predicted to have any recovery since cattle apparently continue to graze it at levels that may hinder any recovery.

Implementation of Alternative 1 would allow the maintenance of suitable willow stand structure for willow flycatcher nesting in portions of the meadows away from where pack stock trail and graze. Observations during the course of the wilderness field analysis trips from 2001 through 2004 suggest that pack stock grazed meadows tend to retain substantial areas of robust willow communities since pack stock forage on herbaceous species and not willow.

It may be necessary under an adaptive management strategy through the annual operating plan to manage stock away from key willow meadows such as those below 8,000 feet. Field assessments will need to be made to identify these stands, any effects that may be occurring if the meadows are actually grazed, and mitigation measures needed to manage pack stock away from willow stands if stand characteristics are being unacceptably impacted. There is insufficient research data at this time to suggest that even the willow stands in grazed areas will not continue to provide suitable nesting habitat. However, if willow flycatcher were to select such stands there is an increased risk of inadvertent nest destruction and/or egg or young being dislodged from a nest

where pack stock move through willow clumps and birds have placed their nests in the outer, lower crowns of the shrubs. This is a very low probability event in any case.

Pack stock use of meadows may attract brown-headed cowbirds to the meadow where they can parasitize willow flycatcher nests. This usually results in failure of the willow flycatchers to produce fledgling young (Green et al 2003). The cowbird attraction to meadows is linked to the presence of cattle in an area or a nearby pack station where loose grain is present to feed cowbirds (Green et al. 2003). The only meadows likely to experience cowbird influx are those such as Jackass, Double, Blayney, Hellhole, Poison, and Graveyard that have pack stations or pack stock holding facilities within 4 to 6 miles according to cowbird dispersal distances from these facilities as cited by Verner and Rothstein (1985).

Fifty three meadows listed in Tables 3.24 and 3.25 (Chapter 3) that are not listed in Table 4.87 were not requested for grazing by commercial pack stations and have no history of reported use from 2001 through 2003. These meadows could be potentially grazed under Alternative 1 to allowable forage utilization standards, however it is unlikely they would be utilized based on recent destination use analyses and grazing patterns. The majority of these meadows are in the Ansel Adams West and John Muir Southwest Geographic Units where commercial pack stock operations are at very low use numbers. There would likely be no effect to suitable willow flycatcher habitats from commercial pack stock use in these meadows based on the assumption of very light to no grazing use in these meadows. If in the unlikely event the meadows were grazed by commercial pack stock at moderately high use levels on a regular basis then the effects stated above would be likely. In that event, additional assessment including willow flycatcher surveys may be warranted.

Graveyard Meadow, Second Crossing and Cascade Valley have been determined to be unsuitable for grazing. The latter two meadows have been closed for a number of years and would remain closed. The closure of Graveyard meadow would be implemented at some future date as part of the implementation of the 2001 Wilderness Plan direction to determine and implement grazing suitability determinations. Very light commercial pack stock grazing may likely continue until the closure is implemented. This should not adversely affect willow flycatcher habitat.

Table 4.87 shows the meadows from Chapter 3, Tables 3.24 and 3.25 where commercial pack stock grazing would likely continue to occur under Alternative 1. There is no column for forage utilization/stock nights under Alternative 1 since (other than range readiness criteria) there are no commercial pack stock forage grazing utilization standards currently in place in the AA/JM Wildernesses.

Table 4.87. Proposed allowable commercial pack stock grazing in suitable unoccupied Willow flycatcher habitat in Alternative 1 through 4.

Geo Unit	Analysis Unit	Meadow Name (Elevation)	Mdw ID#	Proposed Forage Utilization Stock Nights* (Alt 1*-4)		
				Alt2	Alt 2 Mod and Alt3	Alt4
Meadows 8,000 feet and lower

Mono Creek/Rock Creek	Second Recess	Mono Creek at Second Recess	Sec15	323 for Mono Creek entire zone	Same as 2	Same as 2
	Graveyard	Graveyard** (8865)	Gra9	0	Same as 2	Same as 2

* Alternative 1 is not listed since there are no existing forage utilization standards. Stock night estimates in the other Alternatives except for sak17, hoo1 and 2, and eaf1 and 2 correspond to forage utilization rates of 30 percent for meadows in fair ecological condition meadows, and 40 percent for meadows in good ecological condition per 2001 Ansel Adams, John Muir, and Dinkey Lakes Wildernesses Management Plan grazing standards and guidelines..

**Indicates meadow has substantial historical hydrologic degradation and probable loss of some portion of its wet meadow habitats available for use by willow flycatcher.

Pack stock camps, destinations, and social and access trails contribute to habitat disturbance effects in some of these meadow habitats. In these destination areas, some impacts would continue to occur, including: localized areas of willow stem breakage, localized stream bank impact areas where channel widening occurs, and lower productivity of herbaceous meadow

vegetation from trampling by humans and stock. These types of effects are considered to be of low significance in the majority of meadows identified in Chapter 3, Tables 3.24 and 3.25 since the vast majority of these meadows are not destinations where camps or associated sock holding and grazing areas occur. System and user created trails may pass along the meadow perimeter or through some meadows, particularly the lower elevation meadows, where commercial pack stock operations are only passing through the area en route to other destinations. Adverse effects would not likely occur from continuation of these activities since they have not been observed to substantially impact the willow portions of these meadows and subsequently the willow flycatcher structural habitat component.

Implementation of Alternative 1 trail transportation system and management level designation, and commercial pack stock system and use trail suitability determinations would continue the existing low impacts to willow stands where trails course through or adjacent to them in suitable willow flycatcher habitats in the meadows identified in Chapter 3, Tables 3.24 and 3.25. The extent of these localized impacts is thought to be minor, and not considered a major affecter of the potential for willow flycatcher to occupy the habitats.

The Sierra Nevada Forest Plan Amendment would require willow flycatcher surveys for implementation of this alternative in Jackass and Hellhole Meadows since these meadows are within the 5 mile radius from a known occupied habitat meadow. Surveys may also be warranted at some future date in habitats in wilderness below 8,000 feet where the most suitable habitat, along with the highest probability of detection, might occur. These surveys would be warranted if detections of willow flycatchers increased with confirmed nesting in occupied willow flycatcher habitats and emphasis habitats outside of wilderness within a 5 mile radius of the occupied sites.

Cumulative Impacts

A thorough discussion of cumulative effects on willow flycatcher habitats in the Sierra Nevada, including the Sierra and Inyo National Forests and the AA/JM Wildernesses, can be found in the Sierra Nevada Forest Plan Amendment affected environment and effects analysis for the 2001 Environmental Impact Statement (USDA Forest Service 2001). The principal effects noted, such as grazing, and water diversions and dams, have been present and continue to this day at dramatically reduced levels in the AA/JM Wildernesses.

Willow flycatcher populations have been in decline across the Sierra Nevada, initially as a result of habitat loss, as well as the range extension of the nest parasite, the brown-headed cowbird. The current regional willow flycatcher population demographic trend is uncertain at this time (USDA Forest Service 2004). When other data is examined, including preliminary nest-site re-occupancy data and the Central Sierra nest success and fecundity rates information, it appears the population may have been declining over the last two decades (USDA Forest Service 2004). The willow flycatcher population today may be at such low numbers that the species may have trouble maintaining long-term viability in spite of protective habitat management actions. The Forest Service has identified the species as having the highest probability of extirpation from the Sierra Nevada of any land bird (USDA Forest Service 2001).

The majority of highly suitable nesting willow flycatcher habitat lies outside the AA/JM wildernesses below 8,000 feet in elevation. The suitable unoccupied nesting habitat adjacent to the wilderness boundaries may be subject to impacts from commercial livestock grazing

operations in Forest Service grazing allotments, along with private and Forest Service pack station corrals and pastures. These land uses may be affecting suitable willow flycatcher habitats and may contribute to the cumulative effects operating on the species.

Areas outside wilderness with livestock, such as allotments and holding facilities, that attract brown-headed cowbirds to feed continue to create a hub from which cowbirds can parasitize willow flycatcher nests. Suitable wilderness nesting habitat is identified above that is within cowbird range. Developed campgrounds, picnic areas, and summer homes, as well as nearby subdivisions and rural communities create similar feeding opportunities for cowbirds, and may contribute to entry of cowbirds into the lower elevations of the wilderness adjacent to these areas. In addition, recreation areas that may be suitable willow flycatcher nesting habitat draw people to recreate in or near the willows to fish, hike, and enjoy the day. Inadvertently, human presence may disturb the breeding and young rearing activities of the birds as well as attract nest predators such as jays, ravens, or mammalian predators. Habitat loss can also occur from rural sprawl and community development, meadow drainage and fill, willow eradication, and home construction in meadows.

All of these factors may be contributing to the decline of willow flycatchers from habitat degradation, loss, and fragmentation, as well as small population isolation, and ultimately may prevent recruitment into other suitable areas such as in wilderness.

The existing and future contribution of commercial pack stock operations and the trail plan to cumulative effects is considered minor at this time since Inyo and Sierra Forest Plans standards and guidelines are in place to adaptively manage suitable habitats to maintain willow and wet meadow habitats. Implementation of Alternative 1 with grazing standards and adaptive management monitoring should maintain favorable structural habitat characteristics for willow flycatcher occupation and prevent nest disturbance should a nesting pair be located.

Willow flycatcher – Alternative 2

Analysis

Effects from commercial pack stock grazing under Alternative 2 to suitable unoccupied willow flycatcher meadows listed in Table 4.87 are likely to be similar to Alternative 1 meadows that were requested for grazing and determined to be suitable, except where critical areas of the meadow may be established under Alternatives 2 and managed for a 5 percent maximum allowable disturbance standard. These areas would be identified as part of the Operating Plan so it is not possible at this time to determine where they would be established or what percent of the meadow they would occupy and how that might affect suitable willow flycatcher habitat. The 53 suitable unoccupied meadows not requested for grazing would not be grazed under Alternative 2. These meadow habitats would not be subject to the grazing effects on suitable unoccupied willow flycatcher habitats approved for grazing areas under Alternative 1.

The commercial pack stock use regulating system would have the same effects as Alternative 1 since actual camp and destination use is unlikely to substantively change in suitable unoccupied willow flycatcher habitats shown in Chapter 3, Tables 3.24 and 3.25. The proposed trail plan would have the same effects as in Alternative 1.

Cumulative Impacts

Same as Alternative 1

Willow flycatcher – Alternative 2 – Modified, and 3**Analysis**

Under these two alternatives commercial pack stock grazing allowable use levels would be substantially higher than Alternative 2 in Double, Jackass, Poison, Hellhole, and Lower Blayney. This could result in increased potential adverse effects to suitable willow flycatcher habitats. Commercial pack stock would be more likely under higher allowable use levels to graze in, and trail through, the dispersed willow clumps and potentially break and trample willow stems that would decrease the horizontal willow foliage cover as well as lower willow stem density. This could make the suitable unoccupied habitats somewhat less suitable over time since willow shrub cover would be reduced. Like Alternative 2, it would be difficult to predict exactly how much of this effect would occur and where without multi-year monitoring.

Cumulative Impacts

Same as Alternative 1

Willow flycatcher – Alternative 4**Analysis**

Under this alternative, suitable unoccupied willow flycatcher habitat in Chetwood Cabin, Detachment, and Knoblock Meadows would receive full protection over the other alternatives since no grazing would be allowed in these meadows. Some willow stands would likely slightly improve in density and crown foliage volume since there would be no potential for stock trailing through willow stands where stem breakage might occur. This alternative would also allow for maximum vegetative and hydrologic functioning recovery potential, though it is recognized that these meadows may not show substantive recovery for many decades.

Allowable grazing use levels would be the same as Alternative 2 for Jackass, Lower Blayney, Posion, and Hell Hole Meadows and therefore the effects would be the same.

Rattlesnake Lake, 77 Corral, and Island Crossing/Fox Meadows would be grazed at light stocking rates that are not likely to adversely affect willow habitats in these meadows.

In addition 53 other suitable unoccupied meadows not requested for grazing would not be grazed under Alternative 4. These meadow habitats would not be subject to the grazing effects on suitable unoccupied willow flycatcher habitats approved for grazing areas under Alternative 1.

The commercial pack stock use regulating system would have the same effects as Alternatives 1 through 3 since actual camp and destination use is unlikely to substantively change in suitable unoccupied willow flycatcher habitats shown in Chapter 3, Tables 3.24 and 3.25. The proposed trail plan would have the same effects as in Alternative 1.

Cumulative Impacts

The discontinuation of grazing in the meadows identified above would contribute to a decrease in cumulative effects on willow flycatcher habitats in the Sierra Nevada overall and may improve some structural habitat characteristics at these meadows. It is unknown whether this would make any substantive difference in the probability of willow flycatcher occupancy of suitable habitat in wilderness particularly because of the continued low willow flycatcher occupancy and use status of non-wilderness highly suitable habitats.

Willow flycatcher – Alternative 5

Analysis

Implementation of Alternative 5 would provide full protection for all suitable willow flycatcher habitat meadows listed in Chapter 3, Tables 3.24 and 3.25. No potential for adverse effects to suitable willow flycatcher would exist. The proposed trail plan would have no effect on suitable willow flycatcher habitats or changes in potential for occupancy of those meadows noted above.

Cumulative Impacts

The elimination of commercial pack stock grazing in all suitable unoccupied willow flycatcher meadows listed in Chapter 3, Tables 3.24 and 3.25 would remove any potential effects of this activity to the willow shrub components and herbaceous wet meadows areas that comprise the important structural features of suitable willow flycatcher habitat. Meadows that currently have hydrologic functioning problems would likely recover at somewhat faster rates without commercial pack stock grazing.

The elimination of all commercial pack stock use of camps, destinations, and trails in the AA/JM Wildernesses is unlikely to appreciably change the cumulative effects on willow flycatcher habitats since there is very little destination use associated with the meadows shown in Chapter 3, Tables 3.24 and 3.25. Suitable habitats where trail systems and camps course in and adjacent to these meadows would still be subject to human disturbance from the remaining wilderness user groups. There may be some minor, localized, and insignificant level of suitable habitat improvement where commercial pack stock use of trails has resulted in a widened treadway through riparian areas that would likely narrow in width once commercial stock use ceases.

Northern Goshawk

The Biological Evaluation prepared for this EIS has determined that implementation of Alternatives 1 through 4 may affect individual goshawk but would not contribute to a trend toward federal listing for this species, or loss of viability within the planning area. Implementation of Alternative 5 would not affect the goshawk.

Northern Goshawk – Alternative 1

Analysis

The direct and indirect effects of commercial pack stock operations that represent 11 to 13 percent of overall use in the wilderness cannot be easily separated out from the total human disturbance presence and low levels of habitat modification effects that may affect goshawk use of suitable habitats for nesting and foraging. If all commercial pack stock operations were ceased

there would still be a substantial continuous human disturbance presence from day hikers, backpackers, and recreational stock users during the goshawk nesting and young rearing period from June through August along the same popular trails, camps, and destinations.

There would continue to be localized areas of habitat impact with implementation of Alternative 1 around trails, camps, and stock holding areas; however, the overall suitable habitat would be unlikely to be substantively affected to the point where goshawk could not find suitable nesting areas within a territory.

Individual goshawk have demonstrated varying levels of tolerance to adjacent human presence, such as around camps and trails. On the Inyo National Forest nests are occasionally constructed along trails to take advantage of open flight-paths to the nest. These nests are often abandoned if young have not hatched once human recreation presence begins in June (USDA Forest Service 2001). If young are present, goshawk will become highly territorial and display aggressive flight attacks toward recreationists who come within close proximity to the nest. This can result in recreationists further harassing, and occasionally attempting to chase, goshawk out of the area and in rare worst case scenarios, attempt to harm the birds. There are no records in the AA/JM Wildernesses of recreationists including commercial pack station operators or clients attempting to harm goshawk.

Pack station wranglers could possibly guide clients to known nests to view goshawk in a non-threatening manner. This type of event can be benign or lead to birds leaving the nest area temporarily, and possibly temporarily abandoning young. Goshawk, like other raptors, may adapt to tolerate low levels of this type of activity, especially once young are present in the nest. Hargis et al. (1991) examined several goshawk territories around Mammoth Lakes California outside of wilderness in areas of commercial timber harvest and dispersed recreation. They found that small scale human developments had no apparent effect on home range configuration or reproductive success of the goshawk territories studied. In addition, the goshawk territories they studied where these conclusions were made were bordered by coniferous forests that provided goshawk the potential to avoid or escape human disturbance. The study conclusion may shed light in how goshawk may respond to camps and destination uses in wilderness in suitable habitats. There are similarly substantial undisturbed areas of adjacent habitat around trail corridors, camps, and destinations in wilderness where goshawk have the ability to avoid human disturbance areas within their territories

In the case of the Davis Lake nest territory, there are historical records of the birds successfully nesting and fledging young amidst nearby human disturbance, including system and user trail use, recreational and commercial pack stock camps, and stock holding areas. The territory has been inactive for several years now and intensive territory searches in 2003 and 2004 have failed to detect goshawk presence or signs of nest maintenance. There could be a number of reasons why goshawk are not currently occupying the territory; including the death of one of the birds from unknown causes, or the shift of the birds' use of the territory to an unknown location away from the areas searched. The particular factor that causes nest sites to become unoccupied is extremely difficult to determine. A nest territory closure to recreation users could be implemented through the Sierra Nevada Forest Plan Amendment direction when an active territory is discovered. A biological evaluation would be conducted at the site specific level to determine an appropriate buffer zone to reduce human disturbance levels. The closure could be implemented through the annual pack station permit operating plan.

There are nest territories that have been monitored for years on the Inyo National Forest where goshawk successfully nest and fledge young adjacent to high human use trails, roads, and campgrounds that are as close as 100 yards from the nest tree. The birds continue to occupy the territories without closure buffers year after year and produce young at levels similar to nest territories more distant from human use areas.

Table 3.26, Chapter 3 displays the suitable habitat acreages by geographic unit. This table demonstrates that for six of the eight geographic units, there is considerable suitable habitat available where goshawk can shift nest locations in response to human use patterns on the landscape, such as commercial pack operations, and still have a high probability of maintaining a successful nest territory. Goshawk nest territories vary considerably to over 5,000 acres per pair (USDA Forest Service 2001). Goshawk typically have more than one nest in a territory and shift nest use around from one year to the next year, especially in territories with substantial human disturbance. Goshawk have shown an ability to successfully nest and rear young in these situations on the Inyo National Forest.

Adjacent non-wilderness suitable habitat acres are available in the remaining three units (Bishop-Humphreys and John Muir Southeast) where goshawk can find enough suitable habitat to maintain territories.

Direct structural habitat impacts with implementation of Alternative 1 associated with trails and camps used by commercial pack stock operations may be locally high around a camp but are likely minor when considered over the entire suitable habitat areas shown in Table 3.26. Impacts are generally minor losses of understory vegetation, ground compaction, and loss of woody debris that packers use for campfires, all of which can have minor effects on goshawk prey abundance such as Douglas squirrels. Such effects are probably of minor consequence to the maintenance of goshawk territories that may be present.

Cumulative Impacts

Cumulative effects in the two wilderness areas have already been mentioned above in terms of the effects of all recreational activities and how they can influence goshawk use of suitable habitat, as well as the ability of goshawk to successfully rear young. An intensive research study would be needed to fully assess such effects that would require considerable effort and funding to locate nests and design a study to fully understand how goshawk are responding to recreational uses of wilderness.

Wilderness is probably the lowest priority area for such an intensive analysis since habitat modification is low. Also, overall recreational pressure is substantially lower relative to non-wilderness habitats where goshawk can encounter significantly higher levels of human disturbance and habitat modification events. Such affectors outside wilderness include campgrounds, road networks, high use recreation areas around lakes and streams that overlap highly suitable nesting habitats, resorts, pack stations, developments associated with Mammoth Mountain, and rural developments along the Inyo and Sierra National Forest boundaries.

The implementation of the Sierra Nevada Forest Plan Amendment designation of Protected Activity Centers for active nest sites as well as management standards and guidelines are designed to reduce the cumulative effects on the species within Forest Service lands. These standard and guidelines apply to wilderness areas as well.

Also, some level of falconry take of young goshawk from nests occurs in wilderness as well as non-wilderness. The Sierra Nevada Forest Plan Amendment analysis for goshawk in the Sierra Nevada noted that the legal harvest of goshawk for falconry is low in the Sierra and does not impact the population (USDA Forest Service 2001).

Northern Goshawk – Alternative 2 – Modified

Analysis and Cumulative Impacts

The effects of implementation of this alternative may provide some overall improvement in suitable goshawk habitat since overnight stock use will be restricted to designated camps that may restrict human disturbance to a smaller area within suitable habitat. This is speculative in many ways, since clients would still be able to day hike from the camps into suitable habitat, and other user groups would continue to use the areas for camping and destinations.

The continuation of commercial pack stock use around the unoccupied south Davis Lake nest site area and the potential for direct and indirect effects would be the same as Alternative 1. The one nest along the system trail would continue to experience a high level of human disturbance and it is likely goshawk would not use it as long as the system trail remains in that location. Similarly, under this alternative, the maintenance of the two trails to Grass Lake at the North Fork of Bishop Creek would continue to maintain a high level of human disturbance in this territory. The Davis Lake territory has considerable suitable habitat for birds to potentially nest away from the heavy human disturbance areas. The North Fork territory has substantially less undisturbed habitat so any additional disturbance could be problematic for long-term maintenance of this territory. The Sierra NF goshawk territories identified in Chapter 3 would be unaffected by this alternative.

Alternative 2 – Modified can implement the same nest territory closure to recreation users as Alternative 1 under the Sierra Nevada Forest Plan Amendment direction when an active territory is discovered.

The disapproval of the south user trail by commercial stock under Alternative 2 – Modified would maintain a lower level of human disturbance through this section of the territory. The main system trail to Lamarck Lakes that bisects the territory would continue to cumulatively experience a high level of human traffic from all user groups under both alternatives, and maintain a high level of human disturbance within the trail corridor portion of the territory. The goshawk appears to have selected the least disturbed areas within the available suitable habitat in the territory in which to place their nest.

The other aspects of the trail transportation system, trail management levels, system and user trail suitability determinations for commercial pack stock, and use regulating systems of this alternative are not likely to cause any measurable changes in the quality of goshawk habitat. This is because human disturbance potential would likely remain at similar levels throughout the wildernesses as Alternative 1. There may be a slight reduction in overall human disturbance effects with designated overnight stock holding camps, the NSCS system trail designation, and commercial pack stock use prohibitions over Alternative 1. The North Fork of Bishop Creek territory is an example of a territory unlikely to have any substantive changes in cumulative effects since it would continue to experience high levels of disturbance effects with the non-wilderness campground, non-wilderness day use, and wilderness day hiker and backpacker

popularity of the area and trail system. The Davis Lake site would also likely still maintain a high level of human traffic through the nest territory around the south lakeshore.

Northern Goshawk – Alternatives 2 and 3

Analysis and Cumulative Impacts

The effects of implementation of these alternatives may provide some overall improvement in suitable goshawk habitat since overnight stock use will be restricted to designated camps and may restrict human disturbance to a smaller area within suitable habitat. This is speculative in many ways, since clients would still be able to day hike from the camps into suitable habitat, and other user groups would continue to use the areas for camping and destinations.

The implementation of the buffer closure around the south Davis Lake nest site area to commercial pack stock use may improve the nest site potential for goshawk to re-occupy the area if the birds are still present in the territory. The one nest along the system trail would continue to experience a high level of human disturbance and goshawk likely would not use it as long as the system trail remains in that location. Similarly, the maintenance of the two trails to Grass Lake at the North Fork of Bishop Creek under both alternatives would continue to maintain a high level of human disturbance in this territory. The south user trail upgrade into the system under Alternative 3 would encourage additional human use in that part of the territory and somewhat decrease habitat suitability. The Davis Lake territory has considerable suitable habitat for birds to potentially nest away from the heavy human disturbance areas. The North Fork territory has substantially less undisturbed habitat, so any additional disturbance could be problematic for long-term maintenance of this territory.

Alternatives 2 and 3 can implement the same nest territory closure to recreation users as Alternative 1 under the Sierra Nevada Forest Plan Amendment direction when an active territory is discovered.

The disapproval of the south user trail by commercial stock under Alternative 2 would maintain a lower level of human disturbance through this section of the territory. The main system trail to Lamarck Lakes that bisects the territory would continue to experience a cumulative high level of human traffic from all user groups under both alternatives, and maintain a high level of human disturbance within the trail corridor portion of the territory. The goshawk appears to have selected the least disturbed areas within the available suitable habitat in the territory in which to place their nest.

The other aspects of the trail transportation system, trail management levels and system and user trail suitability determinations for commercial pack stock, as well as use regulating systems of the 2 alternatives are not likely to cause any measurable changes in the quality of goshawk habitat. This is because human disturbance potential would likely remain at similar levels throughout the wildernesses as Alternative 1. There may be a slight reduction in overall human disturbance effects with designated overnight stock holding camps, the NSCS system trail designation, and commercial pack stock use prohibitions over Alternative 1. The North Fork of Bishop Creek territory is an example of a territory unlikely to have any substantive changes in cumulative effects since it would continue to experience high levels of disturbance effects with the non-wilderness campground, non-wilderness day use, and wilderness day hiker and backpacker popularity of the area and trail system. The Davis Lake site would also likely still maintain a high level of human traffic through the nest territory around the south lakeshore.

Northern Goshawk – Alternative 4

Analysis and Cumulative Impacts

Implementation of Alternative 4 may provide for a higher level of goshawk habitat suitability than Alternatives 2 and 3 with the reduction of overall commercial pack stock use areas, and designated drop camps in addition to stock holding camps, as well as the substantially increased number of not recommended for commercial stock system trail designations, and use trail prohibitions. Goshawk would still be subject to human disturbance in many of these areas from other user groups as described for Alternatives 2 and 3. Alternative 4 may increase commercial pack stock use in other suitable habitats such as Tamarack Basin suitable goshawk habitat as commercial pack stock operators shift use to adapt to new use regulations.

The designation of Alternative 4 trail management levels would not likely affect goshawk habitat in any substantive way. No trails would be closed or re-located with implementation; therefore, human disturbance patterns through suitable habitat would remain the same. The changes in trail width or trail structures under the various classes would not impact the suitability of goshawk in any substantive way since it is unlikely to change actual use on that trail by user groups.

Alternative 4 can implement the same nest territory closure to recreation users as Alternatives 1 through 3 under the Sierra Nevada Forest Plan Amendment direction when an active territory is discovered.

Northern Goshawk – Alternative 5

Analysis and Cumulative Impacts

The removal of all commercial pack stock use in the AA/JM Wildernesses would likely result in some improved habitat conditions and reduce the potential for human disturbance at all traditional commercial packer camps found below 10,000 feet in old growth and mature lodgepole, lodgepole-hemlock, mixed conifer, and pine-associated forests. Use would be largely discontinued, but sites could always be occupied by other user groups. Therefore, it is unknown how many of the sites would truly have reduced human disturbance and improved habitat conditions from re-vegetation of the site.

The elimination of packer campfires in these zones would allow for increased downed woody material for use by goshawk prey for variable zones around each camp.

A reduction in cumulative effects would occur in the wilderness areas within suitable goshawk habitat since there would likely be less human traffic and disturbance. In addition, less structural habitat modification would occur as a result of the reduction in campfires and disturbed camp zones and perimeters.

The vast majority of human use of trails and camps would likely continue in wilderness from other user groups, so the magnitude and extent of this lowered cumulative effect would be difficult to predict. Use would very likely increase by day hikers and backpackers if commercial pack stock use were discontinued in an area like Davis Lake. Under a shift like this, goshawk might still experience human disturbance levels and habitat modifications that would maintain similar cumulative effects as Alternatives 1 through 4.

Great Gray Owl

The Biological Evaluation prepared for this EIS has determined that implementation of Alternatives 1 through 4 may affect individual great gray owls but would not contribute to a trend toward federal listing for this species, or loss of viability within the planning area. Implementation of Alternative 5 would not affect the great gray owl.

Great Gray Owl – Alternatives 1 through 4

Analysis

Table 4.88 displays the suitable acres of great gray owl habitat identified within the AA/JM Wildernesses, and the proposed grazing management by alternative. Suitable habitat acres up to 8,200 feet elevation were determined from GIS analysis of satellite imagery.

Table 4.88. Great gray owl suitable meadow foraging habitat adjacent to suitable nesting habitat, relationship to identified grazing zones, reported grazing from 2001 through 2003, and allowable pack stock grazing levels by alternative.

Geo Unit	Analysis Unit	Meadow area with Suitable Habitat	Grazing Zone	Reported stock nights 2001/2002/2003* Proposed Use by Alternative (percent) forage use/stocknights(SN)**
AA East	Minaret	Johnston Meadow, Min 11	Minaret Creek	0/20/0* (Alt 1 no standard) (193 SN alt 2) (no grazing alt 2 mod, alt 3 and 4)**

	Spanish	Spa 6	none	0 (0)
	Rodgers	Crown, Rod 5, 6, 31	none	0 (0)

Under Alternative 1, no direct effects would occur to nesting great gray owls from commercial pack stock use since there are no known nest sites in the AA/JM Wildernesses. The continuation of commercial pack stock grazing use similar to recent use levels in the meadows identified in Table 4.88 may result in variable levels of reduction in vole prey species density on an annual basis. This level probably does not amount to a substantive reduction in vole density; however, increased reduction of voles could occur if meadows are grazed to higher forage utilization levels.

Implementation of range readiness dates would mitigate adverse effects to owl foraging success that could influence nesting and rearing of young. The majority of pack stock grazing would occur after July 15, after owls have fledged young, and it would likely be well into August before pack stock forage utilization levels cropped vegetation low enough to substantially influence vole prey density. Great gray owls can also forage for pocket gophers that are widely distributed and occur on non-meadow types as well.

Alternative 1 does not implement forage utilization standards in the near-term; therefore, prediction is difficult as to what effects would actually occur to vole prey density. Grazing levels that will occur is unknown, other than what grazing numbers have been reported in the past. There is a higher probability under this alternative of higher forage utilization events by commercial pack stock due to the lack of utilization standards. According to Beck and Winter (2000), the taller grass and sedge stubble height (especially greater than five inches) allows for sufficient cover to provide for vole occupancy of meadow habitat. The species numbers decline as residual vegetative stubble heights are reduced. The meadows where decline could be a concern would be Double, Blayne, Hellhole, Poison and Jackass meadows since they are more traditionally used on an annual basis as commercial pack stock grazing areas. The other meadows have received infrequent and light grazing.

Alternative 2 – Modified, 2, 3, and 4 would have similar effects to great gray owls in Cargyle, Junction and Shooting Star Meadows during the nesting season, since they would implement the same range readiness dates as Alternative 1. The alternatives also implement moderate utilization levels for these meadows. Potentially, a similar reduction of vole prey density would occur in Alternatives 2 Modified, and 3, which would allow for substantively higher forage utilization levels in Jackass, Double, Poison, Hellhole and Blayney Meadows. This may even further affect vole prey density. Johnston Meadow would be rested or closed to commercial pack stock grazing under Alternatives 2 Modified, 3, and 4 that would allow for higher quality prey habitat for use by great gray owls.

Use of the existing trail system in Alternatives 1 through 4 by commercial pack stock where trails course through or along the perimeter forested zones around the meadows in suitable habitat (Table 4.88) may cause great gray owls to be displaced from these habitats. Owls may avoid using the immediate trail corridor areas while the trails are in use and may utilize habitats further away from the trail corridor, or be flushed from perches around the meadow for some period of time.

The system trails, such as around Blayney and Johnston Meadows, are main high-use thoroughfares that are used by all wilderness user groups. Commercial pack stock operations are a relatively small contributor to human disturbance activities in and around these low elevation meadows. The majority of trail use by other user groups would continue to maintain a significant disturbance potential that may have some effect on owl occupancy of suitable habitat, even if all commercial pack stock trail use ceased under Alternative 5. Whether great gray owls are being affected by this use is unknown.

The proposed trail alternatives do not substantively change the potential for great gray owl occupancy of the habitats identified in Table 4.88 since the proposed actions are to designate a trail transportation system, management levels, and NSCS system trail and user trail suitability determinations. The alternatives do not consider trail location and potential relocation scenarios to favor great gray owl use of surrounding meadow habitats. Protocol surveys should be initiated, if practical, when future sightings do occur. Trail relocation and grazing management modification may be desirable future proposals after monitoring indicates such actions would be necessary to avoid adverse effects to the species.

Direct effects to forested nesting habitats from all commercial pack stock alternatives are localized areas of forest denudation around camps, including social trails and access trails.

Cumulative Impacts

Under Alternatives 1 through 4, the presence of a trail network through and around forested meadow perimeters (listed in Table 4.88) would maintain a substantial conduit for human disturbance within suitable great gray owl nesting habitat. Trail system use and associated off-trail hiking by all wilderness users around meadows can lower habitat suitability, especially since the majority of great gray owl use of suitable habitat occurs within 900 feet of meadow perimeters according to Winter (1986).

Excessive forage utilization by all classes of livestock in and out of wilderness can have substantial effects on meadow habitat, and subsequently great gray owl prey species abundance, and can potentially affect owl foraging success and influence nesting success and productivity. Loss of forested habitats from the logging of old growth mixed conifer forests, and degradation

of meadow habitats are listed as the principal factors for the reduction of suitable great gray owl habitat in the Sierra Nevada (USDA Forest Service 2002). Implementation of Sierra Nevada Forest Plan Amendment survey requirements allows for implementation of a protective management strategy when a reliable sighting of a great gray owl occurs and once an occupied territory is confirmed. This strategy would include standards and guidelines for grazing management and the development of Protected Activity Centers around all great gray owl occupied habitats to maintain habitat and limit human disturbance in known territories.

Great Gray Owl – Alternative 5

Analysis and Cumulative Impacts

Elimination of all commercial pack stock use activities within suitable great gray owl habitats shown in Table 4.88 would provide for improved meadow habitat conditions to support vole populations and Great gray owl foraging habitat at traditional grazing areas such as at Jackass, Poison, Hellhole, Blayne and Double Meadows. The implementation of a trail transportation system, and trail management levels would not have a measurable change in great gray owl habitat suitability since no trails would be closed or relocated. The elimination of the commercial pack stock use component may provide for lower human disturbance levels along the trail system if great gray owls are using the meadows adjacent to the system. A similar reduction in human disturbance associated with the elimination of commercial pack stock use would occur at destinations such as at Grassy Meadow and Jackson Meadow, two high use destination areas. Whether the cessation of use would affect any use of the available habitat by great gray owls in these areas is unknown.

Cumulative effects would likely decline because of the elimination of commercial pack stock use on the trail system and at destinations, including the elimination of all grazing with implementation of Alternative 5. Traditional camp areas and associated social and access trails may re-vegetate with localized improvement in vegetative cover and reduced human disturbance potential at these sites. How such reductions in human disturbance and grazing impacts would influence great gray owl occupancy and use of suitable habitats is unknown. All other wilderness users would continue to use the trail system and destinations within suitable great gray owl habitat.

Wide-Ranging Carnivores – Alternatives 1 through 4

The Biological Evaluation prepared for this EIS has determined that implementation of Alternatives 1 through 4 may affect individual Pacific fisher, wolverine, Sierra Nevada red fox, and American marten, but would not contribute to a trend toward federal listing for any of these species, or loss of viability within the planning/analysis area.

Fisher

Analysis

Commercial pack stock operations within the AA/JM wildernesses are outside the range of known fisher populations in the Southern Sierra. The species may be present on the Sierra National Forest side of the Wildernesses, predominantly in lower elevation coniferous forest habitats where brief human disturbance encounters with commercial pack stock operations could

occur. Suitable habitat has been listed as generally below 8,000 feet in elevation (USFS 2001), but can include higher elevation forest habitats into the subalpine. There is a very low probability of insignificant human disturbance encounters in these forested habitats along trails, and camps. Commercial pack stock operation effects to suitable habitat are insignificant and include collection of firewood around camps, which may reduce habitat suitability for fisher prey species.

Implementation of any of the alternative trail transportation system and management level designations, and commercial pack stock system and use trail suitability determinations would have insignificant effects to the species and its habitat. Trails create small habitat fragmentation corridors that also provide access pathways where human disturbance encounters may occur, along with insignificant habitat reductions for the species and its prey.

Cumulative Impacts

Commercial pack station operations and wilderness trails probably do not contribute significantly to cumulative factors adversely affecting fisher populations because of the minor range overlap of the species with wilderness, and the low impacts of these operations on late successional forest habitats. The distinct population segment of the fisher in its West Coast Range (that includes the Sierra Nevada population) is a candidate for federal listing (USFWS 2004) because of significant Sierran population declines and the isolation of the southern Sierra population from the northern population. Fisher populations and their habitat have historically been affected by timber harvesting of mature and old growth forests. Fuels reduction projects may affect the structural habitat characteristics of suitable habitat outside of wilderness. Legal trapping in the early part of the twentieth century and continued mortality from inadvertent traps set for other animals has significantly reduced fisher populations and are thought to be a hindrance to their population recovery (USFWS 2004). In addition, the Federal Register proposed rule to list the species under the Endangered Species Act also lists the loss and fragmentation of fisher habitat from roads, urban development, recreation, and stand replacing fire. The Sierra Nevada Forest Plan Amendment has a Fisher Conservation Strategy designed to maintain and recover the westside Sierra population by maintaining the southern Sierra population habitat, providing suitable habitat linkages between the northern and southern populations, protecting all den sites, and the providing suitable habitat to allow for possible fisher reintroductions.

Wolverine

Analysis

The status of wolverine and how human recreational activities may influence its presence and persistence in the AA/JM Wildernesses is unknown. No verifiable sightings have occurred in many years (USFS 2001). If the species is present, there is a very low probability of a human disturbance encounter with commercial pack stock operations, since wolverine appear to avoid areas of human occupation. Human disturbance encounters can have negative effects on this species when they do occur, to the point where wolverine may avoid areas of continuous human use (USFS 1994). The wilderness provides the lowest probability areas where such encounters are likely to have significant impacts to the species because large areas of suitable habitat allow wolverine to escape.

Implementation of any of the wilderness trail transportation system alternatives, trail management levels, and system and use trail suitability determinations would continue to maintain human travel corridors that provide areas of potential human disturbance to the wolverine. How the trail system may affect wolverine viability is unknown, since there is no known population of the species to monitor, and no data exists to support such an analysis for the AA/JM Wildernesses.

Cumulative Impacts

Ruggerio et al (1994) concluded in the publication “The Scientific Basis for Conserving Forest Carnivores” that the wolverine population in the Sierra ecoprovince might be isolated from other wolverine populations. They suggest the species may maintain its viability in the short-term; however, their long-term persistence is in doubt without dispersal corridors to connect with other populations. The rapid and continued development of low elevation habitats outside of the AA/JM Wildernesses continues to fragment and isolate habitat patches that the wolverine could use as connectivity corridors with known populations to the north. The species viability and long-term persistence becomes more problematic as development continues.

Sierra Nevada Red Fox

Analysis

The Sierra Nevada Forest Plan Amendment states that the current distribution and population status of the Sierra Nevada red fox is uncertain (USFS 2001). There have been no sightings of the fox in many years in the two wildernesses; therefore, analyzing the effects of these alternatives is difficult.

Sierra Nevada red fox, like the wolverine, seem to be intolerant of human presence; consequently, encounters with commercial pack stock operations would potentially cause a disturbance (USFS 2001). Pack stock grazing in meadows where forage utilization levels approach 30 to 40 percent may decrease some meadow-dependent prey species abundance, such as voles. This is unlikely to have any significant effect on red fox presence in the analysis area. Numerous ungrazed, or lightly grazed, meadows are present in the wilderness areas that support prey species, including an abundance of forested habitat prey species (such as rabbits and small mammals).

The effects of implementation of any of the wilderness trail system alternatives are the same as for the fisher.

Cumulative Impacts

The cumulative effect of recreational use in the AA/JM Wildernesses on this species is unknown. Outside wilderness areas, human encroachment of fox habitat through winter and summer motorized vehicle use, non-motorized recreation, rural sprawl, and developments such as ski areas all adversely affect potential use of an area by Sierra Nevada red fox (USFS 2001). Heavy livestock grazing is also noted as a potential adverse effector of prey species abundance in non-wilderness meadow habitats.

Marten

Analysis

Commercial pack stock operations are likely to have localized direct and indirect effects on marten around trail corridors, camps, and destinations in montane-forested habitats. The effects are considered of minor consequence to the overall marten population in the two wilderness areas since there is abundant high-quality habitat. Marten may avoid areas around camps where commercial pack stock operations are present; however, the species can range over large areas to find suitable foraging habitats and rest sites. There will likely be some minor, insignificant reduction in prey availability and marten rest sites because of the removal of downed woody material for collection of firewood around camps where fires are allowed.

Implementation of any of the alternative trail transportation system and management level designations, and commercial pack stock system and use trail suitability determinations would have insignificant effects to the species and its habitat. Trails create small habitat fragmentation corridors that also provide access pathways where human disturbance encounters may occur, along with insignificant habitat reductions for the species and its prey.

Cumulative Impacts

Marten use of habitats within the AA/JM Wildernesses is likely affected by the cumulative effect of all recreational activities. The continuous presence of all recreation users in Category 3, and to a lesser degree Category 2, areas of wilderness could lead to marten avoidance, or reduced use of those areas. The collection of firewood and the denudation of camp areas, along with user and social trails in popular destinations, reduce habitat for small mammal and bird prey species and decrease rest site cover habitats for marten. The influence of these impacts on marten populations is unknown; however, the impacts are not thought to be significant enough to threaten marten population viability because vast areas of high quality suitable habitat are available.

Cumulative effects outside of wilderness that adversely affect marten use of habitats include the continued use and development of the Mammoth Ski Area, rural sprawl, resort use and development, and campgrounds in forested habitats. Summer and winter recreation activities, such as hiking, and camping, off-road vehicles, stock trail rides, snowmobiling and cross country skiing, affect marten seasonal use of habitats. Forest thinning projects and fuel reduction treatments reduce dense forested conditions that marten favor and reduce the habitat for marten prey species. Marten are also occasionally reported killed from motor vehicles, entrapment in structures, and trap-sets put out to catch other species.

Wide-Ranging Carnivores –Alternative 5

Analysis

Cessation of all commercial pack stock operations in the AA/JM Wildernesses would obviously reduce the human disturbance potential from encounters with marten in particular and to a much lesser degree other species. Some improvement of foraging and resting habitats would occur since traditional packer camps, social trails, and grazed meadows would be vacated and vegetation would recover over time. This improvement would be confounded by the continued

use of trails, destinations, and camps by all other recreation groups that comprise the largest percentage of use in the AA/JM Wildernesses.

Cumulative Impacts

The contribution of commercial pack stock operations to the overall disturbance and habitat effects stated for Alternatives 1 through 4 would be eliminated; however, how this change would affect the populations of wide-ranging carnivores and habitat use patterns in wilderness areas is unknown. The implementation of the trail plan would not have a measurable change in wide-ranging carnivore habitat suitability since no trails would be closed or relocated. Cumulative effects would not measurably change since all other wilderness users would continue to use the trail system and destinations within suitable habitat.

California Spotted Owl –All Alternatives

Analysis

The Biological Evaluation prepared for this EIS has determined that implementation of Alternatives 1 through 4 may affect individual California spotted owls but would not contribute to a trend toward federal listing for any of these birds, or loss of viability within the planning/analysis area. Implementation of Alternative 5 would have no effect on the species.

Implementation of any of the action alternatives would have minor effects, if any, on the spotted owl. The species is nocturnal and roosts in trees during the day in dense mature and old growth mixed conifer and red fir forests where it is unlikely to be disturbed by passing pack stock or to experience any substantial improvement without pack stock on trails and around camps. There is very little overlap of commercial pack stock operations with late successional forested habitats where the spotted owl may exist in the two wilderness areas. These habitats are in the lower elevation portions of the AA/JM Wildernesses, below the destinations commercial pack stock operations utilize.

Cumulative Impacts

Overall, human activities inside and adjacent to the two wilderness areas may have minor effects on spotted owl use of habitats for nesting and foraging; however, no data exists on which to assess this further. The disturbance potential is not thought to be a significant affector that has contributed to the decline in spotted owl populations in the Sierra Nevada. The predominant factors affecting this species have been, and continue to be: the conversion of late successional forests to younger stand conditions that eliminate nesting and foraging habitats, forest fuel reduction projects that eliminate or drastically reduce structural habitat features (such as multi-layered forest canopies), and large amounts of downed woody material and snags needed for prey base populations.

Catastrophic large landscape wildfires have also modified, and potentially eliminated, a number of spotted owl territories in recent years. The Sierra Nevada Forest Plan Amendment FSEIS (USDA Forest Service 2004) states that eighteen Protected Activity Centers (PACs) designated to protect and manage spotted owl nest territories could be considered lost due to the amount of habitat that was burned and no longer meeting habitat suitability criteria. It also notes an annual average of 4.5 PACs have been lost or severely modified by wildfires since 1998. Natural and

human-caused landscape fires will likely continue to substantially modify spotted owl habitats and possibly cause localized population changes.

Peregrine Falcon – All Alternatives

Analysis and Cumulative Impacts

The Biological Evaluation prepared for this EIS has determined that implementation of any of the alternatives would not affect the peregrine falcon or result in a loss of viability for the species within the planning/analysis area.

The only recreational activity occurring in wilderness areas that could affect the peregrine falcon is rock climbing, which is typically not associated with commercial pack station operations or client activities except where client's supplies are ferried to base camps for mountaineering. The implementation of any of the trail system alternatives would also not affect this species since trails have not been identified as issues around the known falcon aeries.

Under any of the alternatives, known aeries are protected by a limited operating period that closes the area around the aeries to rock climbing while nesting activities are taking place. Implementation of any alternative does not promote, nor hinder, the existing level of wilderness rock climbing. Implementation of any of the alternative trail transportation system and management level designations, and commercial pack stock system and use trail suitability determinations would have no effect on the peregrine falcon since trails have not been determined to be adversely affecting the species' use of available habitat.

Peregrine falcon nest site disturbance from increasing human recreational use near aeries can have a cumulative effect in wilderness if left unmanaged; however, the Sierra has limited operating period restrictions in place to protect important nesting habitats.

Pallid and Townsends Big-Eared Bat – All Alternatives

Analysis and Cumulative Impacts

The Biological Evaluation prepared for this EIS has determined that implementation of any alternative would have no effect on the pallid bat or the Townsends big-eared bat, nor would they contribute to a trend toward federal listing for any of these species, or loss of viability within the planning/analysis area. There would be no direct, indirect or cumulative effects on key roosting and hibernation habitats present in the two wilderness areas. There may be changes in insect prey abundance in grazed riparian meadows; however, there is no evidence to suggest these changes are having any substantive effect on use of these habitats by these bat species.

Cumulative effects on these species are largely from loss of hibernation and maternity habitats these bats have established in human made structures (such as abandoned mines and buildings) that subsequently are closed or torn down, and recreational activities that disturb bat use of natural caves. Riparian habitat loss and modification has adversely affected foraging habitats for this species outside of wilderness. There also appears to be potential effects from pesticides that reduce insect prey densities and availability.

Management Indicator Species

MIS Mule Deer, Yellow Warbler, and Riparian Meadow, and Meadow Edge Bird Species – Alternative 1

Analysis

Commercial pack stock meadow grazing

Table 4.89 displays the relative changes in the number of meadows where grazing would be allowed versus closed by alternative of the subset of meadows analyzed during field meadow evaluations from 2001 through 2004. It also shows the relative changes of open and closed meadows by alternative for meadows that have hydrologic functioning problems. The numbers can be used as an index to allow comparison of the alternatives as to which alternatives provide for the best wilderness MIS riparian, meadow edge bird species, and mule deer meadow habitat potentials and restoration capability, especially where meadows have stream functioning at risk problems or other meadow hydrology problems that can have adverse effects on meadow habitats.

The assumption is that ungrazed meadows provide the best wilderness MIS wildlife habitat conditions. These meadows provide improved nesting cover for ground and shrub nesting birds, fawning cover for mule deer, and overall foraging habitats. They also have the least amount of avoidance and disturbance impacts to MIS species associated with commercial pack stock use of the meadows and human related management activities. Ungrazed meadows are more likely to have a more rapid MIS habitat recovery rate potential where hydrologic functioning problems exist that could be adversely affecting wildlife habitat components such as vegetative productivity and composition, as well as special aquatic habitats such as springs, seeps, vernal pools, and marshes identified in the Riparian Conservation Area goals and objectives of the Sierra Nevada Forest Plan Amendment.

Approximately 131 meadows under Alternative 1, out of approximately 1503 meadows mapped in the AA/JM Wildernesses that have had reported grazing from 2001 through 2003, are the most likely to continue to experience highly variable levels of grazing use up to maximum allowable forage utilization standards and ground disturbance standards. Another 253 meadows requested for grazing that have not had reported use from 2001 through 2003 may be grazed at highly variable levels, most likely light to very light utilization levels. This alternative would allow commercial pack stock grazing to occur in all wilderness meadows (unlike Alternatives 2 through 4) since all meadows are open for grazing, except for four meadows where grazing closures exist in Cascade Valley and Pioneer Basin. Some additional meadows under Alternative 1 may be closed at some point in the future because of unsuitable for grazing determination analyses directed by the Ansel Adams, John Muir, and Dinkey Lakes Wilderness Management Plan (USDA Forest Service 2001).

One hundred and eight meadows under Alternative 1 determined to be unsuitable for grazing during the interdisciplinary wilderness grazing field assessments would continue to remain open until a grazing closure process is implemented. In addition, Alternative 1 permits grazing in a subset of 59 meadows where stream hydrologic functioning problems are occurring, a condition that may be adversely affecting wildlife habitat. A 20 percent maximum allowable disturbance standard within the meadow and critical area habitats, such as fens and wetlands, would allow

for a higher level of trampling and chiseling disturbance impacts to habitats than Alternatives 2 through 4 where a maximum 5 percent allowable disturbance standard would be implemented.

Table 4.89 Number of analyzed meadows approved for commercial pack stock grazing and determined to be unsuitable and closed to grazing with functioning at risk stream hydrology (PFC) assessment by alternative

	Number of meadows approved for grazing	Number of Meadows determined to be unsuitable	Number of Meadows open/closed for grazing with functional at risk hydrology downward trend	Number of Meadows open/closed for grazing with functional at risk hydrology no apparent trend	Number of Meadows open/closed for grazing with functional at risk hydrology upward trend	Total number of Meadows open/closed for grazing with all functional at risk hydrology categories
Alternative 1	246	4	16/1	29/0	16/0	61/1
Alternative 2	139	108	6/11	24/5	11/5	41/21
Alternative 2 - Modified	143	110	2/15	23/6	9/7	34/28
Alternative 3	143	110	1/16	24/5	9/7	34/28
Alternative 4	120	138	0/17	20/9	7/9	27/35

The following generalized effects discussion for MIS birds and mule deer applies to all meadow habitats potentially open to grazing. The pack stock grazing period from July 15th onward, depending on range readiness dates from one year to the next, overlaps with the nesting and young rearing period of meadow and meadow edge bird species. This grazing also overlaps with an important period when many songbird species arrive at meadows after nesting and fledging young to forage prior to migration from the Sierra. Riparian meadow habitats become important foraging habitats for songbirds during this period. Samson (1980) noted that only a few species of birds nest in mountain meadows, while up to five times as many feed there.

Grazing impact on birds is variable and depends on where a species feeds or nests and when grazing takes place (Skovlin 1984). Implementation of Alternative 1 would likely cause some level of displacement and avoidance effects to riparian meadow and meadow edge songbird species' use of available habitat. The songbird species most likely to experience localized direct effects are primarily ground and low shrub nesters that utilize the ungrazed cover to place their nests. Direct effects of grazing on habitat structural characteristics include a reduction in nesting cover, and a reduction in available food sources (such as seeds and possibly some species of insects living in ungrazed vegetation).

Skovlin (1984) stated that grazing could result in trampling of bird nests, reduced cover, and removal of bird food: such as insects, seeds, or fruits. The reduced cover volume increases the potential for exposure of nests to weather and predation events, increasing the potential for egg and nestling mortality. In addition, adult parent birds may be flushed from the nest as stock move into the meadow and graze near a nest. This could result in temporary displacement of the adults from the nest that could increase the probability of predation, nest parasitism by brown-headed cowbirds, or exposure to weather and temperature impacts to the eggs and young. Ground

nesting birds such as the dark-eyed junco and white-crowned sparrow may likely be the most affected since they place their nests in grass clumps and low shrub cover, such as low willow clumps.

Kaufmann and Kreuger (1984) noted that grazing effects on songbird species are neither uniform or easily defined, principally because grazing varies so much in its local intensity and because of the general difficulties in unraveling cause-effect relationships. They cited a study by Mosconi and Hutto (1982) that found no significant difference in total breeding bird densities between heavily grazed and lightly grazed riparian communities. There were, however, significant differences in bird species composition and foraging guilds. They noted the majority of the bird species significantly affected included flycatcher, ground-foraging, or foliage gleaning insectivore guilds. Grazed riparian communities were preferred by birds of insect foraging guilds, while ungrazed riparian habitats were preferred by birds of the herbivorous graminoid foraging guilds.

Dobkin et al. (1998) found that avian species richness and relative abundances were greater on ungrazed exclosure plots inside a grazed meadow complex. The ungrazed exclosure plots were dominated by wetland and riparian bird species; whereas the open grazed riparian meadow areas were dominated by upland (non-riparian) bird species. Their interpretation of the results was that the ungrazed areas provided improved hydrologic conditions that favored wetland and riparian bird species. DeSante (1995) stated that apparently, the major deleterious effects of grazing on montane meadows are the decreased amount of herbaceous vegetation in the meadow. His opinion was that many of the land bird species that utilize the meadows feed on insects that are either located directly on the herbaceous growth, or that depend on the vegetative production for food. The implication was that cropping and trampling of the herbaceous layer by pack stock grazing resulted in lowered insect production and availability for songbird food. His status report of Sierra Nevada birds noted that montane meadows might be the single most critical habitat in mid-summer for many species, such as the Nashville and orange-crowned warblers and many forest nesting birds, which come to the meadow to feed after breeding and fledging of young. The meadows serve as critical molting and pre-migratory staging areas for the young birds, and adults to a lesser extent.

The yellow warbler and its habitat may experience a low level of disturbance from pack stock grazing in a subset of meadows with tall willow stands occurring mostly below 9,500 feet. The meadows listed in the willow flycatcher analysis section would be highly suitable examples of yellow warbler habitats. The species has been observed to nest as high as 9,937 feet in elevation on the east side of the Sierra Nevada at North Lake in the North Fork of Bishop Creek outside the wilderness boundary (Sacha Heath personal communication, Point Reyes Bird Observatory 2005). Pack stock grazing that occurs in wet meadows with as little as a half an acre of dense tall willow patches can overlap with this species' use of meadows for nesting. There is a chance pack stock could bump a nest in the outer branches of a willow shrub as stock move through willow clump areas of a meadow in search of forage and as a result knock eggs, young, or the nest out of the shrub. Yellow warblers usually place their nest in shrubs from 3 to 8 feet above the ground (USDI Fish and Wildlife Service 1982). This type of impact may likely be a very rare incidence if current light forage utilization levels continue in most meadows where grazing is likely to occur. The probability would increase the closer forage utilization levels approach the maximum allowable use levels since stock would be more likely to graze herbaceous vegetation around the edges and inside willow clumps.

The impacts described above may affect riparian meadow and meadow edge species population numbers at some unknown level but it is unlikely the impacts are substantive enough to adversely affect the viability of these MIS bird species. Meadow habitats are widespread throughout the AA/JM Wildernesses where grazing impacts are light to non-existent, as evidenced by the fact that only 131 meadows out of 1503 have experienced commercial pack stock grazing. The subset of meadows in more heavily used wilderness Recreation Category 3, and to a lesser extent Recreation Category 2, areas are where these impacts are most likely to occur. Under the highly unlikely scenario of full implementation of Alternative 1's maximum allowable forage utilization and ground disturbance standards, there would likely be an increase in the level of these habitat impacts, as well as human and livestock disturbance impacts on meadow and meadow edge MIS bird species.

Implementation of range readiness dates from mid-July through mid-August (depending on elevation) may help to slightly mitigate these impacts in grazed meadows since some birds species may complete nesting by the time grazing begins. However, the above effects are more likely to occur if grazing begins earlier with more overlap with the nesting season because of annual modifications in the range readiness dates that allow for an earlier turn-on date.

There may be some level of brown-headed cowbird parasitism of meadow songbird nesting species in lower elevation wilderness meadows that are within approximately 6 miles of pack stations, livestock allotments, and pack stock pastures (Verner and Rothstein 1986). These effects are most likely to occur in wilderness west side meadows such as Hellhole, Poison, Double, Jackass, Blayney Meadows, and on the eastside at Parker Lake, Lower McGee Canyon, and the middle fork of San Joaquin River lower elevation meadows. It is unlikely such parasitism would have significant effects on any songbird species population in the Ansel Adams and John Muir Wildernesses. Verner and Rothstein (1986) stated that nest parasitism would probably not threaten the total population of any host species in the Sierra Nevada, with the possible exception of the willow flycatcher. However, it has already been noted that this species is an unlikely resident nester in the AA/JM Wildernesses.

Mule deer home ranges may increase in areas where pack stock graze a meadow, particularly in areas where pack stock are found more frequently throughout the summer. The effects are likely more pronounced in late July and August at the height of the packing season and in Recreation Category 3 wilderness recreation zones where commercial pack stock operators traditionally set up overnight camps and grazing is likely to be at heavier forage use levels. These areas are a small subset of the 131 meadows where grazing has been reported and they comprise a relatively low number of meadows in the AA/JM Wildernesses.

Mule deer does with fawns in particular would likely avoid some meadows and move to areas where there is lower human and stock disturbance. The effects described above are inferred from a study by Loft et al. (1993) in the Sierra Nevada that found that meadow habitat comprised a greater proportion of a deer home range in the absence of cattle grazing. Deer home ranges increased in size as cattle grazing levels increased. In another study, Loft et al. (1993) noted that deer spent more time feeding and less time resting with increased cattle stocking rates, particularly in late summer, but deer did not display this behavior in ungrazed meadows. The working hypothesis was that cattle competed with deer for herbaceous forage. It is logical to extrapolate these study results to commercial pack stock grazing where similar levels of forage utilization occur, since both cattle and pack stock graze similar herbaceous vegetative components of a meadow.

Cole et al. (2004) studied pack stock grazing effects to vegetation in Yosemite National Park and determined that repeated pack stock grazing over five years increased bare soil, and led to decreased vegetative vigor and productivity that occurred at utilization levels between 15 and 69 percent. The study predicted between 20 and 25 percent productivity declines in moist Brewer's reedgrass and tufted hairgrass meadows at 45 percent forage utilization rates. These meadow types are common types within wilderness meadows. Forty-five percent utilization is close to the 30 to 40 percent use that is allowed under the 2001 Wilderness Plan direction for maximum utilization rates for pack stock grazing. It is unknown how vegetative productivity and species composition changes would affect food availability for deer and MIS riparian and meadow edge birds.

The most obvious observed effects to wildlife habitat structure from pack stock grazing in wetlands, wet and moist meadows, and springs and seeps that are likely to continue under Alternative 1 would be direct removal of vegetation cover from grazing, and mechanical cover and forage losses from vegetation trampling and sod chiseling effects that reduce the productivity and density of this vegetation. This results in variable levels of cover and forage reduction for the MIS species above.

The mechanical effects can be particularly evident in areas of higher forage utilization zones in a meadow, especially in portions of the meadow that are not range ready for all or some part of the grazing season and are usually interspersed with the areas considered to be range ready. Most high country meadows have a highly variable matrix of range ready and non-range ready components. Effects in the non-range ready areas are particularly pronounced where the naturally continuously vegetated and relatively smooth gradient sod is broken up into mud or water pool punches and chisels interspersed with flat or raised areas of remaining vegetated sod (hummocks). The mud holes and chisels that are created appear to remain for years in some areas that are repeatedly grazed on a yearly basis, and appear to recover and re-vegetate at varying rates. They may re-vegetate sparsely over time to lower seral meadow species such as alpine aster or remain un-vegetated as hummocks develop from repeated pack stock use on a yearly basis. These habitat effects are typically seen in meadows that are grazed regularly from year to year at higher stock night numbers that approach moderate forage utilization levels. Headcuts in spring channels and springheads are often observed as well from repeated chiseling of the bank sod (Inyo National Forest wilderness meadow survey records).

These impacts modify MIS wildlife habitat in ways that remain largely un-researched with unknown effects on these wildlife populations. They can directly affect habitat quality and quantity for these riparian dependent and associated wildlife species that utilize the meadows for breeding and nesting, hiding and escape cover, young rearing, and foraging. In the heavier grazed meadows, the effects can be inconsistent with the Sierra Nevada Forest Plan Amendment Aquatic Management Strategy goals and desired conditions, especially RCO #4 direction to ensure management activities enhance or maintain the physical and biological characteristics associated with aquatic and riparian dependent species, and RCO #5 direction to preserve, restore, or enhance special aquatic features such as meadows, lakes, ponds, bogs, fens, and wetlands. Mechanical effects usually occur regardless of proper forage grazing utilization standards since they largely occur in non-range ready areas. The functional at-risk meadows and unsuitable meadow columns for Alternative 1 in Table 4.89 would most likely indicate meadows where RCO inconsistency would be at issue with approved grazing use.

Commercial Pack Stock Destination, Camp and Trail Use Effects

Commercial pack stock use of all trails, including access trails to camps, has been observed to directly impact stream bank, spring and seep habitats, particularly at trail crossings or where stock are led to watering areas. The impacts observed include undercut bank loss and widened shallow stream channel areas, conversion of portions of the moss-sedge-rush spring and seeps areas to mud, riparian sod loss and fragmentation, and a reduced density and vigor of late seral wet and moist meadow vegetation. Lower seral stage vegetation may occupy the areas adjacent to these disturbed areas as a result of trampling and water table disruption. This loss directly effects habitat quality and quantity for MIS species that utilize the meadows for breeding and nesting, hiding and escape cover, young rearing, and foraging. These effects can also occur with backpacker and hiker use of the same trails in meadows and can be substantial where use levels are high, such as in Category 3 use areas.

There is also a direct disturbance to riparian MIS wildlife from use of trails, camps, and destinations by commercial pack stock. Disturbance events where wildlife are displaced or avoid habitats can result in adverse physiological effects associated with fight or flight reactions. These species are also more vulnerable to predation events because they are moving more often, which increases their visibility to predators in the area. The fitness of these species can decrease as a result of displacement events away from key habitats, or where their daily activities are disrupted such as breeding, egg laying, young rearing, feeding or resting and concealment. These events can range from temporary or permanent displacement of the wildlife species away from a key habitat riparian area such as where a doe and her fawn are forced to flee the area temporarily, to a more dramatic effect of animals failing to nest successfully in the immediate trail or camp area.

Miller et al. (1998) found that the composition and abundance of birds were negatively altered adjacent to trails in both grassland and forest ecosystems. Some habitat specialist bird species were found to be absent, or in lower densities than compared to areas where no trails were located, and common habitat generalists (such as robins) were more abundant along trail corridors. Grassland birds were significantly less likely to nest along trails. This relationship is likely to hold true for open meadows that are structurally similar to grasslands. Both forest and grassland birds were more likely to experience nest predation events near trails.

They found this zone of effect to be as much as 75 meters (246 feet) around the trail corridor. The results are an extreme case of disturbance since the study was located on a very heavy use trail within an urban county environment in Colorado. Such effects in wilderness are likely to be substantially reduced, according to the authors, but do serve to demonstrate the influence a heavy use trail such as a main system trail can have on nesting songbirds.

The direct effects of commercial pack stock trail and camp use on wildlife habitat can be inferred from the following studies and reviews. Cole (1989) summarized the effects of pack stock use on trails. He cited a study by Weaver and Dale (1978) that concluded trails produced by 1000 horse passes were 2 to 3 times as wide and 1.5 to 7 times as deep as trails produced by 1000 hiker passes. One-half the vegetative cover was lost after 1000 hiker passes and 600 hiker passes in grassland and after 300 hiker passes and only 50 horse passes in a forest. Another study Cole summarized conducted by Whitaker (1978) found that horse use loosens soil, making it more prone to erosion. Pack stock camps were found to be 6 times as large as backpacker sites, with more than 4 times the unvegetated area, with 11 times as many damaged trees and 25 times as many exposed roots in the study area in the Bob Marshall Wilderness in Montana.

Under Alternative 1, commercial pack stock trail use on system and user trails that course directly through or on the margin of riparian wetlands, riparian willow corridors, and wet and moist meadows may continue to have varying degrees of impacts to riparian MIS mule deer, yellow warbler, and riparian meadow and meadow edge bird species. Alternative 1 could potentially reduce effects along 7 miles of NSCS system trails and 102 miles of prohibited use trail habitat corridors where they course through or immediately adjacent to riparian meadow habitats. This analysis should be considered an index of potential habitat and human disturbance impact reduction, and therefore MIS habitat improvement. The actual improvement could be highly variable in both extent and time, based on the existing condition of the riparian habitat where the trail courses through or adjacent to the meadow, the level of existing commercial pack stock use, the use of the trail by other user groups, and the degree to which the habitat is used by the MIS species. It can range from little change to some higher level of impact reduction and habitat improvement.

Effects that would continue with implementation of the trail transportation system and use trails approved for use would be some level of localized reduction in riparian habitat within the trail-tread and corridor. Parallel rutting can spread the effect out in a wider swath across the meadow.

The effect on adjacent habitat vegetative structure would depend on whether the trail is adversely affecting the immediate area water table. These effects are more pronounced on trails that are in disrepair and ones that are less likely to receive periodic maintenance.

Trail use by all user groups would allow for human disturbance of MIS species along the trail corridor.

Table 4.90: Not suitable for commercial stock and prohibited pack stock use trails, as well as designated approved camps in the Ansel Adams and John Muir Wildernesses by alternative

	System Trail Miles Not Suitable for Commercial Stock Use	Number of User Trails/Miles Prohibited from Commercial Stock Use
Alternative 1	7	94/102
Alternative 2 - Mod	90	86/81
Alternative 2	73	82/80
Alternative 3	63	87/87
Alternative 4	173	153/165

The implementation of the approved Trail Plan and management levels, including approved use trails, would likely continue the commercial pack stock effects identified above over the broadest area of the AA/JM Wildernesses than other alternatives since it allows for use on the highest number of miles of system trails and approved use trails. In addition, the trailhead quota use regulating system allows for the broadest area of use destinations and campsites by commercial pack stock and so the largest area of potential human disturbance effects and habitat modification. There is likely to be the highest number of social and access trails and as a result increased impacts spread out across these destination use areas associated with the highest number of campsites.

Trail Transportation System Designation

The approval of the trail transportation system management levels (except for the commercial pack stock NSCS designations and use trail authorization/prohibitions that are discussed above) would continue to perpetuate the direct habitat effects in riparian and meadow edge habitats, as well as in forested zones. These effects are primarily the loss of habitat from the trail corridor, and the fragmentation of habitats. It is estimated that a trail tread that varies from two to as much as ten feet wide could result in between six tenths and 1.2 acres of habitat lost per mile. This number is minor in comparison to the total acres of available habitat in the wilderness, and it probably does not constitute a substantive loss of habitat.

The loss and impact is potentially greater per unit area in the limited riparian habitats, especially when trails have multiple ruts, and associated adjacent effects on the surrounding habitats such as the diversion of water away from wet meadows, stream or spring channels, or where there are off-trail erosion and sedimentation effects. This is particularly true where trail induced headcuts are resulting in the loss of a portion of a meadow, or the sedimentation of key habitat areas. The current trail inventory is insufficient at a quantitative or qualitative basis to identify the wilderness-wide magnitude and extent of these effects in riparian MIS habitats.

The approval of Alternative 1 transportation system, as well as the other transportation system alternatives, is not likely to change these impacts substantively over the short, or mid term period. The assumptions stated for the alternatives state that primary trails would likely receive basic maintenance on a regular, but limited, basis with heavy maintenance and/or reconstruction on a 20 to 30 year interval. In addition, levels of use by all user groups would not change substantially, except for commercial pack stock NSCS and use trail prohibitions. This assumption infers that the associated human disturbance effects of use of the transportation system on MIS wildlife species would not substantively change from the current situation, or by alternative, except for the NSCS suitability determinations, and commercial pack stock use trail authorizations/prohibitions. The trails analysis section predicts over the next 20 years that there would be a slight upward trend in trail condition, except where there are extremely high risk factors that would drive more immediate efforts to halt the resource impacts. Under any alternative, it is unknown how this urgency would translate into resolving the more serious observed riparian habitat degradation areas that currently exist in the AA/JM Wildernesses that are affecting MIS species habitats.

Therefore, it is probably safe to say there would continue to be some habitat loss effects associated with any of the trail management class transportation proposals. Trail improvement projects and annual maintenance work would mitigate some unknown level of these effects, predominantly on the more regularly used routes. These trail system proposals and their influence on wildlife habitat availability and condition that affect such species as mule deer, yellow warbler, and riparian meadow and meadow edge species would continue to have some adverse effects on these MIS species and their habitats, but are not likely have adverse effects to these species viability over the planning/analysis area.

The effects associated with the trail transportation system management class alternatives are more likely some level of MIS population reduction and fitness. These effects are the result of wildlife avoidance and displacement impacts and associated adverse physiological effects, as well as increased potential for predations events in trail corridors, and the overall lower habitat

availability and suitability level. The correlation of these effects with wildlife population numbers, demographics, and viability is poorly understood.

None of the proposals closes or relocates trails, two considerations that could substantially change the effects between alternatives. Closing and relocating trails, and rehabilitating closed trails in key habitats, especially where those trails are causing resource damage could improve wildlife habitats for MIS species. Such projects are outside the scope of this analysis and would be identified, analyzed, and potentially implemented as funds and Forest priorities dictate.

Cumulative Impacts

Historical effects to MIS wildlife habitats in the AA/JM Wildernesses and adjacent landscapes have been discussed in detail in regional publications such as the Sierra Nevada Forest Plan Amendment EIS and FSEIS (USDA Forest Service 2001 and 2004), past wilderness planning documents, and site specific analyses such as range management environmental assessments, and the Status of the Sierra Nevada Final Report to Congress.

The majority of the discussions are anecdotal and speculative in nature as far as the link between causal factors and changes in wildlife populations. The predominant factors that have affected MIS species and their habitats include reductions in habitat from historical overgrazing practices by all classes of livestock, changes in (or loss of) riparian habitats from mining activities, dams and water diversions, market hunting effects on mule deer, and all types of human disturbance effects from commercial and recreational use activities.

Commercial pack stock grazing, camping, and destination use would likely be light at any one time in wilderness under Alternative 1 in terms of overall numbers of riparian MIS habitats meadows being affected simultaneously so the wilderness scale effects are likely minimal when only this user group is considered. The effect is amplified and compounded when other user groups, such as hikers, backpackers and recreational stock user groups, are considered that are simultaneously using the wilderness riparian meadow landscapes. All user groups contribute to cumulative disturbance events that result in mule deer and MIS bird species displacement and avoidance events in meadow and meadow edge areas. The adverse physiological effects to these species from fight or flight reactions, and associated increased vulnerability to stress induced disease or predation events, is a cumulative effect that will remain unknown in terms of how these effects change the fitness of a species population across a wilderness landscape. The cumulative effects of all these user groups could be a substantial impact especially in category 3 wilderness zones. As an example, mule deer (especially does with fawns) and MIS bird species are likely encountering numerous daytime disturbance events in these heavier use zones in meadows and adjacent forests that are close to trails and popular destinations. Deer are likely to avoid these areas during the day and shift use to more undisturbed riparian habitat areas. MIS bird species may be subject to numerous displacement and avoidance events.

MIS Mule Deer, Yellow Warbler, and Riparian Meadow, and Meadow Edge Bird Species – Alternative 2, 2 – Modified, and 3

Analysis

The implementation of Alternatives 2, 2 – Modified, and 3 would likely have some favorable effects on these MIS species and their habitats across the AA/JM Wildernesses.

The implementation of unsuitable and rest grazing designations at 108 meadows in Table 4.89 under Alternative 2, and 110 under Alternative 2 – Modified and 3 would allow for structural habitat improvements over time for these MIS species and reduce disturbance associated with stock presence in the meadows. In addition, the implementation of stock night guidelines in suitable meadows and the 5 percent critical area maximum allowable disturbance standard would likely maintain or improve wet meadow habitat areas and areas such as springs and ephemeral pool habitats. Implementation of Alternative 2 would still allow grazing at 6 functional at risk meadows with a downward trend, while Alternative 2 – Modified, and 3 would prohibit grazing in all 17 functional at-risk meadows with downward trends.

The designation of over night stock holding camps would likely contain the spread of effects to meadow edge area habitats where pack stock camps are traditionally found. This would amount to a decrease in the number of campsites. This would also likely reduce the amount of access and social trails associated with these camps and therefore provide some habitat improvement, especially where trail crossings are reduced across stream and spring habitats. There may also be a corresponding decrease in the total area of human disturbance around meadows and meadow edges that would provide more favorable habitat conditions and a reduction in avoidance and flight reactions that mule deer and MIS birds, such as the yellow warbler, would exhibit.

Implementation of the trail plan not suitable for commercial stock designations on system trails and use trail prohibitions may have some level of localized habitat improvement associated with a reduction in trail width and narrower stream and spring crossings. This is most likely along use trails predominantly used by commercial pack stock on a regular basis to access destination camps. In addition, there would be some level of reduction of human disturbance events associated with reduced use along these trail corridors.

Alternative 2 would close 73 additional miles of system trail to commercial stock and disapprove 82 use trails for use; while Alternative 2 – Modified and 3 would close 163 additional miles of system trails and disapprove 87 user trails wilderness wide. The exact areas of overlap with meadows have not been calculated for system or user trails to describe the likely effects changes in more detail.

Alternatives 2, 2 – Modified, and 3 would also likely result in less habitat disturbance since overnight stock holding camps would be designated, and subsequently reduced in number, over the AA/JM Wilderness landscape. This could decrease the area of habitat impacts and human disturbance events in and around meadows and meadow edges for MIS species since numbers of camps would decrease as well as social and access trails associated with those trails. As a result, there could be higher levels of impact, however, at designated sites since these sites would likely be used more often.

Cumulative Impacts

There would likely be a positive contribution to the lessening of cumulative effects to MIS mule deer, yellow warbler, and meadow and meadow edge species with implementation of either alternative, with Alternative 3 having a slightly higher reduction from the prohibition of grazing in all functional at risk meadows downward trend. The system trails not suitable for commercial stock additions, use trail disapprovals, and the designation of overnight stock camps would decrease the impacts to MIS habitats in the traditional use areas where these management changes would take effect. These changes would likely produce localized habitat improvements

and a reduction in the potential for human disturbance to MIS species. There would also likely be some level of MIS habitat improvement and a reduction in human disturbance events to these MIS species in meadows determined to be unsuitable for grazing by commercial stock.

MIS Mule Deer, Yellow Warbler, and Riparian Meadow, and Meadow Edge Bird Species – Alternative 4

Analysis

The 138 meadows determined to be unsuitable for grazing in Alternative 4 (shown in Table 4.89) would likely maintain or improve habitat conditions for the MIS species over Alternatives 1 through 3. In addition, all seventeen functioning at risk meadows with a downward trend would be ungrazed, as in Alternative 3. The alternative provides for the highest level of MIS wildlife habitat maintenance and restoration over Alternatives 1 through 3. The additional closures also further reduce the potential for avoidance and disturbance interactions between humans, pack stock, and MIS wildlife species.

Alternative 4 designates 173 miles of system trail as not suitable for commercial stock, and prohibits commercial stock on 153 use trails. This would amount to roughly over twice as many miles of system trail, and numbers of use trails closed over Alternatives 2 and 3 where similar localized habitat improvement effects and decreased human disturbance effects would occur as described under Alternatives 2 and 3. In addition, designated campsites would include designated drop-off sites for spot and dunnage trips. This would include substantive reductions in habitat disturbance areas including associated social and access trail impacts. These habitat impact reductions would be most obvious in the Recreation Category 1 and 2 areas of the AA/JM Wildernesses.

Cumulative Impacts

There would likely be a positive contribution to the lessening of cumulative effects to MIS mule deer, yellow warbler, and meadow and meadow edge species with implementation of this alternative since there would likely be a substantial reduction in human disturbance events to these species.

MIS Mule Deer, Yellow Warbler, and Riparian Meadow, and Meadow Edge Bird Species – Alternative 5

Analysis

Meadow wildlife habitats where commercial pack stock grazing will cease under implementation of this alternative will have variable improvement responses in MIS wildlife habitat conditions. This would depend on the existing condition and hydraulic function of the meadow. Some historically degraded meadows would be less likely to show a marked improvement where wet meadow or wetland habitats may have been lost from former stream incisement events and loss of the meadow hydrologic functioning. Moist meadow, wet meadow, and wetland wildlife habitat recovery will be dependent on the degree of water table integrity of stream and spring channels, and the degree to which active headcuts below the rooting depth are present. It is likely many meadows would experience some level of localized improvement in small areas of meadows such as around springs, stream banks, and wet meadows that may have experienced

trampling and chiseling impacts from commercial pack stock grazing or trailing uses. Such localized improvements are likely to be increases in vegetative productivity, cover, and density all of which would translate to improved nesting, fawning, young rearing and foraging habitats for the MIS species.

Nine of eighteen meadows where hydrologic functioning has been severely degraded will likely rehabilitate over many decades since the individual meadow will have to re-cut a floodplain to develop any substantial areas of floodplain wet meadow and wetland wildlife habitat conditions that were lost or degraded from historical and/or existing land uses. There will be minor improvements of new incised floodplain wet meadow and wetland habitats, and overall improvement of vegetative structural habitat conditions in remnant wet meadow and wetland habitats, and moist and dry meadow habitats.

The most substantive habitat suitability improvement would likely occur in a subset of meadows where the hydrological functioning is largely intact and where localized impacts are present, such as small shallow headcuts, trampled and chiseled springs, seeps, ephemeral pools, wet and moist meadow areas, degraded stream and spring channels where loss of vegetated and undercut bank, and widened channels from bank chiseling and collapse have been recorded. There should be substantial localized improvement over the next 20 years in areas that have had recent annual moderate numbers of stock nights recorded, since the maintained water table will promote rapid rebuilding of bank and vegetative cover as sediment is trapped, and headcuts within the rooting depth of vegetation become stabilized.

Hiding and escape cover, and foraging habitats for MIS wildlife species including deer, riparian meadow and meadow edge songbirds that nest in ground vegetation and low shrubs would improve rapidly in this subset as vegetative species vigor, composition, and density recover toward good ecological condition and potential natural vegetation, or late seral meadow status. This alternative would be most consistent with wilderness wildlife management goals of allowing natural forces to determine wildlife populations across the landscape; however, it is the least consistent with providing recreational opportunities for wilderness users.

Therefore, the elimination of grazing will translate into improved cover and foraging habitat for wildlife species that favor ungrazed habitat conditions.

Skovlin (1984), in his discussion of grazing effects to wildlife, noted that alteration of wildlife habitats would be beneficial to certain species and detrimental to others. Habitat suitability will improve for species such as meadow voles, and ground and low shrub nesting birds, neotropical migratory birds that use meadows for summer foraging areas prior to migration, waterfowl, and amphibians. Mule deer fawn cover is likely to improve since tall forb, sedge, and grass cover would also be maintained in an undisturbed state. Mule deer use of meadows will not be interrupted by commercial pack stock presence in meadows. Degraded spring and seep habitats, including spring channels and ephemeral wetland pools, will re-vegetate and result in improved habitat suitability for amphibians such as mountain yellow-legged frog and Yosemite toad that rely on ungrazed, untrampled herbaceous vegetation for escape and hiding cover, and a foraging substrate for invertebrate food sources.

Elimination of destination camps and associated access and social trails as well as all use of the trail systems would likely result in improved MIS wildlife habitat conditions. Trails would likely decrease in width over the long-term, especially at stream and spring crossings. Destination camps would likely be reduced in size since other user groups would likely continue to use many

of these campsites. Implementation of the trail plan would be similar to Alternative 1 in that trails would still be present, except that one less user group would be using them.

Cumulative Impacts

There would be an overall positive contribution to decreasing the cumulative effects on MIS species in the AA/JM Wilderness with removal of all commercial pack stock operations. There would be less direct habitat impacts and less human disturbance throughout the areas traditionally frequented by these operations.

Some level of light recreational stock use would likely continue in wilderness including trail use, destinations, and grazing of meadows. Private recreational stock impacts would likely continue to cause localized impacts at stream and spring trail crossings, and would likely produce limited, localized effects from grazing, such as heavily trampled vegetation and the creation of erosion nick points along stream and spring channels. In addition, there would be continued use of destinations, trails, and meadows by day hikers and backpackers with some level of human disturbance presence and associated habitat impacts such as stream and trail widening and vegetation trampling. Human disturbance effects to MIS wildlife species would continue along system trail corridors, popular use trails, destinations, and camps.

Summary of Alternatives 1-5 Impacts

Wildlife Biological Evaluation/Assessment determinations common to all alternatives

Threatened and Endangered Species: Implementation of any alternatives would not affect the bald eagle and Paiute cutthroat trout or their habitat found within the analysis area.

Implementation of Alternatives 1 through 4 may affect but would not adversely affect the Sierra Nevada bighorn sheep. Alternative 5 would not affect the Sierra Nevada bighorn sheep or its habitat.

Forest Service Region 5 Sensitive Species: Implementation of Alternatives 1 through 4 may affect individuals of the following species but would not contribute to a trend toward federal listing of any of these species, or lead to a loss of their viability in the planning (analysis) area: Yosemite toad, mountain yellow-legged frog, willow flycatcher, great gray owl, American marten, Pacific fisher, California wolverine, Sierra Nevada red fox, California spotted owl, Townsends big-eared bat, and the pallid bat. Implementation of Alternative 5 would not affect any of these species.

Management Indicator Species or Species Group: Implementation of any alternative would not result in the loss of viability of any other MIS (i.e., species not on the federal threatened, endangered, or proposed species list or Forest Service Region 5 sensitive species list) found within the planning (analysis) area.

No other federally listed threatened, endangered, proposed, or Forest Service Region 5 sensitive species or their habitat would be affected by implementation of any of the alternatives.

Effects Summary by Alternative

Wildlife – Alternative 1

The majority of 267 Yosemite toad occupied breeding meadows within the AA/JM Wildernesses would likely be unaffected by commercial pack stock use if grazing patterns continue as reported and observed from 2001 through 2004. Eighty-seven of the 267 occupied breeding meadows would more likely have commercial pack stock grazing overlap where impacts to Yosemite toad breeding habitats may occur.

Actual grazing use overlap and subsequent impacts would be highly variable based on past use with many meadows likely to receive very light to no use, and therefore a high probability of non-substantive impacts to toad breeding habitat. A small percentage of the 87 occupied breeding meadows (likely < 10 percent) would likely have substantive trampling and chiseling impacts from commercial pack stock grazing in Yosemite toad breeding sites. The 20 percent ground disturbance standard would be implemented to limit the amount of disturbance in critical breeding areas, such as stream banks, lakes and ponds, where toads may be found. Impacts in Yosemite toad breeding sites could substantively increase if meadows are grazed at maximum forage utilization levels allowed in the Ansel Adams, John Muir, and Dinkey Lakes Wilderness Plan.

Gradual implementation of range unsuitable meadow determinations as a reasonably foreseeable action per 2001 Wilderness Plan direction may reduce the total number of Yosemite toad occupied breeding meadows where grazing impacts would likely occur.

Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be affected if meadows are grazed to maximum allowable forage utilization levels.

The alternative allows for the highest level of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it has the least restrictive management control over campsite use, destination impacts such as access and social trails, grazing impacts, and approved system and use trails. All meadows are open to commercial pack stock grazing. Two hundred forty six meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. Four meadows would be closed to grazing. Sixty-one meadows with hydrologic functioning problems that are affecting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems or to slow restoration rates. Habitat structural characteristics could be affected if meadows are grazed to maximum allowable forage utilization levels.

Mountain yellow-legged frog stream habitat could be potentially affected at two meadows approved for commercial pack stock grazing.

Potentially, a reduced level of human disturbance to MIS wildlife species and habitats would occur on approximately 7 miles of system trail closed to commercial stock as a result of resource concerns, and 102 miles on 94 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if sections with resource impacts begin to re-vegetate and narrow in width, such as where trails course through meadow, and at stream and spring crossing areas.

Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of affected areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.

Wildlife – Alternative 2 – Modified

Alternative 2 – Modified manages for an increased level of protection for Yosemite toad meadow breeding habitats since grazing would be managed to avoid Yosemite toad occupied breeding habitats. Fifty-two meadows approved for commercial packer stock grazing overlap with Yosemite toad breeding areas. Thirty-four meadows that are approved for grazing in Alternative 1 are either unsuitable (28) for grazing or rested from grazing (six) in this alternative and would have full protection for the breeding habitats. One hundred ninety seven occupied Yosemite toad breeding meadows outside of grazing zones would be fully protected since grazing would be prohibited. Suitable/unsuitable determinations would be implemented immediately.

The alternative allows for some level of control of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it designates overnight stock holding camps, implements destination quotas that would limit destination impacts such as access and social trails, grazing impacts. All meadows outside of grazing zones are closed to commercial pack stock grazing. One hundred forty three meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. A subset of 110 meadows would be closed to grazing as a result of unsuitable for grazing determinations. Thirty four meadows with hydrologic functioning problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems or slow restoration rates.

Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be affected if meadows are grazed to maximum allowable use levels.

Mountain yellow-legged frog stream habitat could be potentially affected at one meadow approved for commercial pack stock grazing.

There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on 73 miles of system trail not suitable for commercial stock, and 80 miles on 82 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails if affected sections narrow in width, such as where trails course through meadows, and at stream and spring crossing areas.

Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of affected areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.

Wildlife – Alternative 2

Alternative 2 manages for an increased level of protection for occupied Yosemite toad meadow breeding habitats. Fifty-six meadows approved for commercial packer stock grazing overlap with Yosemite toad breeding areas. Thirty meadows that are approved for grazing in Alternative 1 are unsuitable for grazing in this alternative and would have full protection for the breeding habitats. A five percent critical area maximum allowable disturbance standard would be implemented in

all other Yosemite toad breeding habitat areas where commercial pack stock grazing would be approved to minimize trampling and chiseling effects to the breeding habitats, and minimize the potential for stock trampling of metamorph toads. Suitable/unsuitable determinations would be implemented immediately.

The alternative allows for some level of control of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it designates overnight stock holding camps, implements destination quotas that would limit destination impacts such as access and social trails, grazing impacts. All meadows outside of grazing zones are closed to commercial pack stock grazing. One hundred thirty nine meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. A subset of 108 meadows would be closed to grazing as a result of unsuitable for grazing determinations. Forty one meadows with hydrologic functioning problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates.

Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be affected if meadows are grazed to maximum allowable use levels.

Mountain yellow-legged frog stream habitat could be potentially affected at one meadow approved for commercial pack stock grazing.

There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on 73 miles of system trail not suitable for commercial stock, and 80 miles on 82 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if affected sections narrow in width such as where trails course through meadows, and at stream and spring crossing areas.

Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of affected areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.

Wildlife – Alternative 3

Alternative two manages for an increased level of protection for Yosemite toad meadow breeding habitats. Fifty-three meadows approved for commercial packer stock grazing overlap with Yosemite Toad breeding areas. Thirty-three meadows that are approved for grazing in Alternative 1 are either unsuitable (32) for grazing or rested from grazing (one) in this alternative and would have full protection for the breeding habitats. A five percent critical area maximum allowable disturbance standard would be implemented in all other Yosemite toad breeding habitat areas where commercial pack stock grazing would be approved to minimize trampling and chiseling effects to the breeding habitats, and minimize the potential for stock trampling of metamorph toads. Suitable/unsuitable determinations would be implemented immediately.

The alternative allows for some level of control of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it designates overnight stock holding camps, implements destination quotas that would limit destination impacts such as access and social trails, grazing impacts. All meadows outside of grazing zones are closed to commercial pack stock grazing. One hundred forty three meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are

most likely to occur. A subset of 110 meadows would be closed to grazing as a result of unsuitable for grazing determinations. Thirty four meadows with hydrologic functioning problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates.

Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be affected if meadows are grazed to maximum allowable use levels.

Mountain yellow-legged frog stream habitat could be potentially affected at one meadow approved for commercial pack stock grazing.

There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on 63 miles of system trail not suitable for commercial stock, and 87 miles on 87 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if affected sections narrow in width such as where trails course through meadows, and at stream and spring crossing areas.

Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of affected areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.

Wildlife – Alternative 4

Alternative two manages for an increased level of protection for Yosemite toad meadow breeding habitats. Fifty-six meadows approved for commercial packer stock grazing overlap with Yosemite Toad breeding areas. Thirty meadows that are approved for grazing in Alternative 1 are unsuitable for grazing in this alternative and would have full protection for the breeding habitats. A five percent critical area maximum allowable disturbance standard would be implemented in all other Yosemite toad breeding habitat areas where commercial pack stock grazing would be approved to minimize trampling and chiseling effects to the breeding habitats, and minimize the potential for stock trampling of metamorph toads. Suitable/unsuitable determinations would be implemented immediately.

The alternative allows for some level of control of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it designates overnight stock holding camps, implements destination quotas that would limit destination impacts such as access and social trails, grazing impacts. All meadows outside of grazing zones are closed to commercial pack stock grazing. One hundred twenty meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. A subset of 138 meadows would be closed to grazing at an unknown future date as a result of unsuitable for grazing determinations. Twenty seven meadows with hydrologic functioning problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates.

Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be affected if meadows are grazed to maximum allowable use levels.

Mountain yellow-legged frog stream habitat would not be affected since all three meadows would be closed to grazing.

There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on 173 miles of system trail not suitable for commercial stock, and 165 miles on 153 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if affected sections narrow in width, such as where trails course through meadows and at stream and spring crossing areas.

Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of affected areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.

Wildlife – Alternative 5

There would be no commercial pack stock grazing that would overlap with Yosemite toad occupied breeding habitats, or willow Flycatcher and great gray owl meadow suitable unoccupied habitats. Elimination of human and pack stock disturbance on trails, camps, and grazing areas associated with commercial pack stock operations would improve MIS mule deer, yellow warbler, meadow and meadow edge bird guild species habitats, as well as use of these habitats by these species.

Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of affected areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.

Geographic Scale

Ansel Adams East – Alternative 1

Yosemite Toad and Mountain Yellow-legged Frog

Analysis

The Algers/Rush and Thousand Island Analysis Units would likely continue to have the highest number of meadows and level of grazing use overlap with Yosemite toad breeding habitats in the AA/JM Wildernesses. Fifty percent of the breeding sites in these analysis units would likely continue to have grazing overlap in them where trampling and chiseling effects could modify breeding site habitat characteristics, and pose some risk of metamorph trampling. These effects are discussed in detail at the wilderness scale. Crater Creek analysis unit has four meadows with observed grazing; however, grazing use levels and corresponding pack stock impacts to Yosemite toad breeding areas have been very light relative to the units identified above.

Light trampling and chiseling impacts at Yosemite toad breeding sites would likely continue at meadows listed in Table 4.86 that include Deer Creek Meadows (ccd15), Upper Deer Creek (ccd18a), West End of Thousand Island Lake Meadows (thi16), Davis Lake Meadow (uru1), Marie Meadow (uru6), Upper Alger Creek Meadow (rus15), and Lower Alger Creek Terrace Meadow (rus14). Rodgers Lake Meadow (uru5) may continue to have moderate grazing impact overlap with Yosemite toad breeding sites, and may exceed the 20 percent cumulative disturbance standard if it continues to be grazed on an annual basis. Table 4.90 shows the

distribution of commercial pack stock grazing that would likely continue to overlap with Yosemite toad breeding meadows by analysis unit.

Localized stream bank collapse and chiseling impacts to mountain yellow-legged frog stream habitats at the Upper Donahue Camp (uru8) and at the west end of Thousand Island Lake (thi16) are likely to continue under this alternative with current grazing and trailing use patterns. Rodgers Lake Meadow yellow-legged frog stream habitat may experience similar impacts. The localized impacts to the species stream habitat would likely continue a small area of loss of undercut stream bank cover habitat, but would not likely exceed allowable disturbance standards. Impacts could increase if grazing were to approach allowable forage utilization standard and stream bank disturbance standards.

Table 4.91. Distribution of Yosemite toad breeding meadows in the Ansel Adams East Geographic Unit by analysis unit and overlap with grazing areas

Geo Unit	Analysis Unit	Breeding Meadows with Observed or Reported Grazing	Other Breeding sites Requested for Grazing	Not Requested for Grazing Use	Total Breeding Meadows
AA East	Upper Rush (Uru)	4	0	3	7
	Rush (Rus)	2		4	6
	Thousand Island (Thi)	3	0	2	5
	Crater Creek (CCD)	4	2	5	11
	Bloody Canyon (BLC)			1	1
	Parker (Par)			1	1
	Glacier Canyon (Glc)			3	3
Total		13	2	19	34

Ansel Adams East – Alternative 2 – Modified

Yosemite Toad and Mountain Yellow-legged Frog

Analysis

Nine occupied Yosemite toad breeding habitat meadows designated as unsuitable or prohibited in Alternative 2 – Modified in Table 4.86 would be fully protected from any future potential grazing impacts. Light trampling and chiseling impacts would cease in four of these meadows and result in slightly improved vegetative cover, and allow for unmodified breeding site habitat structure in meadows at the west end of Thousand Island Lake (thi16), Upper Algers Creek Meadow (rus15), and Lower Alger Creek Terrace (rus14), Deer Creek Meadows (ccd15), and Upper Deer Creek Meadows (ccd18a). Mountain yellow-legged frog stream habitat would receive full protection at the west end of Thousand Island Lake.

Minor pack stock trampling and chiseling impacts in the breeding habitat areas would likely continue at Rodgers Lake Meadows (uru5), Davis Lake Meadows (uru1), Marie Meadow (uru6) and Middle Deer Creek Meadow (ccd17). The implementation of a three-year grazing rotation at Davis Lake and Rodgers Lake in Upper Rush area would help to minimize the already light to moderate impacts observed at these meadow Yosemite toad breeding sites. The Donahue camp crossing (uru8) mountain yellow-legged frog habitat would likely continue to experience moderate bank chiseling impacts at the crossing areas until the crossing is relocated.

The system trail prohibition to commercial pack stock from Garnet campsite to Emerald Lake would reduce any potential sediment runoff from the trail into the mountain yellow-legged frog pond habitat along the northern section of the trail since the trail tread would likely harden as pack stock use ceased.

Ansel Adams East –Alternative 3

Yosemite Toad and Mountain Yellow-legged Frog

Analysis

The effects of implementation of these two alternatives are essentially the same as Alternative 2 – Modified, with the exception that there would be a maximum five percent ground disturbance standard implemented in the critical Yosemite toad breeding areas. The meadows where the light impacts would occur would be the same as Alternative 2 – Modified.

Ansel Adams East –Alternative 4

Yosemite Toad and Mountain Yellow-legged Frog

Analysis

The effects of Alternative 4 would be similar to Alternatives 2 – Modified, 2 and 3 except that Rodgers Lake Meadow (Uru5) in Upper Rush Creek would be unsuitable for grazing. This would eliminate the moderate impacts observed at the Yosemite toad breeding sites as well as provide protection against any future impacts to mountain yellow-legged frog stream habitat in this meadow.

Ansel Adams East –Alternative 1

MIS Mule Deer, Yellow Warbler, and Riparian Meadow and Meadow Edge Species

Analysis

Alternative 1 continuation of grazing would likely continue to promote impacts to meadow ecological condition and wildlife habitat structural components such as springs, spring and stream channels, and riparian vegetative cover in traditionally grazed areas such as Garnet Lake (thi15), NW Delta of Thousand Island Lake (thi12), and Upper (rus2) and Lower Spooky (rus3) Meadows. In addition, grazing use may continue to occur in suitable meadows where existing headcuts and stream channel incisions at a number of meadows (including the three named above) could potentially become more unstable if grazing occurs on a regular basis at allowable use levels. This could result in further loss of portions of these wet meadow habitats. Meadows

where these effects may occur also include the Emerald Meadow Complex (thi14), Johnston Meadow (min11), and seven meadows in the Crater Creek/Deer Creek grazing area (Lower Crater Meadow (ccd 1), Upper Crater (ccd2), Deer Creek (ccd15), Unnamed (ccd16, 19a and 19b), and Middle Deer Creek (ccd17)).

The continued use of the Garnet to Emerald system trail by commercial pack stock may contribute some additional sediment to the mountain yellow-legged frog pond where the trail courses around its perimeter; however, the impacts are not considered substantive at this time based on current use levels.

The effect of implementation of Alternative 1 commercial pack stock wilderness use regulating system such as trailhead quotas, and existing system and use trail approvals, as well as approved use of camps on MIS mule deer and the yellow warbler habitats are described at the wilderness scale.

Ansel Adams East –Alternative 2 – Modified, 2, 3, and 4

MIS Mule Deer, Yellow Warbler, and Riparian Meadow and Meadow Edge Species

Analysis

Implementation of the grazing prohibitions in Alternatives 2 – Modified, 2, and 3 would potentially improve MIS species habitat recovery potentials over Alternative 1 in functional at risk meadows with a downward trend at Garnet Lake (thi15), and Emerald Meadow Complex (thi14). This would be true for Johnston Meadow (min11) in Alternative 2 – Modified, 3 and 4. The reduction in stock nights at Upper (rus2) and Lower Spooky (rus3) meadows under Alternatives 2 through 4 would also improve MIS habitat conditions over Alternative 1. The prohibition of grazing in four of the Crater Creek/Deer Creek meadows (ccd 1, 2, 15, and 19a) may prevent potential headcut acceleration and wet meadow loss compared to Alternative 1. The prohibition may likely provide for an improvement in hydrologic functioning of these meadows, and restoration of additional wet meadow for the MIS species over the long-term, since it may allow for a higher potential to stabilize headcuts in spring channels and lateral stream channels that threaten meadow integrity.

Implementation of a 3 year grazing rotation for Davis and Rodgers Lake Meadows (uru1 and 5), and the additional closure of Rodgers Meadow in Alternative 4 would contribute to the maintenance of MIS meadow wildlife habitat.

Alternatives 2 through 3 NSCS system trail actions, and use trail closures would likely have a slight decrease in the extent and magnitude of habitat and human disturbance impacts to MIS mule deer and yellow warbler habitats over Alternative 1. Alternatives 2 and 3 have additional limitations over Alternative 1 in the extent of area of potential habitat and human disturbance impacts since there would be designated stock camps.

Alternative 4 would have the greatest reduction on the extent of impacts associated with camps and trails since it has the highest number of system trails and use trail closures, as well as the designation of spot and dunnage drop sites. There would be a reduction in the extent of social and access trails around camps no longer approved for use with a probable improvement in MIS habitat conditions.

Ansel Adams West – Alternative 1

Yosemite Toad and Mountain Yellow-legged Frog

Analysis

Minor amounts of grazing use are likely to continue in this geographic unit that has the potential to overlap Yosemite toad breeding sites. The implementation of this alternative would likely continue to have very minor effects to three Yosemite toad breeding areas if current grazing use levels and patterns continue. No effects to breeding sites had been noted at these areas during the interdisciplinary team field surveys in 2003 and 2004. Table 4.92 indicates that only Stairway meadow in the Cargyle Analysis Unit would likely have any commercial pack stock grazing based on previous use patterns. The meadow has had very light pack stock grazing reported for one year only from 2001 through 2003 in this geographic unit. Sixteen of the 19 meadows with Yosemite toad breeding populations in Table 4.92 have not been requested for grazing and are likely to remain ungrazed with no impacts at the Yosemite toad breeding areas. If all meadows were grazed at full implementation of the alternative allowable use standards, the effects would likely increase substantially; however, this is a highly unlikely scenario. There would be no effect to the one population of Yellow-legged frogs at Onion Peak Meadow.

Implementation of the system and use trail proposals, as well as use regulating mechanisms for commercial pack stock such as trailhead quotas, would not affect Yosemite toad or mountain yellow legged frogs or their habitats, or have any substantive changes over the existing situation in this geographic unit. No issues with commercial pack stock use or the trail system have been identified with these two species or their habitats.

Table 4.92. Distribution of Yosemite toad breeding meadows in the Ansel Adams West Geographic Unit by analysis unit and overlap with grazing areas

Geo Unit	Analysis Unit	Breeding Meadows with Observed or Reported Grazing	Other Breeding Sites Requested for Grazing	Not Requested for Grazing Use	Total Breeding Meadows
AA West	Sadler (Sad)		1		1
	Cargyle (Car)	1 (Very Light Use)	1	3	5
	Junction (Jun)			2	2
	Chiquito (Chi)			2	2
	Jackass (Jac)			1	1
	Onion Springs			1	1
	Arch (Arc)			6	6
	Cold Creek (Coc)			1	1
	Cora (Cor)			1	1
Total		1	2	17	20

Ansel Adams West – 2 – Modified, 2 3 and 4

Yosemite Toad and Mountain Yellow-legged Frog

Analysis

The effects of implementing these alternatives would likely be the same for the Yosemite toad and mountain yellow-legged frog as Alternative 1. The two breeding area meadows Carygle (car1) and Sadler (sad22) identified as suitable for commercial pack stock grazing in Chapter 2 Table 2.30 would have the critical area management protection standards implemented as previously described for the alternatives. These standards would provide for a higher level of potential habitat protection over Alternative 1 if grazing use were to increase above the current light use levels and approach maximum allowable forage use. There would be no effect to the mountain yellow-legged frog population at Onion Peak Meadow.

Implementation of the various system and use trail alternatives, destinations, and use regulating systems are not likely to have any substantive effect to the Yosemite toad or mountain yellow-legged frog and their habitats. No issues with commercial pack stock use or the trail system have been identified with these two species or their habitats.

Ansel Adams West – Alternatives 1 through 4

MIS Mule Deer, Riparian Meadow and Meadow Edge Species

Analysis

Little is known about these MIS species and the status of their habitats within this geographic unit. The yellow warbler is not an MIS species on the Sierra NF. Interdisciplinary team field analysis in 2003 and 2004 identified twelve meadows where moderate to severe hydrologic functioning impacts were evident. The impacts appear to be largely the result of historical land uses. Alternative 1 continuation of grazing would likely continue to promote impacts to meadow ecological condition and wildlife habitat structural components such as springs, spring and stream channels, and riparian vegetative cover in traditionally grazed areas at two of these meadow areas; Sadler Lake Meadow (sad12), and McClure to Sadler Meadow (sad13). McClure to Sadler Meadow stream (sad13) was determined to be functional at risk with a downward trend. The other ten meadows would be open for grazing but are not likely to show any substantive grazing use based on recent reported use information. These meadows may recover MIS habitat components over the long-term if they remain ungrazed or lightly used by commercial pack stock; however, there could be substantive impacts if they are repeatedly grazed at higher utilization levels. There is a very low probability that the meadows would be grazed at the higher utilization levels based on past reported use levels.

McClure to Sadler (sad13), Fernandez Creek (lil4), NW of Fernandez Lake (lil3), and South of Slab Lake (trd6) would be closed to grazing under Alternatives 2 – Modified, 2, 3, and 4. Closure of these meadows to grazing would provide full protection to allow for maximum potential recovery of the hydrologic functioning and vegetative potential of these meadows, and therefore MIS habitat quality over the long-term.

Alternative 4 would additionally prohibit grazing at Fernandez, Detachment, Knoblock, Chetwood, and West of Joe Crane Meadows. Closure of these meadows would similarly provide

full protection to allow for maximum potential recovery of the hydrologic functioning and vegetative potential of these meadows, and therefore MIS habitat quality over the long-term.

The continuation of the existing system and use trails, use regulating mechanisms, and campsites associated with commercial pack stock wilderness use under Alternative 1 would likely perpetuate the generalized effects of human disturbance and minor habitat modification described at the wilderness scale on MIS species and their habitat.

The implementation of NSCS, use trail prohibitions, and designated camps under Alternatives 2 through 4 would have some beneficial effects to MIS species and their habitats as described for the alternatives at the wilderness scale.

Fish Creek/Convict/McGee – Alternative 1

Yosemite Toad

Analysis

Table 4.93 indicates 11 of 44 meadows are likely to continue to have some level of pack stock grazing that overlaps Yosemite toad breeding habitat based on reported grazing use from 2001 through 2003. Another eight meadows may experience some level of use as well but there has been no reported grazing in them from 2001 through 2003. Four McGee Creek meadows were closed to grazing from 2001 through 2003 to protect Yosemite toad habitats per direction in the 2001 Record of Decision (ROD) for the Sierra Nevada Forest Plan Amendment. The closure was removed in 2004 with implementation of the 2004 ROD that removed pack stock grazing direction from the standards and guidelines for grazing management under the Sierra Nevada Forest Plan Amendment. The new ROD deferred the development of management direction to site-specific analyses such as this EIS.

Silver Divide and Upper Fish Creek Analysis Units may likely continue to have a number of meadows where grazing use overlap would occur at Yosemite toad breeding habitats. Eleven breeding meadows out of 20 in these analysis units would likely continue to have grazing overlap in them where trampling and chiseling effects could modify breeding site habitat characteristics, and pose some risk of metamorph trampling. The Stringers West of Squaw Lake (sil18) and Grassy Meadow (sil22) in particular are likely to continue to have locally moderate to heavy pack stock grazing impacts at Yosemite toad breeding sites if the current grazing pattern continues under Alternative 1. Pack stock trampling and chiseling overlap in Yosemite toad breeding sites may occur at other sites, including Peter Pande Tarn Meadow (sil7), in the meadows Between Lone Indian and Grassy (sil13), and Squaw Lake Meadow (sil10) based on monitoring from 2001 through 2004.

The maximum allowable 20 percent stream bank, lakeshore and pond disturbance standards from the 2001 Wilderness Plan would be applied as an upper acceptable trampling and chiseling impact standard if grazing use were to substantially increase. Trampling and chiseling impacts would likely increase substantially at the Yosemite toad breeding sites if this were to occur; however, it is not likely to occur in most of these meadows except at Grassy Meadow, which appears to receive a high level of consistent annual grazing use. The meadow has a degraded hydrologic function condition that potentially allows for increased potential for impacts at the breeding site. Meadow grazing may continue to have moderate impact overlap with Yosemite

toad breeding sites, and may exceed the 20 percent cumulative disturbance standard if it continues to be grazed on an annual basis.

Grazing overlap with Yosemite toad breeding sites in the McGee Analysis Unit would likely occur with light impacts likely only at Round Meadow (mcg8) if the current use pattern continues under Alternative 1.

The continuation of the existing trail system under Alternative 1 and commercial pack stock use of the system would have no substantive changes to Yosemite toad breeding habitat impacts from the existing situation. The trail along Second Meadow (mcg9) above Martin's Meadow would continue to skirt the breeding pool areas and allow for pack stock to veer through the breeding pool areas where direct overlap with metamorph areas was observed in 2003 and 2004. The trail headcut problem in Martin's Meadow that is currently eroding the lower end of the meadow and contributing sediment into Round Meadow critical Yosemite toad breeding area would continue, and commercial pack stock use of this trail may continue to accelerate the headcut expansion. Baldwin Meadow trail erosion sedimentation of the critical Yosemite toad breeding area in this meadow would continue. Commercial pack stock does not currently use the trail and it is unlikely this use would contribute to the problem. Commercial pack stock use of the poorly maintained system trail adjacent to Chute Meadow may continue to accelerate sediment delivery into the Yosemite toad breeding area in this meadow. Red Slate Meadow (ufc3) would continue to have light to moderate trampling and chiseling impacts in the breeding habitats since poor system trail alignment would still steer commercial pack stock to occasionally trail through the breeding sites.

Destination camping patterns are likely to continue as in previous years under this alternative with no identified substantive impacts to Yosemite toad breeding sites.

Table 4.93. Distribution of Yosemite toad breeding meadows in the Fish Creek/Convict/McGee Geographic Unit by analysis unit and overlap with grazing areas for Alternative 1

Geo Unit	Analysis Unit	Breeding Meadows with Observed or Reported Grazing	Other Breeding Sites Requested for Grazing	Not Requested for Grazing Use	Total Breeding Meadows
Fish Creek/Convict/McGee	Upper Fish Creek (Ufc)	2	1		3
	Silver Divide (Sil)	5	2		7
	McGee (Mcg)	3	2	5	10
	Convict (Con)	1		5	6
	Margaret (Mar)		2	15	17
	Purple Bench (Ppb)		1		1
Total		11	8	25	44

Fish Creek/Convict/McGee – Alternative 2 – Modified, 2, and 3

Yosemite Toad

Analysis

Fourteen occupied Yosemite toad breeding habitat meadows designated as unsuitable or prohibited in Alt 2 - Modified in Table 4.86 would be fully protected from any future potential commercial pack stock grazing impacts. Trampling and chiseling impacts would cease in four of these meadows, result in improved vegetative cover and allow for unmodified breeding site habitat structure at Grassy Meadow (sil22), Peter Pande Tarn Meadow (sil7), in the meadows Between Lone Indian and Grassy (sil13), and Squaw Lake Meadow (sil10)

Commercial pack stock grazing could occur at Tully Lake Meadow (ufc4), Fern Lake Meadow (mar9), Frog Lake North Meadow (mar17), Chief Lake (sil19), and Big McGee Meadow (mcg12). Grazing management would be implemented to avoid the Yosemite toad breeding areas in these meadows. Minor pack stock trampling and chiseling impacts in the breeding habitat areas may occur from incidental stock drift.

The system trail prohibition to commercial pack stock in the Baldwin-Scheelore Meadow area would prevent any future commercial pack stock use from contributing to the sedimentation problem in the Yosemite toad breeding area of the meadow. Otherwise, trail effects would be the same as Alternative 1.

Fish Creek/Convict/McGee – Alternative 4

Yosemite Toad

Analysis

The alternative would be similar to Alternatives 2 – Modified, 2, and 3 except that Chief Lake Meadow (sil19), and Fern Lake Meadow (mar9) would be unsuitable for grazing. This would eliminate the potential for any impacts related to commercial pack stock grazing at the Yosemite toad breeding site. Other effects would be the same as Alternatives 2 - Modified.

Fish Creek/Convict/McGee – Alternative 1

MIS Mule Deer, Yellow Warbler, and Riparian Meadow and Meadow Edge Species

Analysis

Alternative 1 continuation of grazing would likely continue to promote impacts to meadow ecological condition and wildlife habitat structural components such as springs, spring and stream channels, and riparian vegetative cover in traditionally grazed areas – particularly at Grassy Meadow (sil22), and Jackson Meadow (sil8).

In addition, grazing use may continue to occur in suitable meadows such as Tully Hole (ufc9), Horse Heaven (ufc8), Purple meadow (ppb12), Second Crossing (cas1), and Ram Meadow (ppb10) where moderate impacts to vegetative herbaceous cover would occur if grazing continues to occur on a regular basis as it has in the past.

The trail system issues described under Yosemite toad would also be applicable to MIS species habitats at the meadows noted in the McGee Creek area. The effect of implementation of Alternative 1 commercial pack stock wilderness use regulating system such as trailhead quotas, and the continued use of other existing system and use trail, as well as use of camps on MIS mule deer and the yellow warbler habitats are described at the wilderness scale.

Fish Creek/Convict/McGee – Alternative 2 – Modified

MIS Mule Deer, Yellow Warbler, and Riparian Meadow and Meadow Edge Species

Analysis

Implementation of the grazing prohibitions in twenty-seven meadows under Alternative 2 – Modified and twenty-six meadows under Alternative 2 would maintain or potentially improve MIS species habitat over Alternative 1, including the functional at risk meadows with a downward trend at Grassy Meadow (sil22), and Jackson Meadow (sil8). Meadows that have been traditionally grazed by commercial pack stock would likely see increases in vegetative density and productivity that may improve habitat conditions over the long-term for MIS species. In Grassy and Jackson meadows, the prohibition may likely provide for an improvement in hydrologic functioning and restoration of additional wet meadow for the MIS species over the long-term, since it may allow for a higher potential to stabilize headcuts in spring channels and lateral stream channels that threaten meadow integrity.

Frog Lake Southeast, Rainbow to Margaret (mar18), Big McGee (Hopkins Bench), and Tully Hole (ufc9) meadows were rated functional at risk with no apparent trend. Big Margaret Lake West (mar11), Coyote Lake (mar7), and Fern lake (mar9) meadows were rated functional at risk, upward trend. There has been no use reported from 2001 through 2003 in most of these meadows. Only Tully Hole has shown consistent grazing use at moderate stock night levels. Rainbow to Margaret, and Coyote would be closed to commercial pack stock grazing under these alternatives.

Approval of commercial pack stock grazing at the other meadows at moderate utilization levels would likely have some effect on the recovery potential of these meadows, and subsequently MIS habitat, over the long-term if the meadows receive regular annual use (which is unlikely).

The Cascade Valley grazing closure would be lifted to allow light grazing under Alternative 2 – Modified, but the closure would continue under Alternatives 2, 3 and 4. Natural long-term restoration of this meadow would likely continue at the same rate under all these alternatives, including Alternative 1. Alternative 2 – Modified would allow only very light commercial pack stock grazing that would have very little effect, if any, on MIS wildlife habitat restoration potential.

Fish Creek/Convict/McGee – Alternative 3 and 4

MIS Mule Deer, Yellow Warbler, and Riparian Meadow and Meadow Edge Species

Analysis

Alternatives 2 and 3 would add two more meadows to the closed to commercial pack stock grazing. Alternative 4 would add five additional meadows where MIS habitats would be fully

protected over Alternative 2 – Modified. Alternative 3 would be similar to Alternative 2 – Modified since grazing would be allowed in the meadows listed under those alternatives as having stream functioning problems.

Alternative 4 would have the greatest reduction to the extent of impacts associated with camps and trails since it has the highest number of system trails and use trail closures, as well as the designation of spot and dunnage drop sites. There would be a reduction in the extent of social and access trails around camps no longer approved for use with a probable improvement in MIS habitat conditions.

Mono Creek/Rock Creek – Alternative 1

Yosemite Toad and Mountain Yellow-legged Frog

Analysis

Pioneer Basin Yosemite toad breeding habitats would continue to be protected since the meadow grazing closure would remain in effect. No commercial pack stock grazing use has been reported or observed from 2001 through 2003 at any of the toad breeding sites as shown in Table 4.94. Interdisciplinary team field visits to the Yosemite toad breeding sites within meadows requested for grazing did not detect any impacts from commercial pack stock grazing. This pattern would likely continue with implementation of Alternative 1.

Six of the twenty-one breeding areas are fully protected with the continuation of the closure of commercial pack stock grazing in all Pioneer Basin meadows. The other requested grazing meadows would not likely experience any substantive grazing use since commercial pack stock operators rarely use areas such as Upper Laurel Creek, Little lakes Valley, and Volcanic meadow areas. There is always the possibility commercial pack stock use could shift to these locations; however, it unlikely given poor trail access, other user group conflicts, and lack of client demand to go to those destinations.

Use of the meadow north of Mono Rock (For1) for commercial pack stock grazing would likely continue with some level of trampling and chiseling effects continuing in the mountain yellow-legged frog spring channel habitat. The maximum 20 percent stream bank disturbance standard would be monitored and implemented at some point to mitigate potential continuation of effects. This use would need to be monitored to ensure no adverse effects were occurring to this habitat. The unit has a number of yellow-legged frog populations. There would likely be no effect to other populations and habitats since commercial pack stock operations do not overlap with them.

Implementation of Alternative 1 system and approved use trails would not likely change the existing situation where very few effects have been identified to toads or frog habitats, except at the Pioneer Basin Trail to 4th Lake (10,900). Use of this trail would continue to be allowed. The trail crosses a stream channel on its way to 4th Lake (10,900). Existing commercial stock use has created a widened stream crossing and incised meadow trail through habitat where Yosemite toads have been observed. These impacts would likely continue since no trail work has been conducted on this use trail, nor would it likely occur.

Table 4.94 Distribution of Yosemite toad breeding meadows in the Mono Creek/Rock Creek Geographic Unit by analysis unit and overlap with grazing areas

Geo Unit	Analysis Unit	Breeding Meadows with Observed or Reported Grazing	Other Breeding Meadows Requested for Grazing	Not Requested for Grazing Use	Total Breeding Meadows
Mono Creek/ Rock Creek	Devils (Dev)		2		2
	Volcanic (Vol)		2		2
	Graveyard (Gra)		1	1	2
	Laurel (Lau)		1	1	2
	Pioneer (Pio)		1	5	6
	Silver Peak (Sip)		1	2	3
	Little Lakes Valley (Llv)		1	2	3
	Morgan Lakes (Mrg)			1	1
	Total			9	12

Mono Creek/Rock Creek – Alternatives 2 – Modified, 2, 3 and 4

Yosemite Toad and Mountain Yellow-legged Frog

Analysis

Implementation of management to avoid critical Yosemite toad breeding areas in Alternative 2 – Modified and the five percent critical area maximum allowable disturbance standard in Alternatives 2 through 4 would provide a higher degree of toad habitat protection in two approved grazing meadows that overlap with Yosemite toad occupied breeding habitat in this geographic unit; Devils Bathtub Meadow (dev1), and Upper Graveyard Meadow (gra11). alternative 2 only if grazing were to occur in the future in those meadows. There has been no reported use in these meadows in recent years so it is unlikely there would be any substantive grazing use. Commercial pack stock grazing would be prohibited in all alternatives in the meadow north of Mono Rock (for1), providing full protection for the mountain yellow-legged frog spring channel habitat.

Implementation of the various commercial pack stock use regulating systems are not likely to have any substantive effect to the Yosemite toad or mountain yellow-legged frog and their habitats since no issues have been identified with destination uses. Similarly, there are no substantive changes to Yosemite toad or mountain yellow-legged frog habitats from system and use trail proposals except for the commercial stock closure of the system trail to Lake 10,900 under Alternatives 2 through 4. This may allow for some rehabilitation of the stream crossing through Yosemite toad habitat.

Mono Creek/Rock Creek – Alternatives 1 - 4

MIS Mule Deer, Yellow Warbler, and Riparian Meadow and Meadow Edge Species

Analysis

Little is known about these MIS species and the status of their habitats within this geographic unit. The yellow warbler is not an MIS species on the Sierra NF but does apply to Inyo NF areas in Rock Creek, Hilton Creek and Tamarack Basin.

Interdisciplinary team field analysis in 2003 identified nine meadows where stream degradation was apparent. Meadow habitat for MIS species may have been adversely affected as a result of impairment of the hydrologic functioning of the meadows. The streams in Upper Graveyard (gra11), Graveyard (gra9), and Silver Pass Meadows (sip6) were determined to be functional at risk with downward trends. The meadows would be approved for grazing under Alternative 1. Commercial pack stock reported grazing use has been light from 2001 through 2003 in the two Graveyard meadows with moderate use in Silver Pass Meadow. Alternative 1 would likely continue this pattern of use that may somewhat inhibit long-term recovery of the stream hydrologic functioning and subsequent improvement potential of MIS habitat.

Graveyard, Upper Graveyard, and Silver Pass meadows would be closed under all other alternatives. Closure of these meadows to grazing may improve the potential for hydrologic functioning and vegetative recovery over the long-term, and therefore MIS habitat quality.

Implementation of Alternative 1 use of trails and destinations would likely continue the existing generalized effects discussed at the wilderness scale, such as human disturbance impacts and overall minor habitat modification associated with trails and destination use on these MIS groups and their habitat. The continued use of the trail to Lake 10,900 and Upper Pioneer Basin under Alternative 1 and 3 would continue to affect the riparian meadow MIS habitat; however, the magnitude of the effect is not significant. There would be some minor habitat improvement with its closure under Alternatives 2 – Modified, 2, and 4.

Human disturbance from commercial pack stock operations would likely remain high at places such as in the Mono Creek corridor and Hilton Lakes areas. Impacts would remain low in places such as Laurel Creek, and First Second and Third Recesses. Designated camps, drop sites, and stock holding areas, NSCS system trail, and use trail prohibitions by alternative would provide some decrease in habitat and human disturbance impacts.

Bishop/Humphreys – Alternative 1

Yosemite Toad

Analysis

Table 4.95 indicates that three out of 26 Yosemite toad breeding sites in the unit have observed grazing impacts in them, Very minor amounts of trampling and chiseling impacts from commercial pack stock grazing use at the three breeding sites have occurred in this geographic unit. All Pine Creek grazing sites on the Inyo NF were closed from 2001 through 2003 as a result of the implementation of grazing closures to meet Sierra Nevada Forest Plan standard and guidelines for grazing management in Yosemite toad habitat. Commercial pack stock grazing

remained open during this time in French Canyon and Piute Creek on the Sierra NF. In 2004, the meadows on the Inyo were re-opened to allow grazing; however, no grazing use was reported.

Merriam Creek confluence meadow in French Canyon, and a meadow above Sierra Camp to Packsaddle Lake have shown light pack stock grazing trampling and chiseling effects in Yosemite toad breeding sites. The implementation of Alternative 1 would likely continue to have this very minor overlap of effects if current grazing use levels and patterns continue.

The maximum allowable 20 percent stream bank, lakeshore, and pond disturbance standards from the 2001 Wilderness Plan would be applied as an upper acceptable trampling and chiseling impact standard if grazing use were to substantially increase. Trampling and chiseling impacts could increase substantially at the Yosemite toad breeding sites if this were to occur; however, it is not likely to occur in most of these meadows.

There would be no effect to the mountain yellow-legged frog populations or their habitats with implementation of Alternative 1 since commercial pack stock use is not likely to overlap with frog habitats.

There would be some light to moderate levels of trampling and chiseling effects that may likely continue with pack stock use of the system trail where it crosses the Yosemite toad breeding meadow at the inlet of Upper Pine Lake. The trail is in a poor location and occasionally pack stock pass through the breeding site. This impact may be addressed at a later date with a proposal to fix the trail or re-locate the crossing. Other than this trail problem, the continuation of use of the system and use trail, as well as use regulating mechanisms for commercial pack stock such as trailhead quotas, would not impact Yosemite toad or mountain yellow legged frogs or their habitats, or have any substantive changes over the existing situation in this geographic unit.

Table 4.95. Distribution of Yosemite toad breeding meadows in the Bishop/Humphreys Geographic Unit by analysis unit and overlap with grazing areas in Alternative 1

Geo Unit	Analysis Unit	Breeding Meadows with Observed or Reported Grazing	Other Breeding Meadows Requested for Grazing	Not Requested for Grazing	Total Breeding Meadows
Bishop Humphreys	Piute (Piu)			1	1
	Humphreys Basin (Hum)		1		1
	Glacier Divide (Gla)	1	3	2	6
	French Canyon (Fre)	2	4		6
	Pine Creek		4	4	8
	Granite Park			4	4
	Total		3	12	11

Bishop/Humphreys – Alternatives 2 – Modified, 2, 3 and 4

Yosemite Toad

Analysis

Alternatives 2 through 4 would fully protect nine of the 15 meadows where grazing was observed or requested under Alternative 1 since commercial pack stock grazing would be prohibited. These meadows are primarily in Pine Creek and Upper Piute Creek from Packsaddle Tributary Confluence upstream to Piute Pass. In practicality, there would not be a substantive difference in the effects of these alternatives over Alternative 1 since grazing use has not been observed to be a substantive concern in this geographic unit.

The implementation of the trail systems proposals, destinations camps, or use regulating mechanisms would not change the existing patterns of use overlap and potential for effects in Yosemite toad habitats. Upper Pine Creek Meadow would continue to have light to moderate trampling and chiseling impacts in the breeding habitats since poor system trail alignment would still steer commercial pack stock to occasionally pass through the breeding sites. This type of effect is not mitigated by a trail management class designation, but rather a site-specific trail relocation NEPA action that is not part of the trail management level designation process.

Bishop/Humphreys – Alternatives 1 - 4

MIS Mule Deer, Yellow Warbler and Riparian Meadow and Meadow Edge Species

Analysis

Alternative 1 through 4 would likely continue to have some habitat impacts from commercial pack stock grazing at Hutchinson Meadow that may maintain the meadow habitat in a fair ecological condition where meadow vegetation species composition, density, and productivity provide lower habitat suitability for these MIS species. Waterfall Camp meadow fen habitat is also in a lower ecological condition and would likely continue to remain in that state if grazing continues under Alternative 1. It has been determined to be unsuitable for grazing and may recover as grazing is discontinued under all other alternatives. Commercial pack stock grazing use is low in this geographic unit and would likely remain so under Alternatives 1 through 4. Most meadow habitats would remain in high quality condition for MIS species except for the impacts of trails coursing through them and associated human disturbance effects on these trail corridors and around camps.

Designated camps, drop sites, and stock holding areas, NSCS system trail, and use trail prohibitions by alternative would reduce the extent of potential area for human disturbance and habitat effects to MIS species around meadow habitats. This may improve habitat conditions somewhat under the more restrictive alternatives, however the changes by alternative do not provide for substantive differences in effects to MIS species.

Florence/Bear – Alternative 1

Yosemite Toad

Analysis

The implementation of this alternative would likely have very minor effects to 14 Yosemite toad breeding areas that may be grazed under this alternative. Only four breeding area meadows have had any grazing use reported in them from 2001 through 2003. Hell Hole Meadow (hoo2) is a low elevation meadow where commercial pack stock grazing can be substantial; however, the meadow analysis report from the Sierra National Forest rated the meadow in good condition and did not document substantive impacts to the Yosemite toad breeding habitat in the meadow.

No effects to Yosemite toad breeding areas were noted at any of the other meadow areas. Forty-one of the 55 meadows with Yosemite toad breeding populations in Table 4.2.22 have not been requested for grazing and are likely to remain ungrazed with no impacts at the Yosemite toad breeding areas.

If all 41 meadows were grazed at full implementation of the alternative allowable use standards, the effects would increase substantially as described for other units. This is a highly unlikely scenario under this alternative. There would be no effect to any mountain yellow legged frog habitats since commercial pack stock grazing use does not overlap with this species' habitat in this unit.

Table 4.96. Distribution of Yosemite toad breeding meadows in the Florence/Bear Geographic Unit by analysis unit and overlap with grazing areas in Alternative 1.

Geo Unit	Analysis Unit	Breeding Meadows with Observed or Reported Grazing	Other Breeding Meadows Requested for Grazing	Not Requested for Grazing	Total Breeding Meadows
Florence/Bear	Seldon (Sel)	3	6		9
	Apollo (Apo)	1	2		3
	Dutch (Dut)		1	26	27
	Ershim (Ers)		1	8	9
	Bear Lakes (Bel)			2	2
	Italy (Ita)			1	1
	Bolsillo (Bol)			4	4
	Total		4	10	41

Florence/Bear – Alternatives 2 – Modified, 2 3 and 4

Yosemite Toad

Analysis

Effects of implementation of these alternatives would likely be the same as Alternative 1 for meadows with Yosemite toad critical areas listed in Table 4.86 since it is unlikely any

substantive grazing use would occur within this geographic unit, except as identified at Hell Hole Meadow. Grazing would be managed in all suitable meadows to avoid Yosemite toad critical breeding areas under Alternative 2 – Modified, and a five percent maximum allowable disturbance under Alternative 2, 3 and 4. Commercial pack stock grazing would be prohibited in thirty-four meadows with Yosemite toad breeding areas since these meadows are outside of grazing zones.

Florence/Bear – Alternatives 1 - 4

MIS Mule Deer, Yellow Warbler and Riparian Meadow and Meadow Edge Species

Analysis

Little is known about these MIS species and the status of their habitats within this geographic unit. The yellow warbler is not an MIS species on the Sierra NF. Field analyses did not identify any major areas of concern with respect to current commercial pack stock operations in this unit. The continuation of the existing situation under Alternative 1 would likely perpetuate the generalized effects of human disturbance and minor habitat modification associated with grazing, trails, and destination use on these MIS groups and their habitat.

Implementation of Alternatives 2 and 3 would not likely substantially change these impacts over the geographic unit.

Actions under these alternatives, such as designated camps and stock holding areas, and not suitable for commercial stock trail actions by alternative may improve habitat conditions for MIS species somewhat.

John Muir Southeast – All Alternatives

Yosemite Toad and Mountain Yellow Legged Frog

Analysis

The range of the Yosemite toad does not extend down into this geographic unit. The mountain yellow-legged frog habitats on the Coyote Plateau at Hidden Lake and Baker Lake would not be affected with implementation of any of the alternatives since the low level of commercial pack stock operations that occur in the area are not affecting the species or its habitat. The populations in the North Fork of Big Pine Creek would be unaffected for the same reason. The populations in the high lakes below Kearsarge Pass would not be affected by implementation of any of the alternatives since the majority of commercial pack stock use is traveling the system trail en route to destinations into Sequoia Kings National Park, or spot and dunnage drops in the lakes basin that do not affect the frog or its habitat. There is no commercial pack stock grazing overlap with mountain yellow-legged frog habitat in this geographic unit.

John Muir Southeast – All Alternatives

MIS Mule Deer, Yellow Warbler, and Riparian Meadow and Meadow Edge Species

Analysis

The geographic unit is entirely on the Inyo NF. The meadow and meadow edge bird guilds are not MIS species on the Inyo NF. The effects to the yellow warbler are the same under Alternatives 1 through 4. Most of the geographic unit has no yellow warbler habitat since the meadows are either too high in elevation and lack good tall shrub and riparian hardwood habitats, or the canyon riparian areas are narrow, confined, lack associated flat gradient wet meadows, and subsequently are of marginal quality. The species generally does not occur in these types of habitat, and is not a good indicator for these areas. The North Fork of Big Pine Creek does have a small area of suitable habitat below First Lake. The meadow habitat is largely in an undisturbed state except for the system trail that courses adjacent to the willow suitable habitat areas. The system trail is used predominantly by backpackers and day hikers so that the continuation of low use levels by commercial pack stock along this trail corridor would not substantively affect the use of the meadow habitat by the yellow warbler anymore than is already occurring by the other predominant user groups.

The approval of commercial pack stock grazing at Windy Gap under Alternative 1 with allowable use standards would likely prevent any long-term recovery of the this highly degraded meadow area, and would likely accelerate meadow loss from erosion due to headcut migration. This would likely accelerate loss of mule deer meadow habitat.

The closure of the Windy Gap grazing area under Alternatives 2 through 4 would prevent any further degradation of mule deer meadow habitat that is a result of trampling and chiseling impacts associated with commercial pack stock grazing. The meadow is likely to continue to erode over the long-term as headcuts continue to migrate up the incised stream channels. The meadow erosion that is the result of headcut migration would not be accelerated with implementation of the grazing closure.

Implementation of any of the wilderness trail transportation system alternatives within this unit, including trail management levels, and system and use trail suitability determinations, would continue to maintain human travel corridors that provide areas of human disturbance potential to mule deer. Alternative 4 would provide a slight decrease in human disturbance potential with the increased NSCS system trail designations and commercial pack stock increased use trail prohibitions. Commercial pack stock use is relatively low in comparison to the other user groups. The proposed trail use changes by alternative would be unlikely to be substantively different as far as changes in human disturbance effects to mule deer.

There is substantial Sierra Nevada bighorn sheep habitat overlap at Mt. Langley, Mt. Williamson, and Mt. Baxter areas in this geographic unit. Effects to Sierra Nevada bighorn sheep are minor and are described at the wilderness scale.

John Muir Southwest – Alternative 1

Yosemite Toad and Mountain Yellow Legged Frog

Analysis

The implementation of this alternative would likely have very minor potential effects to ten Yosemite toad breeding areas that could be grazed under this alternative if requested meadows were grazed. Only four breeding area meadows have had any grazing use reported from 2001 through 2003. No substantive impacts are likely in any of these meadows if grazing continues similar to current levels.

Most of this geographic unit receives very light commercial pack stock use relative to other units. Fifty-seven of the 67 meadows with Yosemite toad breeding populations in Table 4.97 have not been requested for grazing and are likely to remain ungrazed with no impacts to the Yosemite toad breeding areas. There were no unsuitable for grazing determinations in any Yosemite toad breeding meadow. If all 67 meadows were grazed at full implementation of the alternative allowable use standards, the effects would increase substantially as described for other units. This is a highly unlikely scenario under this alternative. There would be no effect to any mountain yellow legged frog populations or their habitat since commercial pack stock grazing use does not overlap with this species habitat in this unit.

Table 4.97. Distribution of Yosemite toad breeding meadows in the John Muir Southwest Geographic Unit by analysis unit and overlap with grazing areas in Alternative 1

Geo Unit	Analysis Unit	Breeding Meadows with Observed or Reported Grazing	Other Breeding Meadows Requested for Grazing	Not Requested for Grazing	Total Breeding Meadows
John Muir SW	Hobler (Hob)	1	1	11	13
	Crown Lake (Crl)		1	2	3
	Rodgers (Rod)			1	1
	Finger (Fin)			14	14
	Dusy (Dus)			1	1

	Crown Basin (Crb)			3	3
	Spanish (Spa)			2	2
	Basin (Bas)			3	3
	South Woodchuck (Sow)			3	3
	Post Corral (Poc)			2	2
	Fleming Mountain (Fle)			1	1

Geo Unit	Analysis Unit	Breeding Meadows with Observed or Reported Grazing	Other Breeding Meadows Requested for Grazing	Not Requested for Grazing	Total Breeding Meadows
	Red Mountain (RMB)			2	2
Total		3	7	57	67

John Muir Southwest – Alternatives 2 – Modified, 2, 3, and 4

Yosemite Toad and Mountain Yellow Legged Frog

Analysis

The implementation of any of the alternatives would likely have very minor effects to Yosemite toad breeding areas within identified meadows that may be grazed with implementation of the manage to avoid critical areas under Alternative 2 – Modified, and the five percent maximum allowable disturbance standard in critical areas in Alternatives 2, 3, and 4. Effects of implementation would likely be similar to Alternative 1 since grazing under this alternative is likely to continue to be very light in this geographic unit. There would be no effects from commercial pack stock grazing to all other meadows in Table 4.97 since they are outside of grazing zones and would be closed to commercial pack stock grazing.

John Muir Southwest – Alternatives 2 – Modified, 2, 3, and 4

MIS Mule Deer, Yellow Warbler, and Riparian Meadow and Meadow edge species

Analysis

Little is known about these MIS species and the status of their habitats within this geographic unit. The yellow warbler is not an MIS species on the Sierra NF. Limited field analyses did not identify any major areas of MIS wildlife habitat degradation with respect to current commercial pack stock operations in this unit. The continuation of the existing situation for commercial pack stock operations, and trail management under Alternative 1 would likely perpetuate the human disturbance and minor habitat modification generalized effects identified at the wilderness scale associated with grazing, trails, and destination camp use on these MIS groups and their habitat.

Implementation of Alternatives 2 through 4 would not likely substantially change these impacts over the geographic unit. Designated camps and stock holding areas, and not suitable for commercial stock trail actions by alternative may decrease impacts and promote localized habitat improvement conditions.

4.3.2 Vegetation

Wilderness Scale

Summary of Alternative 1 Impacts

Grazing Resources: The area used by commercial pack stock would be a minor portion of the total wilderness area, but not limited to grazing zones. The direct, indirect, and cumulative effects of stock use would not be visible and may not be measurable at the wilderness or geographic scale. These effects could be measurable and visible at the analysis unit scale and would be measurable and visible at the site specific scale, and especially in the analysis units and at those sites that have substantial vegetation areas still recovering from past chronic and cumulative adverse impacts due to the impacts of historical uses such as production livestock grazing, water diversion, or mining. These include the Glacier Divide, Silver Peak, Cora, Sadler, Triple Divide, Lillian, Rush Creek, Fish Creek, McGee, Hilton, Cascade Valley, Pioneer, Graveyard, Hooper, and Silver Divide Analysis Units. The vegetative resources could trend away from desired conditions, over the long-term, at an estimated 37 of the locations visited during this project with implementation of Alternative 1.

There would be increased adverse impacts with Alternative 1 over the other alternatives and opportunities for vegetative recovery in fewer locations. The degradation of these riparian areas would become more noticeable over the long-term and many areas with current patterns of repeated use would eventually have to be closed to grazing.

Fens: A greater number of meadows with fens or fen characteristics (17) would remain in degraded conditions in this alternative than any other and the allowable trampling (20 percent) would be higher than in Alternatives 2, 3, and 4. The trampling would most likely be a local, minor, short-term effect, but degraded hydrologic conditions are likely to be long-term and more serious.

Sensitive and Watch List Plants: Individual sensitive or watch list plants may be affected by commercial and private pack stock activities, hiker use, and trail management activities; however, these impacts would be minor, local, and short-term. There are some long-term moderate to severe impacts to sensitive plant habitat regionally from historic grazing that would be somewhat less likely to recover under this alternative.

Under this alternative, the trails would be at the highest trail classes of any alternative, and the trail classes least matched to use, so the impacts to rare plants from trail maintenance and to some extent trail use, although slight, would be greatest of any alternative. There would be less possibility of impacts from avoidance of trail obstacles than in the other alternatives if maintenance actually matches trail class. Any trail impacts would be local, minor, and short-term.

More meadows (527) with potential habitat for sensitive riparian species would be open for use under this alternative than any of the others. Sixteen of the meadows with potential habitat were found to have degraded conditions, mostly due to historic cattle and sheep grazing, and would remain degraded more than under Alternatives 4 and 5.

Firewood: As in Alternatives 4 and 5, there would be no firewood brought in from outside the wilderness, eliminating risk of introducing pathogens and weed seeds from this source.

Weeds: There would be some risk of weed introduction from pack stock use, hiker use, and trail maintenance since there are populations of weeds at trailheads and pack stations. This risk is about the same as Alternative 2 -Modified, 3, and 4, but higher than Alternative 5. Weed effects are generally long-term, but the severity and extent of negative impacts is site dependent.

Summary of Alternative 2 – Modified Impacts

Grazing Resources: The areas used by commercial pack stock are a minor portion of the total wilderness area and limited to grazing zones. The direct, indirect, and cumulative effects of stock use would not be visible and may not be measurable at the wilderness or geographic scale. These effects could be measurable and visible at the analysis unit scale and would be measurable and visible at the site-specific scale. The vegetative resources in most locations are expected to be maintained at or toward desired conditions. The vegetative resources could trend away from desired conditions, for the long-term, at an estimated 21 of the locations visited during this project.

Fens: In this alternative, fens would be more protected from inadvertent commercial pack stock use than in Alternative 1 because no grazing would be permitted in fens. Fewer meadows with fens or fen characteristics (13) would remain in degraded condition than in Alternative 1, but more than Alternatives 4 and 5. There would be an overall long-term beneficial effects to fens under this alternative.

Sensitive and Watch List Plants: Individual sensitive or watch list plants may be affected by commercial and private pack stock activities, hiker use, and trail management activities; however, the effects of these activities would be minor, local, and short-term. There are some long-term moderate to severe impacts to riparian habitat regionally from historic grazing that would be more likely to recover than under Alternative 1.

Under this alternative, the trail classes, and associated use and maintenance impacts to sensitive plants, would be lower than Alternatives 1 and 3, but higher than Alternatives 4 and 5, and more consistent with use. The possibility of impacts from avoidance of trail obstacles would be higher than Alternative 1, about the same as Alternative 3, and lower than Alternatives 4 and 5. Any trail impacts would be local, minor, and short-term.

Fewer meadows (116) with potential habitat for sensitive riparian species would be open for use under this alternative than Alternative 1, but more than under Alternative 5. Grazing use would be similar to Alternative 1 for the most part, but there may be some shifts in use due to meadow closures. Meadows with severe problems would be rested and those for which range readiness is probably never reached over most of the meadow would be closed, so the riparian potential habitat with the highest risks for degradation would not be available for use until recovered. Sixteen meadows with potential habitat for sensitive riparian plants would remain in degraded conditions. The overall effect would be a long-term beneficial reduction in impacts to potential habitat for sensitive riparian species.

Firewood: This alternative would have less risk of weed introduction than Alternatives 2 and 3 because of the use of charcoal. Adjustments in elevation closures at specific sites to reflect actual availability of firewood should protect subalpine soils and vegetation better than, or at least as

well as, Alternative 1. Case-by-case approval of other campfire use could have a minimal negative impact on subalpine vegetation and careful monitoring would be required.

Weeds: There would be some risk of weed introduction from pack stock use, hiker use, and trail maintenance since there are populations of weeds at trailheads and pack stations. This risk is somewhat higher than the other alternatives because firewood may be brought in. If weeds were introduced, the effects would be long-term, moderate to severe, and although beginning locally, could easily become widespread.

Summary of Alternative 2 Impacts

Grazing Resources: The areas used by commercial pack stock are a minor portion of the total wilderness area and limited to grazing zones. The direct, indirect, and cumulative effects of stock use would not be visible and may not be measurable at the wilderness or geographic scale. These effects could be measurable and visible at the analysis unit scale and would be measurable and visible at the site-specific scale. The vegetative resources in most locations are expected to be maintained at or to trend toward desired conditions. With implementation of Alternative 2, the vegetative resources could trend away from desired conditions, for the long-term, at an estimated 21 of the locations visited during this project.

Fens: In this alternative and Alternatives 3 and 4, fens would be more protected from inadvertent commercial pack stock use than in Alternative 1 because of the 5 percent trampling limit. Fewer meadows with fens or fen characteristics (16) would remain in degraded condition than in Alternative 1, but more than Alternatives 4 and 5. There would be overall long-term beneficial effects to fens under this alternative.

Sensitive and Watch List Plants: Individual sensitive or watch list plants may be affected by commercial and private pack stock activities, hiker use, and trail management activities; however, the effects of these activities would be minor, local, and short-term. There are some long-term moderate to severe impacts regionally from historic grazing that would be more likely to recover than under Alternative 1.

Under this alternative, the trail classes, and associated use and maintenance impacts to sensitive plants, would be lower than Alternatives 1 and 3, but higher than Alternatives 4 and 5. The possibility of impacts from avoidance of trail obstacles would be higher than Alternative 1, about the same as Alternative 2 – Modified, 2, and 3, and lower than Alternatives 4 and 5. Any trail impacts would be local, minor, and short-term.

Fewer meadows (116) with potential habitat for sensitive riparian species would be open for use under this alternative than Alternative 1, but more than under Alternative 5. Grazing use would be similar to Alternative 1 for the most part, but there may be some shifts in use due to meadow closures. Meadows with severe problems (and those for which range readiness is probably never reached over most of the meadow) would be closed, so the riparian potential habitat with the highest risks for degradation would be closed. Sixteen meadows with potential habitat for sensitive riparian plants would remain in degraded conditions. The overall effect would be a long-term beneficial reduction in impacts to potential habitat for sensitive riparian species.

Firewood: Under this alternative, there would a moderate risk of the introduction of pathogens and/or weed seeds on firewood brought in from outside the wilderness and increased unauthorized gathering of wood and campfires by non-packer clients. Firewood could only be brought in to sites designated for full service (approximately 42 sites) and only used when a

wrangler is present. If pathogens or weeds were introduced, the effects would be long-term, moderate to severe, and although beginning locally, could easily become widespread.

Weeds: There would be some risk of weed introduction from pack stock use, hiker use, and trail maintenance since there are populations of weeds at trailheads and pack stations. This risk is somewhat higher than the other alternatives because firewood may be brought in. If weeds were introduced, the effects would be long-term, moderate to severe, and although beginning locally, could easily become widespread.

Summary of Alternative 3 Impacts

Grazing Resources: The areas used by commercial pack stock are a minor portion of the total wilderness area and limited to grazing zones. The direct, indirect, and cumulative effects of stock use would not be visible and may not be measurable at the wilderness or geographic scale. These effects could be measurable and visible at the analysis unit scale and would be measurable and visible at the site-specific scale. The vegetative resources in most locations are expected to be maintained at or to trend toward desired conditions. With implementation of Alternative 2, the vegetative resources could trend away from desired conditions, for the long-term, at an estimated 21 of the locations visited during this project.

Fens: In this alternative and Alternatives 3 and 4, fens would be more protected from inadvertent commercial pack stock use than in Alternative 1 because of the 5 percent trampling limit. Fewer meadows with fens or fen characteristics (16) would remain in degraded condition than in Alternative 1, but more than Alternatives 4 and 5. There would be overall long-term beneficial effects to fens under this alternative.

Sensitive and Watch List Plants: Individual sensitive or watch list plants may be affected by commercial and private pack stock activities, hiker use, and trail management activities; however, the effects of these activities would be minor, local, and short-term. There are some long-term moderate to severe impacts regionally from historic grazing that would be more likely to recover than under Alternative 1.

Under this alternative, the trail classes, and associated use and maintenance impacts to sensitive plants, would be lower than Alternatives 1 and 3, but higher than Alternatives 4 and 5. The possibility of impacts from avoidance of trail obstacles would be higher than Alternative 1, about the same as Alternative 2 and 2 – Modified, and lower than Alternatives 4 and 5. Any trail impacts would be local, minor, and short-term.

Fewer meadows (116) with potential habitat for sensitive riparian species would be open for use under this alternative than Alternative 1, but more than under Alternative 5. Grazing use would be similar to Alternative 1 for the most part, but there may be some shifts in use due to meadow closures. Meadows with severe problems (and those for which range readiness is probably never reached over most of the meadow) would be closed, so the riparian potential habitat with the highest risks for degradation would be closed. Sixteen meadows with potential habitat for sensitive riparian plants would remain in degraded conditions. The overall effect would be a long-term beneficial reduction in impacts to potential habitat for sensitive riparian species.

Firewood: Under this alternative, there would be a moderate risk of the introduction of pathogens and/or weed seeds on firewood brought in from outside the wilderness and increased unauthorized gathering of wood and campfires by non-packer clients. Firewood could only be brought in to sites for full service (approximately 42 sites) and only used when a wrangler is

present. If pathogens or weeds were introduced, the effects would be long-term, moderate to severe, and although beginning locally, could easily become widespread.

Weeds: There would be some risk of weed introduction from pack stock use, hiker use, and trail maintenance since there are populations of weeds at trailheads and pack stations. This risk is somewhat lower than Alternative 2, but higher than Alternatives 1, 2 – Modified, 4, and 5. If weeds were introduced, the effects would be long-term, moderate to severe, and although beginning locally, could easily become widespread.

Summary of Alternative 4 Impacts

Grazing Resources: The areas used by commercial pack stock are a minor portion of the total wilderness area and limited to grazing zones. The direct, indirect, and cumulative effects of stock use would not be visible and may not be measurable at the wilderness or geographic scale. These effects could be measurable and visible at the analysis unit scale and would be measurable and visible at the site-specific scale. The vegetative resources in most locations are expected to be maintained at or to trend toward desired conditions. The vegetative resources could trend away from desired conditions, for the long-term, at an estimated 20 of the locations visited during this project.

Fens: Under this alternative, fewer fens would be at risk of degrading and more degraded fens would begin recovery than in Alternatives 1, 2 – Modified, 2, and 3. Fifteen meadows with fens or fen characteristics would remain in degraded conditions. There would be less protection than in Alternative 5, since most of the risk to fens is from commercial pack stock.

Sensitive and Watch List Plants: Individual sensitive or watch list plants may be affected by commercial and private pack stock activities, hiker use, and trail management activities; however, the impacts of these activities would be minor, local, and short-term for the most part. There would be more restrictions on use in this alternative than Alternatives 1, 2, and 3, so there could be some use displaced to adjacent lands (outside wilderness, National Parks, or other National Forests) where there are populations or potential habitat for these sensitive plants, but most of these populations are either on National Parks or National Forests, so there would be protection. Displacement of use would be less likely than in Alternative 5.

Under this alternative, the trail classes, and associated maintenance, would be the lowest of any of the alternatives. However, there would be pack stock use, which there would not be in Alternative 5. There would be more risk from avoidance of trail obstacles than in the other alternatives because of the low maintenance levels. Trail impacts would be minor, local, and most likely short-term.

Fewer meadows (116) with potential habitat for sensitive riparian species would be open for use under this alternative than Alternative 1, but more than under Alternative 5. More meadows would be closed to grazing than in Alternatives 2 and 3, so there may be more shifts in use to meadows not currently used. Meadows with moderate to severe problems (and those for which range readiness is probably never reached) would be closed, so the riparian potential habitat for sensitive and watch list plants with the highest risks for degradation would be closed to commercial pack stock. Thirteen meadows with potential habitat for sensitive riparian species would remain in degraded conditions. There would be more local long-term beneficial effects of closing meadows than in Alternatives 1, 2, and 3, but there would still be some meadows with negative effects from pack stock use that would remain degraded.

Firewood: As in Alternatives 1 and 5, there would be no firewood brought in from outside the wilderness, eliminating risk of introducing pathogens and weed seeds from this source.

Weeds: There would be some risk of weed introduction from pack stock use, hiker use, and trail maintenance since there are populations of weeds at trailheads and pack stations. This risk is about the same as Alternative 1, 2 – Modified, 2, and 3 but higher than Alternatives 5.

Summary of Alternative 5 Impacts

Grazing Resources: No areas of the wilderness would be used by commercial pack stock. The direct, indirect, and cumulative beneficial effects due to increased vegetative seral status would not be visible and may not be measurable at the wilderness or geographic scale. These beneficial effects could be measurable and visible at the analysis unit scale and would be measurable and visible at the site-specific scale. The vegetative resources in most locations are expected to be maintained at or to trend toward desired conditions. The vegetative resources could trend away from desired conditions, for the long-term, at an estimated 18 of the locations visited during this project.

Fens: Since most of the risk to fens is from commercial pack stock, Alternative 5 would provide the best protection for fens, but there still could be impacts from private stock use. Five meadows with fens or fen characteristics that have degraded conditions would continue to have degraded conditions.

Sensitive and Watch List Plants: There would be no commercial pack stock impacts, but private stock use would continue and could increase. Individual sensitive or watch list plants may be affected by private pack stock, hiker use, and trail management activities; however, these activities would not cause a trend toward listing in this or any other alternative.

Under this alternative, the trail classes, and associated maintenance impacts to sensitive plant populations and habitat, would be lower than Alternatives 1, 2 – Modified, 2, and 3, but slightly higher than Alternative 4, and maintenance needs would be less because of the removal of commercial pack stock. There would be the possibility of impacts from avoidance of obstacles by hikers and private pack stock, but the risk would be less than Alternative 4.

There would be no commercial pack stock impacts to sensitive plants or their habitat in meadows in the Ansel Adams and John Muir Wildernesses. There could be some pack stock use displaced to locations outside of these wilderness areas on the Forests, National Parks, or other adjacent lands, where there are populations of these sensitive plants or potential habitat.

Firewood: As in Alternatives 1 and 4, there would be no firewood brought in from outside the wilderness, eliminating the risk of introducing pathogens and weed seeds from this source.

Weeds: Commercial pack stock would no longer be a possible vector for weed distribution into the wilderness from the pack stations or other populations in and near the wilderness, so this alternative would have the lowest risk of weed expansion in the wilderness.

Grazing Resources

Riparian Vegetation, Meadows

Introduction

Definitions

Context: The context considers whether the impact would be local or regional. For the purposes of this analysis, local impacts would be those that occur at site-specific locations, over less than 1/3 of the identified key area. Regional impacts would be impacts on the analysis unit up to the wilderness scale.

Intensity: The intensity considers whether the impact would be negligible, minor, moderate, or major. Negligible impacts are undetectable effects that would have no observable effect on the vegetative resources (species composition, productivity, or seral status). Minor impacts are observable but not expected to have an overall effect on the vegetative resource. Moderate impacts would be clearly observable and could have an appreciable effect on the vegetative resource. Major impacts would have a substantial high noticeable influence and could significantly alter the vegetative resource.

Duration: The duration considers whether the impact would occur in the short-term, long-term, or very long-term. For this analysis, short-term is one to five years. An example is grazing of vegetation expected to re-grow and recovery completely by the subsequent season. Long-term is five to 20 years. An example is repeated grazing in a season with associated trampling and fragmentation of the sod, which would be expected to take longer than five years but less than 20 to recover. Very long-term is expected to persist for greater than 20 years. An example is repeated grazing over several years with trampling impacts that has resulted in bare areas and altered vegetative species composition associated with trail or stream incisement and lowering of the water table where recovery is not expected for several decades.

Type of Impact: Impacts are evaluated in terms of whether they would be beneficial or adverse to the vegetative resource. A beneficial impact would sustain or improve late-seral vegetative productivity, vigor, and abundance. An adverse impact would not sustain or improve late-seral vegetative productivity, vigor, and abundance.

Analysis

This grazing resource analysis is focused on areas of meadow vegetation identified by the operators that are currently being used, were requested for use, or have been used historically for pack stock grazing. The discussion of consequences focuses on the effects of successfully implementing grazing with identified standards for vegetation utilization, range readiness, and stream bank alteration at key areas and provides for protection of critical areas.

Wetland obligate late-seral meadow vegetation (USDI, 1998) has developed historically and should continue to develop in areas where fine textured materials accumulate and are supported by seepage water (Wood, 1975) if the vegetation in those areas is undisturbed. Wood examined meadow stratigraphy exposed by twentieth century erosion, using radiocarbon dating as well as matching stratigraphy of volcanic ash with known eruptions dates and interpreting the evidence to indicate that the meadows and associated stream channels were naturally stable and aggrading

over time. Wood concludes that Sierra meadows, while undergoing changes in vegetation types, had remained vertically stable as sediment sinks, concluding, “Aggradation has been a continuous process”. He developed a sequential history of mountain meadow development and found, “Summer use of meadow by livestock damages the protective sod. During winter plant dormancy, flood waters from torrential winter rain storms initiate gullies leading to erosion of the valley fill and destruction of the meadow” (Wood, 1975).

As discussed by Leopold (1992) and Elmore (1987), the inorganic processes are inseparable from the complex organic processes carried on by plants and animals, and therefore they must be discussed together, especially when analyzing watershed effects. Trampling of vegetation and hoof punching in a meadow results in fragmentation of the plant and soil interface, or sod layer. When repeated trampling reoccurs prior to vegetative healing, there is a synergistic and chronic adverse impact to both plant and soil development at that site, manifested in altered vegetation species, decreased rooting depth, reduced vegetative cover, increased bare soil, and an increase in nick points potentially leading to soil loss. Trampling impacts often occur well before the applicable allowable vegetation utilization levels, of 30 percent or 40 percent, are reached.

Branson et al. (1981) found that soil loss in grass and grass-like vegetation types can be approximately 150 percent higher for bare soil than for a site with nearly 100 percent cover. Because of this relationship between soil cover and soil loss, activities that result in broken sod and reduced vegetative cover result in adverse impacts and associated increased risk to ecological function if they reoccur before the vegetation on a particular site recovers.

An important consideration when discussing effects to the vegetative resource is that grazing related adverse impacts can continue to occur at even low levels of existing use relative to historical use (Cole, 2004; Moore, 2000; Olson-Rutz, Kirchner, 1998; 1996; Cole, 1995; Cole, 1993). Damage occurring at local sites is of significance in the context of individual riparian vegetation complexes even with light and infrequent levels of pack stock use. This is especially true in areas with chronic historical adverse cumulative effects and continuing additive current impacts from grazing, trampling, or regulations of water flows below dams.

These adverse effects are long-term due to a lag time between recruitment of new pioneering, early-seral or mid-seral, species of vegetation, establishment of that new vegetation, trapping of sediment, the time required for recruitment and establishment of stabilizer species of vegetation on of the new sediment, and the resulting time required for morphological development of desirable stream channel characteristics (Winward, 2000; Kondolf, 1993; Sarr, et al, 1996).

Resistance to current impacts and vegetative resiliency (the ability to recover following impacts) is correlated with plant morphological characteristics and these characteristics are affected by the timing and intensity of grazing and trampling (Cole, 2004; Moore, 2000; Olson-Rutz, 1996; Cole, 1995). While initially resistant and resilient, once the vegetation and sod layer is damaged meadows can lose that resiliency and recovery can be a difficult and long-term proposition (Kirchner, 1998; Sarr, 1996; Kondolf, 1993; Odion, et al, 1988). However, given time and proper management conditions, degraded rangeland streams can often produce the same vegetation recovery results that we in the past have spent much time and effort attempting to produce with artificial structures (Elmore and Beschta, 1989).

The recovery of stabilizer species of vegetation and subsequent ecological recovery to satisfactory rangeland condition, both at a specific site and at affected sites throughout a watershed may take many years even in the absence of grazing. Late-seral riparian plant species

are stabilizers and are critical to sustaining meadow ecological processes over time (Winward, 2000). If an impact is repeated before vegetative and hydrological recovery can occur the subsequent erosion processes alters the hydrology which further exacerbates the alteration of vegetation, further weakening the ecological resiliency of the site and resulting in a synergistic and chronic cumulative adverse effect. These chronic, cumulative, and synergistic adverse effects migrate through and affect riparian meadows in the watershed both upstream through headcut movement and downstream through increased sediment loads and decreased vegetation available for buffering of high flows.

Conversely, this analysis assumes that increased vegetative cover provides increased protection and reduces the risks to ecological function at all sites, in all vegetation seral stages. In addition to the value of protecting the soil at individual locations within a watershed, the value of providing adequate vegetative growth and retention, or watershed roughness, to buffer flows throughout a watershed is supported by discussions of Manning's n , the coefficient of roughness in the watershed flow velocity equation, in Branson, et al, (1981); Leopold, et al, 1992, and in discussions by Elmore and Beschta (1989).

Past, Present, and Foreseeable Future Actions

While impacts related to commercial pack stock use and grazing are currently occurring in a relative small percentage of the total project area, the chronic cumulative historical impacts (due to grazing, mining, water diversion, water impoundment, and fire suppression) are widespread.

Historical Grazing

As described in the Wilderness Management Plan Final Environmental Impact Statement (USFS, 2001, Chapter III), and the Grazing Operations section of Chapter III of this document, historical grazing, including incompletely documented levels of sheep, pack stock, and cattle, likely exceeded the current levels of grazing use by up to 100 times throughout the project area. The historical use was also likely more widespread, and in every accessible location; especially by sheep in the late 1800s as competition forced use into remote locations.

The data exist to support the conclusion that Sierra Nevada ecosystems suffered from abusive grazing practices through the turn of the century (USFS, 1999, SNEP Report). There were likely very high levels of grazing by sheep in all geographic areas and most analysis units throughout the early 1900s, then a shift toward cattle grazing and recreational pack stock in the early to mid-1900s, with elimination of sheep grazing and gradual reductions in cattle grazing to the present time. In the analysis area, cattle grazing continues only on the west side of the Sierra, mostly in the southwestern Ansel Adams Wilderness.

Grazing-related historical impacts were likely major to severe in almost all locations of the project area, but especially in the west portion of the Ansel Adams Wilderness area, the Fish Creek area, and the Mono Creek Drainage (Sierra and Inyo National Forest 2200 Files, various dates; Muir, 1894; van Wagendonk and Parsons 1996; Debenedetti, 1979; and Belsky, 1999). This analysis documents conditions at assessed key area locations and concludes that while range conditions are likely improved relative to conditions in the early 1900s, riparian conditions are still degraded due to a combination of historical degradation and/or current impacts in many of these locations. This is consistent with the conclusion in Sierra Nevada Ecosystems in the Presence of Livestock (USFS, 1999, SNEP Report): "It follows then that grazed ecosystems in

the Sierra Nevada are now either in static, improving, or still declining condition because of those past abusive grazing practices.”

Continued loss of and reductions in vegetation and organic material, especially at locations with chronic cumulative historical adverse impacts, such as chronic reduced vegetation seral status due to historically incised streams, can slow or preclude establishment of late-seral, stabilizer, vegetation and delay ecological recovery. These chronic and synergistic adverse impacts are especially pronounced in meadow systems with historical degradation such as altered vegetation seral status (Kirchner, 1998; Sarr, 1995; Odion et al, 1988; Albert, 1982). This relationship has been recognized for many decades (Chapman in 1933; Cottam and Stewart, 1940; Sumner and Leonard, 1947).

For related discussions of existing conditions and historical uses of particular interest to this consequences analysis see the discussions in the Grazing Operations, Meadows, and Hydrologic Function sections and the site-specific discussions in the Mono Creek/Rock Creek (particularly Graveyard), Fish Creek/Convict/McGee, and Ansel Adams West Geographic Areas, of the Grazing Resources, section of Chapter 3 of this document.

Water Diversion and Impoundment

There have been historical water diversions and or impounds in many locations. In many of these locations local water diversions have had a minor localized effect, such as small ponds and temporary interruption of flows. These locations are not catalogued and have negligible cumulative impacts to the riparian vegetation resource. Historical and current water diversion or impoundment continue to have a substantial cumulative effect on the vegetation resources in the Ansel Adams East and Florence/Bear Geographic Areas, a lesser cumulative effect in the Ansel Adams West Area, and a negligible cumulative effect elsewhere in the project area. Other than the currently unknown area of long-term loss of riparian vegetation inundated by the water impoundment, the effects are concentrated in the stream channels and floodplains below the impoundments.

It is reasonably foreseeable that these effects are likely to continue, although slightly mitigated as water diversion and impoundment permits are renewed with new mitigations. The likely adverse cumulative impacts include continued chronic disturbance of and loss of the vegetation on in-stream bars and banks due to artificial changes in water flows and sediment delivery.

When combined with grazing and trampling-related direct and indirect effects in those same locations, the additive, cumulative effects will likely be reduced late-seral riparian vegetation, decreased vegetative cover, decreased vegetation needed to dissipate energy during high flow events, decreased bank stability, decreased vegetative ability to trap and hold sediment, and reduced water-holding capacity of the associated riparian meadows.

Mining

There are many locations where mineral exploration work has had a minor localized effect such as small rock pits or abandoned roads. These locations are not catalogued and have negligible cumulative impacts. There are a few locations where mining activities have historically affected the riparian vegetation or grazing resource and that impact continues today. In most locations, the actual mining activity occurred in relative dry and rocky sites. Often, there have been historical impacts such as a minor and localized loss of riparian vegetation due to construction of

mining infrastructure such as a cabin and roads or deposition of tailings or waste rock from the mining operation. The largest impacts are due to the associated use of pack stock and grazing in nearby meadows, are localized near the mining claims, and are similar to those described for historical grazing. Those locations include the meadows near the mining claims in McGee Creek, Fish Creek, Minaret Creek, Cabin Creek, Horton Creek, Gable Creek, Pine Creek, and Division Creek.

In riparian areas and meadows near these locations, there is usually a minor to moderate localized decrease in vegetation due to these chronic historical effects. These effects, along with the additive or synergistic effects of continued grazing and trampling of the vegetation, will likely be reduced in the vegetation needed to dissipate energy during high flow events, decreased vegetative ability to trap and hold sediment, and reduced water holding capacity of the riparian meadows.

Recreation Pack Stock

The historical recreation uses, including the use by large multiple day recreational stock group trips, are discussed in the Historical Visitor Use section of Chapter 3. The historical grazing by pack stock likely was in the same locations and merged with the grazing by production livestock. The historical cumulative effects of grazing associated with the larger recreational trips is likely the same as and indistinguishable from the effects of production livestock grazing in these same areas.

Recent pack stock use by private non-commercial groups, also discussed in the Historical Visitor Use section of Chapter 3, has likely been insignificant relative to and indistinguishable from the historical cumulative effects of production livestock grazing.

It is reasonably foreseeable that private stock use will continue to be low relative to commercial stock use and that the direct indirect and cumulative effects will be less for all alternatives except Alternative 5. It is unlikely that private stock use will increase significantly and will likely decline over the long-term as the region becomes increasingly urban and developed.

Fire Suppression

Wildfires were common in the thousands of years prior to extensive Euro-American settlement (Parsons and DeBenedetti 1979, Wood, 1975). Many common plants evolved with wildfires and exhibit specific fire-adapted traits, such as thick bark, fire-stimulated flowering, sprouting, and seed release and/or germination. In addition, fire affected the dynamics of biomass accumulation and nutrient cycling, and generated vegetation mosaics at a variety of spatial scales. Because fire influenced the dynamics of nearly all ecological processes, reduction of the influence of fire in these ecosystems because of fire suppression in the twentieth century (while not completely understood) has likely had widespread chronic cumulative effects, including increases in mature and decadent vegetation in the upland environments.

During the last century, suppression policies and modern equipment has cumulatively resulted in generally eliminating fires of low to moderate severity as a significant ecological process and has contributed to forest conditions of high vegetative fuel loads that result in high-severity fires. Thus, fires that affect significant portions of the landscape, which once varied considerably in severity, have been almost exclusively high-severity, large, stand-replacing fires during the last approximately 70 years.

Today the emphasis is shifting toward allow natural fires to burn and using prescribed fires when possible. It is reasonably foreseeable that this shift toward prescribed and prescribed-natural fire will continue and, over the very long-term will at least partially restore a more natural fire regime.

It is likely that fire suppression has had a direct effect on meadows and woody riparian vegetation types, such as aspen, and has had an indirect and cumulative adverse effect as increased upland vegetation due to fire suppression likely has resulted in reduced water and sediment availability which will continue over the long-term to very long-term. Although not catalogued, these effects are likely more common and more visible on the west-side of the Sierra than the east side due to larger areas of dense vegetation, including fire-adapted montane forest and other upland vegetation types.

Grazing Resources – Alternative - 1

Analysis

The most significant difference between Alternative 1 and the other alternatives is that Alternative 1, representing the “existing situation”, assumes little or no implementation of applicable standards in the Wilderness Plan and SNFPA such as site-specific special riparian feature (critical area) protection, utilization standards, and suitability determinations. There would be continued and repeated grazing use and associated impacts at or near existing levels of approximately 6,315 stock nights across the project area. This use would not be adjusted in response to monitoring of standards, existing condition, and trend. All meadows except those specifically closed by forest orders would be available for grazing, although use would probably continue mostly in those with recent reported use.

Without corrective management such as site containment there would be continued expansion of local moderate to severe direct effects of grazing and trampling, such as removal of vegetation, trampling of vegetation, and breaking of the vegetative sod layers in and near stock grazing areas and at stock holding sites in all geographic units. Indirect local and moderate adverse effects in these locations would include decreased late-seral vegetation, reduced vegetative cover, reduced vegetative litter, reduced root depth and density, and an increase in early and mid-seral vegetation.

Overnight stock holding, repeated trips to the same destinations, and repeated grazing uses would continue to be most common in the Fish Creek/Convict/McGee, Mono Creek/Rock Creek, and Ansel Adams East Geographic Areas. There would continue to be a general use pattern of turning the stock out to graze throughout the night, with drift fences used to hold stock in a general watershed area and little site-specific control of stock. The existing management situation results in multiple occurrences of these use patterns over one season or in consecutive seasons, with repeated adverse impacts often occurring prior to sites recovering from previous impacts.

With Alternative 1, there would be a decrease in acreage in late-seral riparian vegetation, especially in the Fish Creek, Mono Creek, Silver Divide, and Ansel Adams East areas relative to all other alternatives. Late-seral plants are stabilizers and are critical to sustaining meadow ecological processes over time (Winward, 2000). There would be a local major to moderate decrease in late-seral vegetation and decreased vegetative cover, decreased root depth and decreased root density, especially in locations experiencing repeated use and utilization above

approximately 25 percent (Olson-Rutz, et al, 1996; Cole, et al, 2004). There would be locally moderate to major adverse ecological impacts due to the loss of late-seral, stabilizer vegetation, especially in locations where the vegetative species composition has been adversely affected by historical uses and or natural events (see Table 3.30 and Table 3.31).

Without implementation of improved management controls, such as the Grazing Response Index (Reed, 1999), there would likely not be recovery of the vegetative resource to levels needed to sustain such meadow ecological processes such as providing protection during runoff events (USDI, 1998). There would be local moderate adverse impacts such as altered vegetative composition, with decreased plant production, vigor, cover, and structural diversity. This effect would be associated with stock access trails, grazing locations, campsites, and stock holding areas. Based on a review of recent research these adverse effects would be most pronounced in locations with repetitious use over a season or in consecutive seasons (Olson-Rutz, 1996; Moore, 2000; Cole, 2004).

There would be increased adverse impacts with Alternative 1 over the other alternatives and opportunities for vegetative recovery in fewer locations. The degradation of these riparian areas would become more noticeable over the long-term and many areas with current patterns of repeated use would eventually have to be closed to grazing.

It is reasonably foreseeable that there would be minor continued chronic effects and additive cumulative adverse impacts due to grazing and trampling related activities in almost all locations of the project area with implementation of Alternatives 1 through 4. It is reasonably foreseeable that these impacts would continue at local sites even with no commercial pack stock use (Alternative 5) due to private and administrative stock use and hiking use. There would be moderate to major continued chronic effects and synergistic cumulative adverse impacts due to grazing and trampling related activities in the west portion of the Ansel Adams Wilderness area, the Fish Creek area, and the Mono Creek Drainage.

Cumulative Effects

In locations with reduced vegetation seral status, whether due to the widespread and often abusive historic grazing practices, water diversions, or naturally occurring events, the continuing direct effects of commercial pack stock grazing and trampling combined with the risk of high intensity flood events (both rain-on-snow events and high intensity summer thunderstorms) or flow regulation such as below water impoundments, could result in a chronic increased risk of loss of riparian vegetation and in additional degradation of riparian conditions (see Table 3.36). Over the long-term, a cumulative effect of continued localized alteration of vegetative species composition and cover would be decreased resiliency of the ecosystem to disturbance due to events such as summer thunderstorms and spring runoff, with the loss exacerbated in locations where historical impacts include a lowering of the water table height.

The cumulative adverse effects of commercial pack stock grazing and grazing-related trailing and trampling of riparian vegetation combined with other past, present and foreseeable future actions are slightly greater for Alternative 1 than the other alternatives. They could be measurable and visible at the analysis unit scale and would be measurable and visible at the site specific-scale, and especially in the analysis units that have substantial vegetation areas still recovering from past chronic and cumulative adverse impacts due to the impacts of historical uses such as production livestock grazing, water diversion, or mining. These include the Glacier

Divide, Silver Peak, Cora, Sadler, Triple Divide, Lillian, Rush Creek, Upper Fish Creek, McGee, Hilton, Cascade Valley, Pioneer, Graveyard, Hooper, and Silver Divide Analysis Units.

Grazing Resources – Alternative 2-Modified

Analysis

Alternative 2 – Modified would identify an initial grazing capacity of approximately 15,559 stock nights in delineated grazing zones, with the number adjusted annually based on monitoring (see Table 2.30). This is the amount of grazing potentially available and it is unlikely that this level of grazing use would occur in any one year. Alternative 2 – Modified, similarly to Alternatives 2, 3, and 4, would implement grazing utilization standards, suitability determinations, and critical area protection. In Alternative 2 – Modified, critical areas are to be avoided entirely, different from Alternatives 2, 3, and 4, where there is a five percent inadvertent trampling allowance. Annual monitoring and permit administration through the Annual Operating Plan process would allow for adjustments in stock night numbers and management and would identify new key, critical, or unsuitable areas, within currently used grazing zones. Some use would be redirected to currently unused grazing zones or new areas over time.

Alternative 2 – Modified and Alternative 3 include the rest or closure of additional meadows (those with stream systems that are functioning at risk with a downward trend) relative to Alternative 2 (see Table 2.30). This will result in an immediate elimination or reduction of direct effects in six meadows, relative to Alternative 2, and will also accomplish this with a reduced need and expense for monitoring. The beneficial effect is that over the long-term the increased protection of these functional-at-risk areas, critical areas, and areas with special aquatic features, will help ensure maximum vegetative recruitment, growth, and recovery and will help ensure progress toward vegetative and ecological desired conditions at these sites. Implementation of the suitability recommendations and standards would also help prevent new adverse effects from developing in many of the sites that are currently not being used.

The implementation of suitability recommendations, allowable utilization and impact standards, and carefully designated campsite locations with Alternative 2 – Modified would help ensure that over the long-term impacts are evenly distributed and either reduced, mitigated, or the use reduced, as changes are implemented through the Annual Operating Plan (AOP) process in response to monitoring. There would likely be increased late-seral vegetation, increased vegetative cover, increased root density, and increased root depth in most of the identified key and critical areas.

Alternative 2 – Modified controls stock numbers primarily by implementation of grazing standards and also by limits on the numbers of trips to destinations. The number of animals per trip is normally limited to 25 head and group size to 15 persons. This may result in increased packing of feed and in increased overall stock numbers at destinations and on trails within a round-trip day-ride of trailheads as grazing limitations are increasingly implemented and as pack stations continually adapt to that implementation over the long-term. There would be increased active management of pack stock while grazing, with increased use of site-specific controls such as hobbles and temporary “quick corral” type fences. There would be increased stock management to avoid critical areas with a combination of site-specific controls and a trend toward only allowing stock to graze for a limited number of hours in the evening rather than leaving stock free to roam and graze all night. There would be increased packing of pellets and

hay cube type feed. Stock that are held in the wilderness overnight will be tied up in designated camps a larger percentage of the time relative to the existing management situation. There would be less dependence on drift fences to hold stock in a general vicinity as the various site-specific controls are implemented.

There would be a high reliance upon the wranglers to self-monitor and control the stock due to the combination of intermingled critical, unsuitable, and suitable areas within meadow complexes and the lack of site-specific or destination controls. Over the short-term to long-term, this may result in some increased trampling impacts to critical areas, and associated loss of late-seral riparian vegetation, and cumulatively over the long-term to very long-term, the consequence could be the need to identify site-specific controls and or the closure of specific locations to grazing use. The increased active management of pack stock and increased site-specific controls would result in additional work for operators or in additional wranglers being needed per trip. The increased packing of pellets and hay cube type feed and increased use of highlines could result in a loss of vegetative cover in and near designated stock holding areas relative to the existing management situation.

Annual monitoring and adaptation through the Annual Operating Plan process would be required and could frequently result in an identified need to cease using the more popular destination grazing areas in the short-term or closure of areas in the long-term. The effect over the long-term would be to distribute the use more evenly over the locations with designated campsites and to distribute the grazing use more evenly throughout grazing zones and into new areas. Overall, there will likely be increased late-seral vegetative status in most of the identified key and critical areas. Cumulative adverse effects such as decreased vegetative cover and structural diversity may increase in some locations as pack station operators disperse use and or move into new areas in response to closures and restrictions in existing use areas.

The nature and location of the effects associated with the designation of campsites and stock holding areas cannot be described in detail until the location and the spatial arrangement relative to trail crossings, critical areas, and grazing key areas is described.

In the long-term to very long-term the effects of implementing Alternative 2 – Modified may be increased impacts to riparian vegetation and critical areas near the more popular and accessible destinations, with the standards thresholds being reached more often and at more key areas at these locations. At these locations, there may be slightly increased risks of adverse impacts, relative to Alternatives 2, 3, 4, and 5, from events such as summer thunderstorms and spring run-off during the time it takes for monitoring and mitigation to be implemented through the Annual Operating Plan process and for vegetative recovery to occur following these adaptive management changes. Alternative 2 – Modified and Alternative 3 would both require the most frequent and extensive monitoring and allow the most flexibility and adaptation of the alternatives that allow grazing.

The impacts at the wilderness scale or geographic area scale would be negligible. If considering just the riparian areas as a focal point for use and resources the cumulative effects would be regionally minor to moderate and persistent over the long-term in some analysis units. Analysis units where adverse cumulative effects would likely continue to be noticeable over the long-term would be Glacier Divide, Silver Peak, Cascade Valley, Silver Divide, Hilton Lakes, Cora, Lillian, Fourth Recess, Upper Rush Creek, Rush Creek, Thousand Island, Margaret Lakes, Graveyard, Pioneer Basin, and Sadler.

As in Alternatives 1, 2, 3, and 4, the chronic adverse effects of grazing and grazing related trailing and trampling of riparian vegetation could be measurable and visible at the analysis unit scale and would be measurable and visible at the site specific scale, and especially in the analysis units that have substantial vegetation areas still recovering from past chronic and cumulative adverse impacts due to the impacts of historical uses such as production livestock grazing, water diversion, or mining. These include the Glacier Divide, Silver Peak, Cora, Sadler, Triple Divide, Lillian, Rush Creek, Upper Fish Creek, McGee, Hilton, Cascade Valley, Pioneer, Graveyard, Hooper, and Silver Divide Analysis Units.

Cumulative Effects

The cumulative effects of Alternative 2 – Modified with other past, present, and foreseeable actions, especially historic grazing, would be similar to Alternative 1, but would be slightly less intense. The cumulative adverse impacts at the overall wilderness scale or geographic area scale would be negligible. If considering just the riparian areas as a focal point for use and resources, the cumulative effects would be locally moderate and persistent over the long-term in some analysis units, at fewer locations than for Alternative 1 and 2 and more locations than Alternatives 3, 4 and 5.

Grazing Resources – Alternative 2

Analysis

Alternative 2 would identify an initial grazing capacity of approximately 11,386 stock nights of grazing use, with the number adjusted annually based on monitoring (see Table 2.30). With Alternative 2 grazing utilization standards, suitability determinations, and critical area protection would be implemented immediately. Annual monitoring and permit administration would allow for adjustments in stock night numbers and stock management. Monitoring would identify new key, critical, or unsuitable areas to be protected within currently used grazing zones.

In general, the effects of Alternative 2 would be similar to those of Alternative 2 – Modified, since there would be destination management, utilization standards, and most of the same meadows would be grazed. Some meadows that would be rested in Alternative 2 – Modified would be closed in Alternative 2. In critical areas, there would be a five percent allowable impact level, rather than the 20 percent as allowed in Alternative 1 or no impact (Alternatives 2 – Modified). Alternative 2 would decrease the trampling-related effects in critical areas and likely result in increased late-seral vegetation. There would be a high reliance upon the wranglers to self-monitor and control stock due to the combination of intermingled critical, unsuitable, and suitable areas within meadow complexes. Over the short-term to long-term this may result in increased trampling impacts to critical areas, an associated loss of late-seral riparian vegetation, and cumulatively over the long-term to very long-term the consequence could be the need to identify site-specific controls and or the closure of specific locations to grazing use.

The beneficial impact of implementation of Alternative 2 would be more rapid vegetative recovery in more locations than Alternative 1, but in fewer locations than Alternatives 2 – Modified, 3, 4, and 5. Successful protection of critical areas, with Alternatives 2, 2 – Modified, 3, and 4, would decrease the grazing related indirect effects in key and critical areas.

While there would be continued local and minor adverse effects, cumulative impacts at the overall wilderness scale or geographic area scale would be negligible. If considering just the

riparian areas as a focal point for use and resources the cumulative effects would be locally moderate and persistent over the long-term in some analysis units, at fewer locations than for Alternative 1, but more locations than Alternatives 2 – Modified, 3, 4, and 5.

Cumulative Effects

The cumulative effects of Alternative 2 with other past, present, and foreseeable actions, especially historic grazing, would be similar to Alternative 2 – Modified. The cumulative adverse impacts at the overall wilderness scale or geographic area scale would be negligible. If considering just the riparian areas as a focal point for use and resources, the cumulative effects would be locally moderate and persistent over the long-term in some analysis units, at fewer locations than for Alternative 1 and 2, and more locations than Alternatives 3, 4 and 5. Analysis units where adverse cumulative effects of historic grazing effects and continuing commercial pack stock use would likely continue to be noticeable over the long-term would be Glacier Divide, Silver Peak, Cascade Valley, Silver Divide, Hilton Lakes, Cora, Lillian, Fourth Recess, Upper Rush Creek, Rush Creek, Thousand Island, Margaret Lakes, Graveyard, Pioneer Basin, Hooper, and Sadler.

Grazing Resources – Alternative 3

Analysis

Alternative 3 would identify an initial grazing capacity of approximately 15,798 stock nights of grazing use, with the number adjusted annually based on monitoring (see Table 2.30). As with implementation of Alternative 2, and 2 – Modified, under Alternative 3 grazing utilization standards, suitability determinations, and critical area protection would be implemented immediately. Annual monitoring and permit administration will allow for adjustments in stock night numbers and management and will identify new key, critical, or unsuitable areas, within currently used grazing zones. Some use will be redirected to currently unused grazing zones.

Alternative 3 implements fewer controls at destinations within the wilderness. This change may result in increased overall grazing and related stock activities such as increased over-night stockholding, increased packing and feeding of supplemental feed, and multiple-day stock grazing use at the more accessible and popular destinations. For example, some operators could choose to pack feed to popular destinations that are within a day round-trip of the trailhead to allow them to continue using these popular destinations even after meadow use standards are reached. There would likely be more all expense and traveling type trips at destinations within a day-long round-trip of the trailheads, with increased use of the more accessible and/or popular destinations.

Alternatives 2 – Modified, 3, and 4 include the rest or closure of meadows with stream systems that are functioning at risk with a downward trend, while Alternative 4 also results in closure of meadows with severe hydrological function alteration. This will result in an immediate elimination or reduction of direct effects, in six meadows for Alternative 3, and 2 – Modified, and nine meadows for Alternative 4 relative to Alternative 2, and will result in a reduced need and expense for monitoring for these alternatives.

Alternative 3 includes the closure of more areas than Alternatives 1 and 2, fewer areas than Alternative 4. The beneficial impacts of closure of areas with degraded resource conditions would be the result of the immediate elimination or reduction of direct effects and more certain

resource protection and recovery. Identification and protection of critical areas would decrease the trampling related effects in critical areas and likely result in increased residual vegetation each year.

The chronic adverse effects of grazing and grazing related trailing and trampling of riparian vegetation would be similar to Alternative 2 – Modified, with slightly increased ecological risks at the more popular destinations relative to Alternatives 2, and 4, much increased relative to Alternative 5, and reduced relative to Alternative 1.

The implementation of suitability recommendations, Primary Operating Areas, allowable utilization and impact standards, and carefully designated campsite locations would help ensure that over the long-term impacts are evenly distributed and either reduced, mitigated, or the use reduced, as changes are implemented through the Annual Operating Plan (AOP) process in response to monitoring. Therefore, the long-term to very long-term adverse impacts would be those associated with ecological risks and would likely be slightly decreased at the more popular destinations relative to Alternatives 1, 2, 2 – Modified, and increased relative to Alternatives 4 and 5.

The reduced controls at destinations within the wilderness would result in additional impacts over the short-term and especially at the more popular destinations, for Alternative 3 relative to Alternatives 1, 2, 4, and 5. However, the implementation of suitability recommendations, Primary Operating Areas, allowable utilization and impacts standards, and designated campsite locations will help ensure that over the long-term impacts are evenly distributed and either reduced, mitigated, or the use reduced, as changes are implemented through the Annual Operating Plan (AOP) process in response to monitoring. With the implementation of Primary Operating Areas, the long-term, cumulative effects and associated ecological risks would likely be decreased at the more popular destinations relative to Alternatives 1, 2-Modified, 2, and 4.

In the short-term, the effects of implementing Alternative 3 may be increased impacts to riparian vegetation and critical areas near the more popular destinations, with the standards thresholds being reached more often and at more key areas at these locations. There may be slightly increased risks of adverse impacts, relative to Alternative 2, from events such as summer thunderstorms and spring run-off during the time it takes for monitoring and mitigation to be implemented through the AOP process and for vegetative recovery to occur following these adaptive management changes. Alternatives 3 and 2 – Modified would require the most frequent and extensive monitoring and adaptation of the alternatives that allow grazing.

Cumulative Effects

The cumulative effects of Alternative 3 with other past, present, and foreseeable actions, especially historic grazing, at the overall wilderness scale or geographic area scale would be negligible. If considering just the riparian areas as a focal point for use and resources, the cumulative effects would be regionally moderate, and persistent over the long-term in some analysis units, at fewer locations than for Alternative 1, 2, and 2 – Modified and at more locations than Alternative 4 and 5. Analysis units where adverse cumulative effects would likely continue to be noticeable over the long-term would be Glacier Divide, Silver Peak, Cascade Valley, Silver Divide, Hilton Lakes, Cora, Lillian, Fourth Recess, Upper Rush Creek, Rush Creek, Thousand Island, Margaret Lakes, Graveyard, Pioneer Basin, Hooper, and Sadler.

Grazing Resources – Alternative 4

Analysis

Alternative 4 would identify an initial grazing capacity of approximately 10,056 stock nights of grazing use, with the number adjusted annually based on monitoring (see Table 2.30). As with implementation of Alternatives 2, 2 – Modified, and 3, under Alternative 4 grazing utilization standards, suitability determinations, and critical area protection would be implemented immediately. Alternatives 3 and 4 include closure of additional meadows with stream systems that are functioning at risk with a downward trend. In addition, Alternative 4 also limits allowable use to 30 percent in meadows with stream systems that are functioning at risk with no apparent trend and eliminates grazing at Rodgers Lake and Baldwin and Martin's Meadows. This will result in an immediate reduction or elimination of direct effects at these sites and will be accompanied with a decreased need for associated monitoring. Alternative 4 would also implement a slightly lower allowable level of vegetation utilization in key areas functioning at risk, 30 percent rather than 40 percent for Alternative 3. The interdisciplinary team consistently noted that the indirect impacts associated with grazing, such as trampling of stream banks and trampling of critical areas was of concern well before allowable vegetation utilization levels were reached. Therefore, the change from 30 percent to 40 percent allowable utilization is not expected to have an appreciable effect. Therefore, in the discussions specific to geographic areas and analysis units, Alternatives 3 and 4 will be discussed together, with any anticipated differences noted in that discussion.

The chronic adverse effects of grazing and grazing related trailing and trampling of riparian vegetation would be similar to Alternative 2 – Modified but less at fewer locations and slightly less intense.

Over the long-term, the beneficial impact of increased protection of these functional-at-risk areas and critical areas would be increased vegetative growth, recruitment, retention, and recovery and progress toward vegetative and ecological desired conditions at these sites, relative to Alternatives 1, 2, 2 – Modified, and 3. There would be less vegetative retention, recruitment, and establishment than for Alternative 5. Implementation of the suitability recommendations and standards would also help prevent new adverse effects from developing in many of the sites that are currently not being used.

With implementation of Alternative 4, there would continue to be localized grazing and trampling related effects to vegetation within meadows, especially near designated campsites, but at lower levels than for Alternative 3. The effects associated with the designation of campsites and stock holding areas could be negligible if the process to designate campsite location also considers the spatial arrangement of meadows, grazing key areas, critical areas, and trail crossings.

In meadows and trailside riparian areas accessed by livestock, there would continue to be localized sites exhibiting a minor to moderate loss of late-seral vegetation. Over the long-term, there would be an increased ecological risk, mostly associated with trampling at stream crossings, at watering access sites, multiple access trails in grazing areas, at dusting locations near designated campsites, and associated with stock holding areas.

Implementation of Alternative 4 would allow for more certain improvement in vegetative resource conditions such as vegetative recruitment, establishment, and growth, with the least

monitoring workload of any of the alternatives (1, 2, 2 – Modified, and 3) that allow commercial pack stock grazing.

In locations with reduced vegetation seral status, whether due to historic grazing practices or due to naturally occurring events, the continuing direct effects of grazing and trampling combined with the risk of high intensity flood events (both rain-on-snow events and high intensity summer thunderstorms) or flow regulation such as below water impoundments, could result in a chronic cumulative increased risk of loss of riparian vegetation and in additional degradation of riparian conditions (see Table 3.36).

A beneficial effect would be that over the long-term the effects of increased protection of these functional-at-risk areas, critical areas, and areas with special aquatic features would help ensure maximum vegetative growth, recovery, and progress toward vegetative and ecological desired conditions at these sites. Implementation of the suitability recommendations and standards would also help prevent new adverse effects from developing in many of the sites that are currently not being used, as the direct effects of grazing use, such as trailing through meadows and trampling vegetation and sod fragmentation, are eliminated.

With implementation of Alternative 4 there would continue to be localized grazing and trampling related effects to vegetation within meadows where grazing would be permitted, especially near designated campsites, but at lower levels than for other grazing alternatives. In meadows and trailside riparian areas accessed by pack stock, there would continue to be localized sites exhibiting a loss of late-seral vegetation, mostly associated with trampling of vegetation and sod fragmentation at stream crossings, at watering access sites, multiple access trails in grazing areas, at dusting locations near designated campsites, and associated with stock holding areas. These effects would be noticeable at the site-specific scale but would not result in cumulative adverse ecological effects.

Implementation of Alternative 4 would allow for more certain improvement in vegetative resource conditions such as vegetative recruitment, establishment, and growth, with the least monitoring workload of any of the alternatives (1, 2, and 3) that allow commercial pack stock grazing.

There would be slightly reduced effects at campsites in popular destinations, slightly reduced effects due to reduced allowable use levels, and the more substantial reduced effects due to eliminating grazing Rodgers Lake, Baldwin, and Martin's Meadows. Otherwise, the grazing related effects to the riparian vegetative resource of Alternative 4 are not distinguishable from those of Alternative 3.

Cumulative Effects

The cumulative effects of Alternative 4 with other past, present, and foreseeable actions, especially historic grazing, at the wilderness scale or geographic area scale would be negligible. If considering just the riparian areas as a focal point for use and resources the cumulative effects would be regionally moderate and persistent over the long-term in some analysis units, and at fewer locations than for the other alternatives that allow grazing by commercial pack stock. Analysis units where adverse cumulative effects would likely continue to be noticeable over the long-term would be Glacier Divide, Silver Peak, Cascade Valley, Silver Divide, Hilton Lakes, Cora, Lillian, Fourth Recess, Upper Rush Creek, Rush Creek, Thousand Island, Margaret Lakes, Graveyard, Pioneer Basin, Hooper, and Sadler.

Grazing Resources – Alternative 5

Analysis

There would no commercial stock use other than an occasional use as needed for maintenance by the State Department of Water Resource or Department of Fish and Game, or for such uses as Forest contract trail work or for Forest Administrative purposes. There would be some private stock use, especially in the Cora, Fernandez, Sadler, McGee Creek, Hilton Creek, and Fish Creek areas. All these uses added together throughout the project area would likely be between 10 and 20 percent of current levels of commercial pack stock use.

There would be low recovery potential at sites where altered vegetative species composition, from late-seral and toward mid-seral or low-seral species, is associated with moderate or severe altered hydrological function, including loss of a water table. Continued access and use by hikers and private stock users in such sites could have a localized adverse effect on vegetative recovery. This effect would be most pronounced at high elevations, on sites with low or very low productivity, and in areas where altered vegetation is associated with altered hydrology and still active vertical or horizontal instability as manifested by headcuts, incised trails, or collapsing stream banks. These areas' vegetation may not appreciably recover for the very long-term.

A direct effect of no grazing would be minimal stock related trampling of and or loss of riparian vegetation in meadows, along access trails, in intermingled wet areas, at creek crossings, or associated with campsites and stock holding areas. In the short-term, the areas of bare soil in the fragmented sod and on the stream banks at these locations would rapidly be re-vegetated with late-seral species in those sites with adequate availability of moisture in the rooting zone.

A direct effect of no commercial pack stock authorization would be minimal stock related trampling of and or loss of riparian vegetation in meadows, along access trails, in intermingled wet areas, at creek crossings, or associated with campsites and stock holding areas. A beneficial cumulative impact would be that in the short-term the areas of bare soil in the fragmented sod and on the stream banks at these locations would be re-vegetated with late-seral species in those sites with adequate availability of moisture in the rooting zone. All drift fences would eventually be removed.

Implementation of Alternative 5 would allow for more certain improvement in vegetative resource conditions such as vegetative recruitment, establishment, and growth, with the least risk and least monitoring workload of any of the alternatives.

Over the very long-term, many locations currently characterized by observable alteration of vegetative species composition would be characterized by increased late-seral vegetation and increased vegetative production, vigor, structural diversity, increased cover, and decreased ecological risk.

Even without commercial pack stock grazing the chronic adverse effects of grazing and grazing related trailing and trampling of riparian vegetation could be measurable and visible at the analysis unit scale and would be measurable and visible at the site specific scale, and especially in the analysis units that have substantial vegetation areas still recovering from past chronic and cumulative adverse impacts due to the impacts of historical uses such as production livestock grazing, water diversion, or mining. These include the Glacier Divide, Silver Peak, Cora, Sadler, Triple Divide, Lillian, Rush Creek, Upper Fish Creek, McGee, Hilton, Cascade Valley, Pioneer, Graveyard, Hooper, and Silver Divide Analysis Units.

In locations with reduced vegetation seral status, whether due to historic grazing practices or due to naturally occurring events, the elimination of continuing direct effects of grazing and trampling may not result in short-term or long-term improvement due to the additive combined risk associated with high intensity flood events (both rain-on-snow events and high intensity summer thunderstorms) or flow regulation such as below water impoundments and continued grazing and grazing related trampling and trampling of riparian vegetation by private and administrative stock. The result could be a chronic cumulative increased risk of loss of riparian vegetation and in additional degradation of riparian conditions even under Alternative 5 through the long-term (see Table 3.36).

If considering just the riparian areas as a focal point for use and resources the cumulative effects would be regionally moderate, and persistent over the long-term in some analysis units, but at fewer locations than for any of the other alternatives as localized sites would continue to be maintained in low-seral or mid-seral vegetative status by episodic events such as flooding and fluvial deposition. There would also continue to be persistent chronic cumulative effects from over a century of production livestock grazing and from uses such as water diversion and impoundment. Analysis units where historical adverse cumulative effects would likely continue to be noticeable over the long-term to very long-term would be Glacier Divide, Silver Peak, Cascade Valley, Silver Divide, Hilton Lakes, Cora, Lillian, Fourth Recess, Upper Rush Creek, Rush Creek, Thousand Island, Margaret Lakes, Graveyard, Pioneer Basin, Hooper, and Sadler.

Cumulative Effects

Without authorized commercial pack stock, no additive cumulative effects of commercial pack stock grazing would occur in areas degraded by historic grazing use. Alternative 5 would allow the most recovery from historic grazing impacts. However, there would continue to be noticeable, chronic cumulative effects due to historical impacts and continued localized current impacts such as flow events, flow regulations, and private stock grazing. These adverse impacts include local moderate to major reduction in the vegetation needed to dissipate energy during high flow events, decreased vegetative ability to trap and hold sediment, and reduced water holding capacity of the riparian meadows in these analysis units and would continue to be most noticeable in the locations most affected by historical and current activities, the same as under the alternatives that allow commercial pack stock use. Alternative 5 would present the least long-term risk to the riparian resources of any of the alternatives.

Table 4.98 Summary of estimated grazing (stock nights) available by grazing alternative

Geographic Area	Alternative 1, Existing (Highest) Reported Grazing Use 2001-2003	Alternative 2 - Modified	Alternative 2	Alternative 3	Alternative 4

Fens

Analysis

Properly functioning fens have a saturated anaerobic environment that forms peat at a very slow rate, approximately 20 cm/1000 years (Cooper, pers. comm., PowerPoint presentation 11/03). Hoof action can add oxygen to the soil of fens, increasing the decomposition rate, and grazing itself removes some of the vegetative material that accumulates in fens. Hoof punching in wet soil can shear roots and eventually eliminate the rhizomatous species that are most likely to form fens, causing a vegetation composition shift toward non-peat forming taprooted and annual species (Cooper et al., 2004b). In sloping fens, on steeper slopes in particular, hoof disturbance of surface vegetation can cause peat to erode. Fens are also very sensitive to changes in ground water supply, so observed changes to hydrologic function could indicate a threat to the fen ecosystems. A preliminary limited study of cattle impacts to fens indicates that fens no longer function (accumulate organic matter) at 20 percent trampling (Cooper et al., 2004b), and function is at least somewhat impaired at lower levels of trampling. Although stock apparently prefer not walking through saturated soils (M. Morse, pers. comm.), the wet conditions often produce palatable forage longer than drier areas of a meadow, and impacts have been observed in these saturated areas in many locations.

The spring impacts noted are mostly local, from hoof punching, and would be expected to recover in a relatively short time, unless channeling of the water occurs that could dewater the fen. The rate of recovery from hoof punches appears to depend partly on the dominant plant species of the fen (USFS, 2004). Any changes to hydrologic condition such as those caused by headcuts and incision are more likely to be long-term and moderate to severe, although they may be local in extent.

Cumulative Impacts

Historic cattle and sheep grazing most likely initiated some of the moderately to severely degraded conditions in meadows with fens or fen characteristics. These historic effects are likely to be long-term and may be regional in extent. The current pack stock use is small compared with historic use, but recovery from historic effects may be slowed by pack stock grazing use.

In some areas, Little Lakes Valley particularly, hiking and fishing use are the main source of impacts to the meadows, since the area has not been used for pack stock grazing recently. Any pack stock grazing in areas like these could lead to additive damaging effects.

Private pack stock use would have impacts to fens similar to commercial pack stock use and the severity, extent, and cumulative effect of these impacts with commercial pack stock use would depend on use levels and location of use. Private pack stock use is not well documented, so the extent and location of effects is not well understood.

A Conservation Assessment for fens, outlining recommended management steps, will be started in 2005 and should provide guidelines for acceptable use and impacts when completed.

Fens – Alternative 1

If grazing continues at current levels and locations, approximately 65 percent of the known meadows with fens or fen characteristics are predicted to continue in good condition. Most of these meadows are only lightly used at present although they have a higher capacity (forage availability). There are also existing range readiness standards that help protect fens, since fens are never range ready because the soil is saturated all season. However, because most meadows would be open to grazing, any fens would be vulnerable to trampling in this alternative and more fens would remain in degraded conditions in this alternative than any other would. There would be a 20 percent trampling standard, so if the fens are monitored, no fen should become non-functional (Cooper, 2004). Existing degraded conditions at 16 meadows and along one trail would not recover. There is a widespread risk of local minor trampling effects and a low risk of local long-term changes to hydrologic condition in this alternative, higher risks than in the other alternatives.

Table 4.99 Predicted fen conditions by geographic unit (Alternative 1)

Geographic Unit	Total number of fens identified	Good conditions would continue*	Degraded conditions would improve	Degraded conditions would continue

BIHU	12	11	0	1
FLBE	2	2	0	0
JMSW	2	1	0	1
JMSE	0	0	0	0

Geographic Unit	Total number of fens identified	Good conditions would continue*	Degraded conditions would improve	Degraded conditions would continue
TOTALS	68 + 1 (trail)	44	3	21 + 1 (trail)

*If current grazing use remains constant, good conditions would continue, however, as grazing numbers approach capacity, conditions could degrade.

As a foreseeable action, approximately 24 meadows with fens or fen characteristics would be closed when suitability determinations are implemented as directed in the Wilderness Plan. In many of these meadows, the fact that large areas never reach range readiness was the cause of the unsuitable determination.

Cumulative Effects

The historic grazing damage, which is mostly the cause of degraded conditions, would have least chance of recovery in this alternative.

There would be no grazing restrictions in Little Lakes Valley or other high day use areas, so although no grazing use has occurred recently, there would be more of a risk of additive impacts to fens than the in the other alternatives.

Private pack stock use would most likely remain at current levels and not significantly increase risk to fens.

Fens – Alternative 2 – Modified

In this alternative, fens would be “critical areas”, as well as never range ready, and protected by direction to avoid grazing in critical areas entirely, reducing the risk of degrading fens to a minimum. The effectiveness of these standards depends on the Forest Service having enough funds and personnel to complete monitoring or the packers doing effective self-monitoring. Given the projected funding levels at or below current funding, it is unlikely that the Forest Service will be able to monitor at most locations, so most of the monitoring would fall on the packers, who would have to be trained in recognizing fens. If wranglers understand range readiness and keep stock out of areas that are not range ready, fens will be protected since they are wetlands that are never range ready. The packers would also have to keep more accurate records of stock numbers and location of use, and be timelier with reports than they have been in many cases for the monitoring to be successful.

This alternative also includes destination management that allows better control of use in areas with special resource features and concerns. The destination management framework should alert permit administrators to the presence of fens and indicate which meadows are of most concern. Given that most of the fens are currently in good condition and that destinations would be managed taking known fens into account, the condition of most fens would be maintained or improved.

In this alternative four of the meadows with fens at risk will be closed or rested, which should improve their condition a long-term beneficial effect, however, some meadows that are not currently grazed may receive use if grazing patterns shift because of restrictions, particularly near the Fish Creek/Silver Divide area.

Table 4.100: Predicted fen conditions by geographic unit (Alternative 2 - Modified)

Geographic Unit	Total number of fens identified	Good conditions would continue*	Degraded conditions would improve	Degraded conditions would continue
AA East	14 + 1 (trail)	8	1 + 1 (trail)	5
AA West	6	2	3	1
FICM	14	10	1	3

FLOB	2	2	0	0
JMSW	2	1	0	1
JMSE	0	0	0	0
TOTALS	68 + 1 (trail)	47	8 + 1 (trail)	13

*If current grazing use remains constant, good conditions would continue, however, as grazing numbers approach capacity, conditions could degrade.

The reduction in use and the limited stays in Cascade Valley should improve the condition of the meadows with fens or fen characteristics in that area.

Fens – Alternative 2

In Alternative 2, no grazing would be planned in the “critical areas”, but they would have a 5 percent inadvertent trampling limit. Otherwise, management would be very similar to Alternative 2 – Modified; only four meadows would have different management (Stevenson, Ram, Purple, and Middle Graveyard). Only in Middle Graveyard would be a continuation of degraded conditions rather than a slight improvement, would the predicted meadow conditions be different than Alternative 2 – Modified.

Table 4.101: Predicted fen conditions by geographic unit (Alternative 2)

Geographic Unit	Total number of fens identified	Good conditions would continue*	Degraded conditions would improve	Degraded conditions would continue
AAEast	14 + 1 (trail)	8	1 + 1 (trail)	5
AAWest	6	2	3	1
FCM	14	10	1	3
MORO	18	13	1	4
BIH	12	11	1	0
FLO	2	2	0	0
JMSW	2	1	0	1
JMSE	0	0	0	0
TOTALS	68 + 1 (trail)	47	7 + 1 (trail)	14

*If current grazing use remains constant, good conditions would continue, however, as grazing numbers approach capacity, conditions could degrade.

Fens – Alternative 3

The effects to fens would be the same as Alternative 2 – Modified (Table 4.101), but the management is slightly different. Several meadows that would be rested in Alternative 2 – Modified would be called unsuitable and closed under Alternative 3. Because there is no specific destination management, there would be less control of use in sensitive areas, although the same five percent trampling standard for critical areas would apply as in Alternative 2.

Fens – Alternative 4

Under this alternative, fewer fens would be at risk of degrading and more degraded fens would begin recovery than in Alternatives 1, 2 – Modified, 2, and 3, because any meadow with existing moderate to severe hydrologic function problems would be closed, including some that would not be expected to recover in the time frame of the pack station permits, even without commercial pack stock use. There would also be a lower utilization rate for any open meadow with hydrologic function or stream problems, reducing the impact.

The lack of destination management gives less control of use in sensitive areas than Alternative 2 – Modified and Alternative 2. The strategy for protecting fens with a five percent trampling standard would be the same as Alternative 2. There would be less protection than in Alternative 5, since most of the risk to fens is from commercial pack stock. There would be a long-term local improvement in fen conditions.

Table 4.102: Predicted fen conditions by geographic unit (Alternative 4)

Geographic Unit	Total number of fens identified	Good conditions would continue*	Degraded conditions would improve	Degraded conditions would continue
AA East	14 +1 (trail)	8	1 +1(trail)	5
AA West	6	2	3	1
FICM	14	10	1	3
MORO	18	13	3	2
BIHU	12	11	1	0
FLOB	2	2	0	0
JMSW	2	1	0	1
JMSE	0	0	0	0
TOTALS	68 +1 (trail)	47	9 +1 (trail)	12

*If current grazing use remains constant, good conditions would continue, however, as grazing numbers approach capacity, conditions could degrade.

Fens – Alternative 5

Since most of the risk to fens is from commercial pack stock grazing activities, Alternative 5 would provide the best protection for fens. The direct impacts to fens from trampling and grazing

by commercial pack stock would be completely removed in this alternative. The condition of fens that have existing trampling impacts would remain constant or improve as the current impacts heal. In meadows where there are currently changes to hydrologic function, it is expected that the condition will improve more quickly without the presence of pack stock, although some would not be expected to recover in the time span of a pack stock permit. There will be no other fens in the AA/JM Wilderness placed at risk due to any shift in pack stock use; however, if use shifts to non-wilderness areas, there could be more impacts there. Several fens are known from meadows outside the wilderness boundary on the Sierra NF. There will still be minimal compaction and trampling impacts from hikers, anglers, and private pack stock. Private pack stock use could increase if commercial service is not allowed, and in that case, there could be riders with less stock knowledge and experience handling the grazing.

Rare Plants and Weeds

Methodology

Context: The context of the impact considers whether the impact would be local or regional. For the purposes of this analysis, local impacts would refer to impacts on one plant population or potential habitat area within the wilderness. Regional impacts would be impacts to rare plant species over their known range. The ranges of the rare plants differ greatly in extent, from only occurring in one wilderness to circumboreal with a southern limit in these wilderness areas. For fens and weeds, regional includes the wilderness and areas within a few miles of the borders of the wilderness areas.

Intensity: The intensity of the impact considers whether the impact would be negligible, minor, moderate, or major. Negligible impacts are effects considered detectable but having no principal effect on biological resources. Minor impacts are effects that are detectable but not expected to have an overall effect on natural community structure. Moderate impacts would be clearly detectable and could have an appreciable effect on individual plants, habitat or potential habitat, including community ecology or natural processes. Major impacts would have a substantial, highly noticeable influence on natural resources. This would include impacts that have a

substantial effect on individual plants, habitat, or potential habitat, including community ecology or natural processes.

The intensity of the impact also considers whether the level of risk of a damaging impact would be very low, slight, moderate, or high. Examples would be the risk of pack stock trampling a rare plant near a trail or the risk of non-native species invading farther into the wilderness.

Duration: The duration of the impact considers whether the impacts would occur in the short-term or the long-term. A short-term impact would be temporary, not persisting from year to year, such as grazing within appropriate utilization and trampling standards. Long-term impact would have a permanent effect on the environment, such as altering ecological processes of meadows, streams or riparian areas.

Type of Impact: The type of impact considers whether the impact would be beneficial or adverse to biological resources. Effects to biological resources are considered beneficial if an action results in an increase in rare species or habitat components, improved native ecosystem processes, native species richness/diversity, habitat quantity or quality.

Rare Plants

Analysis Common to All Alternatives

There is essentially no species-specific research describing effects of pack stock or trail use on the species of rare plants known to occur or with potential habitat within the AA/JM Wildernesses. Effects of commercial pack stock use on plants in general include direct effects such as trampling (crushing plants, soil compaction, shearing, or dislodging soil particles) and removal of plant tissue by grazing (McClaran and Cole 1993). Chances of inadvertently damaging known, or as yet undiscovered, rare plant populations and their habitat increases as the level of ground disturbing activities increases (SNFPA, 2001). Removal of vegetation by grazing would be considered a short-term, minor, local effect in most cases if use levels were within FS utilization standards. The duration and severity of trampling effects are dependent upon site conditions, including soil moisture, soil type, and vegetation type.

Riparian habitats are generally more vulnerable to trampling impacts than rock outcrop or upland habitats. Soil shearing (hoof punching) can sever roots and is more likely when soil is wet. More generally, trampling and chiseling can change the hydrologic function of a meadow or the condition of a stream by causing soil compaction, sod fragmentation, increased bare ground, and changes in vegetation composition (Hagberg, 1995). Hydrologic function of a meadow supports the habitat of the rare plants, and changes to hydrologic function are a threat to the availability of water to plants. Water levels appear to be the main factor determining vegetation types in a meadow (Allen-Diaz, 1991). Hydrologic function changes are usually long-term, but mostly local in extent; except in areas with hydroelectric facilities, where effects are more widespread.

Trails through meadows and other riparian areas also have more effects than in rocky habitats, and a few populations of the known riparian rare plants are near trails or in meadows with moderate to severe trail effects. In meadows, trail incision or headcuts originating from trails can lead to changes in hydrologic function and alteration of the habitat for rare plants.

Although riparian habitats are most vulnerable to damage from pack stock and trails, most of the known rare plant populations (59) are in rocky or upland habitats and trails are the main source of impacts to these populations. Species that grow in rock outcrops are at a very low risk of

impacts from pack stock or trail activities because they grow in rock crevices or sandy spots between boulders, areas where there is little use and difficult access. Most of the activities in this habitat are limited to the trail tread. Plant populations bisected by or near trails may be affected by hiker and pack stock use in the trail tread, trail construction activities, trail erosion problems (soil removal or deposition), and hikers and pack stock leaving the trail to allow passage of a pack string, other hikers, or to avoid an obstacle. The impacts caused by leaving the trail tread would increase with the number of encounters more than with the number in a pack string or hiking party. If the condition of a trail is degraded, it may affect rare plant habitat by increasing soil erosion or changing water availability. Only one (Timber Creek Trail in AA West) of the trails with rare plants had a rating of moderate concern; the other seven trails near rare plant populations that were rated had lower ratings (less concern).

The trail class designations affect maintenance levels and to a limited extent, the use levels of trails. Primary use system trails (TC4, TC3, and high-use TC2) are likely to receive basic maintenance on a regular but limited basis and heavy maintenance or reconstruction at a 20/30 year interval. Trails with higher development and maintenance are more likely to remain stable with stock use. Secondary use system trails (low-use TC2 or TC1) are likely to receive little or no maintenance. Maintenance activities include moving rocks and soil and could affect rare plant populations, however any major rebuilding efforts would be done only after additional NEPA analysis. On trails that receive little maintenance, there is more likelihood of pack stock and hikers detouring around obstacles that may remain for long periods of time. Use trails are not maintained by the Forest Service, but packers may do some maintenance that could disturb habitat.

No rare plant populations are known at any of the campsites normally used by the pack stations, but use by clients is not limited and there is a small risk of trampling by clients to rare plant populations and habitat. This would be the same risk as from any hiker.

Thirty sensitive and watch list plant populations are in remote locations unaffected by pack stock use or trail use or activities and effects will not change among alternatives.

Past, Present, and Foreseeable Actions

The viability of rare plant species depends on not just the numbers of individual plants, but on the numbers of populations of the species. For most of the species considered in this analysis, there are more populations outside than inside the AA/JM Wildernesses, and they are subject to many other types of impacts than commercial pack stock and trail management. See Table 1 in the BE for recorded threats to the sensitive species. Impacts from other recreational activities in the wilderness may have additive effects with commercial pack stock or trail maintenance activities on individual populations of rare plants. Activities outside the wilderness, such as motorized recreation, large-scale mining, or construction activities, often have wider impacts and are more likely to affect a species as a whole. Populations in the wilderness enjoy more protection from human activities in general compared to those outside.

Recreational activities of various types other than commercial pack stock are listed as threats to populations of 32 of the sensitive plant species (CNDDDB, USFS files). In order of frequency of expressed concern are: hikers, OHV use, camping, mountain bikes, rock-climbing, and a ski area. The main impact of the non-motorized/wheeled activities is trampling or crushing, with effects as described for pack stock. In addition to crushing, soil disturbance is likely with OHV

use, mountain biking, and the ski area, and its duration, extent and severity would depend on the intensity of use. Ground disturbing activities at the ski area (on FS land) would be subject to the NEPA process. Impacts from rock climbing include removal of vegetation from rock faces to improve holds in addition to trampling during access to climbing sites. Private pack stock also affects these species in the AA/JM and other areas, and would have similar effects to commercial pack stock. For all these activities, impacts increase with number of users.

Roads, livestock grazing (cattle and sheep), timber management activities, hydroelectric facilities (dams and transmission lines), mining, or housing development have impacts on at least 27 of the rare species under consideration. Cattle grazing is still occurring in some areas on the west side and was only recently removed from others. Many severe and lasting impacts to stream conditions and meadows hydrologic function are a result of this use, and the impacts are great compared to that of commercial pack stock. Mining operations occurred in many locations (Convict, Hilton, McGee, Shadow-Ediza, Silver Divide, etc.), developing some of the roads and trails and affecting some of the riparian areas. These mining operations usually have only a local effect but it is long-term and the actual level of impact depends on the individual operation. Large reservoirs were constructed, inundating habitat and populations of Mono Hot Springs primrose (collection from Vermillion Valley) and possibly other species. The construction of these reservoir systems also altered the hydrology of some meadows with potential habitat for riparian sensitive species. Weed populations developed on access routes and other disturbed areas around these reservoirs (Florence, Edison, Rush Creek) that provide a seed source for expansion of the weed populations into the wilderness, reducing habitat quality for rare species. The effects from these reservoirs are long-term, of moderate extent, and locally severe. The effects of commercial pack stock are very small in comparison to those of dam construction and the removal of stock from meadows affected by dams would probably have very little effect on meadow condition.

Although very hot wildfires are listed as a threat to one species, fires may also have a beneficial effect for plants that need open habitat. For example, the Rainbow fire has apparently had a beneficial effect on the short-leaved hulsea and there is a current habitat improvement project for Father Crowley's lupine that uses controlled burning.

Over-collecting or illegal collecting are threats to species that are used in horticulture, like bitterroot and bleeding heart. Feral horses were also listed as a threat to one species.

The Pack station Permit Renewal process is currently underway and will be completed after this decision is reached. Wilderness use will be as directed in the decision for the current process.

Rare Plants – Alternative 1

Use on the 61 trails near or bisecting sensitive plant occurrences would be similar to the current use. In this Alternative, nine of those trails would be TC4 (four for hiker only), thirty-three would be TC3, eight would be TC2, six would be TC1, four use trails would be approved for stock (one for hunting only).

The trail classes in this alternative would be the highest of any alternative and trail maintenance impacts would be more likely, however any impacts would be local, minor, and short-term. In this alternative, trail classes are not well matched to actual trail use and recreation category, so there is a higher risk of damage to trails and their surroundings because they are being used in ways other than was originally designed.

Eleven sensitive and watch list riparian plant populations are in meadows that would be open to commercial pack stock grazing, so there would be a risk of trampling to individual plants, but the effects would not be significant. There are two additional populations of sensitive upland species near meadows that are grazed that would be at a very low risk of trampling impacts. Of these, only one, Jackass, has degraded conditions and those conditions would be expected to continue, putting the population of Yosemite mousetail at risk. Because the major cause of hydrologic change and the stream impacts in this meadow is the Florence Dam, removal of pack stock use would not improve the meadow conditions. All but 2 of the 529 meadows with potential habitat for riparian sensitive species would be open for grazing and, of the 23 of these meadows found to have degraded conditions, 16 would remain in degraded condition, putting the potential habitat at risk. Most of the degraded conditions that would remain are due to historic cattle use or reservoir construction and are long-term, moderate to severe, and regional effects.

Table 4.104: Summary of effects to rare plant populations and potential habitat for riparian sensitive plants (Alternative 1). The predictions for the approximate number of meadows remaining or becoming degraded is based on grazing use continuing at current levels.

Geographic Unit	Total # known populations	No known trail or pack stock threats	On or near open trails		In meadows open to grazing	Meadows with potential habitat for rare plants	Potential habitat open for grazing	Potential habitat remaining/ becoming degraded
			All use	Hiker only

MORO	6 (one with 2 trails)	2	3	1	0	1 (hiker only)
BIH	6	0	3 (1 NSCS)	0	0	3 (2 hiker only)
FLB	4 (one with 2 trails)	0	3	0	2	0
JMSW	0	0	0	0	0	0
JMSE	21	7 (4 hiker only)	6	5	1	2
TOTALS	61 (2 with 2 trails)	9 (4 hiker only)	33	8	6	7 (3 hiker only)

Cumulative Effects

At current use levels, the cumulative effects of the past, present, and foreseeable activities, listed above, plus pack stock and trail management in Alternative 1 are not expected to cause a trend toward listing for any of the rare plant species. However, Alternative 1 has the highest likelihood of additive effects, especially on riparian resources.

Rare Plants – Alternative 2 - Modified

The destination management in this alternative allows more control of commercial pack stock use in rare plant habitat than Alternatives 1, 3, and 4. Because grazing would be restricted to grazing zones and suitable meadows, the number of meadows with potential habitat for rare plants that would be open for grazing is much smaller than in Alternative 1 (116 compared to 527). However, because the grazing zones were based on areas of current use, actual use would be expected to be at current levels unless a specific meadow closure causes displacement of grazing use. The closures and one-night stay limit in Fish Creek/Silver Divide would be most likely to cause displacement of grazing or increases in packing of feed, but the reduced risk of trampling to the riparian habitat more than balances the very slight increase in risk to rare plants along trails. There would be direction for no grazing in the fen habitat for the two *Meesia* species and round-leaved sundew (see fen discussion above). In this alternative, the trail plan aligns trail class/maintenance levels more closely with actual use and design, so there should be fewer trail impacts to rare plant populations and habitat.

Table 4.106 summarizes effects to rare plant populations. Differences from Alternative 1 include: two more populations (32 total) of rare plants would have no pack stock or trail impacts because there would be no access for commercial stock; two of the trails near rare plants that are open to pack stock use in Alternative 1 would be for hikers only in Alternative 2 – Modified; one less meadow with a rare plant population would be open for grazing; two meadows expected to continue in degraded condition under Alternative 1 would improve under Alternative 2 – Modified, but two others could receive more use. Of the 13 meadows within the elevation range of the west side riparian sensitive species with degraded conditions, 7 could receive more use, 4 would have less than current reported use, and the use would be unchanged at 2 meadows. Three of those with more planned use, Chetwood, Detachment, and Knoblock, were surveyed in 2004 and no sensitive plants were found.

Table 4.106 Summary of effects to rare plant populations and potential habitat for riparian sensitive plants (Alternative 2 - Modified). The predictions for the number of meadows remaining or becoming degraded is based on grazing use continuing at current levels.

Geographic Unit	Total # known populations	No threats from pack stock or trails	On or near open trails		In meadows open to grazing	Meadows with potential habitat for rare plants	Potential habitat open for grazing	Potential habitat remaining/ becoming degraded
			All	Hk

	104	32	51	10	11	529	116	16

Table 4.107: Trail classes of trails with populations of rare plants in Alternative 2 – Modified.

Geographic Unit	Total # populations/ habitat along trails	TC4	TC3	TC2	TC1	Use
AAEast	4	0	1	1 (no pack stock)	1	1 (hunting only)
AAWest	18 (one with 2 trails)	0	9	7	2	0
FCM	2	0	2	0	0	0
MORO	6 (one with 2 trails)	0	3	2	0	1 (hiker only)

Geographic Unit	Total # populations/habitat along trails	TC4	TC3	TC2	TC1	Use
BIH	6	0	2	3 (2 NSCS)	0	1 (hiker only)
FLB	4 (one with 2 trails)	0	3	2	0	0
JMSW	0	0	0	0	0	0
JMSE	21	4 (hiker only)	3	10 (2 NSCS)	1 NSCS	3
TOTALS	61 (3 with 2 trails)	4 (hiker only)	23	25 (5 no pack stock)	4 (1 NSCS)	6 (1 hunting only, 2 hiker only)

There would be no expected displacement of pack stock activity outside the wilderness, so those populations of sensitive plants outside these two wilderness areas would not be affected in this Alternative.

Cumulative Effects

At current use levels, the cumulative effects of the past, present, and foreseeable activities, listed above, and pack stock and trail management in Alternative 2 – Modified are not expected to cause a trend toward listing for any of the rare plant species. Because Alternative 2 – Modified has destination management, rested meadows with resource damage, and better trail/use alignment, it would have fewer additive impacts than Alternatives 1, 2, and 3.

Alternative 2

The effects of Alternative 2 would be the same as Alternative 2 – Modified, except that although no grazing would be planned in critical areas, there would also be a 5 percent inadvertent trampling limit set to allow for inadvertent entry.

Cumulative Effects

At current use levels, the cumulative effects of the past, present, and foreseeable activities, listed above, and pack stock and trail management in Alternative 2 are not expected to cause a trend toward listing for any of the rare plant species. Because Alternative 2 has destination management and better trail/use alignment, it would have fewer additive impacts than Alternatives 1, about the same as Alternative 3.

Alternative 3

The trailhead quota system of this alternative provides less control over site-specific commercial pack stock use that may affect rare plant populations and habitat. Grazing management would be similar to Alternative 2 – Modified, but three more meadows with degraded conditions would be closed to grazing. The trampling standard for fen habitat would be 5 percent, as in Alternative 2.

Under this alternative, the trail classes, and associated use and maintenance, would be lower than Alternatives 1, but higher than Alternatives 2 - Modified, 4 and 5.

There would be no expected displacement of pack stock activity outside the wilderness, so the populations of sensitive plants outside these two wilderness areas would not be affected in this Alternative.

Table 4.108 Summary of effects to rare plant populations and potential habitat for riparian sensitive plants (Alternative 3). The predictions for the number of meadows remaining or becoming degraded is based on grazing use continuing at current levels.

Geo Unit	Total # known populations	No known pack stock or trail threats	On or near open trails		In meadows open to grazing	Meadows with potential habitat for rare plants	Potential habitat open for grazing	Potential habitat remaining/becoming degraded
			All	Hk

JMSW	3	2	0	0	1	178	4	1 (due to private pack-stock)
JMSE	31	10	14	7	0	0	0	0
	104	32	51	11	11	529	116	16

Table 4.109: Trail classes of trails with populations of rare plants in Alternative 3.

Geographic Unit	Total # populations/habitat along trails	TC4	TC3	TC2	TC1	Use
AA East	4	0	1	1	1	1
AA West	18 (one with 2 trails)	0	14	3	1	0
FCM	2	0	2	0	0	0
MORO	5 (one with 2 trails)	0	5	0	0	1 (hiker only)
BIH	6	0	2	3 (2 NSCS)	0	1 (hiker only)
FLB	4 (one with 2 trails)	0	3	2	0	0
JMSW	0	0	0	0	0	0

Geographic Unit	Total # populations/habitat along trails	TC4	TC3	TC2	TC1	Use
JMSE	21	4 (hiker only)	3	10 (2 NSCS)	1 NSCS	3
TOTALS	61 (3 with 2 trails)	4 (hiker only)	24	23 (5 no pack stock)	4 (1 NSCS)	6 (1 hunting only, 2 hiker only)

Cumulative Effects

At current use levels, the cumulative effects of the past, present, and foreseeable activities, listed above, and pack stock and trail management in Alternative 3 are not expected to cause a trend toward listing for any of the rare plant species. Because Alternative 3 has more closed meadows and better trail/use alignment, it would have fewer additive impacts than Alternatives 1, about the same as Alternative 2.

Alternative 4 – Rare Plants

This alternative has the lowest use levels and trail classes of any of the action alternatives, which reduces the risk of impacts to rare plants. There is a trailhead quota system with lower quotas in areas with resource concerns, but fewer site-specific management options than Alternative 2 – Modified. Grazing and fen management would be similar to Alternative 2 – Modified, but with a few more meadows closed.

Compared to Alternatives 1, 2, and 3, more plants are remote from pack stock and trail impacts, fewer meadows with rare plant populations would be open for grazing, and meadows with degraded conditions would have the best chance of recovery.

There could be some displacement of pack stock activity outside the wilderness because of grazing and other restrictions in this alternative, so those populations of sensitive plants outside these two wilderness areas, roughly 80 percent of the known populations in California and Nevada, could be at somewhat higher risk of negative impacts. This risk would be lower than in Alternative 5. Most of the nearby populations where increased use might be expected are either on National Forest or National Park land and would be regulated to protect sensitive plants.

Table 4.110 Summary of effects to rare plant populations and potential habitat for riparian sensitive plants (Alternative 4). The predictions for the number of meadows remaining or becoming degraded are based on grazing use continuing at current levels.

Geographic Unit	Total # known populations	No threats from pack stock or trails	On or near open trails		In meadows open to grazing	Meadows with potential habitat for rare plants	Potential habitat open for grazing	Potential habitat remaining/becoming degraded

Cumulative Effects

At current use levels, the cumulative effects of the past, present, and foreseeable activities, listed above, and pack stock and trail management in Alternative 4 are not expected to cause a trend toward listing for any of the rare plant species. Because Alternative 4 has more closed meadows

and better trail/use alignment, it would have fewer additive impacts than Alternatives 1, 2-Modified, 2, and 3.

Alternative 5 – Rare Plants

There would be no commercial pack stock use in the wilderness, so the existing populations of sensitive, proposed sensitive, and watch list plants will have no direct impacts from pack stock. The hydrologic conditions in meadows (habitats for sensitive riparian species) will likely improve without the trampling and compaction effects of the stock. These effects would be beneficial in the long-term and wilderness-wide. The level of improvement would depend on the condition of the individual meadow.

If commercial pack stock use were allowed outside the wilderness, one watch list riparian plant population would be in a meadow (Jackass) with possible pack stock use. This meadow has degraded conditions and those conditions would be expected to continue, putting the population of Yosemite mouse-tail at risk. Because the major cause of hydrologic change and the stream impacts is the Florence Dam, removal of pack stock use would not improve the meadow conditions.

Although there would be no commercial pack stock grazing, degraded conditions would continue at 12 of the meadows with potential habitat for riparian sensitive species because recovery would be very, very slow from historic cattle and dam construction effects. Private pack stock use could increase under this alternative, so there would still be a very small risk of pack stock impacts to the populations or potential habitat for rare plants.

Table 4.112: Summary of effects to rare plant populations and potential habitat for riparian sensitive plants (Alternative 5). The predictions for the number of meadows remaining or becoming degraded are based on grazing use continuing at current levels.

Geographic Unit	Total # known populations	No threats from commercial pack stock or trails	On or near open trails (no commercial pack-stock)	In meadows open to commercial pack stock grazing	Meadows with potential habitat for rare plants	Potential habitat open for grazing (commercial pack stock)	Potential habitat remaining/becoming degraded

Table 4.113: Trail classes of trails with populations of rare plants in Alternative 5

Geographic Unit	Total # populations/habitat along trails	TC4 – No comm. pack stock	TC3 – No comm. pack stock	TC2 – No comm. pack stock	TC1 – No comm. pack stock	Use – No comm. pack stock
AA East	4	0	1	1	1	1
AA West	17 (one with 2 trails)	0	7	9	1	0
FCM	2	0	1	1	0	0
MORO	6 (one with 2 trails)	0	3	3	0	1
BIH	6	0	2	2	0	2
FLB	4 (one with 2 trails)	0	3	2	0	0
JMSW	0	0	0	0	0	0
JMSE	21	4 (hiker only)	3	10 (2 NSCS)	1 NSCS	3
TOTALS	60 (3 with 2 trails)	4 (hiker only)	23	23 (5 no pack stock)	4 (1 NSCS)	6 (1 hunting only, 2 hiker only)

Pack stock use may be displaced to non-wilderness locations or nearby National Forests or National Parks, where impacts could increase on several populations of sensitive plants. About 80 percent of the known populations of rare plants that occur or have potential habitat in the AA/JM Wildernesses occur outside the wilderness boundary. Areas of particular concern are the Golden Trout Wilderness, the meadows west of the wilderness on the Sierra NF, Yosemite NP and Sequoia-Kings Canyon NP. The National Forest and National Park locations would have management in place to protect these plant populations, so the risk would not be great.

Cumulative Effects

At current use levels, the cumulative effects of the past, present, and foreseeable activities, listed above, trail management in Alternative 5 not expected to cause a trend toward listing for any of the rare plant species and there would be no commercial pack stock use. Because Alternative 5 has no commercial pack stock use, it has fewer additive impacts than any of the other

alternatives. However, use outside the wilderness and private pack stock use would probably be higher, so pack stock effects would more likely be shifted than eliminated.

Weeds

Analysis and Cumulative Impacts

Ecosystem health is threatened by the spread of non-native weeds. They reduce native biodiversity, affect threatened, endangered and sensitive (TES) species, reduce wildlife habitat quality, modify vegetative structure and species composition, change fire and nutrient cycles, and degrade soil structure. Weed propagules can be carried into the wilderness by any users, including pack stock, hikers, and maintenance personnel. Weedy species are most likely to invade areas of disturbed soil, but are able to invade intact ecosystems as well. Lower elevations are more vulnerable to weed invasion because of more favorable temperature and moisture regimes. If new weed populations become established, the effects are likely to be long-term, widespread, and moderate to severe.

There are relatively few weed populations in the wilderness now, mostly in areas where there has been soil disturbance, such as around the reservoirs, or where fires occurred, such as in Cascade Valley. Trail construction or major repair could provide sites for establishment of weeds. In some cases, weeds that have been present for a long time, at trailheads or pack stations for example, but not invasive, may suddenly become much more invasive and spread rapidly (Bossard et al., 2000).

Feed for stock can contain seeds or propagules of non-native weedy species, and there will be a risk of weed introduction unless weed free forage is used or stock is grazed on site. Pellets are processed in such a way that any weed seeds are killed, but other forms of feed may still have live weed seeds.

Past, Present and Reasonably Foreseeable Actions

Non-native weed species were found at almost all the pack stations and are a seed source for possible expansion into the wilderness. It would be a foreseeable action that weed removal at pack stations would be required as part of the operating plans for permits that are scheduled to be issued in 2006.

Weed free forage is currently recommended for use by packers (SNFPA, 2004). There is currently a statewide collaboration between Forest Service, Park Service, BLM, State of California, and County Agricultural Commissioners to develop a certification program for weed free forage and mulch. When certified weed free forage is readily available statewide, its use will be required for all Forest Service activities, including commercial pack stock operations.

The construction and maintenance of the reservoirs at Florence, Edison, and in the Rush Creek drainage is probably the main source of the weed populations in those areas. These populations act as a seed source for invasion further into the wilderness. The cheatgrass in the Florence/Edison area flowers at approximately the same time as Mono Hot Springs evening primrose, also an annual, and occurs near populations there. It could remove water and nutrients when needed by the primrose, causing habitat degradation. The probability of cheatgrass spreading into evening primrose habitat and negatively affecting populations is greater with increasing traffic by pack stock and hikers.

Weeds – Alternative 1

There would be some risk of weed introduction from pack stock use, hiker use, and trail maintenance since there are populations of weeds at trailheads and pack stations. This risk is about the same as Alternatives 2-Modified, 2, 3, and 4, but higher than Alternative 5.

Feed would be packed in for some overnight trips as needed by the packers. Because there would be very few meadows closed to grazing, the amount of packed feed would be less than the other action alternatives.

The risk of weed introduction from trail maintenance activities is highest in this Alternative because trail classes are the highest of any Alternative.

There would be no risk of weed introduction on firewood.

Sanding could occur on any trail with approval by the Forest Service and could possibly be a source of weed seed introduction, although most likely any approved sanding would be done with weed free material.

Cumulative Effects

Weeds that are present due to other activities, particularly around dam construction sites, may be spread by pack stock and other wilderness users. As noted above, the risk of commercial pack stock acting as vectors for weeds is approximately the same for all the action alternatives, so the interaction with the effects of other disturbances that may have introduced or spread weeds would be similar for all alternatives except Alternative 5.

Weeds – Alternative 2 - Modified

The risk of weed introduction from pack stock use, hiker use, and trail maintenance would be about the same as Alternatives 1, 3, and 4, but higher than Alternative 5. Increased packing of feed may occur, which would introduce a low risk of weed introduction until weed-free forage requirements are instituted.

The use of charcoal above elevation fire closure would not be a risk of weed introduction because weed seeds are killed in the process of making charcoal.

Sanding will only occur with Forest Service approval when trail and destination readiness has been determined. Any approved sanding would be done with weed free material.

Cumulative Effects

The cumulative effects of Alternative 2 – Modified would be the same as Alternative 1.

Weeds – Alternative 2

The risks of weed introduction for Alternative 2 would be slightly less than Alternative 2 – Modified.

There would be a risk of weed seed or pathogen introduction on firewood brought in from outside the wilderness. (See Firewood section below)

Sanding would be allowed on Piute Pass only, but with approved materials. The sanding allowed requires Forest Service approval of the source of the sand, so no introduction of weeds via the sand should occur.

Cumulative Effects

The cumulative effects of Alternative 2 would be the same as Alternative 1..

Weeds – Alternative 3

There would be some risk of introducing weeds from populations at pack stations and trailheads. The risk would be higher than Alternative 1, 2 – Modified, 4, and 5, but less than Alternative 2.

The risk of weed introduction via firewood brought in from outside the wilderness would be less than Alternative 2 because the sites where it could be used would be more limited.

The risk of weed introduction by sanding would be the same as Alternative 2 – Modified.

Cumulative Effects

The cumulative effects of Alternative 3 would be the same as Alternative 1.

Weeds – Alternative 4

There would be some risk of weed introduction from pack stock use, hiker use, and trail maintenance since there are populations of weeds at trailheads and pack stations. This risk is about the same as Alternative 1, 2, and 3 but higher than Alternatives 5.

There would be no campfires allowed above the elevation closures, so there would be no risk of weed or pathogen introduction via firewood.

No sanding of passes would be allowed, so there would be no risk of weed introduction on sanding materials.

Cumulative Effects

The cumulative effects of Alternative 4 would be the same as Alternative 1.

Weeds – Alternative 5

Commercial pack stock would no longer be a possible vector for weed distribution into the wilderness from the pack stations or other populations in and near the wilderness. There would be no feed carried in to the wilderness to feed commercial stock.

There would be no firewood brought in by packers, eliminating risk of weed seed introduction into the wilderness.

No sanding of trails would occur, so there would be no risk of weed seed introduction from trail sanding activity.

Cumulative Impacts

The existing weed populations near the reservoirs would remain as sources of weed seed, but would not be spread by commercial pack stock. There would still be the likelihood of weed

spread by other vectors such as hikers, wind, streams, non-commercial pack stock, dam and trail maintenance activities, etc.

Firewood/Campfires above Elevation Closure

Firewood/Campfires – Alternative 1

There would be no firewood or charcoal brought in from outside the wilderness, eliminating risk of introducing pathogens and weed seeds from this source. There could be less risk of other wilderness users gathering firewood illegally. This is a long-term beneficial effect to the subalpine vegetation.

Cumulative Effects

Since Alternative 1 would not allow firewood or charcoal brought in from outside the wilderness, there would be no cumulative effects with other wilderness uses/activities.

Firewood/Campfires – Alternative 2 – Modified

Use of firewood by packers on a case-by-case approval basis only in areas not usually frequented by other wilderness users limits the effects on subalpine vegetation. Monitoring of firewood availability and effects of these uses would be very important.

Charcoal could be brought in to locations above the elevation fire closure by any wilderness users. There would be no risk of introducing weeds or pathogens because seeds or propagules would be killed during the charcoal making process. The use of fire pans and carrying the ashes out of the wilderness would limit effects to the soil and vegetation. Use of extra pack stock to carry charcoal is less likely than if carrying firewood, since it is more compact.

The adjustments to the elevation fire closure would only be made if documented firewood availability has shown that a change is appropriate, so subalpine vegetation would be protected by the changes.

Cumulative Effects

Although there would be no increased risk of weed introduction, there would still be a risk of charcoal campfires encouraging other wilderness users to illegally collect firewood and build illegal campfires. The risk is less than Alternatives 2 and 3, since the conditions of use include being away from other wilderness users.

Firewood/Campfires – Alternative 2

Under this alternative, there would be the highest risk of the introduction of pathogens and/or weed seeds on firewood brought in from outside the wilderness and increased illegal gathering of wood by non-packer clients. Campfires using wood carried into the wilderness would be allowed at any site used by packer clients, including spot and dunnage clients.

It has been found that firewood infected with the pathogen *Phytophthora ramorum* may be able to carry sudden oak death syndrome (Davidson and Shaw, 2003). Black oak and canyon live oak both grow in the wilderness areas at lower elevations and plants like manzanita, heather, Labrador tea, and blueberries, which are closely related to known non-oak hosts (Garbelotto et al., 2003), are common in montane and subalpine environments. Bark beetle infestation is also

possible, particularly if wood is stacked over winter (S. Frankel, pers. comm.). Weed seeds could also become attached to firewood during cutting, transportation, or storage, and fall off on the trail or at campsites. If pathogens or weeds become established in a new location, it is very difficult to eradicate them, so these effects would be long-term, moderate to severe, and could affect a large area. Depending on the type of weed introduced, herbicide could be the most effective and efficient means of eradicating it, introducing different impacts. Additional NEPA analysis would be required before herbicide could be used.

In the subalpine zone, the productivity of the whitebark pine stands is relatively low and consumption of firewood in popular camping destinations could easily surpass the production (Cole, 1989). In these low productivity areas, the downed wood plays a particularly important role in water and nutrient conservation and as habitat for other organisms. There was an inconclusive study (Gorski, 1990) of the effects of observing packer firewood use in closure areas on illegal wood gathering by other wilderness users. The clearest result was that hikers interviewed were not in favor of the packers being allowed to bring in firewood. The impacts to the subalpine vegetation caused by activities associated with unauthorized campfires would probably mostly be local and minor, but recovery time is slow, so there could be long-term effects.

Cumulative Effects

Alternative 2 firewood importing would have the highest risk of interacting with other wilderness use (backpacking) because there would be more locations above campfire closure elevations where commercial pack station clients having campfires could encourage illegal wood gathering and campfires by other users.

Firewood/Campfires – Alternative 3 - Firewood

There would be a reduced risk of introducing pathogens or weeds by packing in firewood from outside the wilderness in this alternative as compared to Alternative 2, but more than Alternatives 1, 2 – Modified, 4, and 5, where no firewood would be packed in. In this alternative, firewood could only be brought to 42 designated full service sites and only be used when a wrangler is present. The effects of a pathogen or weed introduction would be long-term, moderate to severe in intensity, and could affect a large area.

Cumulative Effects

Alternative 3 would have similar but less widespread cumulative effects with other wilderness uses as Alternative 2.

Firewood/Campfires – Alternative 4

There would be no firewood brought in from outside the wilderness, eliminating risk of introducing pathogens and weed seeds from this source.

Other wilderness users would not see packers' campfires in the fire closure area and would be less likely to gather firewood illegally to have their own campfire (INF files), reducing the risk of negative impacts to subalpine vegetation.

Cumulative Effects

There would be no cumulative effects with other wilderness uses, as in Alternative 1.

Firewood/Campfires – Alternative 5

There would be no firewood brought in from outside the wilderness, eliminating risk of introducing pathogens and weed seeds from this source.

Cumulative Effects

There would be no cumulative effects with other wilderness uses, as in Alternative 1.

Geographic Unit Scale

Ansel Adams East

Grazing Resources

Analysis

Historical grazing uses by production livestock, primarily sheep, pack stock supporting mining operations and recreational pack stock has historically been high throughout this geographic area. There have also been water diversion, impoundment, and flow disruption for approximately 70 years. There are persistent chronic effects including loss of late-seral riparian vegetation, incisement and erosion of trails, stream bank instability and stream channel incisement resulting in loss of riparian vegetation needed to dissipate energy, filter sediment and provide for water retention. These effects are most prevalent in the Rush Creek, Shadow Eidza, Thousand Island, and Minaret Analysis Units.

Grazing Resources – Alternative 1

Analysis

With implementation of Alternative 1 the direct and indirect effects of pack stock use, at reported levels of approximately 1,862 stock nights annually, and the cumulative effects to the riparian vegetation, including decreased late-seral vegetation would be most noticeable where there is existing stock use associated with an existing decline in vegetative resource conditions such as at Upper Spooky Meadows, Lower Spooky Meadows, Rodgers Lake Meadows, Garnet Lake Meadows, Thousand Island Lake Meadows, Upper Deer Creek Meadows. The meadows between Garnet and Thousand Island Lakes, around Garnet Lake, and at the west end and near the delta at the northwest corner of Thousand Island Lake are not suitable for grazing and with continued stock entry and use there would be additional trampling of vegetation on the associated unstable stream banks and headcuts.

There could also be decreases in late-seral vegetation in locations near campsites at Rodgers Lake, Marie Lake, Davis Lake, Donahue Camp, Clark Lake, Shadow Creek near the PCT trail junction, Anona Lake, Ashley Lake, and Superior Lake as stock continued to trample the existing vegetation in and along access trails near those campsites.

There is less current stock use and the direct effects may occur to a lesser extent at: the meadows areas near the junction of the Minaret Mine trail; Badger Lake Meadows; the meadow stringers below Deer Lakes; Upper Crater Meadow; the meadows above Upper Crater Meadow; and Middle Deer Creek Meadows.

Parker, Glacier Canyon, Gibbs, and Bloody Canyon: Little pack stock use occurs and there are few concerns with existing conditions in the Parker, Glacier Canyon, Gibbs, and Bloody Canyon Analysis Units. The low levels of use would likely continue under Alternative 1 and there are no expected differences between alternatives in the effects or cumulative consequences.

Upper Rush Creek: The direct effects of the new grazing use patterns developing in the Rodgers Lakes area would be an increase in trampling of vegetation, especially along the new access trails above Rodgers Lake and the meadows adjacent to Rodgers Lake, and localized sod fragmentation in the associated riparian areas.

Direct effects of stock use, especially of trampling in the less resilient moist to dry meadow vegetation types, would be continued localized trampling and loss of the vegetation in the moist to dry meadows near Marie Lake, Davis Lake, and Donahue Camp meadows and localized trampling and loss of vegetation in the short-term near the designated campsites and stock holding areas at these sites.

Over the long-term there would be a reduction in cover of the meadow vegetation and an increase in bare soil, especially near the designated camps and near stream crossing and at watering access locations such the ephemeral pond above Donahue Camp and along the shoreline near Marie Lake camp, as stock develop dusting pits and access drinking water. Cumulatively over the long-term, there could be loss of vegetation adequate to provide watershed protection along the stream at Donahue Camp, the altered vegetation would be observable but the vegetation would likely remain adequate to provide for watershed protection near Davis Lake, Marie Lake, and the benches near Donahue Camp.

Rush Creek: A direct effect would be localized trampling, increased sod fragmentation, loss of riparian vegetation, an associated decrease in vegetative cover in the short-term near the drift fences at Spooky Meadows, along the small stream in Lower Spooky Meadows, in the springs in the upper end of Lower Spooky Meadows, at the confluence of the stream and the spring channels at Upper Spooky Meadows, and in the less resilient moist to dry meadows along the trail between Spooky Meadows and Clark Lake.

There would be limited loss of riparian vegetation in the small riparian areas along the trails and localized loss of high-seral riparian vegetation along the access trail and at the designated campsite and stock holding areas near Weber Lake. The cumulative effect could be a reduction in the vegetation needed to provide protection during high flow events and increased ecological risks, especially along the streams in Upper and Lower Spooky Meadow.

Thousand Island: Continuation of existing grazing use pattern, which are resulting in trampling of the wetlands at the northwest corner and west end of Thousand Island Lake would result in a localized alteration of vegetation at these locations. The indirect effects of continued pack stock use of the access trails and wrangler camp at Garnet Lake and near Emerald Lake and at the meadows between Garnet and Thousand Island lakes would be a loss of riparian vegetation, sod fragmentation.

Cumulatively a reduction in cover and abundance of the late-seral riparian vegetation needed to provide for watershed protection.

Due to the continued trampling related direct effects of stock use in these intermingled wetland complexes, cumulatively over the long-term there would be a localized reduction in cover of the meadow vegetation on the benches to the north of Thousand Island Lake and an increase in bare soil in the areas used by stock for grazing and in the stock holding areas at campsites at Garnet Lake, Thousand Island Lake, and between Garnet and Emerald Lakes.

Shadow-Ediza: The direct effects of the existing pack stock use at the Shadow Creek campsite are trampling of the stream banks along the access trail, trampling of the stream banks at the meadow and trampling of vegetation at the campsite and stock holding area. Over the short-term, there would be continuation of the trampling effects, including sod fragmentation and localized alteration of vegetation.

The cumulative effects could cumulatively result in a reduction in cover of the late-seral meadow vegetation at the Shadow Creek grazing area and an increase in bare soil in the areas used by stock for grazing and in the stock holding areas at the campsite. There could be limited trampling of and loss of riparian vegetation in the small meadows along the Cabin Lake trail, especially along the edge of the pond and associated meadows near Cabin Lake. There would likely continue to be adequate riparian vegetation to provide the natural level of protection during high flow events at these locations.

King Creek: Direct effects related to existing pack stock use would occur near the campsites at Anona Lake, Ashley Lake, and Superior Lake: including localized trampling of vegetation at the creek crossings, in the associated stock holding areas and along associated access trails. Indirect effects over the long-term would include localized reduction of vegetative productivity and a decrease in vegetative cover in the grazing areas, with most effects occurring near the campsites. Effects at Holcomb Lake would be the same as for no grazing over the short-term, with direct effects of trailing related trampling of vegetation along the south shore and between the inlet and the upper meadows over the long-term.

These effects would be noticeable at the local scale but there would likely continue to be adequate riparian vegetation to provide the natural level of protection during high flow events at these locations.

Minaret: The existing conditions would continue at Minaret Mine Meadows. At Trinity Meadows over the short-term, there would be limited loss of vegetative productivity and over the long-term a decrease in cover at Trinity Meadows and near the trail at Middle Minaret Creek. There would likely continue to be adequate riparian vegetation to provide the natural level of protection during high flow events at these locations.

Over the short-term, a direct effect would be continued removal and trampling of vegetation in upper Johnston Meadow, especially along the unstable stream banks and on the terraces with altered vegetative composition, which are now less resilient due to the lowered water table.

Cumulatively there could be an increased risk of loss of soil and vegetation adequate to provide for watershed protection in upper Johnston Meadow. Recovery of riparian vegetation at upper Johnston Meadow may not occur over the long-term even with implementation of all applicable standards.

Crater Creek: These areas are currently used at low levels and use is not anticipated to increase. Few current direct or indirect effects are noted for the Crater Creek area.

Current areas of altered vegetation appear to be an effect of historical stock use and there would be little change with implementation of Alternative 1.

At areas used by stock, such as at the meadow stringers below Deer Lakes, Upper Crater Meadow, the meadows above Upper Crater Meadow, and Middle Deer Creek Meadows, there would be maintenance of mixed vegetative seral conditions over the long-term and eventual localized reductions in vegetative productivity and decreased vegetative cover.

River-High: At the Badger Lake Meadows there would be continued trampling of and a localized loss of riparian vegetation at the springs and along the stream, although in this resilient meadow with existing low levels of use the vegetative growth may be adequate and headcuts may still stabilize.

Late-seral plant species may increase over the long-term if the use can be managed to avoid the critical areas of Badger Lake Meadow. Although there may be some localized and minor effects of use along San Joaquin Ridge, especially associated with deer-hunting camps, there will likely be no substantial loss of vegetation in these locations and no effects, either adverse or beneficial would result from the low levels of use.

Cumulative Effects

There are some meadows, including Johnston, Garnet to Emerald Lake, and Upper Crater Creek, where there are long-term historical unstable watershed conditions and chronic processes such as instability along the associated creek and large active headcuts. With these chronic and synergistic existing conditions there is likely to be loss of riparian obligate vegetation, decreased stabilizer plant species, and increased mid-seral or early-seral vegetative condition. There is not likely to be adequate vegetation to provide for watershed protection because of the synergistic relationship between the historical and currently occurring processes.

Alternative 2-Modified

Analysis

Direct effects of implementation of Alternative 2 – Modified, with approximately 2,267 stock nights of grazing available annually, would be similar to those predicted for Alternative 2. With implementation of Alternative 2 – Modified these effects and the associated cumulative risks, the increased use and increased packing of feed and extended use of the stock holding areas at the destinations would likely result in additional localized loss of vegetation and decreased late-seral vegetation relative to Alternative 2.

The effect would be decreased vegetation needed to provide for watershed protection and an increased risk of ecological damage, relative to Alternatives 1, 2, and 4, over the long-term at and near the popular designated camps at Rodgers Lake, Marie Lake, Davis Lake, Donahue Camp, Clark Lake, Thousand Island Lake, Garnet Lake, Shadow Creek, Anona Lake, Ashley Lake, Superior Lake, Crater Meadow, Deer Creek, and Badger Lake.

Parker, Glacier Canyon, Gibbs, and Bloody Canyon: Little pack stock use occurs and there are few concerns with existing conditions or expected differences between alternatives in the Parker, Glacier Canyon, Gibbs, and Bloody Canyon Analysis Units.

Upper Rush Creek: With implementation of Alternative 2 – Modified there could be increased localized trampling of the vegetation in the moist to dry meadows at Marie Lake, Davis Lake, and Donahue Camp meadows and localized trampling and loss of vegetation in the short-term at designated campsites and stock holding areas.

Over the long-term there would be a reduction in cover of the meadow vegetation and an increase in bare soil, especially near the designated camps and near stream crossing and at watering access locations such the ephemeral pond above Donahue Camp and along the shoreline near Marie Lake camp, as stock develop dusting pits and access drinking water.

Rush Creek: There would be localized loss of riparian vegetation and decreased vegetative cover in the short-term and cumulatively over the long-term along the drift fences at Spooky Meadows and along the trail between Spooky Meadows and Clark Lake. There would be localized loss of riparian vegetation in the small riparian areas along the trails and localized loss of high-seral riparian vegetation along the access trail and at the designated campsite and stock holding areas near Weber Lake.

Over the long-term, cumulative effects and the associated risks to proper functioning condition would likely increase, relative to Alternative 1, 2, and 4 at Spooky Meadows and at Clark Lakes and would be similar to Alternative 3.

Thousand Island: The new grazing use patterns at the northwest corner of Thousand Island Lake would result in limited loss of vegetation along new access trails. There would be elimination of direct impacts such as trampling and bank alteration at the stream delta at the NW corner of Thousand Lake and to the west of the lake compared to alternatives 1, and 2. The other areas would respond as discussed for Alternative 2.

Over the long-term, there would be a localized reduction in cover of the meadow vegetation on the benches to the north of Thousand Island Lake and an increase in bare soil in the areas used by stock for grazing and in the stock holding areas at designated campsites at Garnet and Thousand Island lakes. Cumulatively these impacts would be slightly increased relative to Alternatives 1, 2, and 4, especially at the designated campsites with stock holding areas at Garnet Lake and Thousand Island Lake.

Shadow-Ediza: In the short-term, there would be maintenance of a widened stream crossing accessing the designated campsite and limited reductions in vegetative cover and productivity in the meadow downstream of the designated camp at Shadow Creek.

Over the long-term, there may be increased localized alteration of vegetation, relative to alternatives 1, 2, and 4, especially at the Shadow Creek grazing area and an increase in bare soil in the areas used by stock for grazing and in the stock holding areas at the designated campsite. There could be localized loss of riparian vegetation in the small meadows along the Cabin Lake trail, especially along the edge of the pond and associated meadows near Cabin Lake; although it is probable there will be no measurable difference between alternatives at this location over the long-term.

King Creek: Direct effects at Ashley Lake, near the designated campsite below Anona Lake, Ashley Lake, and Superior Lake would be localized trampling of vegetation at the creek

crossings, in the designated stock holding areas and along associated access trails. Indirect effects over the long-term would include localized reduction of vegetative productivity and a decrease in vegetative cover in the grazing areas, including new grazing areas on the benches south and east of Davis Lake. Effects at Holcomb Lake would be the same as for no grazing over the short-term, with direct effects of trailing related trampling of vegetation along the south shore and between the inlet and the upper meadows over the long-term.

Minaret: The existing conditions would continue at Minaret Mine Meadows. At Trinity Meadows over the short-term, there would be limited loss of vegetative productivity and over the long-term a decrease in cover at Trinity Meadows and near the trail at Middle Minaret Creek, with long-term and cumulative effects being similar for all alternatives that include pack stock use. There would be no grazing related direct effects however there would be continued loss of riparian vegetation in upper portions of Johnston Meadow as the terrace level continues to respond to the incised channel.

Over the very long-term, there may not be vegetative recovery at Johnston Meadow. In other locations in this analysis unit there would likely continue to be maintenance of adequate vegetation to provide for ecological processes.

Crater Creek: At areas proposed for stock use, such as at the meadow stringers below Deer lakes, Upper Crater Meadow, the meadows above Upper Crater Meadow, and Middle Deer Creek Meadows there would be maintenance of mixed vegetative seral conditions over the long-term and eventual localized reductions in vegetative productivity and decreased vegetative cover.

Overall is not likely that there would be measurable differences between alternatives in the Crater Creek analysis unit.

River-High: The direct effects over most of the River-High Analysis Unit would be similar to those effects with no grazing, as this area currently receives limited stock use other than on the system trails. At the Badger Lake meadow there would be limited loss of riparian vegetation at the springs and along the stream.

There would likely be adequate recruitment and retention of riparian vegetation to provide for ecological processes over the long-term throughout this analysis unit.

Cumulative Effects

Because Johnston, Garnet to Emerald Lake, and Upper Crater Creek meadows will be rested or closed in Alternative 2 - Modified, the cumulative effects of this alternative with historic effects would be more rapid recovery of the creek instability and active headcuts.

Alternative 2

Analysis

The direct effects of grazing, with approximately 2,498 stock nights available annually, would be localized, within identified standards, but visually noticeable near designated campsites including at Rodgers Lake, Marie Lake, Davis Lake, Donahue Camp, Clark Lake, Thousand Island Lake, Garnet Lake, Shadow Creek, Anona Lake, Ashley Lake, Superior Lake, Crater Meadow, Deer Creek, and to a lesser extent at Badger Lake meadows and the meadows near the

junction of the Minaret Mine Trail. For Alternative 2, 3, and 4 there would be some decrease in vegetative cover, but not as much of a decrease as for Alternative 1 in the short-term.

There are areas recommended as unsuitable for grazing, including: between Garnet and Thousand Island Lakes; the Meadows around Garnet Lake; the meadows at the west end of Thousand Island Lake; Minaret Mine Meadows; and some meadows in the Deer Creek and Crater Creek areas. The direct effects would be to immediately eliminate trampling of and removal of vegetation in most of these locations, although there would continue to be some trampling related to trailing and access to campsites.

Vegetation would likely continue to be adequate to provide for watershed protection at these sites.

Effects of implementation of the un-suitable recommendation at the applicable locations would be increases in vegetative production in the short-term, especially near springs and streams. Cumulatively, with greatly reduced direct effects of grazing and retention of each year's vegetative growth there would be a transition to late-seral vegetation and then maintenance of high-seral conditions would occur over the long-term in these areas.

Parker, Glacier Canyon, Gibbs, and Bloody Canyon: Little pack stock use occurs and there are few concerns with existing conditions, little changes in use are expected and there are little or no expected differences between alternatives in the effects to the riparian vegetation resource in the Parker, Glacier Canyon, Gibbs, and Bloody Canyon Analysis Units.

Upper Rush Creek: Direct effects of the new grazing use patterns, including increased trailing access to meadows in the Rodgers Lakes area, would be a localized increase in trampling of vegetation, especially along the new access trails, and localized sod fragmentation along the trails and in the meadow areas. Over the long-term indirect effects would be a limited area of decreased high-seral riparian species, increased mid-seral and low-seral vegetation, and decreased vegetative cover. There would be continued localized trampling of the vegetation in the moist to dry meadows at Marie Lake, Davis Lake, and Donahue Camp meadows and localized trampling and reduced vegetative cover in the short-term at designated campsites and stock holding areas. Over the long-term these direct effects would continue and would result in a cumulative reduction in cover of the meadow vegetation and an increase in bare soil, especially near the designated camps and near stream crossing and at watering access locations such the ephemeral pond above Donahue Camp and along the shoreline near Marie Lake camp, as stock continue to develop dusting pits and access drinking water.

There would likely continue to be adequate riparian vegetation to provide the natural level of protection of ecological during and following high flow events.

Rush Creek: There would be limited loss of riparian vegetation and decreased vegetative cover in the short-term and cumulatively over the long-term along the drift fences at Spooky Meadows, along the trail between Spooky Meadows and Clark Lake, and at the Clark Lake Campsite. There would be a minor and localized loss of riparian vegetation in the small riparian areas along the trails and localized loss of high-seral riparian vegetation along the access trail and at the designated campsite and stock holding areas near Weber Lake.

There would likely continue to be adequate riparian vegetation to provide the natural level of protection during high flow events at these locations, although it is likely that intensive site-

specific control would be needed and would require the use of portable electric fence to be effective at the springs and along the creek banks in Upper Spooky Meadow.

Thousand Island: The new grazing and trailing use patterns resulting from shifting use to the benches to the northwest of Thousand Island Lake would result in a minor localized loss of vegetation along new access trails due to the direct effects of trampling of vegetation. Over the long-term, with continued removal and trampling of vegetation in this area of low resiliency there would be a localized reduction in cover of the meadow vegetation on the benches to the north of Thousand Island Lake and an increase in bare soil in the areas used by stock for grazing and in the stock holding areas at designated campsites at Garnet and Thousand Island lakes.

There would likely continue to be adequate riparian vegetation to provide the natural level of protection during high flow events at these locations, except along the stream banks at the delta at the northwest corner of Thousand Island Lake where bank instability would continue beyond the long-term.

Shadow-Ediza: In the short-term direct effects would be continued trampling of vegetation along the stream banks and indirect effects would be maintenance of a widened stream crossing accessing the designated campsite. There would be local minor reductions in vegetative cover and productivity due to continued removal and trampling of vegetation in the meadow immediately downstream of the designated camp at Shadow Creek.

Over the long-term, there would be continuation of the localized alteration of vegetation, including a reduction in cover of the late-seral meadow vegetation at the Shadow Creek grazing area and an increase in bare soil in the areas used by stock for grazing and in the stock holding areas at the designated campsite. There could be local and moderate loss of riparian vegetation in the small meadows along the Cabin Lake trail, especially along the edge of the pond and associated meadows near Cabin Lake. There would likely continue to be adequate riparian vegetation to provide the natural level of protection during high flow events at these locations.

King Creek: Direct effects at Ashley Lake, near the designated campsite below Anona Lake, and Superior Lake would be localized trampling of vegetation at the creek crossings, in the designated stock holding areas and along associated access trails. Indirect effects over the long-term would include localized reduction of vegetative productivity and a decrease in vegetative cover in the grazing areas, including new grazing areas on the benches south and east of Davis Lake. Effects if grazing access is eventually approved at Holcomb Lake would be the direct effects of trailing related trampling of vegetation along the south shore and between the inlet and the upper meadows over the long-term.

If grazing access were not eventually approved at Holcomb Lake the riparian vegetation would increase and over the long-term would become established in these trail locations. Cumulatively throughout this analysis unit there would continue to be adequate riparian vegetation to provide for watershed protection.

Minaret: Little use currently occurs, little change in use is expected, and the existing conditions would likely continue at Minaret Mine Meadows with all alternatives. Over the short-term there would be localized loss of vegetative productivity, primarily associate with trailing and trampling of vegetation and over the long-term a decrease in cover at Trinity Meadows and near the trail at Middle Minaret Creek. Cumulatively there would continue to be adequate riparian vegetation to provide for watershed protection at these locations.

Other than at Johnston Meadow there would likely continue to be adequate riparian vegetation to provide for sustainability of ecological processes.

Crater Creek: At areas proposed for stock use, such as at the meadow stringers below Deer Lakes, Upper Crater Meadow, the meadows above Upper Crater Meadow, and Middle Deer Creek Meadows the direct effects of grazing would include removal of desired vegetative species, trampling of vegetation and sod fragmentation. There would be mixed vegetative seral conditions over the long-term.

There would be localized reductions in vegetative productivity and decreased vegetative cover. There would likely be adequate vegetation to provide for watershed protection at most locations except for some meadows along Deer Creek and Upper Crater Meadow where existing conditions include active erosion features such as unstable stream banks and headcuts.

River-High: The direct effects over most of these areas would be similar to those with no grazing. At the Badger Lake Meadow, there would be a minor localized loss of riparian vegetation at the springs and along the stream associated with pack stock accessing these areas for drinking water.

This is a productive and resilient site and as the applicable standards are enforced, the effects would be retention of vegetative growth and recruitment of new growth to stabilize the headcuts and there would be adequate late-seral plant species to provide watershed protection.

Cumulative Effects

There would be continued loss of riparian vegetation in upper portions of Johnston Meadow as the channel continues to become incised and the terrace level continues to respond to the incised channel (historic grazing damage). Over the long-term, there would not be vegetative recovery at Johnston Meadow and there would not be adequate riparian vegetation to provide watershed protection. Upper Crater Meadow would also continue to be used, slowing recovery from historic damage. Garnet Meadow would be closed, so recovery would be sooner than under Alternative 1. There would be more cumulative effects of Alternative 2 than Alternatives 2-Modified, 3, 4, and 5, but fewer than Alternative 1.

Grazing Resources – Alternatives 3 and 4

Analysis

Overall, the direct effects and indirect effects of implementation of Alternative 3 and 4, with approximately 2,397 and 2,093 stock nights of grazing available respectively annually, would be similar to those predicted for Alternative 2. The only substantial difference in this analysis unit being that Alternative 4 would eliminate grazing at Rodgers Lake Meadows.

With implementation of Alternative 3 and 4 the direct and indirect effects and the associated cumulative risks, along with an anticipated increased use and increased packing of feed and extended use of the stock holding areas at the destinations would likely result in localized loss of vegetation and decreased late-seral vegetation at campsites and stock holding areas. There would be decreased vegetation needed to provide for watershed protection and an increased risk of ecological damage, relative to Alternatives 1, 2, and 4. This would occur over the long-term and locally at and near the popular designated camps at Rodgers Lake, Marie Lake, Davis Lake,

Donahue Camp, Clark Lake, Thousand Island Lake, Garnet Lake, Shadow Creek, Anona Lake, Ashley Lake, Superior Lake, Crater Meadow, Deer Creek, and Badger Lake.

Parker, Glacier Canyon, Gibbs, and Bloody Canyon: Little pack stock use occurs and there are few concerns with existing conditions or expected differences between alternatives in the Parker, Glacier Canyon, Gibbs, and Bloody Canyon Analysis Units.

Upper Rush Creek: With implementation of Alternatives 3 and 4 there could be increased localized trampling of the vegetation in the moist to dry meadows at Marie Lake, Davis Lake, and Donahue Camp meadows and localized trampling and loss of vegetation in the short-term at designated campsites and stock holding areas. With Alternative 4, there would be no grazing or trampling of riparian vegetation through the riparian meadows above Rodgers Lake.

Over the long-term there would be a reduction in cover of the meadow vegetation and an increase in bare soil, especially near the designated camps and near stream crossings and at watering access locations such the ephemeral pond above Donahue Camp and along the shoreline near Marie Lake camp, as stock develop dusting pits and access drinking water. Overall, throughout this analysis unit there would likely be maintenance of the vegetation needed to provide for ecological processes.

Rush Creek: There would be localized loss of riparian vegetation and decreased vegetative cover in the short-term and cumulatively over the long-term along the drift fences at Spooky Meadows and along the trail between Spooky Meadows and Clark Lake. There would be localized loss of riparian vegetation in the small riparian areas along the trails and localized loss of high-seral riparian vegetation along the access trail and at the designated campsite and stock holding areas near Weber Lake.

Over the long-term, the risks to proper function condition would likely increase, relative to Alternative 1, 2, and 5 at Spooky Meadows, and at Clark Lakes.

Thousand Island: The new grazing use patterns at the northwest corner of Thousand Island Lake would result in limited loss of vegetation along new access trails. There would be elimination of direct impacts such as trampling and bank alteration at the stream delta at the NW corner of Thousand Lake and to the west of the lake compared to alternatives 1, and 2. The other areas would respond as discussed for Alternative 2.

Over the long-term, there would be a localized reduction in cover of the meadow vegetation on the benches to the north of Thousand Island Lake and an increase in bare soil in the areas used by stock for grazing and in the stock holding areas at designated campsites at Garnet and Thousand Island lakes. Cumulatively these impacts would be slightly increased relative to Alternatives 1, 2, and 4, especially at the designated campsites with stock holding areas at Garnet Lake and Thousand Island Lake.

Shadow-Ediza: In the short-term, there would be maintenance of a widened stream crossing accessing the designated campsite and limited reductions in vegetative cover and productivity in the meadow downstream of the designated camp at Shadow Creek.

Over the long-term, there may be increased localized alteration of vegetation, relative to alternatives 1, 2, and 5, especially at the Shadow Creek grazing area and an increase in bare soil in the areas used by stock for grazing and in the stock holding areas at the designated campsite. There could be localized loss of riparian vegetation in the small meadows along the Cabin Lake trail, especially along the edge of the pond and associated meadows near Cabin Lake; although it

is likely there will be no measurable difference between alternatives at this location over the long-term.

King Creek: Direct effects at Ashley Lake, near the designated campsite below Anona Lake, Ashley Lake, and Superior Lake would be localized trampling of vegetation at the creek crossings, in the designated stock holding areas and along associated access trails. Indirect effects over the long-term would include localized reduction of vegetative productivity and a decrease in vegetative cover in the grazing areas, including new grazing areas on the benches south and east of Davis Lake. Effects at Holcomb Lake would be the same as for no grazing over the short-term, with direct effects of trailing related trampling of vegetation along the south shore and between the inlet and the upper meadows over the long-term.

There would be isolated and local trampling of vegetation and reduced vegetative cover at creek crossings, campsites, and stock holding areas that would persist from year to year. The effect would primarily be visual and overall there would continue to be adequate vegetation to provide for sustainability of ecological processes.

Minaret: The existing conditions would continue at Minaret Mine Meadows. At Trinity Meadows over the short-term there would be limited loss of vegetative cover and productivity and over the long-term a decrease in cover at Trinity Meadows and near the trail at Middle Minaret Creek. There would be no grazing related direct effects however there would be continued loss of riparian vegetation in upper portions of Johnston Meadow as the terrace level continues to respond to the incised channel.

Long-term and cumulative effects being similar for all alternatives that include pack stock use, with locally visual trampling of riparian vegetation but continued adequate vegetation overall to maintain ecological processes. Over the very long-term, there may not be vegetative recovery at Johnston Meadow.

Crater Creek: At areas proposed for stock use, such as at the meadow stringers below Deer lakes, Upper Crater Meadow, the meadows above Upper Crater Meadow, and Middle Deer Creek Meadows there would be maintenance of mixed vegetative seral conditions over the long-term and eventual localized reductions in vegetative productivity and decreased vegetative cover.

It is not likely that there would be measurable differences between alternatives in the Crater Creek analysis unit. Overall, there would continue to be adequate vegetation to provide for sustainability of ecological processes.

River-High: The direct effects over most of the River-High Analysis Unit would be similar to those effects with no grazing, as this area currently receives limited stock use other than on the system trails. At the Badger Lake Meadow, there would be limited loss of riparian vegetation at the springs and along the stream.

It is not likely that there would be measurable differences between alternatives in the River High analysis unit. Overall there would continue to be adequate vegetation to provide for sustainability of ecological processes.

Cumulative Effects

The cumulative effects of Alternatives 3 and 4 would be similar to those of Alternative 2 – Modified.

Grazing Resources – Alternative 5

Analysis

Many of the meadows and riparian systems in the Ansel Adams East Geographic Area, especially in the north portion, are characterized by a natural appearance with low levels of altered vegetation. In these areas, there would be increased retention of each year's growth of vegetation and reduction or elimination of grazing related direct and indirect effects.

Overall, there would be increased recruitment of vegetation, increased vigor, and there would be high-seral riparian vegetation in most areas within the short-term.

There are localized areas of altered vegetative composition associated with lowered water tables, especially in the Crater Creek Analysis Unit. Recovery of the late-seral riparian vegetation would occur over the long-term in many of these areas, with a few not recovering for the very long-term.

Parker, Glacier Canyon, Gibbs, and Bloody Canyon: Little pack stock use occurs and there are few concerns with existing conditions in the Parker, Glacier Canyon, Gibbs, and Bloody Canyon Analysis Units. Little or no change would occur with implementation of Alternative 5.

Upper Rush Creek: A direct effect of no grazing would be no trampling of vegetation along access trails and in intermingled wet areas. The indirect effect would be that the areas of bare soil in the fragmented sod at Rodgers Lake, Marie Lake, Davis Lake, and Donohue camp would be re-vegetated with late-seral species over the short-term.

There would continue to be adequate vegetation to provide for watershed protection.

Rush Creek: A direct effect of no grazing would be no trampling or loss of vegetation along access trails and in intermingled wet areas, especially in both meadows at Spooky Meadows, between Spooky Meadows and Clark Lake, and in the stock holding areas at designated campsites. The indirect effect would be that in the short-term the areas of bare soil in the fragmented sod and on the stream banks at Spooky meadows would be re-vegetated with late-seral species in the short-term to long-term.

Over the long-term, there would be adequate vegetation to protect the stream banks and to provide for watershed protection. The vegetative recovery would occur but would be long-term to very long-term at Upper Alger Lakes Meadow and in the designated stock holding areas.

Thousand Island: A direct effect of no grazing would be no trampling of or loss of vegetation along access trails and in intermingled wet areas, especially along the north side of Thousand Island Lake, in the wet meadow areas at the west end of the lake, at the wrangler camp between Thousand Island and Garnet Lakes, along the north side of Garnet Lake, at the packer camp at the north east corner of Garnet Lake, along the access trail (the old trail) to the wrangler camp, and in the stock holding areas at campsites. The indirect effect would be that in the short-term the areas of bare soil in the fragmented sod and on the stream banks at these locations would rapidly be re-vegetated with late-seral species.

The vegetative recovery would occur but would be long-term at the meadow near the wrangler camp above Garnet Lake. The active headcuts in the meadow near the wrangler camp may remain active over the very long-term but could eventually be stabilized by riparian vegetation.

The stream banks at the delta of Thousand Island Lake would remain unstable over the very long-term.

Shadow-Ediza: A direct effect of no grazing would be no trampling of or loss of vegetation along access trails, in intermingled wet areas, or at the creek crossing accessing campsites and grazing areas especially at the campsites along the Shadow Creek above the PCT junction and along the trail at the wetland near Cabin Lake. In the short-term the areas of bare soil in the fragmented sod and on the stream banks at these locations would be re-vegetated with late-seral species.

Over the long-term, these areas would be characterized by high-seral vegetation, with a few localized sites, such as the avalanche chute at Cabin Lake Meadow continuing to be disturbed and maintained in lower-seral vegetative status by episodic events such as flooding and fluvial deposition.

King Creek: A direct effect of no grazing would be no trampling of or loss of vegetation along access trails, at stock use campsites and in intermingled wet areas, especially at Ashley Lake, Anona Lake, Holcomb Lake, Superior Lake, and Davis Lake. The indirect effect would be that in the short-term the areas of bare soil in the fragmented sod and on the stream banks and at stream crossings at these locations would be re-vegetated.

These areas would be at high vegetative seral status adequate to provide for watershed protection.

Minaret: Minaret Mine Meadows is currently little used by stock and existing conditions would continue. There would be continued loss of riparian vegetation in upper portions of Johnston Meadow as the terrace level continues to respond to the incised channel.

Over the very long-term, there may not be vegetative recovery at Johnston Meadow. Current impacts from stock are minor in the Middle Minaret area and at Trinity Lakes. There would be increased vegetative growth, productivity, and cover especially at the meadows near Trinity Lakes, high-seral vegetative stage would be reached over the very long-term.

Crater Creek: Many areas of Crater Creek and Deer Creek are currently used lightly or not at all, in these areas, such as Lower Crater Meadow, Upper Crater Meadow, Deer Lakes Meadows, and Upper Deer Creek Meadows, the direct effects of no grazing would be to continue vegetative recruitment and establishment of historically affected areas. In the areas that are currently being used by pack stock, such as Deer Creek Meadows a direct effect of no grazing would be no trampling of or loss of vegetation along access trails, in intermingled wet areas, or at the creek crossing accessing campsites and grazing areas. The indirect effect would be that in the short-term the areas of bare soil in the fragmented sod and on the stream banks at these locations would be re-vegetated with late-seral species.

Long-term these areas would be characterized by high-seral vegetation, with a few localized sites continuing to be disturbed and maintained in lower-seral vegetative status by episodic events such as flooding and fluvial deposition.

River-High: Most of this area is used infrequently and lightly by grazing pack stock. The direct effects of no grazing would be little change from existing conditions. The meadow near Badger Lake is used more frequently. The limited loss of riparian vegetation at the small springs and spring channels in this meadow would be reversed with a rapid recovery of vegetative vigor and

growth. The small headcut in the stream at this meadow would be stabilized by vegetative growth in the long-term, eventually increasing the area covered by vigorous late-seral species. The analysis unit would continue to be characterized by high seral vegetative conditions.

Cumulative Effects

The cumulative effects of Alternative 5 would be mostly beneficial in that the meadows with historic grazing damage or mining effects would have the most chance for recovery.

Fens

Fens – Alternative 1

The 14 meadows and one trail with fens or fen characteristics identified in this geographic unit would all be at some risk of trampling impacts since all would be open for grazing. Eight of them are currently in good condition and would probably remain so, and the somewhat degraded condition of the other six would continue:

- **Rush Creek AU:** Grazing would most likely continue at current levels at Upper Spooky and the spring with fen characteristics would continue to have some level of trampling, but would probably still be functional. At Lower Alger and Alger Terraces, the fens would continue to have light impacts, but the current good condition is expected to continue.
- **Thousand Island AU:** Garnet Lake would be grazed at current levels, so the current stream, meadow hydrology, and vegetation composition problems would remain, putting the area with fen characteristics at risk.
- **Minaret AU:** The Emily Lake Trail would be open, causing damage to the small wet meadow with fen characteristics. At Gladys/Rosalie, current use would continue, but the area with fen characteristics would probably remain functional.
- **River High AU:** The current low use of Badger Meadow would continue with slight risks to hydrologic (and fen) function.
- **Crater Creek AU:** There would be grazing in this analysis unit with continued moderate to severe impacts to springs causing risks to the fens. The access to the campsite at ccd5b Meadow would still be causing damage to the fen. The fen at Crater Meadow would remain in good condition, but there would be a risk of trampling.

Foreseeable closures due to resource condition inventory findings:

- Garnet Meadow. If this meadow is closed, either feed will have to be packed in or other meadows in the area that are not currently grazed will receive more use.
- The Emily Lake trail would possibly be closed until the wet meadow crossing is rerouted or repaired. Use could be displaced to nearby Rosalie or Gladys, which would slightly increase trampling risks near the area with fen characteristics.
- Campsite at ccd5b Meadow and its access would possibly be closed due to fen damage. Crater Meadow could also be closed due to resource concerns.

Cumulative Effects

In this geographic unit, the heavy use by hikers and backpackers is unlikely to add to effects of commercial pack stock and trail management, because few of the effects such as trampling of lakeshores and proliferation of campsites (bare ground) occur in saturated soil areas. Under Alternative 1, the most fens would remain degraded, so the cumulative effect, although very small, would be greatest of the alternatives.

Fens – Alternative 2 - Modified

Approximately 42 percent of the meadows will be in grazing zones, and inadvertent trampling and grazing impacts to any unknown fens would be more likely in these meadows.

The 14 meadows/trail with known fens or fen characteristics would continue to have some level of pack stock use, at about the same levels as current reported use. There would be direction to avoid the fens as critical areas with a 5 percent trampling “limit”, and monitoring would be required to ensure compliance. It is expected that some inadvertent trampling and use will occur, but grazing use will be reduced or discontinued if no satisfactory method of consistent avoidance is found.

- **Rush Creek AU:** There would continue to be grazing at Upper Spooky Meadow at levels similar to current grazing. Trampling to the spring with fen characteristics would be difficult to keep at less than 5 percent without changes to stock management. At Lower Alger, stock levels would be similar to current use and the slight trampling of the fen would probably continue (<5 percent). The current condition of the fen is good, and there would be no expected change.
- **Thousand Island AU:** Garnet Lake would not be grazed, so the degraded stream, hydrologic function, and vegetative composition would improve.
- **Minaret AU:** The Emily Lake trail would be closed until repaired or rerouted, so the area with fen characteristics would begin to recover. The area with fen characteristics in Gladys/Rosalie would continue to have slight trampling impacts, but would remain functional.
- **River High AU:** Very light grazing would continue at Badger Meadow, but the fen would remain in good condition.
- **Crater Creek AU:** Crater Meadow, Upper Crater Meadow, and the three meadows in Deer Creek drainage with fens at risk will be closed to grazing, so the fens should recover, but there could be inadvertent trampling. Summit and ccd4 Meadows would be open to grazing, so the fens will probably continue to have trampling impacts. The campsite at ccd5b Meadow would not be designated as a stock camp, but impacts would continue from private stock or hikers.

Cumulative Effects

The cumulative effects of hikers and backpackers with the commercial pack stock use and trail management would be even less than Alternative 1, approximately the same as Alternatives 2, 3, and 4, and slightly more than Alternative 5.

Fens – Alternative 2

The effects to the meadows with fens will be the same as Alternative 2 - Modified.

Fens – Alternative 3

The effects to the meadows with fens will be the same as Alternative 2 - Modified.

Fens – Alternative 4

Although the utilization level at Upper Spooky, Badger, and Gladys/Rosalie Meadows would be reduced, slightly reducing the risk of trampling to the areas with fen characteristics, there would be no expected difference in meadow condition from Alternative 2 - Modified. In general, the effects to the meadows with fens would be the same as Alternative 2 – Modified.

Fens – Alternative 5

The six meadows with identified fens or fen characteristics and moderate to severe spring impacts or changes in hydrologic condition will no longer have commercial pack stock impacts and would be expected to have improved conditions. These meadows are Lower Alger, Upper Spooky, 3 in the Deer Creek drainage, and Upper Crater Creek.

Cumulative Effects

There would be no commercial pack stock effects, but trail maintenance and possibly increases of private pack stock use would add to any hiker and backpacker effects.

Rare Plants

Rare Plants – Alternative 1

Of the 11 populations of sensitive and watch list plants known from in or near Ansel Adams East Geographic Unit, three are in locations remote from trails and no impacts are expected, six are in meadows (four open to grazing but no downward trends are expected), and four are near trails (two TC3, one TC1, and one use trail). Of the 52 meadows with potential habitat for sensitive species, two would have persistent or newly degraded conditions and all would be open for pack stock use. Three more meadows would remain in degraded condition if use increases over current levels. The northern AA East units are not in current pack station operating areas, so would not be expected to have use.

- **Glacier Canyon AU:** The Glacier Canyon Trail would be TC1, but stock access would require special approval, so there would be very few impacts to the populations of Congdon's sedge near this trail
- **Gibbs AU:** The population/habitat of Tahoe draba is inaccessible and there are no known threats.
- **Bloody AU:** Both Tioga sedge populations are in small meadows outside current pack station operating areas, so most of the possible impacts to these populations would be from hikers.
- **Parker AU:** There would be a small risk of pack stock impacts to the population of Tioga sedge along the Alger Trail (TC3) at Parker Pass where there are no restrictions on

use, although there is no recent reported use beyond Alger Lakes. The TC3 designation means more frequent maintenance with accompanying possibility of disturbance to this population near Parker Pass.

- **Northern AA East:** Of the 14 meadows in the elevation zone of Tioga sedge, meadow and stream conditions would remain good, except at Rodgers, where there may be a minor downward trend in vegetation composition, and Marie, where there would be no improvement in stream condition. The minor trampling damage to the lakeshore meadow potential habitat for Tioga sedge will continue.
- **Upper Rush AUs:** There would be no effects to the populations of fell-field claytonia because of their inaccessible location and rocky habitat.
- **Crater Creek AU:** The populations of alpine fireweed are in meadows that would be open to use under this alternative. There would be no predicted change in hydrologic function, PFC, or vegetation composition at these meadows, although there would be a slight trampling risk. The population of short-leaved hulsea was stimulated by the Rainbow fire and will probably decline as the area recovers from the fire and becomes more shaded. Use and maintenance of the TC3 Fish Creek Trail may cause impacts to individual plants, but no overall negative effects to the population.
- **River High AU:** The San Joaquin Peak use trail would be approved and there would be a slight risk of individual Pinzl's rock cress plants outside the wilderness and potential habitat inside the wilderness being trampled. Southern
- **AA East:** Of the 38 meadows with potential habitat for the west side sensitive riparian species, five would be closed to commercial pack stock grazing and 18 others would be in grazing zones. Conditions at Crater would remain degraded. There would be minor improvements in conditions at Johnston, Summit, and JMT/Shadow Creek Junction if stock use stays at current levels. If use increases, conditions could remain degraded.

JMT/Shadow Junction Meadows would possibly be closed as a foreseeable action.

Cumulative Effects

In this geographic unit, the heavy use by hikers and backpackers is likely to add to effects of commercial pack stock and trail management, especially by trampling of lakeshores and proliferation of campsites (bare ground). Under Alternative 1, the most potential riparian habitat would remain degraded, so the cumulative effect would be greatest.

Rare Plants – Alternative 2 Modified

Of the 11 populations of sensitive and watch list plants known from in or near Ansel Adams East Geographic Unit, five are in areas where there are no destinations and so no pack stock activity, although 1 would be on a TC1 hiker trail. In the areas where pack stock use will occur, two are remote from trails, one would be on a TC3 trail, one near an approved use trail, and two are in areas open to grazing.

- **Glacier Canyon AU:** The Glacier Canyon Trail would be TC1 and there would be no destinations in this AU, so there would only be hiker impacts to the population of Congdon's sedge.

- **Gibbs AU:** The population/habitat of Tahoe draba is inaccessible and there are no known threats.
- **Bloody AU:** Because there would be no destinations open for use in this AU and the populations of Tioga sedge are away from the trail, there would be no risk of pack stock or trail impacts to the populations of Tioga sedge, although hikers and anglers would continue to use the area and could trample individual plants.
- **Parker AU:** Because Alger Trail would be TC2 and there are no destinations beyond Alger Lake, the risk of disturbance due to trail use and maintenance of the populations of Tioga sedge is lower than the very small risk in Alternative 1 and there would be no risk of commercial pack stock impacts.
- **Northern AA East:** Because the grazing rotation plan includes East of Davis which has no current reported grazing, there will be a new area of impacts to the lakeshore and meadow potential habitat for Tioga sedge. Of the 14 meadows in the elevation zone of Tioga sedge, six are within grazing zones, which are predicted to cause minor downward trends in PFC and vegetation composition at East of Davis and in vegetation composition at Rodgers, but no change in hydrologic condition, PFC, or vegetation composition at three others. At Marie Meadow, fewer stock than currently reported would be allowed to graze, so there could be a minor improvement in conditions.
- **Upper Rush Creek:** There would be no effects to the populations of fell-field claytonia because of their inaccessible location and rocky habitat.
- **Crater Creek AU:** The effects to the populations of alpine fireweed and short-leaved hulsea are the same as Alternative 1.
- **River High AU:** The San Joaquin Ridge use trail would be approved for hunting only, so any impacts to the Pinzl's rock cress population or habitat would take place late in the season when impacts would be less damaging.
- **Southern AA East:** Under this alternative, the grazing management of the four somewhat degraded meadows with potential habitat for the west side sensitive riparian species would result in no change at Crater Meadow (trail problems), JMT/Shadow Creek Junction. Meadows and Summit Meadows, and Johnston. Eighteen other meadows, of the thirty-eight in the elevation zone for potential habitat, are in designated grazing zones and there could be more grazing in them than currently, since thirteen meadows in this geographic unit would be closed to grazing. As grazing use approaches capacity, it could lead to a minor downward trend in meadow conditions.

Cumulative Effects

The cumulative effects of hikers and backpackers with the commercial pack stock use and trail management would be less than Alternative 1, approximately the same as Alternatives 2, 3, and 4, and slightly more than Alternative 5.

Rare Plants – Alternative 2

The effects of Alternative 2 would be the same as Alternative 2 – Modified.

Rare Plants – Alternative 3

Of the eleven populations of sensitive and watch list plants known from in or near Ansel Adams East Geographic Unit, four are in areas where there are no threats from pack stock or trail activity, four are on or near trails (three system, one use trail), two are in areas open to grazing (only one with likely grazing), and one is in an area closed to grazing and unlikely to be used by pack stock.

- **Glacier Canyon AU:** The Glacier Canyon Trail would be TC1 and the trail would not be closed to commercial pack stock use, although there has been no recent reported use, so there would be a slight risk of hiker or pack stock impacts to the population of Congdon's sedge.
- **Gibbs AU:** The population/habitat of Tahoe draba is inaccessible and there are no known threats.
- **Bloody AU:** There would be no grazing zones designated in this analysis unit, but it would be possible but unlikely that pack stock would use the Bloody Canyon Trail (TC2), so there would be a very slight risk of commercial pack stock and hiker/angler impacts to the populations and habitat of Tioga sedge in small meadows away from the trail.
- **Parker AU:** The Parker Pass trail would be TC2 and open to pack stock use, but use would probably be insignificant (similar to current use), so there would be a very slight risk of trail use and maintenance, pack stock, and hiker effects to the population of Tioga sedge.
- **Northern AA East:** The effects on the potential habitat for Tioga sedge are the same as in Alternative 2 - Modified.
- **Upper Rush AUs:** There would be no effects to the populations of fell-field claytonia because of their inaccessible location and rocky habitat.
- **Crater Creek AU:** The effects on the populations of alpine fireweed and short-leaved hulsea are the same as Alternative 1.
- **River High AU:** The effects to the potential habitat of Pinzl's Rock Cress would be the same as Alternative 1.
- **Southern AA East:** Under this alternative, the grazing management of the four somewhat degraded meadows with potential habitat for the west side sensitive riparian species would result in minor improvements at Johnston and Summit Meadows, and major improvement at JMT/Shadow Creek junction Meadow, but no change at Crater Meadow (trail problem). 18 other meadows, of the 38 in the elevation zone for potential habitat, are in designated grazing zones and there could be more grazing in them than currently, since 12 meadows in this geographic unit would be closed to grazing. As grazing use approaches capacity, it could lead to a minor downward trend in meadow conditions.

Cumulative Effects

The cumulative effects would be the same as Alternative 2 – Modified.

Rare Plants – Alternative 4

Of the 11 populations of sensitive and watch list plants known from in or near Ansel Adams East Geographic Unit, 6 are in remote locations and no impacts are expected, 2 are in meadows open to grazing but no downward trends are expected, and 3 are near trails (2 TC3 and one use trail) open to all uses. Of the 52 meadows with habitat for sensitive species, 2 would have persistent or new degraded conditions.

- **Glacier Canyon AU:** The Glacier Canyon Trail would be TC1 and NSCS, so there would only be hiker impacts to the population of Congdon's sedge.
- **Gibbs AU:** The population/habitat of Tahoe draba is inaccessible and there are no known threats.
- **Bloody AU:** There would be no commercial pack stock use of this analysis unit this Alternative so the populations of Tioga sedge would be at no risk
- **Parker AU:** The Alger Trail would be TC2, but commercial pack stock use would be unlikely past Alger Lakes, so there would be a slight risk of trail use and maintenance, hiker, and commercial pack stock impacts to the population of Tioga sedge near Parker Pass.
- **Northern AA East:** Because the rotational grazing would not include Rodgers, but would increase the use of East of Davis, which currently has no reported grazing, there would be protection for the potential habitat for Tioga sedge at Rodgers Meadow and slightly increase the impacts expected at East of Davis, the overall effect being a slight improvement over Alternatives 2 - Modified and 3, where both meadows would be grazed.
- **Upper Rush AUs:** There would be no effects to the populations of fell-field claytonia because of their inaccessible location and rocky habitat.
- **Crater Creek AU:** The effects to the populations of alpine fireweed and short-leaved hulsea are the same as Alternative 1.
- **River High AU:** The San Joaquin Peak use trail would be prohibited, so there would be no pack stock impact to the potential habitat of Pinzl's rock cress.

Cumulative Effects

The cumulative effects would be the same as Alternative 2 – Modified.

Rare Plants – Alternative 5

Of the 11 populations of sensitive and watch list plants known from in or near Ansel Adams East Geographic Unit, 2 are in remote locations and no impacts are expected, 3 are in meadows open to grazing but no downward trends are expected, and 3 are near trails (2 TC3 and one use trail) open to all uses. Of the 52 meadows with habitat for sensitive species, 2 would have persistent or new degraded conditions. There would be no commercial pack stock use in this alternative, but there could be increases in private pack stock use or displacement of use to areas outside the AA/JM Wildernesses.

- **Glacier Canyon AU:** The Glacier Canyon Trail would be TC1, so there would only be hiker impacts to the population of Congdon's sedge.
- **Gibbs AU:** The population/habitat of Tahoe draba is inaccessible and there are no known threats.
- **Bloody AU:** There would be a no risk of trail or commercial pack stock impact to the populations of Tioga sedge, although there would still be hiker and angler use and a slight risk associated with those uses.
- **Parker AU:** There would be a slight risk of hiker and trail use and maintenance impacts on the population of Tioga sedge near the TC2 Alger Lakes Trail.
- **Northern AA East:** There would be no commercial pack stock use in this Alternative so the populations and potential habitat of Tioga sedge would be at no risk from pack stock use and the degraded stream conditions at Marie Meadow would improve.
- **Upper Rush AUs:** There would be no effects to the populations of fell-field claytonia because of their inaccessible location and rocky habitat.
- **Crater Creek AU:** The populations of alpine fireweed would be at no risk from commercial pack stock use, although there could still be private pack stock using meadows for grazing. There would be no risk of trampling by commercial pack stock to the population of short-leaved hulsea, but there would still be hiker and private pack stock using the TC3 trail, as well as maintenance impacts.
- **River High AU:** The effects to the potential habitat for Pinzl's rock cress would be the same as Alternative 4.
- **Southern AA East:** There would be no commercial pack stock grazing, and meadow conditions would improve at 3 of the 4 currently degraded meadows. Stream conditions in Crater Meadow would remain degraded until the trail problems are resolved. The 38 meadows with potential habitat for the sensitive riparian species would only be at risk for impacts from private pack stock or hikers.

Cumulative Effects

There would be no commercial pack stock effects, but trail maintenance and possibly increases of private pack stock use would add to any hiker and backpacker effects.

Weeds

See Wilderness Scale discussion above.

Cumulative Effects

The construction and maintenance of the hydro facilities in Rush Creek, other recreational facilities near trail heads, and the high volume of hikers and backpackers in this geologic unit add to the risks of weed spread and introduction by commercial pack stock and trail maintenance activity.

Campfires

See Wilderness Scale discussion above.

Cumulative Effects

The high volume of hikers and backpackers in this geographic unit make the risk of illegal wood gathering and campfires higher in Alternatives 2 Modified, 2, and 3.

Ansel Adams West

Grazing Resources

Analysis

The vegetation in the riparian areas of the Ansel Adams West Geographic Area continues to be affected by the chronic and synergistic effects of historical production livestock and pack stock grazing, recent production livestock grazing, current production livestock grazing. These effects are substantial and widespread enough to alter the character of the riparian areas in this Geographic Area. The recovery of these areas from the widespread and chronic effects of historical and recent production livestock grazing will take decades, regardless of the Alternative selected.

Grazing Resources – Alternative 1

Analysis

A direct effect of continued grazing, at a level of 258 stock nights of grazing reported annually, in the meadows of the Ansel Adams West Geographic Area would be localized sites with reduced vegetative cover, and or bare areas, associated with designated camps and grazing areas as animals entered nearby areas to access drinking water, roll in the dust, and feed.

There would be limited alteration of stream bank vegetation, also especially near camps, as animals accessed the streams to water and or crossed streams to find forage or to access campsites. As is discussed in the Analysis section these types of effects are of less concern in fully functional systems but, while within identified standards, may still hinder recovery or increase the risk of cumulative adverse effects during episodic events in locations that have the cumulative effects of historical and recent production livestock grazing, such throughout most of the western Ansel Adams Wilderness Area.

Implementation of Alternative 1 would continue the existing situation, which does not include adaptive management mechanisms to respond to resource concerns. The cumulative effect could be an increased loss of riparian vegetation, inadequate vegetation to provide for ecological processes, and increased risk of damage due to events such as summer thunderstorms and spring snowmelt. There would be a chronic and synergistic continued loss of late-seral vegetation and reduced ecological status at historically affected locations and increased cumulative risk at locations with current impacts.

All Analysis Units: A direct effect of existing pack stock use would be localized sod fragmentation in meadow areas, especially: along the south side of Sadler Lake; at the springs and springs channels in the Sadler to McClure Lake meadow; at Joe Crane Lake inlet meadows;

at the wrangler camp west of Joe Crane Lake; at Fernandez Creek junction meadow, at Isberg Meadow; and in the grazing area along Silver Creek near Coyote Lake. A direct effect of stock use would be continued trampling of the trail from Coyote Lake and the trail through the meadow area along Silver Creek near Coyote Lake. The resulting loss of vegetation would prevent stabilization of the active headcutting along the trail in this meadow. There would be local and minor to moderate sod fragmentation at Corral 77, Stevenson Meadow, Falls Meadow, and Stairway Meadow. There would be unknown but likely minor grazing related impacts in the Bridge Crossing, Junction, and Iron Creek areas.

A direct effect would be localized loss of vegetation along new access trails or loss of vegetation in partially recovered, formerly bare, areas in meadows and along historic production livestock trails. Indirect effects at these locations would include reduced recruitment of vegetation on in-stream bars and on the stream banks of the incised channels. There would be continued trampling effect, including reduced vegetative cover in camps, at stock holding areas, and along the associated access trails, especially along the incised trails associated with Fernandez Junction Meadow, Anne Lake, and at the Sadler Lake campsites.

Effects over the long-term would include a reduction in adequate vegetation to provide protection during flow events especially. There could continue to be reductions in late-seral riparian vegetation along the incised trail along the south side of Sadler Lake. The gully would begin to move laterally into the springs and spring channels in the Sadler to McClure Lake meadow, which would reduce the water table and result in decreased riparian vegetation. The incised and eroding trail in Fernandez Junction meadow would continue to reduce the water available for vegetation resulting in decreased riparian vegetation. There would likely be continued loss of riparian vegetation at all of these locations until and unless improved management and an active watershed and trail restoration program is implemented.

Cumulative Effects

There are some meadows, including Knoblock, Chetwood, Detachment, Fernandez Lakes, Fernandez Junction, Sadler Lake, and Joe Crane Lake where historically altered vegetative composition is combined with altered hydrological function. With these chronic existing conditions there is likely to be continued loss of riparian obligate vegetation, decreased stabilizer plant species, and increased mid-seral or early-seral vegetative condition with implementation of any alternative. There is likely to not be adequate vegetation to provide for dissipation of energy, filtering of sediment, and retention of water with implementation of any alternative at these locations, as a result of the synergistic relationship between the historical, relatively recent, and currently occurring effects and processes.

Grazing Resources – Alternative 2-Modified

Analysis

Commercial pack stock grazing under this alternative, with approximately 1,509 stock nights available annually, and grazing even with applicable standards enforced, in many of the meadows throughout the west-side of the Ansel Adams Wilderness could slow vegetative recovery and perpetuate risk of damage due to events such as summer thunderstorms and spring snowmelt of areas which have been affected by over a century of production livestock grazing. Localized sites of low-seral vegetation, reduced vegetative cover, and or bare areas would be

associated with designated camps as animals focused on nearby areas to access drinking water, roll and feed.

Effects over the long-term would include a reduction in adequate vegetation to provide protection during flow events especially: along the south side of Sadler Lake; the springs and springs channels in the Sadler to McClure Lake meadow; Fernandez Creek junction meadow; Isberg Meadow; and Fernandez Junction Meadow. There would likely be continued loss of riparian vegetation at all of these locations until and unless an active watershed and trail restoration program is implemented.

There would be local alteration of stream bank vegetation, also especially near designated camps, as animals accessed the streams to water and or crossed streams to find forage or to access campsites.

A direct effect of existing pack stock use would be localized sod fragmentation in meadow areas, especially: along the south side of Sadler Lake; at the springs and springs channels in the Sadler to McClure Lake meadow; at Joe Crane Lake inlet meadows; at the wrangler camp west of Joe Crane Lake; at Fernandez Creek junction meadow, at Isberg Meadow; and in the grazing area along Silver Creek near Coyote Lake. A direct effect of stock use would be continued trampling of the trail from Coyote Lake and the trail through the meadow area along Silver Creek near Coyote Lake. The resulting loss of vegetation would prevent stabilization of the active headcutting along the trail in this meadow. There would be local and minor to moderate sod fragmentation at Corral 77, Stevenson Meadow, Falls Meadow, and Stairway Meadow. There would be unknown but likely minor grazing related impacts in the Bridge Crossing, Junction, and Iron Creek areas.

A direct effect would be localized loss of vegetation along new access trails or loss of vegetation in partially recovered, formerly bare, areas in meadows and along historic production livestock trails. Indirect effects at these locations would include reduced recruitment of vegetation on in-stream bars and on the stream banks of the incised channels. There would be continued trampling effect, including reduced vegetative cover in the stock holding areas and along the associated access trails, especially along the incised trails associated with Fernandez Meadow, Anne Lake, and at the Sadler Lake campsites.

Cumulative effects over the long-term would include a reduction in adequate vegetation to provide protection during flow events especially. There could continue to be reductions in late-seral riparian vegetation along the incised trail along the south side of Sadler Lake. The gully would begin to move laterally into the springs and spring channels in the Sadler to McClure Lake meadow which would reduce the water table and result in decreased riparian vegetation. The incised and eroding trail in Fernandez Junction meadow would continue to reduce the water available for vegetation resulting in decreased riparian vegetation. There would likely be continued loss of riparian vegetation at all of these locations until and unless improved management and an active watershed and trail restoration program is implemented.

Cumulative Effects

There are some meadows, including Knoblock, Chetwood, Detachment, Fernandez Lakes, Fernandez Junction, Sadler Lake, and Joe Crane Lake where historically altered vegetative composition is combined with altered hydrological function. With these chronic existing conditions there is likely to be continued loss of riparian obligate vegetation, decreased stabilizer

plant species, and increased mid-seral or early-seral vegetative condition with implementation of any alternative. There is likely to not be adequate vegetation to provide for dissipation of energy, filtering of sediment, and retention of water with implementation of any alternative at these locations, as a result of the synergistic relationship between the historical, relatively recent, and currently occurring effects and processes.

These cumulative effects could increase in these meadows areas, currently little used by pack stock, if pack stock use shifted in response to grazing restrictions elsewhere.

Grazing Resources – Alternative 2

Analysis

A direct effect of grazing, with approximately 535 stock nights available annually, would be localized sites of low-seral vegetation, reduced vegetative cover, and or bare areas associated with designated camps and grazing areas as animals entered nearby areas to access drinking water, roll in the dust, and feed.

There would be local alteration of stream bank vegetation and loss of the vegetation needed to provide stability, also especially near designated camps, as animals accessed streams to water and or crossed streams to find forage or to access campsites. These types of limited and localized effects are of less concern in fully functional systems but, while within identified standards, may still hinder recovery or increase the risk of cumulative adverse effects during episodic events in locations with historically impaired riparian ecosystems that are functioning at risk.

As detailed below on a site-specific basis in the Analysis Unit section, these effects would be most likely at: Sadler Lake; Joe Crane Lake inlet meadows; the wrangler camp west of Joe Crane Lake; Fernandez Creek junction meadow; Isberg Meadow; along Silver Creek near Coyote Lake; Fernandez Meadow; and Anne Lake. At most of these locations the riparian vegetation is being affected by trail related erosion as well as by grazing utilization. There could be similar effects if use shifts to areas currently little used including; Cora Lakes; Chetwood Meadow; Knoblock Meadow; Detachment Meadow; Joe Crane Trail Junction Meadows; and Flat Lake.

Several key areas are recommended as unsuitable for grazing, including the Meadow between Sadler and McClure Lakes; Fernandez Creek Meadows; Fernandez Lake meadows; and the meadows South of Slab Lake. At these locations, the direct effects of prohibiting grazing would be increases in vegetative production in the short-term, especially near springs and streams. Transition to late-seral vegetation and then maintenance of high-seral conditions would occur over the long-term in these areas. There would likely be continued loss of riparian vegetation at Fernandez Lake Meadows and the meadow between Sadler and McClure lakes until an active watershed restoration program is implemented.

A direct effect of would be localized sod fragmentation in meadow areas, especially: along the south side of Sadler Lake; at Joe Crane Lake inlet meadows; at the wrangler camp west of Joe Crane Lake; at Fernandez Creek junction meadow, at Isberg Meadow; and in the grazing area along Silver Creek near Coyote Lake. A direct effect of stock use would be continued trampling of the trail from Coyote Lake and the trail through the meadow area along Silver Creek near Coyote Lake. The resulting loss of vegetation would prevent stabilization of the active headcutting along the trail in this meadow. There would be local and minor to moderate sod fragmentation at Corral 77, Stevenson Meadow, Falls Meadow, and Stairway Meadow. There

would be unknown but likely minor grazing related impacts in the Bridge Crossing, Junction, and Iron Creek areas.

A direct effect would be localized loss of vegetation along new access trails or loss of vegetation in partially recovered, formerly bare, areas in meadows and along historic production livestock trails. Indirect effects at these locations would include reduced recruitment of vegetation on in-stream bars and on the stream banks of the incised channels. There would be continued trampling effect, including reduced vegetative cover in the stock holding areas and along the associated access trails, especially along the incised trails associated with Fernandez Junction Meadow, Anne Lake, and at the Sadler Lake campsites.

Effects over the long-term would include a reduction in adequate vegetation to provide protection during flow events especially: along the south side of Sadler Lake; Fernandez Junction Meadow; Isberg Meadow; and Fernandez Junction Meadow. There would likely be continued loss of riparian vegetation at all of these locations until and unless an active watershed and trail restoration program is implemented.

Cumulative Effects

Cumulative effects of continued grazing and proposed grazing in the areas which have been affected by over a century of production livestock grazing, would be loss of late-seral vegetation and inadequate vegetation to provide watershed protection and perpetuation of risks of increased damage due to events such as summer thunderstorms and spring snowmelt.

Cumulative effects at Knoblock, Chetwood, Detachment, Fernandez Lakes, Sadler Lake, and Joe Crane Lake would be the same as Alternative 2-Modified.

Grazing Resources – Alternatives 3 and 4

Analysis

Commercial pack stock grazing, with approximately 1,511 stock nights in Alternative 3 and 1,056 stock nights available in Alternative 4, in many of the meadows throughout the west-side of the Ansel Adams Wilderness which continue to be affected by the chronic cumulative impacts of over a century of production livestock grazing, could slow vegetative recovery and perpetuate risk of damage due to events such as summer thunderstorms and spring snowmelt of areas.

Alternative 4 would reduce the allowable vegetation utilization level in several meadows, however the levels of trampling and related impacts would likely be similar, as these impact levels are typically reached before the allowable vegetation utilization levels. Alternative 4 would also result in prohibiting grazing in several additional areas with severe alteration of hydrological function, most notably Fernandez Junction, Chetwood, Detachment, and Knoblock meadows and the meadow West of Joe Crane Lake. However, these areas are currently little used and recovery of hydrological and vegetation would take decades, with or without grazing.

Therefore, the effects of implementing Alternative 3 and 4 would not be substantially different.

Localized sites of low-seral vegetation, reduced vegetative cover, and or bare areas would be associated with designated camps as animals focused on nearby areas to access drinking water, roll and feed. There would be local minor to moderate alteration of stream bank vegetation, also especially near designated camps, as animals accessed streams to water and or crossed streams to find forage or to access campsites.

Overall there would be slightly increased risks to watershed functioning conditions with implementation of Alternative 3 relative to Alternative 4. Even without grazing or with grazing managed by applicable standards there would be some continued loss of riparian vegetation associated with the active headcuts, gullies, and unstable stream banks over the short-term to long-term because the erosion features would likely not recover without active restoration.

All Analysis Units: There would be localized trampling of vegetation, trailing through the lakeshore meadows at Sadler Lake, sod fragmentation of meadow areas along the south side of Sadler Lake, at Joe Crane Lake inlet meadows, at the wrangler camp west of Joe Crane Lake, at Fernandez Creek junction meadow, at Isberg Meadow, in the grazing area along Silver Creek near Coyote Lake, and in the stock holding areas at the associated stock used campsites, especially at Fernandez Meadow, Anne Lake, and Sadler Lake.

Similar effects could occur in some areas, currently little used by pack stock, such as Cora Lakes, Joe Crane Trail Junction Meadows, and Flat Lake, if pack stock use shifted in response to grazing restrictions elsewhere. There may be increased use relative to existing reported use and increased related effects in the Corral 77, Hemlock Crossing and Stevenson areas as well. A direct effect would be localized trampling of and decrease of vegetation along new access trails or loss of vegetation in partially recovered, formerly bare, areas in meadows and along historic production livestock trails. Direct effects at these locations would include reduced recruitment of vegetation on in-stream bars and on the stream banks of the incised channels.

There would be no grazing at the Sadler to McClure Lake meadow, or with Alternative 4 at Chetwood Meadow, Knoblock Meadow, Detachment Meadow, and West Joe Crane Lake Meadow. With either Alternative 3 or Alternative 4 there would be some continued loss of riparian vegetation associated with the active headcuts, gullies, or unstable stream banks over the short-term to long-term and as lateral adjustments occurred over the long-term.

There would be a continual decrease in the vegetation required to provide for watershed restoration at many locations in the Ansel Adams West Geographic Area. There would be additional similar effects as use shifts to areas currently little used such as Cora Lakes, Joe Crane Trail Junction Meadows, and Flat Lake. With implementation of Alternative 3, there could be increased overnight use of these sites as well and a cumulative effect would be a gradual increase in stock use trails to and within grazing locations, decreased vegetative cover at stock holding areas and an increase in dusting pits near the designated campsites. There could be increased riparian vegetation, especially at the developing floodplain level, over the very long-term at these locations, however complete recovery would not occur for decades.

Cumulative Effects

The cumulative effects of Alternatives 3 and 4 would be similar to those of Alternative 2 - Modified.

Grazing Resources – Alternative 5

Analysis

There would be no commercial pack stock use with implementation of Alternative 5. Many of the meadows and riparian systems in the Ansel Adams West are characterized by altered vegetative composition associated with historical chronic impacts, including lowered water

tables, especially in the montane meadows of the Sadler, Cora, Lillian, and Fernandez Analysis Units. In many locations, these conditions would persist for many decades with or without the direct effects of current pack stock grazing.

Recovery of the late-seral riparian vegetation may occur more quickly without grazing and in some locations an increased retention of each year's growth of vegetation. Elimination of grazing effects would help to recruit and establish late-seral vegetation.

Cumulatively there would be slow recovery of vegetative conditions, with continued risk factors such as inadequate vegetation on incised stream banks over the long-term to very long-term.

All Analysis Units: A direct effect of no grazing would be reduced impacts including: reduced trampling of and loss of vegetation along access trails and in intermingled wet areas, especially along the south side of Sadler Lake, the Sadler to McClure Lake meadow, Joe Crane Lake, at the wrangler camp west of Joe Crane Lake, Fernandez Creek junction, Isberg Meadow, the grazing area along Silver Creek near Coyote Lake, and in the stock holding areas at the associated stock used campsites. The indirect effect would be that in the short-term the areas of bare soil in the fragmented sod and on the stream banks at these locations would rapidly be re-vegetated with late-seral species. Private recreational stock use may result in continued impacts, at or near acceptable standards but still maintaining altered vegetative conditions, at Fernandez Creek Junction, Cora Lake, and Sadler Lake.

Vegetative recovery would occur over the long-term at the meadow near the wrangler camp above Joe Crane Lake. The riparian vegetation at the meadow between Sadler and McClure Lakes would increase in vigor and productivity near the springs and spring channels, with recovery not likely until the very long-term. There would be continued loss of riparian vegetation and an increase in upland species such as lupine and lodge pole pine near the active headcut and gully on the south side of the meadow.

Some areas, currently little used by pack stock, such as Cora Lakes, Chetwood Meadow, Knoblock Meadow, Detachment Meadow, Joe Crane Trail Junction Meadows, and Flat Lake, would experience little change, with current conditions persisting over the long-term.

Over the long-term the gullies in the meadow between Sadler and McClure lakes could be stabilized by vegetation, rock, boulders, and woody debris, allowing the riparian areas at the springs and on the north side of the meadow to recover and to begin expanding. There could be continued incisement and reductions in riparian vegetation associated with the trail through the meadows along the south shore of Sadler Lake as private stock and hiker traffic continue the trampling related impacts.

Throughout this geographic unit, the vegetation on the degraded meadow terraces would continue to be characterized by mid-seral and low-seral species, with high-seral species occurring and increasing in vigor and abundance over the long-term in areas that are sub-irrigated by springs and spring channels. Cumulatively the in-stream bars would be slowly vegetated, with early-seral annual herbaceous vegetation in the short-term and with perennial, late-seral, riparian vegetation over the long-term to very long-term.

Cumulative Effects

Altered vegetative composition associated with historical chronic impacts, including lowered water tables, especially in the montane meadows of the Sadler, Cora, Lillian, and Fernandez

Analysis Units would persist for many decades with or without the direct effects of current pack stock grazing. Alternative 5, however, offers the best opportunity for recovery of historic effects of any of the alternatives.

Fens

Fens – Alternative 1

Most meadows would be open for grazing, so there would be risk of trampling and grazing impacts, most likely in currently used meadows.

- **Sadler AU:** There would continue to be grazing at the McClure to Sadler Meadow, which would continue existing trampled condition of the spring area with fen characteristics, and there would be a minor downward trend in the stream and meadow conditions generally.
- **Lake Catherine AU:** At Stevenson Meadow, grazing would continue at current levels and the fen would continue to be in good condition, with a slight risk of trampling.
- **Cargyle AU:** The four meadows with fens will be open to grazing, but they would probably not be used because there has been no recent reported grazing use. Fen conditions would remain as they are currently or improved unless grazing increases dramatically.

Cumulative Effects

Historic and current livestock grazing effects are most severe in this geographic unit and therefore there is the highest probability of current commercial pack stock use preventing recovery of historic impacts or continuing/expanding the damage to meadows in general and any fens in these meadows. Since commercial pack stock grazing use is currently light in this GU, the additive effect is very small, but any increased use might slow recovery.

Fens – Alternative 2 - Modified

Approximately 23 percent of the meadows will be open for grazing, and inadvertent trampling and grazing impacts to any unknown fens would be more likely in these meadows.

- **Sadler AU:** McClure to Sadler Meadow would be rested until conditions improve, so the fen would begin to recover from the trampling impacts.
- **Lake Catherine AU:** At Stevenson Meadow, grazing would be allowed and current use levels would be expected. Because the fen is avoidable, there would be no more than inadvertent trampling, and it would remain in good condition.
- **Cargyle AU:** Three of the meadows with fen impacts would not be grazed, so there would be recovery from trampling. At the other two, grazing would be allowed, but may not occur, since the meadows have not recently been grazed.

Cumulative Effects

The cumulative effects of commercial pack stock use, trail management activities, and historic grazing impacts would be somewhat less than Alternative 1 because of the resting of some meadows, destination management, and standards and guidelines to avoid fens as critical areas.

Fens – Alternative 2

The effects to meadows in Cargyle AU and the number in grazing zones would be the same as Alternative 2 - Modified, except for the following:

- **Sadler AU:** Sadler to McClure, which would be closed to grazing entirely. The closure would make recovery more likely.
- **Lake Catherine AU:** There would be no grazing at Stevenson Meadow, so the fen would have no trampling impacts associated with grazing.

Cumulative Effects

The cumulative effects to fens would be essentially the same as Alternative 2 modified.

Alternative 3

The effects to fens would be the same as Alternative 2 - Modified, except that Sadler to McClure would be closed as in Alternative 2.

Cumulative Effects

The cumulative effects to fens would be essentially the same as Alternative 2 modified.

Alternative 4

The percentage of meadows in grazing zones is the same as Alternative 2 - Modified.

Effects to the seven meadows with fens at risk would be also be the same, but a lower utilization standard would be in effect at Between Cargyle and Stairway Meadow and the risk of trampling would be very slightly lower.

Cumulative Effects

The cumulative effects to fens would be essentially the same as Alternative 2 modified.

Alternative 5

The degraded stream and hydrologic function conditions at McClure to Sadler Meadow would not recover over the period of the grazing permit, although there could be some slight improvement in vegetative condition. Removal of the pack stock should allow springs to recover from trampling impacts at Cargyle North, Middle East Fork Meadow, and Between Stairway and Cargyle Meadows.

Cumulative Effects

The cumulative effects to fens would be less than the other alternatives because there would be no commercial pack stock grazing.

Rare Plants

Rare Plants – Alternative 1

Of the 24 populations of sensitive and watch list plants known from in or near Ansel Adams West Geographic Unit, 3 are in remote locations and no impacts are expected, 3 are in meadows open to grazing but no downward trends are expected, and 18 are near trails open to all uses. In this alternative, the trails that could have impacts on the sensitive and watch list populations have the highest trail classes of any alternative. Of the 209 meadows with habitat for sensitive species, 5 would have persistent or newly degraded conditions.

- **Fuller Buttes AU:** The French Trail would be TC2 and there would be continued maintenance by a volunteer group, but infrequent or no FS maintenance. The population of Mono Hot Springs evening primrose bisected by the trail would be at a very low risk for trampling by pack stock, weed introduction, and trail maintenance activities. Most trail use and maintenance takes place after the flowering of this species. The population of Yosemite lewisia is not expected to be affected by pack stock or trail activities because of its remote location.
- **Cassidy AU:** The population of Yosemite lewisia is in a remote location and there would be no impacts.
- **Lower Mono Creek AU:** The Mono Hot Springs Cutoff (Soda Springs Trail) would be TC1 and use would probably continue to be mostly by hikers, so there would be a very light risk of hiker or pack stock impacts to the population of Mono Hot Springs evening primrose, and probably no trail maintenance activity.
- **Hot Springs AU:** The Mono Hot Springs trail would be TC1 and continue to be used mostly by Forest Service stock, not commercial, so there would be a minimal risk of pack stock trampling and maintenance impacts to the population of Mono Hot Springs evening primrose.
- **Staniford AU:** The Lillian Lake Loop and Walton Trails would be TC3, so there would be minimal pack stock trampling risk, and trail maintenance and use activities could slightly affect the four populations of Kettle Dome buckwheat.
- **Jackass AU:** Both the Norris Lake and Fernandez Trails would be TC3, so the populations of Kettle Dome buckwheat at the trailheads would be at a low risk for pack stock, hiking, and trail maintenance activities.
- **Lake Catherine AU:** Grazing would probably continue at current levels and there would be no change in conditions expected at Stevenson and Hemlock Crossing Meadows, so the habitat for the west side riparian sensitive species would remain in good condition. The Stevenson Trail would be TC3 with related small risk of trampling from use and trail maintenance to the two populations of Kettle Dome buckwheat. Since this is a plant of granite outcrops, risk is very low.
- **Lillian AU:** The population of Congdon's sedge is in a remote location and there would be no impacts. The Timber Creek Trail would be TC2 and there would be a slight risk of pack stock, hiker, or trail maintenance impacts to the population of Kettle Dome buckwheat, but its rocky habitat provides some protection. Degraded conditions would

continue at Fernandez Meadow so the habitat for Bolander's candle moss would be at risk. No change in meadow or stream condition would be expected at the other meadows with potential habitat for Bolander's candle moss, so degraded stream and hydrologic function conditions would continue at Fernandez Meadow.

- **Cargyle AU:** The fen environment of the round-leaved sundew at Cargyle, North Cargyle, and Upper High Meadows would be open for grazing, but there would be no predicted change in hydrologic function, PFC, or vegetation composition if use continues at current low levels. There would be a 20 percent trampling limit and the fen would be a special riparian feature that would be protected under the SNFPA. The meadow between Cargyle and Stairway would have minor improvements in hydrologic conditions if grazing numbers stay low as expected.
- **Triple Divide AU:** There would be no expected change in the use or conditions at the 4 meadows with habitat for the west side sensitive riparian species.
- **Sadler AU:** There would be minor improvement to the moderately degraded stream and hydrologic function conditions at Joe Crane Trail Junction Meadow where there is potential habitat of Bolander's candle moss.
- **Cora AU:** Degraded conditions would continue at Knoblock, Detachment, and Chetwood Meadows, affecting the potential habitat for alpine fireweed, Bolander's clover, and Bolander's candle moss, although surveys did not locate any populations. Since the degraded conditions were caused by cattle use, the minimal impacts from pack stock would probably not further degrade these meadows. All 17 meadows with potential habitat for these species would be open for grazing by pack stock, but very little use occurs now and no changes would be expected. The Stevenson, Isberg, and Chetwood Cabin Trails would be TC3, so there would be low risk of trampling and maintenance impacts to the 4 populations of Kettle Dome buckwheat.
- **Bridge Crossing and Arch AUs:** No expected change in the use or condition of the three meadows that are potential habitat for the west side sensitive riparian species. All would be open to grazing.
- The rocky outcrop habitat of Congdon's lewisia would be at very low risk of impacts from pack stock or trail impacts.

Cumulative Effects

Recent and continuing cattle grazing is the major source of degraded meadow conditions in this geographic unit. Where cattle grazing continues, the effect of current levels of commercial pack stock use on potential habitat for sensitive riparian species is minimal compared to the cattle grazing.

The construction of the Edison Reservoir inundated at least one population of Mono Hot Springs evening primrose as evidenced by a plant collection from Vermillion Valley, reducing the total population of this species and reducing the area of potential habitat. There is also more risk that commercial pack stock will act as weed vectors into the remaining populations because of the introduction of weeds near Edison Lake, apparently associated with the dam construction.

Alternative 2 Modified – Rare Plants

Of the 22 populations of sensitive and watch list plants known from in or near this geographic unit, 3 are in remote locations and no impacts are expected, 3 are in meadows open to grazing but no downward trends are expected, and 16 are near trails open to all uses. Of the 209 meadows with habitat for sensitive species, 4 would have persistent or newly degraded conditions.

- **Fuller Buttes AU:** The impacts to the population of Mono Hot Springs evening primrose would be the same as Alternative 1. The population of Yosemite lewisia is not expected to be impacted by pack stock or trail activities because of its remote location.
- **Cassidy AU:** The population of Yosemite lewisia is not expected to be impacted by pack stock or trail activities because of its remote location.
- **Lower Mono AU:** The effects to the population of Mono Hot Springs evening primrose along the Mono Hot Springs Cutoff (Soda Springs trail) would be the same as Alternative 1.
- **Hot Springs AU:** The risks to the population of Mono Hot Springs evening primrose would be the same as Alternative 1.
- **Staniford AU:** The Lillian Lake Loop would be TC3 and the Walton Trail would be TC2, so there would be a slightly smaller risk of pack stock trampling and trail maintenance impacts to the 4 populations of Kettle Dome buckwheat than in Alternative 1.
- **Jackass AU:** The effects to the Kettle Dome buckwheat populations would be the same as Alternative 1.
- **Lake Catherine AU:** Stevenson Meadow would be closed to grazing and Hemlock Crossing would be grazed at current levels, so there would be reduced commercial pack stock impacts to the potential habitat for the west side riparian sensitive species. The Stevenson Trail would be TC2 and there would be a slightly lower risk of trampling or trail maintenance impacts on the two population of Kettle Dome buckwheat, but the rocky habitat offers protection from most impacts.
- **Lillian AU:** The population of Congdon’s sedge is in a remote location and there would be no impacts. The effects to the population of Kettle Dome buckwheat would be the same as Alternative 1. There would be continued degraded conditions at Fernandez Meadow under Alternative 2 - Modified, although it would be rested. No change in meadow or stream condition would be expected at the other meadows with potential habitat for Bolander’s candle moss.
- **Cargyle AU:** The fen environments of the round-leaved sundew at Cargyle Meadow, North Cargyle, and Upper East Fork Meadows would be “critical areas” and have a 5 percent trampling standard. All three meadows are in a grazing zone, but there would be no predicted change in hydrologic function or PFC, but vegetation composition could have a minor downward trend if grazing use approaches meadow capacity. Of the 34 meadows in Cargyle AU that are in the elevation range of the west side riparian species, all are in a grazing zone and would be expected to have minor trampling impacts, but at two, Stairway and Between Stairway and Cargyle, there would be predicted minor

downward trends in vegetation composition. At Between Stairway and Cargyle, there would also be downward trends in hydrologic condition and stream PFC.

- **Triple Divide AU:** There would be no expected change in the use or conditions at the 4 meadows with habitat for the west side sensitive riparian species.
- **Sadler AU:** The effects to the potential habitat of Bolander's candle moss would be the same as Alternative 1.
- **Cora AU:** The effects to the potential habitat of alpine fireweed, Bolander's clover, and Bolander's candle moss would be the same as Alternative 1. Nine meadows in Cora would be in grazing zones. The impacts to the populations of Kettle Dome buckwheat would be the same as Alternative 1 and 3.
- **Bridge Crossing and Arch AUs:** The effects to potential habitat for the west side sensitive riparian species would be outside of any grazing zone, so no use would be expected. Since no use has been recently reported, there would be no change in the current condition.
- The rocky outcrop habitat of Congdon's lewisia would be at very low risk of impacts from pack stock or trail impacts.

Cumulative Effects

The cumulative effects of cattle grazing and hydrologic facilities with commercial pack stock use and trail management activities is less than in Alternative 1 because fewer meadows would be open for grazing, there would be better implementation of standards and guidelines, and more control of use because of destination management.

Rare Plants – Alternative 2

The effects of Alternative 2 would be the same as those of Alternative 2 – Modified.

Rare Plants – Alternative 3

Of the 22 populations of sensitive and watch list plants known from in or near Ansel Adams West Geographic Unit, 3 are in remote locations and no impacts are expected, 3 are in meadows open to grazing but no downward trends are expected, and 16 are near trails open to all uses. Of the 209 meadows with habitat for sensitive species, 4 would have persistent or newly degraded conditions.

- **Fuller Buttes AU:** The impacts to the population of Mono Hot Springs evening primrose would be the same as Alternative 1. The population of Yosemite lewisia is not expected to be impacted by pack stock or trail activities because of its remote location.
- **Cassidy AU:** The population of Yosemite lewisia is not expected to be impacted by pack stock or trail activities because of its remote location.
- **Lower Mono AU:** The effects to the population of Mono Hot Springs evening primrose along the Mono Hot Springs cutoff (Soda Springs trail) would be the same as Alternative 1.

- **Hot Springs AU:** The Mono Hot Springs trail would be TC2, but probably continue to be used mostly by Forest Service stock, not commercial, so there would be a minimal risk of pack stock trampling and a slightly higher risk of maintenance impacts to the population of Mono Hot Springs evening primrose.
- **Staniford AU:** The impacts to the Kettle Dome buckwheat would be the same as Alternative 1.
- **Jackass AU:** The effects to the Kettle Dome buckwheat populations would be the same as Alternative 1.
- **Lake Catherine AU:** If Stevenson is grazed to capacity, there could be a minor downward trend in stream condition, putting the potential habitat for the west side riparian sensitive species at risk. At Hemlock Crossing, there would be no change from present condition. The effects to the populations of Kettle Dome buckwheat would be the same as Alternative 2 - Modified.
- **Lillian AU:** The population of Congdon's sedge is in a remote location and there would be no impacts. The effects to the population of Kettle Dome buckwheat would be the same as Alternative 1. The effects to potential habitat for Bolander's candle moss would be the same as Alternative 2 - Modified.
- **Cargyle AU:** The effects to the fen environments of the round-leaved sundew at Cargyle Meadow, North Cargyle, and Upper East Fork Meadows would be the same as Alternative 2 - Modified. For the 34 meadows in Cargyle AU with potential habitat for the west side riparian sensitive species, the effects would be the same as Alternative 2 - Modified, but Cargyle Meadow would also have a downward trend in vegetation composition.
- **Sadler AU:** The effects to potential habitat for Bolander's candle moss would be the same as Alternative 1.
- **Triple Divide AU:** There would be no expected change in the use or conditions at the 4 meadows with habitat for the west side sensitive riparian species.
- **Cora AU:** the effects to potential habitat for alpine fireweed, Bolander's clover and Bolander's candle moss would be the same as Alternative 2 - Modified. The impacts to the populations of Kettle Dome buckwheat would be the same as Alternative 1 and 2 - Modified.
- **Bridge Crossing and Arch AUs:** The effects to potential habitat for the west side sensitive riparian species would be the same as Alternative 2 - Modified.
- The rocky outcrop habitat of Congdon's lewisia would be at very low risk of impacts from pack stock or trail impacts.

Cumulative Effects

The cumulative effects of Alternative 3 would be similar to those of Alternative 2 – Modified.

Alternative 4

Of the 22 populations of sensitive and watch list plants known from in or near Ansel Adams West Geographic Unit, 3 are in remote locations and no impacts are expected, 3 are in meadows open to grazing but no downward trends are expected, and 15 are near trails open to all uses and 1 would be on a hiker use trail. Of the 209 meadows with habitat for sensitive species, 4 would have persistent or newly degraded conditions.

- **Fuller Buttes AU:** The impacts to the population of Mono Hot Springs evening primrose would be the same as Alternative 1. The population of Yosemite lewisia is not expected to be impacted by pack stock or trail activities because of its remote location.
- **Cassidy AU:** The population of Yosemite lewisia is not expected to be impacted by pack stock or trail activities because of its remote location.
- **Lower Mono Creek AU:** There would be no risk of pack stock trampling or maintenance impacts to the population of Mono Hot Springs evening primrose along Soda Springs trail, as it would not be in the system, and would not be approved as a use trail for commercial stock.
- **Hot Springs AU:** The risk to the population of Mono Hot Springs evening primrose would be the same as Alternatives 1 and 2 - Modified.
- **Staniford AU:** The impacts to the Kettle Dome buckwheat would be the same as Alternative 2 - Modified.
- **Jackass AU:** The Norris Lake Trail would be TC3 and Fernandez Trails would be TC2, so the populations of Kettle Dome buckwheat at the trailheads would be at a slightly lower risk for pack stock, hiking, and trail maintenance activities than in Alternatives 1, 2 - Modified, and 3.
- **Lake Catherine AU:** The effects to the potential habitat for the west side riparian sensitive species would be the same as Alternative 3. The impacts to the Kettle Dome buckwheat would be the same as Alternative 2 - Modified.
- **Lillian AU:** The population of Congdon's sedge is in a remote location and there would be no impacts. The effects to the population of Kettle Dome buckwheat would be the same as Alternative 1. Although grazing would be prohibited at Fernandez meadow, the degraded conditions (due to cattle use) would probably not improve within the time period of the pack stock permits. There would be no predicted change to hydrologic or stream function in the other meadows with potential habitat for Bolander's candle moss.
- **Cargyle AU:** the effects to the round-leaved sundew and the west side riparian sensitive species would be the same as Alternative 2 - Modified. There would be a 30 percent utilization standard at between Cargyle and Stairway Meadow, so there would be a slightly higher chance of the meadow conditions improving than in Alternatives 1, 2 - Modified, and 3.
- **Sadler AU:** There could be slightly more improvement to the degraded conditions at Joe Crane Trail Intersection meadow where there is potential habitat for Bolander's candle moss because there would be a 30 percent utilization limit rather than 40 percent.

- **Triple Divide AU:** There would be no expected change in the use or conditions at the four meadows with habitat for the west side sensitive riparian species.
- **Cora AU:** The effects to potential habitat for alpine fireweed, Bolander's clover, and Bolander's candle moss would be the same as Alternative 2 - Modified. The impacts to the populations of Kettle Dome buckwheat would be slightly less than Alternatives 1, 2 – Modified, and 3 because the Chetwood Cabin trail would be TC2 and maintenance would be less frequent.
- **Bridge Crossing and Arch AUs:** The effects to potential habitat for the west side sensitive riparian species would be the same as Alternative 2 - Modified.
- The rocky outcrop habitat of Congdon's lewisia would be at very low risk of impacts from pack stock or trail impacts.

Cumulative Effects

The cumulative effects of Alternative 4 would be similar to those of Alternative 2 – Modified.

Alternative 5

There would be no commercial pack stock use under this Alternative, but there could be an increase in private stock use. Of the 22 populations of sensitive and watch list plants known from in or near this geographic unit, 3 are in remote locations and no impacts are expected, 3 are in meadows open to grazing but no downward trends are expected, 15 are near trails open to all uses and 1 would be on a hiker use trail. Of the 209 meadows with habitat for sensitive species, 4 would have persistent or newly degraded conditions.

- **Fuller Buttes AU:** There would be a slight risk of trail maintenance effects on the population of Mono Hot Springs evening primrose along the French Trail (TC2), but there would be no commercial pack stock use. There would be no effect on the population of Yosemite lewisia because of its remote location.
- **Cassidy AU:** The population of Yosemite lewisia is not expected to be impacted by trail activities because of its remote location and there would be no commercial pack stock activity.
- **Lower Mono Creek AU:** The effects to the populations of Mono Hot Springs evening primrose would be the same as Alternative 4.
- **Hot Springs AU:** There would be no commercial pack stock activity, but Forest Service pack stock use would continue, so the risks to the population of Mono Hot Springs evening primrose would be only slightly lower than Alternative 1, 2, and 4.
- **Staniford AU:** There would be no commercial pack stock use, Lillian Lake Loop would be TC3, and the Walton trail would be TC2, so this alternative would have the least impact on the 4 populations of Kettle Dome buckwheat.
- **Jackass AU:** The effects to the Kettle Dome buckwheat would be slightly less than in Alternative 4 because commercial pack stock would not be using the trails and there would only be hiker, private stock, and maintenance effects.

- **Lake Catherine AU:** There would be no commercial pack stock grazing, so there would only be a risk of impacts to potential habitat for the west side riparian sensitive species from private pack stock. The effects to the Kettle Dome buckwheat on the Stevenson trail would be the same as Alternative 2 - Modified.
- **Lillian AU:** The population of Congdon's sedge is in a remote location and there would be no impacts. The effects to the population of Kettle Dome buckwheat would be the same as Alternative 1, except that there would be no risk of trampling by commercial pack stock. There would be no commercial pack stock grazing, so there would be minor improvements of meadow conditions and the only risk of impacts to potential habitat for the west side riparian sensitive species would be from private pack stock.
- **Cargyle AU:** There would be no risk of degrading the condition of the three meadows where the round-leaved sundew is found, the spring impacts in Upper East Fork Meadow should improve in condition, improving the habitat for this species. With the removal of commercial pack stock there would be minor improvement to two of the meadows in Cargyle AU that are potential habitat for the west side riparian sensitive species, and the at other meadows there would be no change.
- **Sadler AU:** There could be slightly more improvement than in Alternative 4 to the degraded conditions at Joe Crane Trail Intersection meadow where there is potential habitat for Bolander's candle moss because there would be no commercial pack stock grazing.
- **Triple Divide AU:** There would be no commercial pack stock use, so conditions at the 4 meadows with habitat for the west side sensitive riparian species could improve slightly.
- **Cora AU:** There would be minor improvements to Knoblock, Chetwood, and Detachment meadows as in Alternative 1, and there would be no risk of any grazing impacts. The impacts to the populations of Kettle Dome buckwheat would be lower than the other alternatives because there would be no commercial pack stock and the trail levels would be the same as Alternative 4.
- **Bridge Crossing and Arch AUs:** There would be no pack stock use at all, but there has been no recent reported use, so there would be no expected change to the potential habitat for the west side sensitive riparian species.
- The rocky outcrop habitat of Congdon's lewisia would be at very low risk of impacts from trail impacts and there would be no commercial pack stock use.

Cumulative Effects

The cumulative effects of Alternative 5 would be somewhat less than those of Alternative 2 – Modified.

Weeds/Campfires

See Wilderness Scale discussions above.

Cumulative Effects

There would be very few cumulative effects in this geographic unit because very few campsites are above the elevation closure and backpacking use is light to moderate.

Fish Creek/Convict/McGee

Analysis

Historical grazing uses by production livestock, primarily sheep but some cattle, pack stock supporting mining operations and recreational pack stock has historically been high throughout this geographic area. There are persistent chronic effects including loss of late-seral riparian vegetation, incisement and erosion of trails, stream bank instability and stream channel incisement resulting in loss of riparian vegetation needed to dissipate energy, filter sediment and provide for water retention. These effects are most prevalent and accompanied by the additive cumulative effects of current pack stock grazing and use in the McGee, Fish Creek, Cascade valley, and Silver Divide Analysis Units.

Grazing Resources – Alternative 1

Analysis

The high reported grazing in 2001-2003 was 1,789 stock nights in this geographic area. Many meadows in the Fish Creek watershed will experience direct effects of grazing under Alternative 1. They are often grazed now and would likely experience continued grazing in the short-term, sometimes in meadows that may be unsuitable for grazing. The direct effects in these meadows would be a localized loss of vegetation where stock roll and dust themselves near campsites and in stock holding areas. Indirect effects would be localized reduced vegetative vigor and productivity. Indirect effects over the long-term would be a reduction of late-seral vegetative species, a decrease in vegetative cover and areas with early-seral species and bare areas within meadows.

There would be a decrease in riparian vegetation adequate to protect the watershed during flow events, reduced recovery potential of riparian vegetation. Depending upon the timing, location and intensity of events the cumulative effect may be increased degradation of meadow and riparian areas.

These direct and indirect effects of pack stock grazing use would occur over the short-term at: Deer Camp; Purple Meadow; High Camp; Purple Bench; Ram Tarn meadow along the trail above Purple Meadow; lower Long Canyon Meadow; Lee and Cecil Lakes; Jackson Meadow; Grassy Lake Meadow; most of the higher elevation meadows in the Silver Divide area; Duck Lake meadows; Second Meadow; the tarn pond and riparian areas along access trails below Lee Lake; Martin's Meadow, Round Meadow, Baldwin Meadow, north of Big McGee Lake; and along the trail to Steelhead Lake. The direct and indirect effects of pack stock use may occur but are less likely due to little existing use at: the box canyons above Grassy and Jackson meadows; Pika and Virginia Lake; the meadows east of Duck Pass; Chute Meadow; Genevieve Lake camp; and Cloverleaf Lake.

There would be no grazing or related effects such as hoof punching of vegetation and sod at Second Crossing. The late-seral vegetation would increase near the trails leading from the campsite into the meadow and along the stock access trails in the meadow.

Coldwater, Purple Bench, Upper Fish Creek, Cascade Valley, Silver Divide, and Margaret:

The meadows in Cascade Valley near the confluence of Fish Creek with Minnow and Purple Creek were closed to grazing in 1988. Direct effects would be continued vegetative recovery with annual herbaceous vegetation filling in formerly bare areas and late-seral riparian vegetation increasing at or below the bank full level of the associated streams.

There may be some increased trampling and loss of annual vegetation as stock roaming between drift fences periodically enters these sites. There would be trampling of and localized loss of riparian vegetation at the designated stock camps at Virginia Lake, and on the access trail to and near the camps at Deer Camp and Horse Heaven. There would continue to be excessive deposition over the long-term and until repair and restoration work is accomplished along the trails in the Minnow Creek watershed upstream of Grassy Lake, including the trail near Lake of the Lone Indian and the incised and eroded trail toward Peter Pande Lake from Grassy Lake and at Peter Pande Lake.

Direct effects would be localized decreased vegetative growth, maintenance of existing bare stock dusting areas and continuation of localized altered vegetative species composition. Long-term there would be localized decreased vegetative recruitment, productivity, and establishment and an increase in mid-seral and early-seral plant species.

Over the long-term there would be localized reduced recruitment and establishment of vegetation on in-stream bars. These processes would be especially noticeable at: the meadow areas along the incised and eroded trail to Sheep Camp below Lee and Cecil Lakes; the meadows near Duck Lake; Purple Meadow; Purple Bench; Ram Tarn meadow along the trail above Purple Meadow; Jackson Meadow; Horse Heaven; lower Long Canyon Meadow; Island Crossing (Fox) meadow; Tully Hole; and Third Crossing Meadow. The cumulative adverse impact of these effects would be reduced resiliency and persistence of an at risk functioning condition over the very long-term.

The large headcuts in Jackson Meadow and stream bank instability at Tully Hole would remain active due to the degree of channel incisement.

Convict: There would be some continued loss of riparian vegetation along the trail between Edith and Clover lakes, at the inlet to Edith Lake, and associated with pack stock related trampling along the access trails and designated campsites and stock holding areas at Edith and Genevieve lakes. There would be trampling of vegetation and localized sod fragmentation at the small ponds near the stock holding area at the Genevieve Lake designated campsite.

These effects would not be likely to result in a lack of adequate riparian vegetation to provide protection and likely would not result in increased ecological risks in these locations.

McGee: There would be localized decreases in vegetative productivity, vigor, and recruitment at Second Meadow, Martin's Meadow, Round Meadow, Baldwin Meadow, and along the trail at the junction north of Big McGee Lake. In Martin's meadow the large headcut would remain active for the long-term, but may be stabilized by riparian vegetation over the very long-term. There would be localized vegetation damage and sod fragmentation due to trampling in riparian areas along the trail toward Golden Lake. However, these areas would continue to be at risk until

trail restoration is accomplished. Elsewhere there would be little change from the current condition and trend as most areas in McGee canyon have not been grazed in the last few years.

In most areas of McGee Creek, increased vegetative growth would allow a trend toward the potential natural vegetative community and provide watershed protection.

Cumulative Effects

The effects of historic grazing, mining, and pack stock use are most prevalent and accompanied by the additive cumulative effects of current pack stock grazing and use in the McGee, Fish Creek, Cascade Valley, and Silver Divide Analysis Units.

There are some meadows, including Martin's Meadow, Grassy Meadow, Jackson Meadow, Island Crossing (Fox) meadow, Third Crossing Meadow, Cascade Valley meadows, riparian meadows along the trail to Lee Lake, and Tully Hole Meadow where there are long-term historical unstable watershed conditions and chronic processes such as instability along Fish Creek, instability along Minnow Creek, and active headcuts. With these chronic existing conditions there is likely to be loss of riparian obligate vegetation, decreased stabilizer plant species, and increased mid-seral or early-seral vegetative condition. There is likely to not be adequate vegetation to provide for watershed protection with implementation of any alternative, as a result of the synergistic relationship between the historical and currently occurring processes.

Grazing Resources – Alternative 2-Modified

Analysis

There would be an estimated 1,369 stock nights of grazing available with implementation of Alternative 2-Modified. Locations where direct grazing and trailing related effects would occur include: Virginia Lake; Deer Camp; Horse Heaven; Purple Bench; Cascade valley; Horse Heaven; lower Long Canyon Meadow; Island Crossing (Fox) meadow; Third Crossing Meadow; Genevieve Lake camp; Second Meadow, Martin's Meadow, Round Meadow, Baldwin Meadow, north of Big McGee Lake; and along the trail to Steelhead Lake.

There would likely be increased effects, over the long-term and cumulatively due to increased risk factors at Horse Heaven, Tully Hole, Third Crossing, Long Canyon, and Purple Bench.

Areas categorized as not suitable for grazing or where grazing would be prohibited would see increases in vegetative production, especially near springs and streams. Transition to late-seral vegetation would occur over the long-term in these unsuitable areas: Lee and Cecil Lakes; the box canyons above Grassy and Jackson; most of the higher elevation meadows in the Silver Divide area; Ram Tarn meadow along the trail above Purple Meadow; Jackson Meadow; Purple Meadow; Pika and Duck Lake meadows; Virginia Lake Meadows; meadows east of Duck Pass; the tarn pond and riparian areas along access trails below Lee Lake; Second Crossing Meadow; the majority of Convict basin; most of McGee Creek; and at Coyote Lake Meadows. Grassy Lake Meadow; would not be grazed, however, the stream bank instability and associated loss of riparian vegetation would likely continue over the long-term at these locations.

Coldwater, Purple Bench, Upper Fish Creek, Cascade Valley, Silver Divide, and Margaret:

The meadows in Cascade Valley near the confluence of Fish Creek with Minnow and Purple Creek were closed to grazing in 1988 and there would be resumed grazing at low levels. There

would likely continue to be vegetative recovery, with annual herbaceous vegetation filling in formerly bare areas. There may be some increased trampling and loss of annual vegetation as stock roaming between drift fences periodically enters these sites. The effects in the meadows categorized as not suitable would be similar to no grazing, these include Grassy Lake Meadow, the box canyons above Grassy and Jackson, most of the higher elevation meadows in the Silver Divide area, Pika and Duck Lake meadows, Virginia Lake Meadows, meadows east of Duck Pass, the tarn pond and riparian areas along access trails below Lee Lake, Second Crossing Meadow, Purple Meadow, Ram Tarn meadow along the trail above Purple Meadow, and at Coyote Lake Meadows. The large headcuts in Jackson Meadow would remain active over the long-term; however increased controls and reductions or elimination of grazing related direct effects such as trampling of vegetation and stream banks, along the stream and near the headcuts would allow for increased vegetative growth and establishment over the very long-term. There would be limited loss of riparian vegetation at the designated stock camps at Virginia Lake, and on the access trail to and near the camps at Deer Camp and Horse Heaven.

At locations available for grazing the direct effects of this alternative would be localized decreased vegetative growth and bare stock dusting areas.

Long-term there would be localized decreased vegetative recruitment and establishment and an increase in mid-seral and early-seral plant species. Over the long-term, there would be reduced recruitment and establishment of vegetation on in-stream bars. These processes would be especially noticeable at Purple Bench, Horse Heaven, lower Long Canyon Meadow, Island Crossing (Fox) Meadow, and Third Crossing Meadow. There would likely be increased effects such as development of rolling and dusting pits, decreased vegetative cover and cumulative decreases in late-seral vegetation near designated campsites at Horse Heaven, Third Crossing, lower Long Canyon, and Purple Bench.

Convict: No grazing is proposed. There would be some continued loss of riparian vegetation along the trail between Edith and Clover lakes, at the inlet to Edith Lake, and associated with the access trails and designated campsites and stock holding areas at Edith and Genevieve lakes.

McGee: There would be localized decreases in vegetative productivity, vigor, and recruitment at Second Meadow, Martin's Meadow, Round Meadow, Baldwin Meadow, and along the trail at the junction north of Big McGee Lake. In Martin's Meadow, the large headcut would remain active in the short-term, but may be stabilized by vegetation over the very long-term. There would be localized vegetation damage and sod fragmentation due to trampling in riparian areas along the trail toward Golden Lake. Elsewhere there would be little change from the current condition and trend, as most areas in McGee canyon have not been grazed in the last few years.

In most areas, the increased vegetative growth would allow a trend toward the potential natural vegetative community.

Cumulative Effects

The resting of the meadows with the most degraded conditions would make the cumulative effects of Alternative 2-Modified with the historic grazing effects less than those in Alternative 1, although there would still be long-term instabilities along Fish Creek and Minnow Creek.

Grazing Resources – Alternative 2

Analysis

There are an estimated 1,573 stock nights of grazing available under Alternative 2 in this geographic area. Some meadows assessed in the McGee Creek watershed and many meadows in the Fish Creek watershed will experience the direct effects of grazing as described for Alternative 1, including: Virginia Lake; Deer Camp; Purple Meadow; Purple Bench; Ram Tarn meadow along the trail above Purple Meadow; lower Long Canyon Meadow; Genevieve Lake camp; Second Meadow; Martin's Meadow; Round Meadow, Baldwin Meadow; north of Big McGee Lake; and along the trail to Steelhead Lake. The effects at these sites would be reduced relative to Alternative 1, with increase probability of meeting the applicable standards in key and critical areas.

The indirect effects in these meadows would be limited to a localized loss of vegetation, reduced vigor, cover, and productivity where stock roll and dust themselves near designated campsites and in stock holding areas.

Cumulative effects over the long-term would be a localized reduction of late-seral vegetative species and limited areas with early-seral species and bare areas. There would continue to be adequate riparian vegetation in most locations to meet vegetative desired conditions for the meadow resource and to provide for watershed protection. A long-term cumulative effect would be localized areas with increased risks to proper functioning condition due to inadequate vegetative cover.

There are some areas identified as suitable for grazing where long-term unstable watershed conditions exist such as instability along Fish Creek, and large active headcuts. These conditions indicate that even with implementation of all standards, there is likely to be at least a portion of these areas continuing to degrade as a result of these ongoing processes, including Martin's Meadow, Jackson Meadow, Horse Heaven, Island Crossing (Fox) Meadow, Third Crossing Meadow, and Tully Hole Meadow.

In the areas recommended as not suitable for grazing would be immediate elimination of pack stock trailing and trampling and increases in vegetative production and cover in the short-term, especially near springs and streams. Transition to late-seral vegetation would occur over the long-term in these ungrazed areas: Lee and Cecil Lakes and along the associated access trailing; the box canyons above Grassy and Jackson; most of the higher elevation meadows in the Silver Divide area; Pika and Duck Lake meadows; Virginia Lake Meadows; meadows east of Duck Pass; the tarn pond and riparian areas along access trails below Lee Lake; Second Crossing Meadow; the majority of Convict basin; and most of McGee Creek. Cumulatively, over the long-term to very long-term the riparian vegetation in these areas should reach high-seral status. Several of these areas identified as not suitable would exhibit continued degraded conditions in a large portion of the meadows over the long-term, or possibly for decades, including Coyote Lake Meadows and Grassy Lake Meadow.

Coldwater, Purple Bench, Upper Fish Creek, Cascade Valley, Silver Divide, and Margaret:

The meadows in Cascade Valley near the confluence of Fish Creek with Minnow and Purple Creek were closed to grazing in 1988 and would continue to see vegetative recovery with annual herbaceous vegetation filling in formerly bare areas and late-seral riparian vegetation increasing, especially at or below the level of the associated streams. There is reduced recovery potential and

there would likely be slow vegetative recovery over the very long-term at the second terrace level. There may be some increased trampling and loss of annual vegetation as stock roaming between drift fences periodically enters these sites.

The effects in the meadows categorized as not suitable would be similar to no grazing, these include Grassy Lake Meadow, the box canyons above Grassy and Jackson, most of the higher elevation meadows in the Silver Divide area, Pika and Duck Lake meadows, the meadows east of Duck Pass, the tarn pond and riparian areas along access trails below Lee Lake, Second Crossing Meadow, and at Coyote Lake Meadows. There would be limited loss of riparian vegetation at the designated stock camps at Virginia Lake, and on the access trail to and near the camps at Deer Camp and Horse Heaven.

At locations available for grazing the direct effects of this alternative would be localized decreased vegetative growth and maintenance of existing bare stock dusting areas and continuation of localized altered vegetative species composition.

Long-term there would be localized decreased vegetative recruitment and establishment and an increase in mid-seral and early-seral plant species. Over the long-term, there would be reduced recruitment and establishment of vegetation on in-stream bars. The above direct effects of grazing and trailing would be especially noticeable at: the meadow areas along the trail to Lee and Cecil Lakes; Purple Meadow; Purple Bench; Ram Tarn meadow and along the trail above Purple Meadow; Jackson Meadow; Horse Heaven; lower Long Canyon Meadow; Island Crossing (Fox) meadow; and Third Crossing Meadow. The large headcuts in Jackson Meadow and the unstable stream banks in Tully Hole would remain active over the long-term; however, these meadows are large enough to allow management of stock while still avoiding additional impacts to these unstable areas. There may be increased vegetative growth and establishment over the very long-term in these locations; however, unstable conditions would persist over the long-term.

Convict: Little grazing currently occurs and no grazing is proposed. There would be some continued loss of riparian vegetation due to the direct effects of trampling along the trail between Edith and Clover lakes, at the inlet to Edith Lake, and associated with the access trails and designated campsites and stock holding areas at Edith and Genevieve Lakes.

Over the long-term, there may not be adequate vegetation to provide for watershed protection along the trail between Edith and Cloverleaf lakes.

McGee: There would be localized minor decreases in vegetative productivity, vigor, and recruitment at Second Meadow, Martin's Meadow, Round Meadow, Baldwin Meadow, and along the trail at the junction north of Big McGee Lake associated with trampling of vegetation and sod fragmentation which would not recover annually in given the low resiliency at these sites.

In Martin's Meadow the large headcut would remain active for the long-term, but may be stabilized by vegetation over the very long-term. There would be localized vegetation damage and sod fragmentation due to trampling in riparian areas along the trail toward Golden Lake. Elsewhere there would be little change from the current condition and trend, as most areas in McGee canyon have not been grazed in the last few years. Cumulatively in most areas of McGee Canyon other than the above, the increased vegetative growth would result in a trend toward the potential natural vegetative community.

Cumulative Effects

The cumulative effects of Alternative 2 would be similar to those of Alternative 2-Modified, but the most degraded meadows would be closed rather than rested. Since the historic effects are expected to take a long time to recover, there would probably be no difference in effects.

Grazing Resources – Alternatives 3 and 4

Analysis

There would be approximately 1,476 stock nights of grazing available with Alternative 3 and 689 stock nights available with Alternative 4. Locations where direct grazing and trailing related effects would occur include: Virginia Lake; Deer Camp; Horse Heaven; Purple Bench; Horse Heaven; lower Long Canyon Meadow; Island Crossing (Fox) meadow; Third Crossing Meadow; Genevieve Lake camp; Second Meadow, Martin's Meadow, Round Meadow, Baldwin Meadow, north of Big McGee Lake; and along the trail to Steelhead Lake.

Areas categorized as not suitable for grazing or where grazing would be prohibited would see increases in vegetative production, especially near springs and streams.

Transition to late-seral vegetation would occur over the long-term in the ungrazed, unsuitable areas: Lee and Cecil Lakes; the box canyons above Grassy and Jackson; most of the higher elevation meadows in the Silver Divide area; Ram Tarn meadow along the trail above Purple Meadow; Jackson Meadow; Purple Meadow; Pika and Duck Lake meadows; Virginia Lake Meadows; meadows east of Duck Pass; the tarn pond and riparian areas along access trails below Lee Lake; Second Crossing Meadow; the majority of Convict basin; most of McGee Creek; and at Coyote Lake Meadows.

Jackson Meadow (under Alternative 4) and Grassy Lake Meadow, under both Alternative 3 and Alternative 4; would not be grazed, however the stream bank instability and associated loss of riparian vegetation would likely continue over the long-term at these locations. There would likely be increased effects, over the long-term and cumulatively due to increased risk factors at Horse Heaven, Tully Hole, Third Crossing, Long Canyon, and Purple Bench.

Coldwater, Purple Bench, Upper Fish Creek, Cascade Valley, Silver Divide, and Margaret:

The meadows in Cascade Valley near the confluence of Fish Creek with Minnow and Purple Creek were closed to grazing in 1988 and there would continue to be vegetative recovery, with annual herbaceous vegetation filling in formerly bare areas. There may be some increased trampling and loss of annual vegetation as stock roaming between drift fences periodically enters these sites. The effects in the meadows categorized as not suitable would be similar to no grazing, these include Grassy Lake Meadow, the box canyons above Grassy and Jackson, Jackson Meadow (under Alternative 4); most of the higher elevation meadows in the Silver Divide area, Pika and Duck Lake meadows, Virginia Lake Meadows, meadows east of Duck Pass, the tarn pond and riparian areas along access trails below Lee Lake, Second Crossing Meadow, Purple Meadow, Ram Tarn meadow along the trail above Purple Meadow, and at Coyote Lake Meadows. There would be limited loss of riparian vegetation at the designated stock camps at Virginia Lake, and on the access trail to and near the camps at Deer Camp and Horse Heaven.

At locations available for grazing, the direct effects of this alternative would be localized decreased vegetative growth and bare stock dusting areas.

There would likely be increased effects such as development of rolling and dusting pits, decreased vegetative cover and cumulative decreases in late-seral vegetation near designated campsites at Horse Heaven, Third Crossing, lower Long Canyon, and Purple Bench. Over the long term, there would be reduced recruitment and establishment of vegetation on in-stream bars. These processes would be especially noticeable at Purple Bench, Horse Heaven, lower Long Canyon Meadow, Island Crossing (Fox) Meadow, and Third Crossing Meadow. Long-term there would be localized decreased vegetative recruitment and establishment and an increase in mid-seral and early-seral plant species. The large headcuts in Jackson Meadow would remain active over the long-term; however elimination of grazing related direct effects such as trampling of vegetation and stream banks, along the stream and near the headcuts would allow for increased vegetative growth and establishment over the very-long term under Alternative 4 and to a slightly lesser extent with increased control of grazing under Alternative 3.

Convict: No grazing is proposed. There would be some continued loss of riparian vegetation along the trail between Edith and Clover lakes, at the inlet to Edith Lake, and associated with the access trails and designated campsites and stock holding areas at Edith and Genevieve lakes.

There would continue to be adequate vegetation to provide for normal ecological processes throughout the Convict Analysis Unit.

McGee: There would be localized decreases in vegetative productivity, vigor, and recruitment at Second Meadow, Martin's Meadow, Round Meadow, Baldwin Meadow, and along the trail at the junction north of Big McGee Lake. In Martin's Meadow, the large headcut would remain active in the short-term, but may be stabilized by vegetation over the very long-term. There would be localized vegetation damage and sod fragmentation due to trampling in riparian areas along the trail toward Golden Lake. Elsewhere there would be little change from the current condition and trend, as most areas in McGee canyon have not been grazed in the last few years.

In most areas, the increased vegetative growth would allow a trend toward the potential natural vegetative community.

Cumulative Effects

The cumulative effects of Alternatives 3 and 4 would be similar to those of Alternative 2.

Grazing Resources – Alternative 5

Analysis

Little grazing currently occurs in the McGee Creek and Convict Creek drainages. The direct effects of no grazing in most of the key area meadows assessed in these areas would not be substantially different from the existing condition. Some impacts such as increased sediment deposition would continue associated with the trails and abandoned mining access routes. Indirect effects would include increased vegetative establishment and growth and a trend toward late-seral vegetation in the short-term on most of the meadow assessed. There is some private pack stock use, especially in the fall during deer hunting season. This use is not thought to be substantial enough to affect recovery of the riparian vegetation, especially as it occurs late season, well after range readiness and when stock parties tend to carry supplementary feed.

The Fish Creek portion of this geographic area currently receives substantial grazing. No grazing would result in increased vegetative production, vigor and recruitment over the short-term and

increases in late-seral vegetation over the long-term, especially in meadows located along tributaries to Fish Creek and near springs in all meadows. Several meadows along Fish Creek, including those at Third Crossing, Tully Hole, the confluence of Minnow Creek, the Confluence of Purple Creek, and Island Crossing could continue to be adversely effected by incisement along the Fish Creek channel. Several meadows in the McGee Creek watershed, including Baldwin, Martin's, Big McGee Lake inlet, Cable Meadow, and Round meadow, could continue to be adversely affected by the flows from McGee Creek, by runoff from trails, or by runoff from the Sheelore mining road.

Over the long-term to very long-term most of the meadows would return to the potential natural vegetation for that site.

Coldwater, Purple Bench, Upper Fish Creek, Cascade Valley, Silver Divide, and Margaret:

The meadows in Cascade Valley near the confluence of Fish Creek with Minnow and Purple Creek were closed to grazing in 1988. With continued no grazing long-term there would be increased vegetative recruitment and establishment and an increase in late-seral species.

Over the long-term there would be recovery of conditions such as re-vegetation of bare dusting areas with annual herbaceous vegetation, as is currently occurring. There would be continued establishment of late-seral riparian vegetation on stream banks, and establishment of early-seral vegetation in the short-term and late-seral vegetation in the long-term on in-stream bars.

There would be increased establishment of late-seral riparian vegetation on stream banks, and establishment of early-seral vegetation on in-stream bars. These processes would be especially noticeable at: the meadow areas along the trail to Lee and Cecil Lakes; the tarn pond below Lee Lake; Purple Meadow; Purple Bench; Ram Tarn meadow along the trail above Purple Meadow; Jackson Meadow; and Grassy Meadow; Horse Heaven; lower Long Canyon Meadow; Island Crossing (Fox) meadow; and Second Crossing Meadow.

At Jackson Meadow and Grassy Lake Meadows, the vegetation on the old meadow terraces would continue to be characterized by mid-seral and early-seral species, with high-seral species occurring and increasing in vigor and abundance over the long-term in areas that are sub-irrigated by springs and spring channels. High-seral riparian vegetation would increase in productivity, vigor and abundance along the small spring channels and at the springs. The in-stream bars would be slowly vegetated, first with annual herbaceous vegetation in the short-term and with perennial, late-seral, riparian vegetation over the long-term. Some of the unstable stream banks and larger headcuts could remain active over the long-term, but may be stabilized by late-seral riparian vegetation over the very long-term. Recovery to fully function late-seral riparian vegetation on the terraces and stream banks may not occur even over the very long-term and cumulatively there may not be adequate vegetation to provide for watershed protection near the deeper incisement and headcuts.

Convict: There would be vegetative growth and increased cover at the small ponds adjacent to Genevieve Lake. There would also be increased vegetative growth, recruitment and establishment in the riparian areas along the trail between Edith and Cloverleaf Lakes and at the inlet to Edith Lake.

Other than at Genevieve, Edith, and Cloverleaf lakes, there would be little change from existing conditions elsewhere in Convict Basin. Cumulatively over the long-term there would be adequate vegetation to provide for watershed restoration.

McGee: With elimination of the direct effects of pack stock use, such as trampling of vegetation and sod fragmentation, there would be limited increases in vegetative productivity, vigor, and recruitment at Second Meadow, Martin's Meadow, Round Meadow, and along the trail at the junction north of Big McGee Lake. There would be a reduction or elimination of vegetation damage by trampling in riparian areas along the trail to Golden Lake.

Elsewhere, there would be little change from the current as most areas in McGee canyon have not been grazed in the last few years. In most areas, the increased vegetative growth would cumulatively allow a trend toward potential natural vegetative community. In Martin's Meadow, the large headcut would remain active for the long-term, but may eventually be stabilized by vegetation. The vegetation at Baldwin Meadow and Round meadow would continue to be effected by frequent fluvial deposition, retaining a mix of seral classes over the long-term.

Cumulative Effects

Since there would be no commercial pack stock impacts to interfere with recovery of historic effects, Alternative 5 would have beneficial effects on the grazing resource.

Fens

Fens – Alternative 1

All meadows except Second Crossing would be open for grazing.

- **McGee AU:** Grass Lake and Steelhead would be open to grazing but no use has occurred recently, so the fen would stay in its current good condition if no increase in grazing occurs.
- **Purple Bench AU:** The grazing management plan implemented in 2002 in the Purple Meadow area, does not allow use in saturated areas, so the fens are protected and conditions should improve. The low stock numbers at Purple Bench should maintain the fen in good condition.
- **Upper Fish Creek AU:** The three meadows with areas with fen characteristics would be open to grazing, but only at Tully Hole would the condition be expected to decline due to continuing use.
- **Cascade Valley AU:** There is a temporary closure of Second Crossing to grazing, so it would be protected from most trampling impacts. At Third Crossing, grazing would be allowed so there would be no expected recovery of hydrologic function. The fens at Island Crossing and Iva Belle Hot Springs would remain in good condition because there is no change in use expected.
- **Silver Divide AU:** There would continue to be grazing allowed at Peter Pande tarn so the area with fen characteristics would receive some impacts, but it would remain functional.
- **Margaret AU:** There would continue to be trampling impacts to the fen at Coyote grazing area, and there may be a downward trend.
- **Convict AU:** Mildred Lake would not be in the operating areas of the pack stations, so the fens would have virtually no risk of pack stock impact.

Cumulative Effects

In this geographic unit, many of the meadows show negative effects of heavy historic livestock and recent commercial pack stock use. Continued commercial pack stock grazing use at current levels in this area would be likely to prevent recovery of meadows with fens or continue degraded conditions in more places than the other alternatives.

Use of Iva Belle Hot Springs, where there are some fens, by hikers and backpackers adds to use by commercial pack station clients at that location, although holding or grazing pack stock is not allowed at the Hot Springs.

Fens – Alternative 2 - Modified

Approximately 41 percent of the meadows will be open for grazing, and inadvertent trampling and grazing impacts to any unknown fens would be more likely in these meadows.

- **McGee AU:** Grass Lake and Steelhead Meadows would be closed to grazing, so there would be no risk of pack stock impacts to the fen.
- **Purple Bench AU:** The grazing management and effects would be the same as Alternative 1, continuing the grazing management plan in the Purple Meadow area (Ram and High Camp). Use at Purple Bench would be limited to current low levels, so fen conditions should remain good.
- **Upper Fish Creek AU:** No grazing would be allowed at Red Slate Meadow, so there would only be inadvertent use impacts. Tully Lake would be open for grazing and there may be some shift from closed areas, so use may increase somewhat, but the fen area would have critical area protection, so should remain in good condition. At Tully Hole, use will be somewhat less than current use, but no change is expected in hydrologic condition and there will still be trampling impacts.
- **Cascade Valley AU:** The closure will continue at Second Crossing, so the fen condition will continue to improve. Third Crossing will have a reduced number of stock nights from its current use, but there will still be some trampling impacts and no change in meadow conditions is expected. Iva Belle Hot Springs will remain closed to pack stock camping and grazing, so the fen condition would remain the same.
- **Silver Divide AU:** Grazing would not be allowed at Peter Pande tarn, so the hydrologic function would show minor improvement as would the area with fen characteristics. Grazing will be allowed at Island Crossing, but at very restricted numbers, so the area with fen characteristics would remain in good condition.
- **Margaret AU:** Grazing will be allowed at the Coyote Grazing area, but at slightly reduced numbers. The trampling of the fen will continue.
- **Convict AU:** No grazing would be allowed in Mildred Meadow, so the fens should continue to be in good condition.

Cumulative Effects

The resting of some meadows and closer control of grazing numbers and locations should help the meadows recover from previous livestock and commercial pack stock use, so the cumulative effect would be less than Alternative 1, beneficial in some places that get less use.

Fens – Alternative 2

The effects to the meadows with fens or fen characteristics would be the same as Alternative 2 - Modified.

Fens – Alternative 3

The effects to the meadows with fens or fen characteristics would be the same as Alternative 2 – Modified, except in the Purple AU. Ram Meadow would be closed due to a stream problem, so there would be no risk of impacts to the fen.

Fens – Alternative 4

The effects to fens and areas with fen characteristics would be the same as Alternative 2 - Modified, except that at Tully Hole and Third Crossing, utilization rates are reduced, so there would be a very slightly lower risk of trampling, but there would be no expected change in meadow conditions.

Fens – Alternative 5

There would be only minimal expected change in the degraded conditions of Third Crossing, Ram Meadow, and Tully Hole, but fen conditions would improve at Second Crossing and Coyote Grazing area with the removal of pack stock trampling impacts.

Cumulative Effects

Because there would be no commercial pack stock grazing, there would be beneficial effects to meadows previously damaged by livestock and commercial pack stock grazing.

Rare Plants

Rare Plants – Alternative 1

Of the six populations of sensitive and watch list plants known from in or near this geographic unit, four are in a meadow where there is no pack stock use, one is near a trail open to all uses, and one is on a use trail outside the wilderness with little current use. Of the 20 meadows with habitat for sensitive species, 1 would have persistent or newly degraded conditions.

- **Cascade Valley AU:** Second Crossing and Cascade Valley would remain closed and they would have moderate and minor meadow function improvements, respectively. The other meadows would have no change to hydrologic function, stream condition, or vegetation composition, so the riparian habitat would show local improvements in this AU. The Fish Creek Trail would continue to be TC3, so there would continue to be a risk of trampling of the short-leaved hulsea population if pack stock leave the trail.
- **Silver Divide AU:** Continued use of Long Canyon would prevent recovery of the stream and could cause a minor downward trend in vegetation composition in potential habitat for Bolander's candle moss.
- **Convict AU:** There would be no use at Mildred without special permission, so no impacts are expected to the sensitive and watch list plants in Mildred Meadow.

- **McGee AU:** The population of Inyo beardtongue near McGee Pack Station on a use trail outside the wilderness currently receives little or no impact from pack stock, and there would be no expected displacement of wilderness use. Any new day ride routes would have to be approved by the Forest Service.
- **Purple AU:** The Purple to Cascade Valley trail would be TC3, and there would be some risk of trampling and maintenance impacts to the subalpine fireweed population. These effects would be the same as those of Alternatives 2 Modified - 4.
- There would be very few impacts to the potential habitat for Congdon's lewisia because it is rocky and would not receive much pack stock use. Trail impacts would mostly be limited to the tread, a minimal percentage of the habitat.

Cumulative Effects

In this geographic unit, many of the meadows show negative effects of heavy historic livestock and recent commercial pack stock use. Continued commercial pack stock grazing use at current levels in this area would be likely to prevent recovery of meadows with potential habitat for sensitive plants or continue degraded conditions in more places than the other alternatives. The heavy use of Fish Creek trail by hikers and backpackers could have additional effects, with commercial pack stock use, on sensitive plant populations and habitat.

Rare Plants – Alternative 2 - Modified

Of the six populations of sensitive and watch list plants known from in or near this geographic unit, 4 are in a meadow where there is no pack stock use, and 1 are near a trail open to all uses.

- **Cascade Valley AU:** The effects to the population of short-leaved hulsea would be the same as Alternative 1. Allowing very limited grazing of Cascade Valley Meadows could slow recovery somewhat, but the small numbers should be insignificant.
- **Silver Divide AU:** There would be minor downtrend in vegetation composition at Long Canyon Meadow because Grassy Meadow would be closed to stock. Limiting the stay to one night in this analysis unit should improve riparian habitat in general, but may displace use to areas not currently used or used only at low levels, such as Long Canyon.
- **Convict AU:** There would be no grazing in Mildred Meadow, so populations of Mingan moonworts and the four watch list species would be at no risk from grazing. Trail use in the area would be limited to accessing Mildred from Dorothy Lake, as stock would be prohibited from the Convict Canyon and Mildred-Bright Dot trails and no trips are authorized to Mildred. There would be a very minimal risk of trampling by pack stock to the sensitive and watch list species present.
- **McGee AU:** The effects to the population of Inyo beardtongue just outside the wilderness would be the same as Alternative 1.
- **Purple AU:** The effects to subalpine fireweed AU would be the same as Alternative 1, 3, and 4.
- The effects to the potential habitat for Congdon's lewisia would be the same as Alternative 1.

Rare Plants – Alternative 2

Effects would be the same as Alternative 2 – Modified.

Rare Plants – Alternative 3

Of the six populations of sensitive and watch list plants known from in or near this geographic unit, 4 are in a meadow where there is no pack stock use, 1 is near a trail open to all uses, and 1 is on a use trail with little current use. Of the 20 meadows with habitat for sensitive species, 1 would have persistent or newly degraded conditions.

- **Cascade Valley AU:** The effects to riparian habitat and to the population of short-leaved hulsea would be the same as Alternative 1.
- **Silver Divide AU:** The effects to riparian habitat in Long Canyon would be the same as Alternative 2 - Modified.
- **Convict AU:** The effects to Mingan moonwort and the four watch list species are the same as Alternative 2 - Modified.
- **McGee AU:** The effects to the population of Inyo beardtongue just outside the wilderness would be the same as Alternative 1.
- **Purple AU:** The effects to subalpine fireweed would be the same as Alternative 1, 2 – Modified, and 4.
- The effects to the potential habitat of Congdon’s lewisia would be the same as Alternative 1.

Cumulative Effects

Cumulative effects of Alternative 3 would be similar to those of Alternative 2 – Modified.

Rare Plants – Alternative 4

Of the six populations of sensitive and watch list plants known from in or near this geographic unit, four are in a meadow where there is no pack stock use, one is near a trail open to all uses, and one is on a little used use trail. Of the 20 meadows with habitat for sensitive species, 1 would have persistent or newly degraded conditions.

- **Cascade Valley AU:** The effects to the potential habitat for the west side riparian species would be the same as Alternative 1, although there could be slightly less impact at Third Crossing Meadow because utilization would be limited to 30 percent rather than 40 percent. The effects to riparian habitat and to the population of short-leaved hulsea would be the same as Alternative 1.
- **Silver Divide AU:** The effects to riparian habitat in Long Canyon would be the same as Alternative 1. Limiting the stay to one night in this analysis unit should improve riparian habitat in general.
- **Convict AU:** The effects to Mingan moonwort and four watch list species are the same as Alternative 2 - Modified.

- **McGee AU:** The effects to the population of Inyo beardtongue would be the same as Alternative 1.
- **Purple AU:** The effects to subalpine fireweed would be the same as Alternative 1-3.
- The effects to the potential habitat of Congdon's lewisia would be the same as Alternative 1.

Cumulative Effects

Cumulative effects of Alternative 4 would be similar to those of Alternative 2 – Modified.

Rare Plants – Alternative 5

Of the six populations of sensitive and watch list plants known from in or near this geographic unit, four are in a meadow where there is no pack stock use, one is near a trail open to all uses, and one is on a little used use trail. Of the 20 meadows with habitat for sensitive species, 1 would have persistent or newly degraded conditions.

- **Cascade AU:** Because there would be no pack stock grazing or trail use, effects would be less than the other alternatives and there would only be private pack stock use of the meadows.
- **Silver AU:** There would be minor improvements to vegetation composition at Long Canyon, improving the habitat for the Bolander's candle moss and alpine fireweed.
- **Convict AU:** there would be no risk of pack stock trampling to Mingan moonwort or the watch list plants at Mildred Meadow.
- **McGee AU:** There could be displacement of use to outside the wilderness, and it would be more likely that the use trail where there is a population of Inyo beardtongue would be used for day rides, increasing the possibility of trampling.
- **Purple AU:** The Purple to Cascade Valley Trail would be TC2 and there would be no commercial pack stock, so the risk of trampling and maintenance impacts would be less than Alternatives 1-4.
- The potential habitat for Congdon's lewisia would be a risk from private pack stock, hikers, and trail maintenance only, not commercial pack stock.

Cumulative Effects

The lack of commercial pack stock use would allow recovery of historic livestock and pack stock grazing effects.

Weeds

See Wilderness Scale discussion.

Cumulative Effects

Hikers and backpackers on Fish Creek and Minnow Creek Trail, especially accessing Iva Belle Hot Springs, act as additional vectors, with commercial pack stock, for weed spread from existing cheatgrass infestations (unknown origin) in the Reds Meadow and Island Crossing areas.

Campfires

See Wilderness Scale discussion.

Cumulative Effects

There are many campsites in this geographic unit above the existing campfire closure where backpackers may be encouraged to illegally gather firewood and make campfires if commercial packers are allowed to bring in charcoal or firewood (Alternatives 2 – Modified, 2, and 3).

Mono Creek/Rock Creek

Analysis

The Mono Creek/Rock Creek Geographic Area continues to be affected by the chronic and synergistic effects of historical grazing, recent production livestock grazing, current production livestock grazing, and the additive cumulative effects of current pack stock grazing.

Grazing Resources – Alternative 1

Analysis

The high reported grazing between 2001 and 2003 was 838 stock nights in this geographic area. The locations in this geographic area where there is likely to be continued stock use with existing management include: Volcanic Knob meadows; Pocket Meadow; Mudd Lake meadows; lower Laurel Creek meadows; Quail Meadow; Hopkins Bench Camp meadows; Upper Graveyard Meadows; Cold Creek meadows; Turk Meadow; Davis Lake meadows; Dorothy Lake outlet meadows; the lakeshore meadows at lower Graveyard Lakes; Graveyard Meadow; meadows at Hilton Lakes 4-6; the meadows at Lower Hopkins Lake; Grinnell Lake Meadows; upper and middle meadows at Laurel Lake; Silver Pass Lake meadows; Silver Pass Meadow (SIP6); north of Mono Rock (FOR1); and the meadows of Pioneer Basin above and near Mudd Lake. The localized direct effects of stock use are would be trampling of vegetation along trails, at access to campsites and stock holding areas, and in the associated meadows.

Long-term effects would be decreased vegetative productivity and vigor, with loss of the riparian vegetation needed to provide for watershed protection.

There would continue to be some localized loss of late-seral riparian vegetation especially at: Volcanic Knob meadows; Pocket Meadow; Mudd Lake meadows; lower Laurel Creek meadows; Silver Pass Lake meadows; Quail Meadow; Hopkins Bench Camp (upper meadows); Upper Graveyard meadows; Cold Creek meadows; Turk Meadow; Davis Lake meadows. There would continue to be localized altered riparian vegetation in these areas, with some cumulative decreases in vegetation adequate to provide for watershed protection.

Little grazing currently occurs in Little Lakes Valley, however there is likely to be continued direct and cumulative adverse effects related to trampling by hiker traffic throughout this analysis unit. Little or no grazing or even hiking use occurs and there would be little change in the Morgan Lakes area.

Hilton Creek: Continued localized direct effects at Turk Meadow and in the meadows near Davis Lake would include localized loss of vegetation where stock roll and dust themselves near designated campsites, loss of vegetation in stock holding areas, reduced vegetative vigor,

reduced productivity, and a decrease in vegetative cover. Indirect effects over the long-term would be a reduction of late-seral vegetative species and an increase in early-seral species and bare areas at these limited locations.

Effects to the meadows elsewhere in the Hilton Lakes areas could be limited to local and minor trampling in riparian areas along trails near Lakes 4 and 5.

There would continue to be adequate vegetation to provide for normal ecological processes.

Tamarack: There would continue to be limited grazing and trampling effects to riparian vegetation near and to the east of Dorothy Lake and at several isolated riparian areas along trails as stock accessed drinking water and at stream crossings. Much of the perennial grass portion, including approximately half of the meadow area, has recently died and the remnant sod continues being lost to wind erosion in the meadow at the outlet of Dorothy Lake.

The areas of lost vegetation and other bare areas in this meadow would be colonized by annual herbaceous vegetation over the long-term. There would continue to be adequate vegetation to provide for normal ecological processes.

Little Lakes Valley: Little grazing currently occurs in the Little Lakes Valley Analysis. There would be limited trampling effects to and loss of riparian vegetation near Marsh Lake and at several isolated riparian areas along trails as stock accessed drinking water and at stream crossings. There would be continued trampling damage to vegetation and a localized loss of vegetative cover and altered plant species composition along popular hiking trails such as adjacent to Marsh Lake, the east shore of Long Lake, along the west side of Chickenfoot Lake, and near the outlet of Gem Lake.

There would continue to be adequate vegetation to provide for normal ecological processes.

Morgan Lakes: No grazing is proposed in the Morgan Lakes Analysis Unit, little or no grazing currently occurs and the effects would be the same as for no grazing.

There would continue to be adequate vegetation to provide for normal ecological processes.

Pioneer Basin and Fourth Recess: The meadows in Pioneer Basin were closed to grazing in 1988 and current conditions would continue above Mudd Lake. There would likely be continued loss of riparian vegetation at multiple associated with erosion of the trail from Mudd Lake to the Lake at 10,900 feet elevation and at a few locations on the trail from Mudd Lake to Lake #2.

At Hopkins Bench Meadow (FOR8) the direct effects would be trampling of the vegetation in the meadow and trampling of the vegetation on the banks of the small tributary stream that must be crossed to access the campsite. Indirect effects would be localized decreased vegetative growth.

Long-term there would also be continued loss of riparian vegetation associated with the collapsing stream banks of Mono Creek at Hopkins Bench Camp, the associated headcut would continue to advance laterally as it and the associated gully are used by pack stock to access the creek for drinking water, resulting in a localized trampling related loss of riparian vegetation along the edges and below the developing gully. There would be limited loss of riparian vegetation along the small tributary stream in the short-term, expanding along the stream over the long-term. Over the short-term to long-term there would be a decrease in riparian vegetation adequate to mitigate the risk factors relating to Proper Functioning Condition. It is likely that there would be persistent cumulative adverse effects over the very long-term at this location.

Hopkins, Laurel and Second Recess: In the short-term there would be continued trampling and removal of vegetation and a reduction in vegetative cover near Lower Hopkins Lake, at Lower laurel Creek Meadows, and at Second Recess Meadows.

In the upper meadows and at Laurel Lake Meadows and Second Recess Meadows there would be a limited decrease in vegetative productivity, with localized decreases in mid-seral and low-seral vegetation cumulatively over the long-term to very long-term

Silver Peak: There would be continued localized alteration of vegetative species composition, with reduced cover of late-seral species associated with trails in the meadows at Silver Pass Lake (SIP11) in the short-term. The vegetation at Pocket Meadow (SIP4) adjacent to Mono Creek would be characterized by late-seral species on the terrace level under the lodge pole. The in stream bars would continue to be dominated by bare soils and early-seral species for the long-term. The meadows along the trail to Mott Lake (SIP5) currently receive little overnight use, although some dunnage drops occur there. The vegetation is currently dominated by late-seral plants; there would continue to be a localized loss of riparian vegetative species composition primarily due to trampling.

There would continue to be a loss of late-seral riparian vegetation in the meadow along the system trail above the switchbacks north of the Mott Lake Trail junction (SIP6) especially on the meadow terraces above the stream, on the stream banks, and at creek crossings in this meadow.

There would continue to be inadequate riparian vegetation to provide for ecological processes such as to mitigate the functioning condition risk factors over the long-term to very long-term at Silver pass Meadow.

Volcanic: Current conditions at Volcanic Knob Meadow include low use and limited trampling and rutting in the wetter riparian sites along the system trail and along the access to the snow survey cabin.

These conditions would likely continue as there would be continued administrative access to the snow survey site and otherwise it is likely that these areas would be used by an occasional hunting group. There would continue to be adequate riparian vegetation to provide watershed protection.

Graveyard: Current use by cattle appears to occur often at Graveyard Meadow and infrequently above Graveyard Meadow. Graveyard Meadow has extensive areas of altered vegetative species composition with reductions in late-seral riparian vegetation and increased mid-seral and low-seral vegetation, especially on the meadow terrace level, and on stream banks. There are also actively unstable stream banks and bare point and mid-stream bars with stock trails along the edges of actively collapsing banks. These conditions will continue over the long-term regardless of the level of pack stock grazing. Current pack stock use is low and is not expected to increase significantly over the long-term. There are some old erosion control structures on a tributary in the south side of the meadow that are failing, with an associated loss of riparian vegetation.

On benches between the lowermost Graveyard Lake and the junction with the Goodale Pass Trail is a moist to dry meadow system that is occasionally used by pack stock. There are little to no changes in vegetation species on these benches, and with current levels of grazing there would be little change. There would be some localized trampling and sod fragmentation near lower Graveyard Lake, mostly associated with dunnage drops.

The sites with loss of riparian vegetation and altered vegetative species in Graveyard, Middle Graveyard and through upper Cold Creek to the upper meadows below Goodale Pass would continue with or without pack stock grazing until and unless an active restoration program addressed the current and historic trail related affects.

There would be localized loss of riparian vegetation associated with the designated camps, stock holding areas, and grazing areas, especially along the grazing access trail in the center of the meadow and along that trail to the upper spring, at Quail Meadow and near the designated packer camp near the outlet of Lower Graveyard Lake. The majority of Quail Meadow would remain in late-seral vegetative status, with adequate riparian vegetation.

Cumulative Effects

The recovery from the widespread affects of historical and recent production livestock grazing will take decades in many locations. Commercial pack stock use has minimal effects compared to any continuing cattle grazing. However current levels of commercial pack stock use will continue to have a substantial synergistic effect only in some locations, such as in the Silver Pass, Hilton Creek, Little Lakes Valley, and Graveyard Analysis Units. Current levels of commercial pack stock grazing and use will have a noticeable but less substantial cumulative effect in the Mono Creek, Bear, and Pioneer Analysis Units.

There are some meadows, including Graveyard (see discussion above), meadows near the junction of the Graveyard Lake trail, and Silver Pass Meadow where there are long-term historical unstable watershed conditions and chronic processes such as instability along the associated creek. With these chronic existing conditions there is likely to be loss of riparian obligate vegetation, decreased stabilizer plant species, and increased mid-seral or early-seral vegetative condition. There is likely to not be adequate vegetation to provide for watershed protection with implementation of any alternative, as a result of the synergistic relationship between the historical and currently occurring processes. There would likely be continued substantial loss of riparian vegetation at Silver Pass Meadow (SIP6). There would continue to be altered riparian vegetation and inadequate riparian vegetation to provide for watershed protection in these areas until and unless a watershed restoration program is successfully implemented.

In Little Lakes Valley, hiker and angler compaction effects may have cumulative effect with pack stock use, but since commercial pack stock use is light in this area, it is only slight and local.

Grazing Resources – Alternative 2-Modified

Analysis

There would be approximately 2,025 stock nights of grazing available in this geographic area with implementation of Alternative 2-Modified. There would be continued localized effects similar to those described for Alternative 2, although at a slightly increased level over time and cumulatively at the popular destination locations including: near the Lower Graveyard Lake trail junction; near Davis Lake; Turk Meadow; Quail Meadow; near Mudd Lake; and the meadows near Hopkins Bench Camp. There could be new grazing effects such as localized loss of vegetative cover, alteration of vegetative species composition cumulative over time at Laurel Lake meadows below the lake and at Second Recess meadows.

Direct effects would be elimination of grazing related trampling of and removal of vegetation at areas recommended as not suitable for grazing or to not be grazed by commercial pack stock and at the additional locations recommended for rest to ensure recovery. There would be increases in vegetative production in the short-term, especially near springs and streams. Transition to late-seral vegetation would occur over the long-term in these ungrazed areas including: the meadows at Hopkins Bench Camp; Upper Graveyard meadows; meadows at Hilton Lakes 4-6; the meadows at Lower Hopkins Lake; Grinnell Lake meadows; upper and middle meadows at Laurel Lake; north of Mono Rock (FOR1); and the meadows of Pioneer Basin above Mudd Lake. Cumulatively there would be establishment of vegetation adequate to provide for watershed protection and decreased risk, especially if watershed and trail restoration work is accomplished.

No grazing is proposed for all of Little Lakes Valley, however there is likely to be continued direct and cumulative effects related to trampling by hiker traffic throughout this analysis unit.

There would likely be continued loss of riparian vegetation and continued inadequate vegetation to provide watershed protection at Graveyard Meadow; the lakeshore meadows of lower Graveyard Lakes; Silver Pass Meadow (SIP6) and the Dorothy Lake outlet meadows over the long-term.

There may be increased recruitment and growth of riparian and vegetative recovery over the long-term to very long-term at these locations, depending upon the effects of factors other than commercial pack stock, such as hikers at Lower Graveyard Lake, cattle grazing and trampling at Graveyard Meadow, and unstable stream banks at Silver Pass Meadow. Although little grazing, by cattle or pack stock occurs upstream of the junction of the Graveyard Lakes and Goodale Pass Trails and in the meadows between that junction and Graveyard Meadow, there is active erosion and loss of riparian vegetation associated with historical trails and uses. This instability and loss of riparian vegetation is likely to continue until an active restoration program is successfully implemented.

Hilton Creek: Some meadows assessed in the Hilton Creek watershed and several meadows in the Mono Creek watershed will experience direct effects of grazing. The direct effects in these meadows would be a localized loss of vegetation where stock roll and dust themselves near designated campsites, loss of vegetation due to trampling and manure accumulation in stock holding areas, reduced vegetative vigor, reduced productivity, and a decrease in vegetative cover. Indirect effects over the long-term would be a reduction of late-seral vegetative species and an increase in early-seral species and bare areas at these limited locations.

With implementation of the Alternative 2-Modified there may be limited direct effects, such as trampling of the vegetation and sod fragmentation at Turk Meadow and in the meadows near Davis Lake. Effects to the meadows elsewhere in the Hilton Lakes areas could be limited to isolated riparian areas along trails near Lakes 4 and 5.

Long-term effects would be overall increased vegetative cover along the trail between lakes 5 and 6 and limited trampling related loss of riparian vegetation in the meadows near Davis Lake and in Turk Meadow.

Tamarack: No grazing is proposed in the Tamarack Analysis Unit. There would continue to be limited trampling effects to riparian vegetation near and to the east of Dorothy Lake and at several isolated riparian areas along trails as stock accessed drinking water and at stream

crossings. Much of the perennial grass portion, including approximately half of the meadow area, has recently died and the remnant sod continues being lost to wind erosion in the meadow at the outlet of Dorothy Lake.

The areas of lost vegetation and other bare areas in this meadow would be colonized by annual herbaceous vegetation over the long-term; there may not be adequate riparian vegetation to provide for sustainability of ecological processes over the long-term. Elsewhere in the Tamarack Analysis Unit there would continue to be adequate vegetation to provide for watershed protection.

Little Lakes Valley: No grazing is proposed in the Little Lakes Valley Analysis and the effects of implementation of Alternative 2-Modified are the same as for the other alternatives. There would be limited trampling effects to and loss of riparian vegetation near Marsh Lake and at several isolated riparian areas along trails as stock accessed drinking water and at stream crossings. There would be continued trampling damage to vegetation and localized loss of vegetative cover and altered plant species composition along popular hiking trails such as adjacent to Marsh Lake, the east shore of Long Lake, along the west side of Chickenfoot Lake, and near the outlet of Gem Lake.

Morgan Lakes: No grazing is proposed in the Morgan Lakes Analysis Unit, effects of Alternative 2-Modified are the same as for no grazing.

Pioneer Basin, Fourth Recess: The meadows in Pioneer Basin were closed to grazing in 1988 and current conditions would continue above Mudd Lake. The effects in the meadows categorized as not suitable would be similar to no grazing; these include Upper Pioneer Basin, the Meadow north of Mono Rock, and the meadows in the Laurel Creek drainage above the lowermost meadows. At Mudd Lake, especially in the meadows immediately to the east, along the east shores and around to the southwest corner, in the short-term there would be a localized decrease in vegetative growth, and decreased vegetative cover.

Near Mudd Lake, and near Lower Laurel Creek meadows, there could be an increase in mid-seral and low-seral vegetation and increased bare areas cumulatively over the long-term. Cumulatively, over the long-term there may not be maintenance of adequate vegetation to provide watershed protection, especially in the moist to dry meadows to the east of Mudd Lake. There would likely be continued loss of riparian vegetation at multiple associated with erosion of the trail from Mudd Lake to the Lake at 10,900 feet elevation and at a few locations on the trail from Mudd Lake to Lake #2.

At Hopkins Bench Meadow (FOR8) in the short-term there would be localized decreased vegetative growth and in the long-term an increase in mid-seral and low-seral vegetation. Long-term there would be continued loss of riparian vegetation associated with the collapsing stream banks of Mono Creek, the associated headcut would continue to advance, resulting in loss of riparian vegetation along the developing gully. There would be limited loss of riparian vegetation along the small tributary stream in the short-term, expanding along the stream over the long-term. Over the very long-term late-seral riparian vegetation could become established on the headcuts and stream banks. Cumulatively there would continue to be inadequate vegetation to provide for watershed protection over the long-term.

Hopkins, Laurel and Second Recess: Over the short-term the existing riparian vegetation would fill in and restore the wetter areas of the meadows around Hopkins Lake.

Over the long-term riparian and moist meadow vegetation would increase in productivity and increase the vegetative cover in the current dusting sites and along the user-defined trails on the west side of Lower Hopkins Lake. In the upper meadows and at Laurel Lake Meadows, Second Recess Meadows, and near the designated camp and stock holding areas, there would be increased grazing use and over the short-term a limited decrease in vegetative productivity, with localized increases in mid-seral and low-seral vegetation over the long-term to very long-term.

Silver Peak: There would be continued localized alteration of vegetative species composition, with reduced cover of late-seral species associated with trails in the meadows at Silver Pass Lake (SIP11) in the short-term. The vegetation at Pocket Meadow (SIP4) adjacent to Mono Creek would be characterized by late-seral species on the terrace level under the lodge pole. The in stream bars would continue to be dominated by bare soils and early-seral species for the long-term. The meadows along the trail to Mott Lake (SIP5) currently receive little overnight use, although some dunnage drops occur there. The vegetation is currently dominated by late-seral plants; there would continue to be a localized loss of riparian vegetative species composition primarily due to trampling.

No grazing is proposed in the meadow along the system trail above the switchbacks north of the Mott Lake Trail junction (SIP6) on the meadow terraces above the stream and on the stream banks in this meadow.

Cumulatively there would be continued loss of late-seral vegetation and limited loss of vegetative cover on the stream banks at the upper and lower ends of Silver Pass Meadow as pack stock groups traveling through would continue to use these locations for resting and watering after climbing the switchbacks from the Mott Lake Trail Junction. Over the long-term these continued impacts could reduce or prevent the recovery of this meadow to a more desirable ecological condition.

Volcanic: Current conditions at Volcanic Knob Meadow include low use and limited trampling and rutting in the wetter riparian sites along the system trail and along the access to the snow survey cabin.

These conditions would likely continue as there would be continued administrative access to the snow survey site and it is unlikely that these areas would be used by more than occasional hunting groups.

Graveyard: Current use by cattle appears to occur often at Graveyard Meadow and infrequently above Graveyard Meadow. Graveyard Meadow has extensive areas of altered vegetative species composition with reductions in late-seral riparian vegetation and increased mid-seral and low-seral vegetation, especially on the meadow terrace level, and on stream banks. There are also actively unstable stream banks and bare point and mid-stream bars. These conditions will continue over the long-term regardless of the level of pack stock grazing. Current pack stock use is low and is not expected to increase significantly over the long-term.

On benches between the lowermost Graveyard Lake and the junction with the Goodale Pass Trail is a moist to dry meadow system that is occasionally used by pack stock. There are little to no changes in vegetation species on these benches, and with grazing there would be little change. There would be some localized trampling and sod fragmentation near lower Graveyard Lake, mostly associated with dunnage drops, which would likely increase with Alternative 3.

Rest from grazing will result in increased late-seral riparian vegetation needed to provide watershed protection at Upper Graveyard Meadow. Some of the sites associated with active erosion features that have historical loss of riparian vegetation and altered vegetative species in Upper Graveyard and through upper Cold Creek would continue with or without pack stock grazing until and unless an active restoration program resolves the current and historic trail and grazing related effects.

There would be localized loss of riparian vegetation associated trampling impacts near the designated camps, stock holding areas, and grazing areas, especially along the grazing access trail in the center of the meadow and along that trail to the upper spring, at Quail Meadow and near the designated packer camp near the outlet of Lower Graveyard Lake. The majority of Quail Meadow would remain in late-seral vegetative status, with adequate riparian vegetation.

Cumulative Effects

Because of resting Graveyard and Silver Pass Meadows, the cumulative effects of Alternative 2-Modified with existing historic and current livestock grazing effects would be less than Alternative 1.

Grazing Resources – Alternative 2

Analysis

There would be approximately 2,088 stock nights of grazing available in this geographic area with implementation of Alternative 2. locations in this geographic area where grazing is proposed and where localized direct effects, as detailed in the site-specific discussions in the Analysis Units section, of grazing and trailing would occur include: Volcanic Knob meadows; Pocket Meadow; Mudd Lake meadows; lower Laurel Creek meadows; Quail Meadows; Hopkins Bench Camp meadows; Upper Graveyard meadows; the meadows to the east of lower Graveyard Lakes; Cold Creek meadows; Turk Meadow; and Davis Lake meadows.

Direct effects at areas recommended as not suitable for grazing by commercial pack stock would be increases in vegetative production in the short-term, especially near springs and streams. Transition to late-seral vegetation would occur over the long-term in these unsuitable areas including: meadows at Hilton Lakes 4-6; the meadows at Lower Hopkins Lake; Grinnell Lake meadows; upper and middle meadows at Laurel Lake; north of Mono Rock (FOR1); and the meadows of Pioneer Basin above Mudd Lake.

No grazing is proposed for all of Little Lakes Valley. There is likely to be continued direct, indirect, and cumulative effects related to trampling by hiker traffic and camping throughout this analysis unit but especially around the lakeshores of the lakes between the trailhead and Chickenfoot Lake.

There would likely be continued loss of riparian vegetation and continued inadequate vegetation to provide watershed protection at Graveyard Meadow; at localized sites around the lakeshore meadows of lower Graveyard Lakes (due largely to hiker campsites and social trails); Silver Pass Meadow (SIP6) and, in the Tamarack Analysis Unit, the Dorothy Lake outlet meadows over the long-term. Cumulatively there may be increased recruitment and growth of riparian and vegetative recovery over the long-term to very long-term at these locations, depending upon the effects of factors other than commercial pack stock, such as hikers at Lower Graveyard Lake,

cattle grazing and trampling at Graveyard Meadow, continued loss of riparian vegetation at Dorothy Lake, and unstable stream banks and stock watering at Silver Pass Meadow. Although little grazing, by cattle or pack stock occurs upstream of the junction of the Graveyard Lakes and Goodale Pass Trails and in the meadows between that junction and Graveyard Meadow, there is active erosion and loss of riparian vegetation associated with historical trails and uses. This instability is likely to continue until an active watershed restoration program is implemented.

Hilton Creek: Some meadows assessed in the Hilton Creek watershed and several meadows in the Mono Creek watershed will experience the direct effects of grazing. The direct effects in these would be a localized loss of vegetation where stock roll and dust themselves near designated campsites, loss of vegetation in stock holding areas. Indirect effects would be reduced vegetative vigor, reduced productivity, and a decrease in vegetative cover. Cumulative effects over the long-term would be a localized reduction of late-seral vegetative species needed to provide watershed protection and an increase in early-seral species and bare areas at these limited locations.

In the locations recommended as un-suitable for grazing there would be elimination of the direct effects of grazing and increases in vegetative production, vigor and recruitment especially near springs and streams. Long-term there would be full development of the natural late-seral communities in these areas, including the meadows at Hilton Lakes 5 and 6.

With implementation of Alternative 2 there may be localized direct effects of grazing, trailing, and trampling at Turk Meadow and in the meadows near Davis Lake. Effects to the meadows elsewhere in the Hilton Lakes areas could be limited to isolated riparian areas along trails near Lakes 4 and 5. Long-term effects would be overall increased vegetative cover along the trail between lakes 5 and 6 and limited trampling related loss of riparian vegetation in the meadows near Davis Lake and in Turk Meadow.

Cumulatively, vegetative resources would likely remain within desired condition at these locations over the long-term with continued vegetation adequate to provide for watershed protection.

Tamarack: Little grazing currently occurs and no grazing is proposed in the Tamarack Analysis Unit. There would continue to be limited trampling effects to riparian vegetation near and to the east of Dorothy Lake and at several isolated riparian areas along trails as stock accessed drinking water and at stream crossings. Much of the perennial grass portion of this meadow, including approximately half of the meadow area, has recently died and the remnant sod continues being lost to wind erosion in the meadow at the outlet of Dorothy Lake.

The areas of lost vegetation and other bare areas in this meadow would be colonized by annual herbaceous vegetation and cumulatively there may not be adequate vegetation to provide watershed protection over the long-term. Elsewhere in the Tamarack Analysis Unit there would continue to be adequate vegetation to provide for watershed protection.

Little Lakes Valley: No grazing is proposed in the Little Lakes Valley Analysis. There would be limited trampling effects to and loss of riparian vegetation near Marsh Lake and at several isolated riparian areas along trails as stock accessed drinking water and at stream crossings as trailing stock trampled the stream bank vegetation. There would be continued trampling damage to vegetation and localized loss of vegetative cover and altered plant species composition along

popular hiking trails such as adjacent to Marsh Lake, the east shore of Long Lake, along the west side of Chickenfoot Lake, and near the outlet of Gem Lake.

Morgan Lakes: No grazing is proposed and little currently occurs in the Morgan Lakes Analysis Unit, effects of the Proposed Action are the same as for no grazing, with little change in resource conditions expected.

Pioneer Basin, Fourth Recess: The meadows in Pioneer Basin were closed to grazing in 1988 and current conditions would continue above Mudd Lake. There would likely be continued and increased loss of riparian vegetation along the trail from Mudd Lake to the lake at 10,900 feet elevation and at some locations along the trail to Lake 2 unless restoration is accomplished. The effects in the meadows categorized as not suitable would be similar to no grazing; these include Upper Pioneer Basin, the Meadow north of Mono Rock, meadows in the Laurel Creek drainage above the lowermost meadows, and Hopkins Lake Meadows.

At Mudd Lake, especially in the meadows immediately to the east, along the east shores and around to the southwest corner, in the short-term the direct effects of grazing and trailing along the lakeshore would be a localized decrease in vegetative growth, and decreased vegetative cover. Indirect effects in these areas would be a localized increase in mid-seral and low-seral vegetation and increased bare areas. Cumulatively there may not be maintenance of adequate riparian vegetation over the long-term to provide for watershed protection and there may be an increased risk of loss of watershed function during high flow events, especially in the moist to dry meadows to the east of Mudd Lake.

At Hopkins Bench Meadow (FOR8) in the short-term there would be localized decreased vegetative growth and in the long-term an increase in mid-seral and low-seral vegetation. Long-term there would be continued loss of riparian vegetation associated with the collapsing stream banks of Mono Creek, the associated headcut would continue to advance, resulting in a localized loss of riparian vegetation along the edges and below the developing gully. There would be limited loss of riparian vegetation along the small tributary stream in the short-term, expanding along the stream over the long-term.

Over the long-term to very long-term there may not be adequate late-seral riparian vegetation to provide watershed protection on the headcuts and stream banks.

Hopkins, Laurel and Second Recess: Over the short-term, without the direct effects of grazing and trampling of the vegetation, the existing vegetation would fill in and restore the wetter areas of the meadows around Lower Hopkins Lake. Over the long-term riparian and moist meadow vegetation would increase in productivity and increase the vegetative cover in the current dusting sites and along the user-defined trails on the west side of Lower Hopkins Lake. In the upper meadows and at Laurel Lake Meadows, Second Recess Meadows, and near the designated camp and stock holding areas, there would be increased grazing use and over the short-term would be a localized decrease in vegetative productivity, with localized increases in mid-seral and low-seral vegetation cumulatively over the long-term to very long-term.

There would continue to be adequate riparian vegetation to provide for watershed protection over the long-term.

Silver Peak: There would be continued localized direct effects of grazing, trailing, and trampling of vegetation, including alteration of vegetative species composition, with reduced cover of late-seral species associated with trails in the meadows at Silver Pass Lake (SIP11) in

the short-term. Over the long-term, with continued low levels of use expected, the vegetation at Pocket Meadow (SIP4) adjacent to Mono Creek would be characterized by late-seral species on the terrace level under the lodge pole. The in stream bars would continue to be dominated by bare soils and early-seral species for the long-term. The meadows along the trail to Mott Lake (SIP5) currently receive little overnight use, although some dunnage drops occur there.

No grazing is proposed in the meadow along the system trail above the switchbacks north of the Mott Lake Trail junction (SIP6) on the meadow terraces above the stream and on the stream banks in this meadow. The consequences in most of this meadow would be similar to Alternative 5 (no pack stock use) although with implementation of any pack stock use alternative (Alternatives 2, 3, and 4) there would be some additional localized trampling related loss of late-seral vegetation and loss of vegetative cover on the stream banks at the upper and lower ends of this meadow as pack stock groups traveling through, especially traveling from south to north, would continue to use these locations for resting and watering after climbing the switchbacks from the Mott Lake Junction.

There would be a localized and minor loss of riparian vegetative species composition primarily due to trampling but there would be adequate riparian vegetation over the long-term.

Volcanic: Current conditions at Volcanic Knob Meadow include low use and limited trampling and rutting in the wetter riparian sites along the system trail and along the access to the snow survey cabin. With the expected low levels of use by pack stock these conditions would likely continue as there would be continued administrative access to the snow survey site. It is unlikely that these areas would be used by more than occasional hunting groups.

There would continue to be adequate riparian vegetation for watershed protection at Volcanic Knob Meadow.

Graveyard: Current use by cattle does not appear to occur often above Graveyard Meadow and overnight use by pack stock is low in this area as well. Graveyard Meadow has extensive areas of altered vegetative species composition with reductions in late-seral riparian vegetation and increased mid-seral and low-seral vegetation, especially on the meadow terrace level, and on stream banks. There are also actively unstable stream banks and bare point and mid-stream bars. Current use by pack stock is low and is not expected to increase significantly over the long-term.

On benches between the lower Graveyard Lake and the junction with the Goodale Pass Trail is a moist to dry meadow system that is occasionally used by pack stock. There are little to no changes in vegetation species on these benches, and with grazing there would be little change. There would be some localized trampling and sod fragmentation near lower Graveyard Lake associated with dunnage drops.

The limited sites with loss of riparian vegetation and altered vegetative species in Middle Graveyard, Graveyard, and through upper cold Creek to the upper meadows below Goodale Pass would continue with or without pack stock grazing until an active restoration program is implemented.

There would be localized loss of riparian vegetation associated with trampling of vegetation at the designated camps, stock holding areas, and grazing areas, especially along the grazing access trail in the center of the meadow and along that trail to the upper spring at Quail Meadow and near the designated packer camp near the outlet of Lower Graveyard Lake.

Cumulatively the majority of this Analysis Unit would remain in late-seral vegetative status with adequate vegetation to provide for watershed protection.

Cumulative Effects

The cumulative effects of Alternative 2 with existing historic and continuing cattle grazing would be less than Alternative 1, but more than Alternatives 2-Modified, 3, 4, and 5.

Grazing Resources – Alternatives 3 and 4

Analysis

There would be approximately 2,025 stock nights of grazing available with implementation of Alternative 3 and 1,541 stock nights available with implementation of Alternative 4 in this geographic area. There would be continued localized effects similar to those described for Alternative 2, although at a slightly increased level over time and cumulatively at the popular destination locations including: near the Lower Graveyard Lake trail junction; near Davis Lake; Turk Meadow; Quail Meadow; near Mudd Lake; and the meadows near Hopkins Bench Camp. There could be new grazing effects such as localized loss of vegetative cover, alteration of vegetative species composition cumulative over time at Laurel Creek meadows below Laurel Lake and at Second Recess meadows.

Direct effects would be elimination of grazing related trampling of and removal of vegetation at areas recommended as not suitable for grazing or to not be grazed by commercial pack stock and at the additional locations recommended for rest to ensure recovery. There would be increases in vegetative production in the short-term, especially near springs and streams. Transition to late-seral vegetation would occur over the long-term in these ungrazed areas including: the meadows at Hopkins Bench Camp; Upper Graveyard meadows; meadows at Hilton Lakes 4-6; the meadows at Lower Hopkins Lake; Grinnell Lake meadows; upper and middle meadows at Laurel Lake; north of Mono Rock (FOR1); and the meadows of Pioneer Basin above Mudd Lake. Cumulatively there would be establishment of vegetation adequate to provide for watershed protection and decreased risk, especially if watershed and trail restoration work is accomplished.

No grazing is proposed for all of Little Lakes Valley, however there is likely to be continued direct and cumulative effects related to trampling by hiker traffic throughout this analysis unit.

There would likely be continued loss of riparian vegetation and continued inadequate vegetation to provide watershed protection at Graveyard Meadow; the lakeshore meadows of lower Graveyard Lakes; Silver Pass Meadow (SIP6) and the Dorothy Lake outlet meadows over the long-term. Cumulatively there may be increased recruitment and growth of riparian and vegetative recovery over the long-term to very long-term at these locations, depending upon the effects of factors other than commercial pack stock, such as hikers at Lower Graveyard Lake, cattle grazing and trampling at Graveyard Meadow, and unstable stream banks at Silver Pass Meadow. Although little grazing, by cattle or pack stock occurs upstream of the junction of the Graveyard Lakes and Goodale Pass Trails and in the meadows between that junction and Graveyard Meadow, there is active erosion and loss of riparian vegetation associated with historical trails and uses. This instability is likely to continue until an active watershed restoration program is implemented.

Hilton Creek: Some meadows assessed in the Hilton Creek watershed and several meadows in the Mono Creek watershed will experience direct effects of grazing. The direct effects in these meadows would be a localized loss of vegetation where stock roll and dust themselves near designated campsites, loss of vegetation due to trampling and manure accumulation in stock holding areas, reduced vegetative vigor, reduced productivity, and a decrease in vegetative cover. Indirect effects over the long-term would be a reduction of late-seral vegetative species and an increase in early-seral species and bare areas at these limited locations.

With implementation of the proposed action, there may be limited direct effects, such as trampling of the vegetation and sod fragmentation at Turk Meadow and in the meadows near Davis Lake. Effects to the meadows elsewhere in the Hilton Lakes areas could be limited to isolated riparian areas along trails near Lakes 4 and 5.

Long-term effects would be overall increased vegetative cover along the trail between lakes 5 and 6 and limited trampling related loss of riparian vegetation in the meadows near Davis Lake and in Turk Meadow.

Tamarack: No grazing is proposed in the Tamarack Analysis Unit. There would continue to be limited trampling effects to riparian vegetation near and to the east of Dorothy Lake and at several isolated riparian areas along trails as stock accessed drinking water and at stream crossings. Much of the perennial grass portion, including approximately half of the meadow area, has recently died and the remnant sod continues being lost to wind erosion in the meadow at the outlet of Dorothy Lake.

The areas of lost vegetation and other bare areas in this meadow would be colonized by annual herbaceous vegetation over the long-term; there may not be adequate riparian vegetation to provide for watershed protection over the long-term. Elsewhere in the tamarack Analysis Unit there would continue to be adequate vegetation to provide for watershed protection.

Little Lakes Valley: No grazing is proposed in the Little Lakes Valley Analysis and the effects of implementation of Alternative 3 are the same as for the other alternatives. There would be limited trampling effects to and loss of riparian vegetation near Marsh Lake and at several isolated riparian areas along trails as stock accessed drinking water and at stream crossings.

There would be continued trampling damage to vegetation and localized loss of vegetative cover and altered plant species composition along popular hiking trails such as adjacent to Marsh Lake, the east shore of Long Lake, along the west side of Chickenfoot Lake, and near the outlet of Gem Lake.

Morgan Lakes: No grazing is proposed in the Morgan Lakes Analysis Unit, effects of Alternative 3 are the same as for no grazing.

Pioneer Basin and Fourth Recess: The meadows in Pioneer Basin were closed to grazing in 1988 and current conditions would continue above Mudd Lake. The effects in the meadows categorized as not suitable would be similar to no grazing; these include Upper Pioneer Basin, the Meadow north of Mono Rock, meadows in the Laurel Creek drainage above the lowermost meadows, and Hopkins Lake Meadows. At Mudd Lake, especially in the meadows immediately to the east, along the east shores and around to the southwest corner, in the short-term there would be a localized decrease in vegetative growth, and decreased vegetative cover. In these areas, there would be an increase in mid-seral and low-seral vegetation and increased bare areas cumulatively over the long-term.

At Hopkins Bench Meadow (FOR8) in the short-term there would be localized decreased vegetative growth and in the long-term an increase in mid-seral and low-seral vegetation. Long-term there would be continued loss of riparian vegetation associated with the collapsing stream banks of Mono Creek, the associated headcut would continue to advance, resulting in loss of riparian vegetation along the developing gully.

At Hopkins Bench Camp there would be limited loss of riparian vegetation along the small tributary stream in the short-term, expanding along the stream over the long-term. Over the very long-term late-seral riparian vegetation could become established on the headcuts and stream banks. Cumulatively, over the long-term there may not be maintenance of adequate vegetation to provide watershed protection, especially in the moist to dry meadows to the east of Mudd Lake. There would likely be continued loss of riparian vegetation at multiple associated with erosion of the trail from Mudd Lake to the Lake at 10,900 feet elevation and at a few locations on the trail from Mudd Lake to Lake #2.

Hopkins, Laurel and Second Recess: Over the short-term the existing riparian vegetation would fill in and restore the wetter areas of the meadows around Hopkins Lake.

Over the long-term, riparian and moist meadow vegetation would increase in productivity and there would be increased vegetative cover in the current dusting sites and along the user-defined trails on the west side of Lower Hopkins Lake. In the upper meadows and at Laurel Lake Meadows, Second Recess Meadows, and near the designated camp and stock holding areas, there would be increased grazing use and over the short-term a limited decrease in vegetative productivity, with localized increases in mid-seral and low-seral vegetation over the long-term to very long-term.

Silver Peak: There would be continued localized alteration of vegetative species composition, with reduced cover of late-seral species associated with trails in the meadows at Silver Pass Lake (SIP11) in the short-term. The vegetation at Pocket Meadow (SIP4) adjacent to Mono Creek would be characterized by late-seral species on the terrace level under the lodge pole. The in stream bars would continue to be dominated by bare soils and early-seral species for the long-term. The meadows along the trail to Mott Lake (SIP5) currently receive little overnight use, although some dunnage drops occur there. The vegetation is currently dominated by late-seral plants; there would continue to be a localized loss of riparian vegetative species composition primarily due to trampling.

No grazing is proposed in the meadow along the system trail above the switchbacks north of the Mott Lake Trail junction (SIP6) on the meadow terraces above the stream and on the stream banks in this meadow. Consequences would be similar to no grazing, with some additional limited loss of late-seral vegetation and limited loss of vegetative cover on the stream banks at the upper and lower ends of this meadow as pack stock groups traveling through would continue to use these locations for resting and watering after climbing the switchbacks from the Mott Lake Trail Junction.

Over the long-term, these continued synergistic impacts together with the chronic impacts from the historical degradation could reduce or prevent the recovery of Silver Pass Meadow to a more desirable ecological condition.

Volcanic: Current conditions at Volcanic Knob Meadow include low use and limited trampling and rutting in the wetter riparian sites along the system trail and along the access to the snow survey cabin.

Existing conditions would likely continue as there would be continued administrative access to the snow survey site and it is unlikely that these areas would be used by more than occasional hunting groups.

Graveyard: Current use by cattle appears to occur often at Graveyard Meadow and infrequently above Graveyard Meadow. Graveyard Meadow has extensive areas of altered vegetative species composition with reductions in late-seral riparian vegetation and increased mid-seral and low-seral vegetation, especially on the meadow terrace level, and on stream banks. There are also actively unstable stream banks and bare point and mid-stream bars. These conditions will continue over the long-term regardless of the level of pack stock grazing. Current pack stock use is low and is not expected to increase significantly over the long-term.

On benches between the lowermost Graveyard Lake and the junction with the Goodale Pass Trail is a moist to dry meadow system that is occasionally used by pack stock. There are little to no changes in vegetation species on these benches, and with grazing there would be little change. There would be some localized trampling and sod fragmentation near lower Graveyard Lake, mostly associated with dunnage drops, which would likely increase with Alternative 3.

Rest from grazing will result in increased late-seral riparian vegetation needed to provide watershed protection at Upper Graveyard Meadow.

There would be localized loss of riparian vegetation associated trampling impacts near the designated camps, stock holding areas, and grazing areas, especially along the grazing access trail in the center of the meadow and along that trail to the upper spring, at Quail Meadow and near the designated packer camp near the outlet of Lower Graveyard Lake.

The majority of Quail Meadow would remain in late-seral vegetative status, with adequate riparian vegetation. Some of the sites associated with active erosion features that have historical loss of riparian vegetation and altered vegetative species in Upper Graveyard and through upper Cold Creek would continue with or without pack stock grazing until and unless an active restoration program resolves the current and historic trail and grazing related effects.

Cumulative Effects

The cumulative effects of Alternatives 3 and 4 would be similar to those of Alternative 2-Modified.

Grazing Resources – Alternative 5

Analysis

The riparian vegetation in the Mono Creek portion of this geographic area is currently affected by grazing and trailing related impacts at several locations. No grazing would result in increased vegetative recruitment, production, and vigor over the short-term and increases in late-seral vegetation over the long-term.

The Hilton Creek, Morgan Lakes, Little Lakes Valley, and Tamarack areas currently receive little grazing use, and no grazing would represent no significant change. The Hilton Lakes area

may see a substantial increase in hiker traffic and existing levels of hiker traffic would continue in Little Lakes Valley, resulting in some level of continued adverse trampling related impacts to the riparian vegetation, over the long-term, in these areas.

Hilton Creek: Currently little overnight stock holding or actual grazing use occurs in the Hilton Lakes Basin. With implementation of the no grazing alternative there would be continued vegetative recovery of riparian vegetation in the lower end of Turk Meadow near the old packer camp, including increased vegetative cover, as well as increased cover and vigor of the riparian vegetation at the springs and along the spring channels in the upper south end of Turk Meadow.

There would be increased vegetative vigor over the long-term in the meadows around Davis Lake and continued recovery of the riparian areas along the trail between Lakes 5 and 6. Cumulatively, over the long-term, these riparian areas would reach potential natural vegetative cover and composition. There would be limited reductions in vegetative alteration due to trampling, especially near Dorothy Lake and at the outlet and meadows around Davis Lake and to a lesser extent the meadow areas near Second Lake. The riparian vegetation would likely not be re-established at the many of the campsites over the long-term, due to anticipated increases in use by hikers.

Tamarack: There would be some limited recovery of riparian vegetation near the Dorothy Lake outlet and at scattered riparian or stream bank areas that are currently trampled while watering pack stock. Much of the perennial grass portion, including approximately half of the meadow area, has recently died and in the short-term the remnant sod would continue to be lost to wind erosion in the meadow at the outlet of Dorothy Lake.

The areas of lost vegetation and other bare areas in this meadow could be colonized by annual herbaceous vegetation over the long-term. There would likely continue to be adequate vegetation throughout the Tamarack Analysis Unit to provide for watershed protection over the long-term.

Little Lakes Valley: There would continue to be localized trampling and loss of riparian vegetation by hiker traffic in many of the riparian areas and meadows in the Little Lakes Valley Analysis Unit.

There would be some limited recovery of riparian vegetation near Marsh Lake, at the junction of the Ruby Lake and Mono Pass trails and at scattered riparian or stream bank areas that are currently trampled while watering pack stock. The effects would be visual apparent but there would be adequate vegetation to provide for watershed protection.

Morgan Lakes: There would continue to be limited and minor trampling and loss of riparian vegetation from hiker use in the riparian areas along the trail above Morgan Lakes.

Pioneer Basin and Fourth Recess: The meadows in Pioneer Basin were closed to grazing in 1988 and current conditions would continue. In the short-term there would be localized loss of riparian vegetation associated with active headcuts and erosion along trails above Mudd Lake and at Mudd Lake.

At Hopkins Bench Camp Meadow (FOR8), no grazing would result in increased vegetative growth and productivity, in the short-term. The riparian vegetation associated with the small tributary stream near the campsite would recover productivity and vigor in the short-term. There would be increased vegetative growth along the stream banks of Mono Creek, near the associated lateral headcuts in the lower meadow, and near the spring between the trail and the lower meadow over the long-term. There would be no grazing related impacts to the wet

meadow north of Mono Rock and the existing late-seral riparian vegetation would quickly fill in the bare and trampled areas. Substantial reductions in stock traffic along the main trail would result in reduced erosion and deposition and increased vegetative recruitment and establishment along the entire Mono Creek corridor.

Over the long-term, most of these would be stabilized by recruitment and establishment of riparian vegetation. Some of the trail sites with deeper incision may not recover vegetatively without restoration work and cumulatively over the long-term there could be reduced riparian vegetation and increased watershed risk factors. Cumulatively, over the long-term to very long-term there would be adequate vegetation to provide for watershed protection.

Hopkins and Laurel: There would be retention of each year's growth of vegetation throughout the Analysis Unit.

Over the short-term the existing riparian vegetation would fill in and restore the wetter areas of the meadows around Hopkins Lake. Over the long-term, late-seral riparian and moist meadow vegetation would increase in productivity and increase vegetative cover, especially at the dusting sites and along user-defined trails on the west side of Lower Hopkins Lake. The vegetation may not recover along some of the deeper trails over the long-term; however cumulatively there would be adequate vegetation to provide for watershed protection.

Silver Peak: There would be continued localized alteration of vegetative species composition associated with trails in the meadows at Silver Pass Lake (SIP11) in the short-term, as in this low resiliency areas the hiker traffic would continue to affect the vegetation. Late-seral vegetation for the site would become established in the majority of these locations over the long-term to very long-term.

The vegetation at Pocket Meadow (SIP4) adjacent to Mono Creek would be characterized by late-seral species on the terrace level under the lodge-pole pine forest within the long-term. The in-stream bars would continue to be dominated by bare soils and early-seral species for the long-term to very long-term.

The meadows along the trail to Mott Lake (SIP5) currently receive little overnight use, although some dunnage drops occur there. The vegetation is currently dominated by late-seral plants, with limited loss of riparian vegetative species composition due to trampling. With no grazing these areas would fill in with late-seral vegetation in the short-term.

The meadow along the system trail above the switchbacks north of the Mott Lake Trail junction (SIP6) has received repeated stock use throughout the summer. There is widespread altered vegetative species composition on the meadow terraces above the stream and on the stream banks in this meadow, with reduced late-seral riparian vegetation and increased mid-seral and early-seral vegetation. This vegetative alteration is associated with unstable and eroding stream banks, active headcuts, soil compaction, and a lowered water table. These conditions would persist in the main portion of the meadow for the long-term to very long-term.

Cumulatively, over the very long-term, there would be increased cover by mid-seral and then late-seral species over the very long-term. The east portion of this meadow has several spring and small spring channels where the vegetation is currently trampled, with fragmented sod and bare areas. There would be increases in late-seral riparian vegetation in these areas in the short-term, with recruitment and establishment of late-seral riparian vegetation over the long-term.

Volcanic: Current conditions at Volcanic Knob Meadow include low use and limited trampling and rutting in the wetter riparian sites along the system trail and along the access to the snow survey cabin. These conditions would likely continue as there would be continued administrative access to the snow survey site, with associated low levels of trampling in the adjacent wet meadow areas.

Cumulatively overall in the analysis unit there would continue to be adequate vegetation to protect the watershed.

Graveyard: This area is part of a cattle allotment. Use by cattle does not appear to occur often above Graveyard Meadow. Graveyard Meadow has extensive areas of altered vegetative species composition with reductions in late-seral riparian vegetation and increased mid-seral and early-seral vegetation, especially on the meadow terrace level, and along the stream banks. There are also actively unstable stream banks, bare point and mid-stream bars, trampled and fragmented sod in springs, and unstable erosion control structures along a tributary stream. These conditions will continue over the long-term to very long-term regardless of the level of pack stock grazing, until and unless a watershed restoration plan is implemented.

On benches between the lowermost Graveyard Lake and the junction with the Goodale Pass Trail is a moist to dry meadow system that is occasionally used by pack stock. There are little to no changes in vegetation species on these benches, and the with no grazing there would be little change, as most of the areas of affected vegetation would continue to exhibit the effects of continual hiker traffic and camping throughout the summer.

The limited sites with loss of riparian vegetation and altered vegetative species in Middle Graveyard and through upper cold Creek to the upper meadows below Goodale Pass would continue with or without pack stock grazing until and unless an active restoration program addresses the current and historic grazing and trail related affects.

Cumulative Effects

The cumulative effects of Alternative 5 would be beneficial since the historic and current cattle grazing and hiker use effects would have most chance of recovery.

Fens

Fens – Alternative 1

Most meadows would be open for grazing, except Pioneer Basin which has been closed for resource concerns.

Little Lakes Valley AU: This analysis unit is not currently used for grazing although it would be open for grazing in this Alternative. The four meadows with fens would be at very little risk for pack stock trampling, but one of the two fens in Marsh Meadow would remain degraded. Most impacts in this unit are from heavy hiker and angler use.

Fourth Recess AU: At North of Mono Rock meadow, grazing would be allowed and impacts would continue, so the spring impacts would continue and the area with fen characteristics would continue to be trampled. Third Recess Creek meadow would be open to grazing, but trail access is not good, so use may be somewhat restricted, but there would continue to be trampling damage.

Volcanic AU: Volcanic Knob meadow would continue to be open to grazing, but as there is no current use, very little impact to the areas with fen characteristics is expected.

Graveyard AU: All the meadows in the Graveyard drainage would be open to grazing by both cattle and pack stock. The meadows with fens do not appear to be used by either currently, although they were in the past. The existing spring headcuts below the fen in Goodale Pass Meadow puts this fen at risk and the degraded meadow conditions at the other two meadows would not improve. Use at Feather Lake would most likely remain light and the fen in good condition.

Hilton AU: Turk Meadow, East of Davis, and the outlet of Davis Lake would be open for grazing, but use would be expected to stay at current very low levels. The fens are currently in good condition, but at risk for some trampling.

Pioneer AU: There would be no grazing at Camp Meadow because of a closure, but trails are causing the hydrologic problems and they would be open for use. There would be no expected recovery of the hydrologic function of the meadow.

Second Recess AU: Second Recess is currently open to grazing, but only lightly used because the trail is not easily passable to stock. Until the trail is repaired, the fen is at only slight risk of impacts.

Bear AU: The meadow near Kip Camp is open for grazing, but has not been used recently, so the area with fen characteristics is in good condition and would be expected to continue that way.

Cumulative Effects

The cumulative effects of commercial pack stock use with historic and current pack stock grazing would be similar to those in Ansel Adams West. The previous closure of Pioneer Basin to commercial pack stock grazing would continue, allowing recovery of meadow conditions in that area.

Fens – Alternative 2 - Modified

Approximately 35 percent of the meadows will be open for grazing, and inadvertent trampling and grazing impacts to any unknown fens would be more likely in these meadows. If grazing use patterns change from the current situation, monitoring would be required to determine impact to the fens.

Little Lakes Valley AU: No grazing would be allowed in this AU, so the fens would be at very little risk of pack stock trampling. The dried out fen at Marsh Meadow would continue in degraded condition.

Fourth Recess AU: There would be no grazing in the North of Mono Rock meadow, allowing the fen to recover from trampling impacts. There would be limited grazing in the Third Recess Meadow, so there would be no expected change in the meadow conditions or fen impacts.

Volcanic AU: Volcanic Meadow would be open for grazing with a large number of stock nights available. If all these nights were used, the areas with fen characteristics would probably have negative effects and monitoring would be required, however, it is not expected that the meadow will have much increase in use.

Graveyard AU: Three meadows with fens would be open for grazing, with a total of approximately 400 stock nights capacity in the grazing zone. If grazed to this capacity, there would be negative impacts to the fens, particularly at Goodale Pass Meadow. None of these meadows has any recent reported grazing by pack stock although cattle may use them occasionally. Since some of the meadows in Silver Divide would be closed in this alternative it is possible that some use may be displaced here. Feather Lake would not be open to grazing, so the fen would remain in good condition.

Hilton AU: Grazing would be allowed at Turk Meadow with a large number of stock nights capacity compared to its current low use. Because there is heavy pack stock-supported use at Hilton Lake, there may be more use at Turk Meadow if allowed. This would increase the risk of impacts to the fen in the upper part of the meadow. At Davis outlet and East of Davis, limited grazing would be allowed, so there could be some fen impacts, but no downward trend would be expected.

Pioneer AU: No grazing or trail use would be allowed at Camp Meadow, so the hydrologic function, that supports the fen, could begin to recover.

Second Recess AU: Second Recess Meadow would be open to grazing, but there would be no access until the trail is repaired. If the maximum grazing were used, there would be negative effects to the areas with fen characteristics.

Bear AU: The meadow near Kip Camp would be closed to grazing, so the fen would remain in good condition.

Cumulative Effects

The cumulative effects of commercial pack stock use with historic and current pack stock grazing would be similar to those in Ansel Adams West. The previous closure of Pioneer Basin to commercial pack stock grazing would continue, allowing recovery of meadow conditions in that area.

Fens – Alternative 2

The effects to meadows with fens or fen characteristics would be the same as Alternative 2 - Modified, except that light grazing would be allowed at Middle Graveyard, so the fens would be at a slight risk of trampling.

Fens – Alternative 3

The effects to meadows with fens or fen characteristics would be the same as Alternative 2 – Modified. Middle Graveyard would be closed rather than rested with the same effect.

Fens – Alternative 4

The effects to meadows with fens or fen characteristics would be the same as Alternative 2 – Modified with the following exceptions.

- **Fourth Recess AU:** North of Mono Rock Meadow and Third Recess Meadow would be closed, so the areas with fen characteristics would recover from trampling effects.

- **Graveyard AU:** Middle Graveyard Meadow would be closed to grazing, so the fen would begin to recover. Upper Cold Creek Meadow would have a lower utilization standard, so there would be a slightly reduced risk of trampling to the fen.
- **Hilton AU:** Turk Meadow would be closed to grazing which would reduce the risk of pack stock impacts to almost nothing.

Fens – Alternative 5

The degraded conditions at Upper Cold Creek, North of Mono Rock, and Third Recess would improve by removal of pack stock trampling impacts. There would be no risk of commercial pack stock trampling to the fens.

Cumulative Effects

Because there would be no commercial pack stock grazing, the historic effects of grazing would be more likely to recover, except in areas with continuing cattle grazing.

Rare Plants

Rare Plants – Alternative 1

Of the nine populations of sensitive and watch list plants known from in or near this geographic unit, 1 is in a meadow open to grazing but no downward trend is expected, one is in a meadow where degraded vegetation composition conditions would continue, one is in a pasture, five are near trails open to all uses, and one is on a trail used only by hikers. Of the 17 meadows with habitat for sensitive species, 2 would have persistent conditions.

- **Hilton AU:** There would be no improvement in vegetation composition at Turk meadow and the fen/Blandlow's feather moss population at the top of the meadow would require monitoring if there is more than the current very low use in this meadow. There is no current use in the unnamed meadow with the Blandlow's feather moss population in the wilderness, but there is a third population at Rock Creek's lower pasture that is at slight risk from grazing. There would be no expected increase in pack stock use of the Hilton Creek trail, but the trail would be TC4, with a very high level of maintenance that could disturb the subalpine fireweed and Inyo beardtongue populations along the trail.
- **Fourth Recess AU:** There would be a minor downward trend in stream condition and vegetation composition at Hopkins/Bench Camp, putting habitat for Bolander's candle moss at risk. The Golden Lake hiker trail is not currently approved for pack stock use, so there would be no pack stock impacts to the Congdon's sedge population.
- **Silver Pass AU:** There would be no change expected in the degraded stream bank potential habitat of Bolander's candle moss at Pocket Meadow.
- **Graveyard AU:** The potential habitat for the west side riparian sensitive species will not recover at Graveyard Meadow due to the continuing cattle use. There would be no predicted improvement in the moderately degraded vegetation composition or slight hydrologic function changes at Quail Meadow where there is also potential habitat for these species. The Mono Creek Trail (Edison) would be TC3 and the PCT would be TC4 with expected high levels of use and maintenance. There could be minor trampling of

Mono Hot Springs evening primrose if use occurs early in the season. Grazing would be less likely to impact this species, unless stock wanders away from the meadow environment. The existing cheatgrass could spread in to the population of Mono Hot Springs evening primrose and degrade the habitat.

- **Bear AU:** The habitat for the west side riparian sensitive species at Kip Camp would remain in good condition, as long as the very low use levels of 2001-2003 continue. At the other meadows, no change would be expected. The Bear Creek Trail would be TC3 and the Bear Creek Cutoff TC2 in this alternative. The current moderate use would continue, but there is no camping or grazing currently in this area, so the current minimal impacts to the Mono Hot Springs evening primrose would probably continue.
- There would be very little impact to the rock outcrop potential habitat of Congdon's lewisia in the geographic unit.
- The populations of scalloped moonwort and Blandlow's feather moss at lower Rock Creek corral (outside of wilderness) have a slight risk of trampling. The stream in the meadow below the habitat is FAR, but the effects on the wetter hillsides is unknown.

Cumulative Effects

The cumulative effects of commercial pack stock use with historic and current pack stock grazing and hydrologic facilities would be similar to those in Ansel Adams West.

Rare Plants – Alternative 2 - Modified

Of the 8 populations of sensitive and watch list plants known from in or near this geographic unit, 1 is in a meadow closed to grazing, 1 is in a meadow where degraded conditions would continue, 1 is in a pasture, 4 are near trails open to all uses, and 1 is on a hiker use trail. Of the 17 meadows with habitat for sensitive species, 2 would have persistent or newly degraded conditions.

- **Hilton AU:** There would be a minor downward trend in meadow functions at Turk meadow if the meadow is used to capacity, but that appears unlikely, given the current very low use. The fen/Blandlow's feather moss population at the top of the meadow would have a 5 percent trampling limit, so monitoring would be required if stock use increases over current levels. The meadow with the second population of Blandlow's feather moss would not be in a grazing zone and so would have no expected pack stock impacts. The pasture would still be used, so the third population of Blandlow's feather moss would be subject to some impacts. There would be no expected increase in pack stock use of the Hilton Lakes trail outside the wilderness, and the trail would be TC3, with regularly scheduled maintenance every 20-30 years, so the population of Inyo beardtongue would be disturbed by trail work only rarely.
- **Fourth Recess AU:** There would be very limited grazing allowed at Bench Camp Meadow (for8), so there would be moderate improvement in stream condition, minor improvement in hydrologic function, and major improvement in vegetation condition, improving the potential habitat of Bolander's candle moss. The effects to Congdon's sedge would be the same as Alternative 1.

- **Silver Pass AU:** The effects to the potential habitat of Bolander’s candle moss would be the same as Alternative 1.
- **Graveyard AU:** The effects to the potential habitat of the west side sensitive riparian species and the Mono Hot Springs evening primrose would be the same as Alternative 1.
- **Bear AU:** There would be no grazing at Kip Camp, so the potential habitat for the west side riparian species would remain in good condition. Five other meadows with potential habitat are within grazing zones, so there could be some trampling impacts. In this Alternative both Bear Creek Trail and Bear Creek Cutoff would be TC3, so maintenance levels would be higher than in Alternative 1, but use would be similar. Because there are no current reported resource problems and the Mono Hot Springs evening primrose blooms very early in the season, there would be no more than minimal impacts to this species.
- The effect to the populations of Blandlow’s feather moss and scalloped moonwort at Lower Rock Creek Pack Station corral would be the same as Alternative 1.
- There would be very little impact to the rock outcrop potential habitat of Congdon’s lewisia in the geographic unit.

Cumulative Effects

The cumulative effects of commercial pack stock use with historic and current cattle and pack stock grazing and hydrologic facilities would be similar to those in Ansel Adams West.

Rare Plants – Alternative 2

The effects to rare plants would be the same as Alternative 2 – Modified except in the Hilton AU. The Hilton Creek Trail between Second and Third Lakes would be TC3, so the risk of trampling and maintenance impacts would be less than in Alternative 1, but more than Alternatives 2 – Modified, 4, and 5.

Rare Plants – Alternative 3

Of the nine populations of sensitive and watch list plants known from in or near this geographic unit, one is in a meadow closed to grazing, one is in a meadow where degraded conditions would continue, one is in a pasture, five are near trails open to all uses, and one is on a hiker use trail. Of the 17 meadows with habitat for sensitive species, 2 would have persistent or newly degraded conditions.

- **Hilton AU:** The effects to the populations of subalpine fireweed, Blandlow’s feather moss and Inyo beardtongue would be the same as Alternative 2.
- **Fourth Recess AU:** The effects to Congdon’s sedge and the potential habitat of Bolander’s candle moss would be the same as Alternative 1.
- **Silver Pass AU:** The effects to the potential habitat of Bolander’s candle moss would be the same as Alternative 1.
- **Graveyard AU:** The effects to the potential habitat of the west side sensitive riparian species would be the same as Alternative 1. Both the PCT and the Mono Creek Trail (Edison) would be TC3 with expected high levels of use and moderate levels of

maintenance. There could be minor trampling of Mono Hot Springs evening primrose if use occurs early in the season. Grazing would be less likely to impact this species, unless stock wanders away from the meadow environment.

- **Bear AU:** The effects to the potential habitat for the west side sensitive riparian species and the populations of Mono Hot Spring evening primrose would be the same as Alternative 2 - Modified.
- The effect to the populations of Blandlow's feather moss and scalloped moonwort at Lower Rock Creek Pack station corral would be the same as Alternative 1.
- There would be very little impact to the rock outcrop potential habitat of Congdon's lewisia in the geographic unit.

Cumulative Effects

The cumulative effects of Alternative 3 with historic and current cattle and pack stock grazing and dam facilities would be similar to Alternative 2 – Modified.

Rare Plants – Alternative 4

Of the nine populations of sensitive and watch list plants known from in or near this geographic unit, two are in meadows closed to grazing, one is in a pasture, three are near trails open to all uses, and three are on trails that would not be used by commercial pack stock. Of the 17 meadows with habitat for sensitive species, 1 would have persistent degraded conditions.

- **Hilton AU:** There would be no grazing allowed at Turk Meadow which would result in minor improvements in hydrologic function and stream condition. There would be very little risk of pack stock trampling to the fen/Blandlow's feather moss habitat at the top of the meadow. The effects to the other 2 populations of Blandlow's feather moss and Inyo beardtongue would be the same as Alternative 2 - modified. Because the section of Hilton Creek Trail between Second and Third Lakes would be TC2 NSCS, the risk of trampling and maintenance impacts to subalpine fireweed would be the least of any alternatives.
- **Fourth Recess AU:** The effects to Congdon's sedge and the potential habitat of Bolander's candle moss would be the same as Alternative 2 - Modified.
- **Silver Pass AU:** The effects to the potential habitat of Bolander's candle moss would be the same as Alternative 1.
- **Graveyard AU:** The effects to the potential habitat of the west side sensitive riparian species would be the same as Alternative 1. The effects to Mono Hot Springs evening primrose would be the same as Alternative 3.
- **Bear AU:** The effects to the potential habitat of the west side sensitive riparian species would be the same as Alternative 2 - Modified. The Bear Creek Trail would be NSCS in this Alternative and Bear Creek Cutoff would be TC2. There would be less use and maintenance than Alternatives 1, 2, and 3.
- The effect to the populations of Blandlow's feather moss and scalloped moonwort at Lower Rock Creek Pack station corral would be the same as Alternative 1.

- There would be very little impact to the rock outcrop potential habitat of Congdon's lewisia in the geographic unit.

Cumulative Effects

The cumulative effects of Alternative 4 with historic and current cattle and pack stock grazing and dam facilities would be similar to Alternative 2 – Modified.

Rare Plants – Alternative 5

Of the nine populations of sensitive and watch list plants known from in or near this geographic unit, two are in meadows closed to commercial pack stock grazing, one is in a pasture that may or may not be used depending on whether pack stock used is allowed outside the wilderness, five are near trails open to private pack stock and hikers, and one is a hiker use trail. Of the 17 meadows with habitat for sensitive species, 1 would have persistent or newly degraded conditions.

- **Hilton AU:** There would be no risk of commercial pack stock to the fen/Blandlow's feather moss habitat at Turk and the unnamed meadow. The pasture would not be used if there were no commercial pack stock permits at all, but would be used if only outside the wilderness use was allowed. The effects maintenance of the Hilton Creek Trail on the populations of Inyo beardtongue and subalpine would be the same as Alternative 2, but there would be no commercial pack stock impacts.
- **Fourth Recess AU:** The effects to Congdon's sedge and the potential habitat of Bolander's candle moss would be the same as Alternative 2 - Modified, except that all risk of pack stock trampling would be removed.
- **Silver Pass AU:** The effects to the potential habitat of Bolander's candle moss would be the same as Alternative 1, except that all risk of pack stock trampling would be removed.
- **Graveyard AU:** The effects to the potential habitat of the west side sensitive riparian species at Graveyard Meadow would be the same as Alternative 1. There would be moderate improvement in hydrologic condition and vegetation composition in Quail Meadow, improving the habitat for these species. The population of Mono Hot Springs evening primrose would not be affected by pack stock trampling or grazing, but would still be subject to the use and maintenance of the PCT and Mono Creek Trail, both TC3.
- **Bear AU:** The meadow at Kip Camp would be expected to maintain its current good condition, and there would be no risk of pack stock trampling. Pack stock would not use Bear Creek Trail or Bear Creek Cutoff and both would be TC2. Use and maintenance would be low on these trails, having the least impact on the population of Mono Hot Springs evening primrose of any of the alternatives.
- Although there would be no wilderness commercial pack stock use, there would probably still be use of the corral outside the wilderness and the effects to the populations of Blandlow's feather moss and scalloped moonwort at Lower Rock Creek Pack station corral would probably be similar to Alternative 1, although there may be reduced or no use.

- There would be slightly less risk of impact to the rock outcrop potential habitat of Congdon's lewisia in the geographic unit because there would be no commercial pack stock use.

Cumulative Effects

Because there would be no commercial pack stock grazing, the cumulative effects of Alternative 5 would be mostly beneficial improvement of the grazing resources.

Weeds

See Wilderness Scale discussion.

Cumulative Effects

The cumulative effects of historic and current cattle and pack stock grazing in this geographic unit would be similar to those in Ansel Adams West.

Campfires

See Wilderness Scale discussion.

Cumulative Effects

There are some campsites above the current campfire closure, so there would be some interactive effects with hikers in Alternatives 2-Modified, 2, and 3, as in Ansel Adams East and Fish Creek Geographic Units.

Bishop/Humphreys

Grazing Resources

Analysis

Overall vegetation conditions are within desired condition and vegetation is adequate to provide for watershed protection throughout this geographic area, with some local minor to moderate alteration of vegetative composition accompanied by current pack stock grazing and use at some locations such as Hutchinson Meadow, near Golden Trout lakes, Waterfall Camp, Moon Lake, and Elba Lake.

Grazing Resources – Alternative 1

Analysis

Reported grazing between 2001 and 2003 was 357 stock nights. The majority of riparian areas within analysis units in the Bishop and Humphreys geographic area have little or no observable riparian vegetation species alteration and with relatively low levels of use these conditions would not change with implementation of any alternative. The small number of key areas assessed with a well defined alteration of riparian vegetative species due to grazing is primarily localized sites in the French Canyon, Glacier Divide, and to a lesser extent the Pine Creek Analysis Unit. The direct effects of pack stock use at these locations would include trampling of vegetation,

decreased vegetative vigor, and localized reductions in late-seral vegetation and decreased plant cover, especially along trails and near campsites and stock holding areas.

Locations in this geographic area where grazing and trampling related effects to the vegetative resource would occur include: French Canyon below 10,700 feet in elevation; the meadows near Moon and Elba lakes; the upland in Humphreys Basin between Golden Trout Lakes and Desolation Lake; the meadows near Hutchinson Meadow; the wet meadows adjacent to Waterfall Camp; near Merriam Lake; and to a lesser extent French Canyon above 10,700 feet; near Upper Pine Lake; and at the inlet of Honeymoon Lake. Most of these locations with adverse effects, such as fragmented sod and decreased cover are associated with trampling of vegetation at campsites and along trails rather than actual grazing utilization.

Overall vegetation conditions are within desired condition and vegetation is adequate to provide for watershed protection throughout this geographic area with implementation of any alternative, with some local minor to moderate alteration of vegetative composition at locations such as Hutchinson Meadow, near Golden Trout lakes, Waterfall Camp, near Moon and Elba Lakes.

Gable, North Piute, Piute, and Horton: Little to no change would occur in riparian vegetation with implementation of any alternative. There may be limited and localized loss of riparian vegetation associated with trailing and trampling effects near the trail crossing of the creek above Sonny Boy mine and on the lakeshore meadows of Lower Horton Lake, at stock watering access points and along the trail to Grass Lake.

North Piute, Lamarck, Sabrina, Tyee, Treasure, and Bishop Creek: Little grazing use occurs and no grazing key areas are identified in these analysis units. There are few identified concerns with identified grazing areas and with little grazing use effects would be limited to those associated with trailing activities.

Granite Park: No grazing is proposed in the Granite Park Analysis Unit, none presently occurs and there would be little change in use or resource conditions with implementation of any alternative.

Pine Creek: There are small meadow complexes adjacent to the lakes in the Pine Creek watershed. These are currently little used for grazing; direct effects are at creek trail crossings and watering access locations. At these locations direct effects are trampling of stream banks and associated loss of vegetative cover. There would continue to be localized sites with hoof punching, sod fragmentation, and loss of riparian vegetation, primarily at stream crossings and near campsites around Honeymoon Lake and Upper Pine Lake.

Over the long-term, there would likely be adequate riparian vegetation to provide protection during flows events in these locations.

Glacier Divide: There would continue to be grazing, access to the stream for water, and trampling of vegetation in the area of Hutchinson meadow nearest the large packer camp. This local area would continue to be dominated by mid-seral to early-seral plant species with decreased vegetative cover for the short-term. Cumulatively there would continue to be local sites with mid-seral and low-seral vegetation in these areas over the long-term. There would continue to be decreased cover of riparian vegetation in limited sites along Piute Creek between Hutchinson Meadow and Summit Lake, especially near the campsites near the user trail to Packsaddle Lake and along the access trails on the north side of Golden Trout Lakes.

Over the long-term, there would likely be adequate riparian vegetation to provide protection during flows events in these locations. With all alternatives there would continue to be erosion from the old trail between the Packsaddle Lake tributary and Hutchinson Meadow, with associated loss of riparian vegetation until restoration work is accomplished.

Humphreys: There would be little or no change in vegetative conditions in most of Humphreys Basin. There would be direct effects of pack stock trailing and trampling of vegetation along the trail corridors.

Cumulatively there would be localized decreases in riparian vegetation and decreased vegetative cover in riparian areas along the existing trails, especially nearest the Golden Trout Lakes vicinity in the long-term. Cumulatively there may not continue to be adequate vegetation to provide for watershed protection over the long-term.

French Canyon: There would be localized decreases in riparian vegetation in French Canyon, above the junction of the trail to Elba Lake, primarily associated with stream crossings and stock access points at several small vernal pools. There would be localized decreases in riparian vegetation in the main portion of French Canyon, primarily associated with trampling and trail erosion related effects in springs and spring channels along the main French Canyon system trail. There would be little change in conditions in the moist to dry forest understory meadows with implementation of any alternative.

Over the long-term, there would be decreased productivity of the late-seral riparian vegetation and decreased vegetative cover in this wetland complex adjacent to Waterfall Camp. There would be localized loss of riparian vegetation and decreased vegetative cover along the small riparian areas due to trailing and trampling of vegetation near and along the access trails and to Merriam, Elba, Moon, Royce, and “L” lakes. There would be localized loss of riparian vegetation and decreased vegetative cover near the campsites and stock holding areas at Merriam Creek Junction, Waterfall Camp, Merriam, Elba, Moon, and “L” lakes. In the short-term there may be some increased direct effects and a long-term cumulative effect would be an increased risk of loss of wetland function.

Cumulative Effects

Because the historic effects of livestock grazing and pack stock use are mostly local in this geographic unit, the cumulative effects of the historic use with current pack stock use are very slight. The most obvious site of cumulative effects is Hutchinson Meadow, where there could be some additive effects of current commercial pack stock use.

Grazing Resources – Alternative 2-Modified

Analysis

There would be approximately 988 stock nights of grazing available with implementation of Alternative 2-Modified. The majority of riparian areas within analysis units in the Bishop and Humphreys geographic area have little or no observable riparian vegetation species alteration and these conditions would not change with implementation of any alternative. The portion of key areas assessed with a well defined alteration of riparian vegetative species are primarily local sites in the French Canyon, Glacier Divide, and to a lesser extent, Pine Creek Analysis Unit. Conditions at these areas would include continued trampling of and localized reductions in late-

seral vegetation and decreased plant cover, especially along trails and near designated campsites and stock holding areas.

Cumulatively these effects would be greater with implementation of Alternative 2 Modified at popular destinations such as the Waterfall Camp area of French Canyon, near and along Piute Creek downstream of Golden Trout lakes, and near Hutchinson Meadow. There would be increased use of designated sites and local reductions in vegetation and fragmentation of sod associated with trampling in sites and along access routes. Cumulatively there would likely continue to be adequate riparian vegetation to provide for watershed protection.

Gable, North Piute, Piute, and Horton: Little to no change would occur in riparian vegetation with implementation of any alternative. There may be limited loss of riparian vegetation due to trailing related trampling impacts near the trail crossing of the creek above Sonny Boy mine and on the lakeshore meadows of Lower Horton Lake, at stock watering access points and along the trail to Grass Lake, especially during high snow pack years.

North Piute, Lamarck, Sabrina, Tyee, Treasure, and Bishop Creek: Little grazing use occurs and no grazing is proposed in these analysis units. There would likely be no differences in effects between alternatives.

Granite Park: No grazing is proposed in the Granite Park Analysis Unit, none is proposed, and there would be no differences in effects between alternatives.

Pine Creek: There are small meadow complexes adjacent to the lakes in the Pine Creek watershed. Late-seral riparian vegetation would become more abundant as trail repair is accomplished and trampling impacts are reduced, however there would continue to be limited sites with hoof punching and loss of riparian vegetation, primarily at stream crossings and near designated campsites near Honey Moon Lake and Upper Pine Lake.

There would be adequate vegetation to provide for watershed protection.

Glacier Divide: The local area of Hutchinson meadow nearest the large packer camp and the stock holding areas at the designated campsite locations would continue to be trampled by pack stock accessing drinking water and would continue to be dominated by aster and other mid-seral to low-seral plant species and decreased vegetative cover for the short-term, there would continue to be limited sites with of mid-seral and low-seral vegetation in these areas over the long-term.

There would continue to be decreased cover of riparian vegetation in limited sites along Piute Creek between Hutchinson Meadow and Summit Lake, especially due to trampling and sod fragmentation near the designated campsites near the user trail to Packsaddle Lake and along the access trails on the north side of Golden Trout Lakes. With all alternatives there would continue to be erosion from the old trail between the Packsaddle Lake tributary and Hutchinson Meadow, with associated loss of riparian vegetation until restoration work is accomplished.

Humphreys: There would be little or no change in vegetative conditions in most of Humphreys Basin. There would be limited decreases in riparian vegetation associated with trailing and trampling of vegetation and sod.

Cumulatively there would be decreased vegetative cover in riparian areas along the existing trails, especially nearest the Golden Trout Lakes vicinity in the long-term. In this low resiliency

area there may not be adequate vegetation to continue to provide for watershed protection along these trails over the long-term.

French Canyon: There would be limited increases in riparian vegetation in upper French Canyon, above the junction of the trail to Elba Lake, primarily associated with stream crossings and stock access points a several small vernal pools. There would be limited decreases in riparian vegetation in the main portion of French Canyon, primarily associated with trampling and trail erosion related effects in springs and spring channels along the main French Canyon system trail and along the trails accessing the Moon Lake area.

There would be little change in conditions in the moist to dry forest understory meadows with implementation of any alternative.

There would be increased productivity of the late-seral riparian vegetation in the short-term and increased vegetative cover in this wetland complex adjacent to Waterfall Camp in the long-term. There would be limited loss of riparian vegetation and decreased vegetative cover along the small riparian areas near access trails to Merriam, Elba, Moon, Royce, and “L” lakes. There would be limited loss of riparian vegetation and decreased vegetative cover near the designated campsites and stock holding areas at Merriam Creek Junction, Waterfall Camp, Merriam, Elba, Moon, and “L” lakes.

Cumulative Effects

The cumulative effects of Alternative 2-Modified would be the same as those of Alternative 1.

Grazing Resources – Alternative 2

Analysis

There would be approximately 988 stock nights of grazing available with implementation of Alternative 2. The majority of riparian areas within analysis units in the Bishop and Humphreys geographic area have little or no observable riparian vegetation species alteration due to grazing activities and these conditions would continue with implementation of any alternative. The small percentage of areas with a well defined alteration of riparian vegetative species are primarily local sites in the French Canyon, Glacier Divide, and to a lesser extent Pine Creek Analysis Unit. Conditions at these areas would include continued localized reductions in late-seral vegetation and decreased plant cover, especially along trails and near designated campsites and stock holding areas. These conditions are mostly associated with the effects of trailing and campsites rather than grazing utilization.

The direct effects of implementation of Alternative 2 are grazing and trampling related effects as described for Alternative 1 and as detailed in the Analysis Unit section below, and could occur at: French Canyon below 10,700 feet in elevation; the meadows near Moon and Elba lakes; the upland in Humphreys Basin between Golden Trout Lakes and Desolation Lake; the meadows near Hutchinson Meadow; and near Merriam Lake.

There are several areas recommended as un-suitable for grazing. Effects at these would be local increases in vegetative production in the short-term.

Cumulative effects would include development of late-seral ecological conditions, especially near springs and streams. These localized effects would occur over the long-term in these areas

including: French Canyon above 10,700 feet; the fen adjacent to Waterfall Camp; near Upper Pine Lake; the inlet of Honey Moon Lake.

Some the areas identified as un-suitable are currently little used, including: meadows near Desolation Lake; meadows near Humphreys Lakes; meadows in the Granite Park area; near the outlet of Packsaddle Lake; and meadows in the Chalfant Lakes area. Cumulatively there would be little change from existing conditions or between alternatives in these locations.

Gable, North Piute, Piute, and Horton: Little to no change would occur in riparian vegetation with implementation of any alternative. There may be limited loss of riparian vegetation due to trampling of vegetation near the trail crossing of the creek above Sonny Boy mine and on the lakeshore meadows of Lower Horton Lake, at stock watering access points and along the trail to Grass Lake.

North Piute, Lamarck, Sabrina, Tyee, Treasure, and Bishop Creek: Little grazing use occurs and no grazing key areas are identified in these analysis units and there are no grazing related differences between alternatives.

Granite Park Analysis Unit: No grazing is proposed and little to no grazing currently occurs in the Granite Park Analysis Unit. There are no grazing related differences expected between alternatives.

Pine Creek: There are small meadow complexes adjacent to the lakes in the Pine Creek watershed. Late-seral riparian vegetation would become more abundant, however there would continue to be limited sites with hoof punching and loss of riparian vegetation, primarily associated with trailing related trampling of vegetation at stream crossings and near designated campsites near Honeymoon Lake and Upper Pine Lake.

There would likely continue to be adequate vegetation to provide for watershed protection.

Glacier Divide: The direct effects of grazing, including trampling of vegetation and sod fragmentation, would continue in the area of Hutchinson meadow nearest the large packer camp and in the stock holding areas at the designated campsite locations. These area would continue to be dominated by aster and similar mid-seral to low-seral plant species and would have decreased vegetative cover for the short-term. Cumulatively, there would continue to be local sites with of mid-seral and low-seral vegetation but overall there would be adequate vegetation to provide for watershed protection in these areas over the long-term.

There would continue to be decreased cover of riparian vegetation in limited sites along Piute Creek between Hutchinson Meadow and Summit Lake, especially near the designated campsites near the user trail to Packsaddle Lake and along the access trails on the north side of Golden Trout Lakes. With all alternatives there would continue to be erosion from the old trail between the Packsaddle Lake tributary and Hutchinson Meadow, with associated loss of riparian vegetation until restoration work is accomplished.

Humphreys: There would be little or no change in vegetative conditions in most of Humphreys Basin. There would be minor and local decreases in riparian vegetation and decreased vegetative cover in riparian areas associated with trailing use and trampling of vegetation along the existing trails, especially nearest the Golden Trout Lakes vicinity in the long-term.

There may not continue to be adequate vegetation to provide for watershed protection.

French Canyon: There would be local decreases in riparian vegetation in French Canyon, above the junction of the trail to Elba Lake, primarily associated with stream crossings and stock access points a several small vernal pools. There would be limited decreases in riparian vegetation in the main portion of French Canyon, primarily associated with trampling and trail erosion related effects in springs and spring channels along the main French Canyon system trail and along the trails accessing. There would be little change in conditions in the moist to dry forest understory meadows with implementation of any alternative.

Without the direct effects of grazing, such as trampling of the wetland vegetation, there would be increased growth and productivity of the late-seral riparian vegetation in the short-term and increased vegetative cover in this wetland complex adjacent to Waterfall Camp in the long-term. There would be limited loss of riparian vegetation and decreased vegetative cover along the small riparian areas near and due to trampling of vegetation along access trails to Merriam, Elba, Moon, Royce, and “L” lakes. There would be localized loss of riparian vegetation and decreased vegetative cover near the designated campsites and stock holding areas at Merriam Creek Junction, Waterfall Camp, Merriam, Elba, Moon, and “L” lakes. Cumulatively there would likely continue to be adequate riparian vegetation to provide for watershed protection in these areas.

Cumulative Effects

The cumulative effects of Alternative 2 would be the same as those of Alternative 1.

Grazing Resources – Alternatives 3 and 4

Analysis

There would be approximately 963 stock nights of grazing available with implementation of either Alternative 3 or Alternative 4. The majority of riparian areas within analysis units in the Bishop and Humphreys geographic area have little or no observable riparian vegetation species alteration and these conditions would not change with implementation of any alternative. The portion of key areas assessed with a well defined alteration of riparian vegetative species are primarily local sites in the French Canyon, Glacier Divide, and to a lesser extent, Pine Creek Analysis Units. Conditions at these areas would include continued trampling of and localized reductions in late-seral vegetation and decreased plant cover, especially along trails and near designated campsites and stock holding areas.

Cumulatively these effects would be greater with implementation of Alternative 3 at popular destinations such as the Waterfall Camp area of French Canyon, near and along Piute Creek downstream of Golden Trout lakes, and near Hutchinson Meadow. There would be increased use of designated sites and local reductions in vegetation and fragmentation of sod associated with trampling in sites and along access routes. Cumulatively there would likely continue to be adequate riparian vegetation to provide for watershed protection.

Gable, North Piute, Piute, and Horton: Little to no change would occur in riparian vegetation with implementation of any alternative. There may be limited loss of riparian vegetation due to trailing related trampling impacts near the trail crossing of the creek above Sonny Boy mine and on the lakeshore meadows of Lower Horton Lake, at stock watering access points and along the trail to Grass Lake, especially during high snow pack years.

North Piute, Lamarck, Sabrina, Tyee, Treasure, and Bishop Creek: Little grazing use occurs and no grazing is proposed in these analysis units. There would likely be no differences in effects between alternatives.

Granite Park: No grazing is proposed in the Granite Park Analysis Unit, none is proposed, and there would be no differences in effects between alternatives.

Pine Creek: There are small meadow complexes adjacent to the lakes in the Pine Creek watershed. Late-seral riparian vegetation would become more abundant as trail repair is accomplished and trampling impacts are reduced, however there would continue to be limited sites with hoof punching and loss of riparian vegetation, primarily at stream crossings and near designated campsites near Honey Moon Lake and Upper Pine Lake.

There would be adequate vegetation to provide for watershed protection.

Glacier Divide: The local area of Hutchinson meadow nearest the large packer camp and the stock holding areas at the designated campsite locations would continue to be trampled by pack stock accessing drinking water and would continue to be dominated by aster and other mid-seral to low-seral plant species and decreased vegetative cover for the short-term, there would continue to be limited sites with of mid-seral and low-seral vegetation in these areas over the long-term. Cumulatively there would continue to be adequate vegetation to provide for watershed protection.

There would continue to be decreased cover of riparian vegetation in limited sites along Piute Creek between Hutchinson Meadow and Summit Lake, especially due to trampling and sod fragmentation near the designated campsites near the user trail to Packsaddle Lake and along the access trails on the north side of Golden Trout Lakes. With all alternatives there would continue to be erosion from the old trail between the Packsaddle Lake tributary and Hutchinson Meadow, with associated loss of riparian vegetation until restoration work is accomplished.

Humphreys: There would be little or no change in vegetative conditions in most of Humphreys Basin. There would be limited decreases in riparian vegetation associated with trailing and trampling of vegetation and sod.

There would be decreased vegetative cover in riparian areas along the existing trails, especially nearest the Golden Trout Lakes vicinity in the long-term. In this low resiliency area there may not be adequate vegetation to continue to provide for watershed protection along these trails over the long-term.

French Canyon: There would be limited increases in riparian vegetation in upper French Canyon, above the junction of the trail to Elba Lake, primarily associated with stream crossings and stock access points a several small vernal pools. There would be limited decreases in riparian vegetation in the main portion of French Canyon, primarily associated with trampling and trail erosion related effects in springs and spring channels along the main French Canyon system trail and along the trails accessing the Moon Lake area.

There would be little change in conditions in the moist to dry forest understory meadows with implementation of any alternative.

There would be increased productivity of the late-seral riparian vegetation in the short-term and increased vegetative cover in this wetland complex adjacent to Waterfall Camp in the long-term. There would be limited loss of riparian vegetation and decreased vegetative cover along the

small riparian areas near access trails to Merriam, Elba, Moon, Royce, and “L” lakes. There would be limited loss of riparian vegetation and decreased vegetative cover near the designated campsites and stock holding areas at Merriam Creek Junction, Waterfall Camp, Merriam, Elba, Moon, and “L” lakes.

Cumulative Effects

The cumulative effects of Alternatives 3 or 4 would be the same as those of Alternative 1.

Grazing Resources – Alternative 5

Analysis

The majority of riparian areas within analysis units in the Bishop and Humphreys geographic area have little or no observable riparian vegetation species alteration and these conditions would continue with implementation of any alternative. The small percent of areas with a well defined alteration of riparian vegetative species are primarily located at localized sites in the French Canyon, Glacier Divide, and to a lesser extent, Pine Creek Analysis Units. Effects at these would be localized increases in vegetative production in the short-term, and development of late-seral ecological conditions, especially near springs and streams over the long-term.

There would continue to be altered vegetation near trails and campsites, and especially near the Golden Trout Lakes area due to low resiliency, slow recovery rates and continued hiker traffic. While there may not be adequate vegetation at some local sites, especially near hiker trails and campsites at Golden Trout Lakes, overall there would be adequate vegetation to provide for watershed protection.

Gable, North Piute, Piute, and Horton: Little to no change would occur in riparian vegetation with no grazing or use by commercial pack stock.

North Piute, Lamarck, Sabrina, Tyee, Treasure, Bishop Creek, and Granite Park: Little grazing use occurs and no grazing is identified in these analysis units. There are few identified concerns and little to no change would occur in riparian vegetation with implementation of any alternative.

Pine Creek: There are small meadow complexes adjacent to the lakes in the Pine Creek watershed. Late-seral riparian vegetation would become more abundant and would be restored on the limited and localized sites with hoof punching and loss of riparian vegetation, primarily at stream crossings and access routes to lakeshore campsites, especially at Upper Lake and Honeymoon Lake. Cumulatively there would be adequate vegetation to provide for watershed protection.

Glacier Divide: The area of Hutchinson meadow nearest the large packer camp and the stock holding areas at the designated campsite locations would continue to be dominated by mid-seral to early-seral plant species and decreased vegetative cover for the short-term. Late-seral riparian vegetation would increase and become dominate at these locations in the long-term to very long-term.

With all alternatives there would continue to be erosion from the old trail between the Packsaddle Lake tributary and Hutchinson Meadow, with associated loss of riparian vegetation

continuing until restoration work is accomplished. Cumulatively there would be adequate vegetation to provide for watershed protection.

Humphreys: There would be little or no change in vegetative conditions in most of Humphreys Basin. There would be limited increase in riparian vegetation and increased vegetative cover along the existing trails, especially nearest the Golden Trout Lakes vicinity in the long-term.

There may be some continued loss of vegetation along the trails, especially those nearest Golden Trout Lakes over the long-term and in this low resiliency area the cumulative impact may be inadequate vegetation to provide for watershed protection at some local sites along these trails.

French Canyon: With elimination of the direct effects of pack stock use, such as trampling of vegetation, there would be localized increases in riparian vegetation in upper French Canyon, primarily associated with stream crossings, stock access points, and at several small vernal pools. There would be local increases in riparian vegetation in the main portion of French Canyon, primarily associated with elimination of trampling and trail erosion related effects in springs and spring channels along the system trail and near the wetland complexes of springs, sphagnum, and very wet meadows at each tributary confluence. Cumulatively there would continue to be adequate vegetation to provide for watershed protection.

There would be little change in conditions in the moist to dry forest understory meadows with implementation of any alternative.

There would be localized increases in riparian vegetation and increased plant cover on granite shelves and benches above French Canyon, especially along trails accessing Elba, Moon, L, Merriam, and Royce Lakes and in the meadows near the designated campsite near Merriam Lake. There would be increased productivity of the late-seral riparian vegetation in the short-term and increased vegetative cover in the wetland complex adjacent to Waterfall Camp in the long-term. Cumulatively there would continue to be adequate vegetation to provide for watershed protection.

Cumulative Effects

The cumulative effects of Alternative 5 would be beneficial because there would be the most chance of recovery from historic effects and other ongoing uses.

Fens

Fens – Alternative 1

Most meadows would be open for grazing, so there is a risk of impacts to any unknown fens.

- **French AU:** Adjacent to Waterfall Camp would be open for grazing, which would continue the degraded condition of the fen. There would be grazing in the other 6 meadows with fens or fen characteristics, but the current good condition would probably continue if grazing continues at current levels. There is a large unused grazing capacity in French Canyon and if use increases, there could be impacts to the many wet areas with fen characteristics.
- **Bishop AU:** Hurd Lake Meadow is open to grazing, but there is no current use and no expected increase, so the area with fen characteristics would remain in good condition.

- **Lamarck AU:** Grass Lake is currently closed to grazing and would remain so, so there would be no change in the good condition of the fen.
- **Pine Creek AU:** East of Pine Creek Pass Meadow would be open for grazing, but there is no expected increase in grazing, so the good condition of the area with fen characteristics would continue.
- **Glacier Divide AU:** Packsaddle and below Packsaddle meadows would remain open for grazing, but current low reported use would continue and there would be no predicted change to fen conditions.

Cumulative Effects

Historic livestock grazing occurred in this geographic unit, but most of the meadows appear to be recovered from effects of this activity, so there would be very little cumulative interaction with current commercial pack stock grazing use. At Waterfall Camp, the negative effects are from previous pack stock use and could be worsened by continuing similar use.

Fens – Alternative 2 - Modified

- **French AU:** Adjacent to Waterfall Camp, Merriam Confluence, and French Canyon above 10,760 would be closed to grazing, so the fens would be protected, but there could still be inadvertent trampling of up to 5 percent. There would be limited grazing at Merriam Lake that would allow the good condition of the fen to be maintained. In the three other meadows with fen characteristics in French Canyon, grazing would be allowed and the capacity is high. The maximum stock nights would probably not be reached, but minor downward trends in meadow condition could occur as grazing numbers approached the capacity estimates.
- **Bishop AU:** Hurd Lake would be closed to grazing, so the area with fen characteristics would be protected.
- **Lamarck AU:** Grass Lake would be closed to grazing, so the fen would be protected.
- **Pine Creek AU:** East of Pine Creek Pass Meadow would be closed to grazing, so the area with fen characteristics would be protected.
- **Glacier Divide AU:** Packsaddle and Below Packsaddle Meadows would be closed to grazing, so the areas with fen characteristics would be protected.

Cumulative Effects

The cumulative effects would be similar to the effects of Alternative 1.

Fens – Alternative 2

The effects to the meadows with fens or fen characteristics would be the same as Alternative 2 - Modified.

Fens – Alternative 3

The effects to the meadows with fens or fen characteristics would be the same as Alternative 2 - Modified.

Fens – Alternative 4

The effects to the meadows with fens or fen characteristics would be the same as Alternative 2 - Modified.

Fens – Alternative 5

The condition of the fen at the meadow adjacent to Waterfall Camp would improve with the removal of the pack stock impacts.

Rare Plants

Rare Plants – Alternative 1

Of the nine populations of sensitive and watch list plants known from in or near this geographic unit, three are on or near a trail open to all uses, three are on trails with hiker use only, and three are in locations without known trails or pack stock use. Of the two meadows with habitat for sensitive species, one would have persistent or newly degraded conditions.

- **North Piute AU:** The documented slender moonwort population in Piute Canyon has not been relocated since the plant was collected in 1968, but since the habitat described is a “crevice along trail”, there is a very little risk that pack stock using the TC3 trail would damage any plants. No grazing or camping is likely in the area of the reported population, but there could be rare trail maintenance activity.
- **Horton AU:** The Longley Reservoir Trail would be approved for use, and there would be a small risk of pack stock trampling impacts to the population of Inyo beardtongue.
- **Bishop Creek AU:** The Chocolate Ruwau Loop would be TC3, open to pack stock use only to Bull Lake. The section of trail where there is a population of Congdon’s sedge would not be used by stock, so there would only be hiker use on this very steep and rocky section of trail and there would be a slight risk of hiker trampling to the population. There would be no pack stock or trail impacts to the populations above Saddlerock Lake.
- **Lamarck AU:** The Grass Lake Outlet Trail would not be a system trail nor approved for pack stock use, so there would be no pack stock effects to the Inyo beardtongue population. Other recreational use is currently incidental so there would be very little risk of damage to the population.
- **Sabrina AU:** The populations of Inyo beardtongue at Sabrina Lake outside the wilderness would be at risk of trampling by pack stock and other users of the Sabrina trail on the south side of the lake and of trampling by anglers and other recreational users of the trail on the north side of the lake. There is no known pack stock use of the areas near North Lake where there are Inyo beardtongue populations.
- **French AU:** There would be no expected change in the meadow condition or potential habitat for veined water lichen at Merriam confluence to Chevaux confluence meadow.
- **Glacier AU:** Hutchinson Meadow would remain in a moderately degraded condition (hydrology and stream), so there would be a risk of damage to the potential habitat for veined water lichen.

- There would be very few impacts to the potential habitat for Congdon's lewisia because it is rocky and would not receive much pack stock use. Trail impacts would mostly be limited to the tread, a minimal percentage of the habitat.

Cumulative Effects

Historic livestock grazing occurred in this geographic unit, but most of the meadows appear to be recovered from effects of this activity, so there would be very little cumulative interaction with current commercial pack stock grazing use. Historic use of Hutchinson Meadow as a Native American gathering place has contributed to its somewhat degraded condition and those effects could be prevented from recovery or continued by current commercial pack stock use.

Rare Plants – Alternative 2 - Modified

Of the nine populations of sensitive and watch list plants known from in or near this geographic unit, four would be on or near a trail open to all uses, two would be near trails open to hikers only, and three are in areas where there would be no trail or pack stock activity. Of the two meadows with habitat for sensitive species, neither would have persistent or newly degraded conditions.

- **North Piute AU:** The documented slender moonwort population in Piute Canyon has not been relocated the plant was collected in 1968, but since the habitat described is a "crevice along trail," there is a very little risk that pack stock using the trail could trample an individual plant. No grazing or full service camping would be allowed in the area of the reported population.
- **Horton AU:** The Longley Reservoir Trail would be TC2, and there would be a small risk of pack stock trampling impacts to the population of Inyo beardtongue.
- **Bishop Creek AU:** The section of the Chocolate/Ruwau Loop Trail from the inlet of Bull Lake to Ruwau would be closed to commercial pack stock, so there would be no risk of pack stock trampling or grazing impacts to the population of Congdon's sedge. The Trail would be TC2, so maintenance effects would be minimal.
- **Lamarck AU:** The Grass Lake Outlet Trail would be TC2, Not Recommended for Commercial Stock. The population of Inyo beardtongue would not be impacted by pack stock, but there would be more maintenance and possibly more hikers that could increase risks of trampling or soil disturbance.
- **Sabrina AU:** The impacts to the Inyo beardtongue at Sabrina Lake would be the same as Alternative 1.
- **French AU:** The meadow between Merriam confluence and Chevaux confluence would be open for grazing, and if it is used to capacity there would be some downward trend in vegetation composition, but hydrologic and stream conditions would not change. The potential habitat for veined water lichen would probably remain in good condition.
- **Glacier AU:** Hutchinson Meadow would have a reduced number of stock from its current use, so there would be expected improvement to hydrologic and stream condition, improving the condition of the potential habitat for veined water lichen.

- The effects to the potential habitat for Congdon’s lewisia would be the same as Alternative 1.

Cumulative Effects

The cumulative effects of Alternative 2-Modified would be the same as those of Alternative 1.

Rare Plants – Alternative 2

The effects to rare plants would be the same as Alternative 2 – Modified.

Rare Plants – Alternative 3

Of the nine populations of sensitive and watch list plants known from in or near this geographic unit, three are in remote areas with no trail or pack stock impacts, four would be on or near a trail open to all uses, two would be on hiker only trails. Of the two meadows with habitat for sensitive species, neither would have persistent or newly degraded conditions.

- **North Piute AU:** Effects to slender moonwort would be the same as Alternative 2 - Modified.
- **Horton AU:** Effects to Inyo beardtongue would be the same as Alternative 2 - Modified.
- **Bishop Creek AU:** The effects to Congdon’s sedge on the Chocolate-Ruwau Trail would be the same as Alternative 2 – Modified.
- **Lamarck AU:** The impacts to the population of Inyo beardtongue would be the same as Alternative 2 - Modified.
- **Sabrina AU:** The impacts to the Inyo beardtongue at Sabrina Lake would be the same as Alternative 1.
- **French AU:** The impacts to the potential habitat for veined water lichen at Merriam confluence to Chevaux confluence would be the same as Alternative 2 - Modified.
- **Glacier Divide AU:** The impacts to the potential habitat for veined water lichen at Hutchinson Meadow would be the same as Alternative 2 - Modified.
- The effects to the potential habitat for Congdon’s lewisia would be the same as Alternative 1.

Cumulative Effects

The cumulative effects of Alternative 3 would be the same as those of Alternative 1.

Rare Plants – Alternative 4

Of the nine populations of sensitive and watch list plants known from in or near this geographic unit, four would be on or near a trail open to all uses, two would be on hiker only trails, and three would be in locations with no expected pack stock or trail activity. Of the two meadows with habitat for sensitive species, neither would have persistent or newly degraded conditions.

- **North Piute AU:** The effects to the population of slender moonwort would be the same as Alternative 2 - Modified.

- **Horton AU:** Effects to Inyo beardtongue would be the same as Alternative 2 - Modified.
- **Bishop Creek AU:** The effects of pack stock use on Congdon's sedge would be the same as Alternative 2 - Modified. The Chocolate/Ruwau Trail would be TC1 and NSCS near the population of Congdon's sedge, so maintenance effects would be unlikely.
- **Lamarck AU:** The Grass Lake Outlet trail would be TC1, NRCS, so there would be no pack stock impacts, and very little use or maintenance would be expected. There would be a very small risk of trampling or soil disturbance to the population of Inyo beardtongue.
- **Sabrina AU:** The impacts to the Inyo beardtongue at Sabrina Lake and near North Lake would be the same as Alternative 1.
- **French AU:** The effects to the potential habitat of veined water lichen would be the same as Alternative 2 - Modified.
- **Glacier Divide AU:** There would be a 30 percent utilization standard for Hutchinson Meadow, so there would be fewer stock than in Alternatives 2 - Modified and 3, which would make recovery of the meadow hydrologic function and stream condition slightly more likely, improving the condition of the potential habitat for veined water lichen.
- The effects to the potential habitat of Congdon's sedge would be the same as Alternative 1.

Cumulative Effects

The cumulative effects of Alternative 4 would be the same as those of Alternative 1.

Rare Plants – Alternative 5

Of the nine populations of sensitive and watch list plants known from in or near this geographic unit, six would be on or near a trail open to hikers and private pack stock and three would be in areas with no trails. Of the two meadows with habitat for sensitive species, neither would have persistent or newly degraded conditions.

- **North Piute AU:** The Piute Canyon trail would still be used by other wilderness users and be maintained as a TC3, but there would be no risk of pack stock impacts.
- **Horton AU:** The Longley Reservoir Trail would be TC2, but there would be no risk of pack stock effects.
- **Bishop Creek AU:** The effects to Congdon's sedge would be the same as Alternative 4.
- **Lamarck AU:** The effects to Inyo beardtongue would be the same as Alternative 1.
- **Sabrina AU:** The impacts to the Inyo beardtongue at Sabrina Lake and North Lake could possibly be increased if there were displaced wilderness pack stock use of those areas for day rides. Any new day ride routes would have to have Forest Service approval.
- **French AU:** There would be no risk of commercial pack stock impacts in the meadow between Merriam confluence and Chevaux confluence, but it would be open to private pack stock use. The condition of the potential habitat for veined water lichen should remain good.

- **Glacier Divide AU:** There would be improvement in the hydrologic and stream conditions at Hutchinson Meadow, but it would probably get use from private pack stock.
- There would be no risk of commercial pack stock impacts to the potential habitat of Congdon's lewisia, but there would be a very slight risk of impacts from private pack stock and hikers.

Cumulative Effects

Because there would be no commercial pack stock use in Alternative 5, there would be very minimal cumulative effects of trail management activity with historic uses.

Weeds

See Wilderness Scale discussion.

Cumulative Effects

There are some non-native plants at existing pack stations and trailheads, so commercial pack stock and trail maintenance personnel could act as vectors for these currently existing weeds.

Campfires

See Wilderness Scale discussion.

Cumulative Effects

Because many of the campsites used in this unit are above 10,000 feet, the effects of bringing charcoal or firewood in to the wilderness would be similar to those in Ansel Adams East.

Florence/Bear

Grazing Resources

Overall vegetation conditions are within desired condition and vegetation is adequate to provide for watershed protection throughout this geographic area, with some local minor to moderate alteration of vegetative composition accompanied by current pack stock grazing and use at some locations such as Bear Creek, Upper Bear Creek, Senger Creek, Shooting Star Meadow, Sallie Keys and Boot lakes Meadows, Rose Lake Meadow, Rose Marie Meadow, Hilgard Meadow, and Lou Beverly Lake Meadow. There is repeated stock use in the meadows at Hellhole, Jackass, Poison, Double, and Blayney Meadows repeated use and there could be cumulative adverse affects at those locations, especially considering the synergistic adverse effects of ongoing stock use with uses such as water diversions and altered flows.

There is expected to be little difference in grazing related effects between different alternatives over most of the Analysis Units in the Florence/Bear Geographic Area. The productivity and estimated number of stock nights available are well within current and anticipated use levels. Most analysis units within this geographic area are not often used for overnight trips, most use is to drop off dunnage; the pack stock then returns to the trailhead. There is an occasional, but relatively rare, traveling trip, originating from the east side that would stop overnight at 3 to 4 locations. These trips usually stop at camps on Bear Creek, Sallie Keys Lake, and Rosemarie Meadow and sometimes at Lou Beverly Lake, Shooting Star Meadow, or Hilgard Meadow.

There could be a minor increase in these traveling trips with implementation of some alternatives due to restrictions elsewhere, such as over Silver Pass and in Fish Creek, however there is adequate carrying capacity in the Florence/Bear Geographic Area to absorb the levels of increases that are likely to occur.

Effects should be limited to localized minor to moderate trampling and related decreases in vegetation associated with areas of stock concentration, with some severe and localized trampling and vegetation loss at stock camps. Effects will be minimized with adequate monitoring of key and critical areas and adaptation each year through the Annual Operating Plan. Locations that do receive overnight grazing use include Bear Creek, Upper Bear Creek, Senger Creek, Shooting Star Meadow, Sallie Keys and Boot lakes Meadows, Rose Lake Meadow, Rose Marie Meadow, Hilgard Meadow, and Lou Beverly Lake Meadow.

Grazing Resources – Alternative 1

Analysis

The high reported grazing between 2001 and 2003 was 999 stock nights. The estimated productivity and potential maximum grazing conservatively available is approximately 5,500 stock nights, so the existing use is well below the estimated carrying capacity. Overall it is unlikely that there will be a substantial difference in consequences to the grazing resource in this geographic area with implementation of any of the alternatives being considered. Most of the key area meadows assessed in the Florence/Bear geographic area exhibit minor or moderate localized altered vegetative species composition, most of these will continue to be in satisfactory condition regardless of the alternative implemented. Some of the key areas assessed do have well defined alteration of vegetative species composition including; Hilgard, Rosmarie, and Shooting Star Meadows. They would continue to have altered vegetation composition with Alternative 1. Some locations, identified as critical areas, such as “Big Fen” Meadow are currently receiving little to no grazing use and with other areas available, there should not be an increase in use with implementation of Alternative 1.

All Analysis Units: There are several key areas in this geographic area where localized grazing and trampling related direct effects would occur in the short-term including: the meadows near Sallie Keys Lakes; Lower Blayney Meadow; Double Meadow; Shooting Star Meadow; Hilgard Meadow; Rosemarie Meadow; Rose Lake Meadow; “Water Trail” meadow; the meadows near Lou Beverly Lake, Jackass Meadow; Poison Meadow; Double Meadow, and Hellhole Meadow. These areas would be directly affected locally by trailing and the associated, minor to moderate, trampling of vegetation. There would be a localized decrease of riparian vegetation, some areas of fragmented sod, and increased mid-seral vegetation mostly associated with stock camps and trails.

There would continue to be localized alteration of vegetative species, and some reduced vegetative cover, due to trampling of vegetation, removal of vegetation by grazing animals, and sod fragmentation, especially near designated camps at Rosemarie Meadows, Hilgard Meadows, Rose Lake, Bear Creek, and to a lesser extent at Shooting Star Meadow and the meadows near Sallie Keys and Boot Lakes. There would continue to be trailing related trampling and trail erosion along the trail through Shooting Star Meadow as stock accessed the campsite, which is on the opposite side of the meadow from the system trail. There could be localized direct effects

including trailing related trampling of vegetation and stream bank alteration that may persist from year-to-year at Lower Blayney Meadow.

There could be little difference in the effects of different alternatives at Lou Beverly Lake. There could be little difference between alternatives in the short-term and limited alteration of vegetative species composition with reduced cover, also to a limited extent, at Water Trail Meadow.

There would likely continue to be adequate vegetation to provide for watershed protection overall in this Geographic Area. However, there several of the meadows where long-term unstable watershed conditions indicate that there is likely to be at least a portion of each meadow continuing to degrade as a result of ongoing processes, including at Rosemarie and Hilgard meadows where unstable stream banks and active headcuts would likely continue to contribute to a chronic loss of riparian vegetation.

There would be localized impacts to riparian vegetation at the meadows at Jackass, Hellhole, Double, Blayney, and Poison meadows. There may be a localized loss of late-seral vegetation and decreased vegetative cover on in-stream bars and along stream banks over the long-term at these sites with inadequate vegetation to provide for watershed protection. Over the long-term, there may not be adequate vegetation to provide for watershed protection in the meadows at Jackass, Hellhole, Poison, Double, and Blayney, especially when considering the chronic and synergistic cumulative effects of commercial pack stock grazing uses, other grazing uses, flow regulation, water diversion, and upstream private land uses.

Overall, there would continue to be adequate late-seral riparian vegetation to provide for watershed protection at most locations in this geographic area.

Cumulative Effects

The meadows at Hellhole, Jackass, Poison, Double, and Blayney Meadows receive pasture use and have had high historic use, so there could be cumulative adverse affects at those locations, especially considering the synergistic adverse effects with uses such as water diversions and altered flows. Overall, the effects of historic grazing effects are slight, so the cumulative effects with Alternative 1 are small.

Grazing Resources – Alternative 2-Modified

Analysis

There would be approximately 5,549 stock nights of grazing available in the geographic area with implementation of Alternative 2-Modified. The effects of implementation of Alternative 2-Modified will be similar to those predicted for Alternative 1. There are meadows with characteristics such as special aquatic features, or resource concerns such poorly located trail crossings, including Big Fen Meadow, Sallie Key Lakes to Boot Lake Meadows, the Lou Beverly inlet camp Meadow, Orchid Lake, and Rose Meadow, which require careful assessment of the effects of implementation of different alternatives and will require careful stock management and monitoring if a grazing alternative is selected.

All Analysis Units: The direct effects of the grazing that would be authorized under Alternative 2-Modified in the meadows at Blayney Meadow, Jackass, Hellhole, Poison, and Double Meadow are likely to be increased trampling at localized sites within these meadows, such as adjacent to

gates, stream bank trampling at favored watering and crossing locations, and a loss of riparian vegetation on instream bars. These effects may be visually noticeable, however, with frequent monitoring to ensure compliance with applicable standards the cumulative effects could be that resources at these locations meet or trend toward desired conditions, depending upon the effects of water diversion and flow regulation.

There are two areas, Upper Hilgard Branch Meadows and Big Fen Meadow, recommended as not suitable for grazing which would be protected from grazing under Alternatives 2, 2-Modified, 3, 4, and 5. Without the trailing and trampling direct effects of grazing, these areas would see more certain maintenance of high-seral vegetative status in the short-term, and continuing through the long-term; however, due to the low levels of current use, this maintenance of late-seral vegetation would also be likely, if not as certain with Alternative 1.

There will continue to be localized alteration of vegetation species, and some reduced vegetative cover, especially near designated camps at Rosemarie Meadows, Hilgard Meadows, Rose Lake, Shooting Star Meadow, and to a lesser extent at Sallie Keys Lake and Boot Lake area. There could be little difference in the effects of different alternatives at Lou Beverly Lake. There could be little difference between alternatives in the short-term and limited alteration of vegetative species composition with reduced cover, also to a limited extent, at Water Trail Meadow and Big Fen Meadow.

There would be localized impacts to riparian vegetation at the meadows at Jackass, Hellhole, Double, Blayney, and Poison meadows. There may be a localized loss of late-seral vegetation and decreased vegetative cover on in-stream bars and along stream banks over the long-term at these sites with inadequate vegetation to provide for watershed protection. Cumulatively, over the long-term, there may not be adequate vegetation to provide for watershed protection in the meadows at Jackass, Hellhole, Poison, Double, and Blayney, especially when considering the chronic and synergistic cumulative effects of commercial pack stock grazing uses, other grazing uses, flow regulation, water diversion, and upstream private land uses.

Cumulative Effects

The cumulative effects of Alternative 2-Modified would be similar to those of Alternative 1.

Grazing Resources – Alternative 2

Analysis

There would be 1,827 stock nights of grazing available in this geographic area with implementation of Alternative 2. The effects of implementing Alternative 2 in the Florence/Bear Geographic area would be similar to those predicted for Alternative 2-Modified for the majority of the Florence/Bear Geographic Area. There are two areas, Upper Hilgard Branch Meadows and Big Fen Meadow, recommended as not suitable for grazing which would be protected from grazing under Alternatives 2, 2-Modified, 3, 4, and 5.

All Analysis Units: Without the trailing and trampling direct effects of grazing, these areas would see more certain maintenance of high-seral vegetative status in the short-term, and continuing through the long-term, this maintenance of late-seral vegetation would be likely, but not as certain with Alternative 1.

As for Alternative 2-Modified, there would be localized impacts, including trampling of instream bars and reduced late-seral riparian vegetation at the pastures at Jackass, Hellhole, Double, Blayney, and Poison meadows, with overall vegetative conditions remaining within vegetative desired condition at these sites over the short-term. Indirect effects may be a localized loss of late-seral vegetation and cumulatively chronic decreased vegetative cover on in-stream bars and along stream banks over the long-term at these sites. Over the long-term, there may not be adequate vegetation to provide for watershed protection in the meadows at Jackass, Hellhole, Poison, Double, and Blayney, especially when considering the chronic and synergistic cumulative effects of commercial pack stock grazing uses, other grazing uses, flow regulation, water diversion, and upstream private land uses.

Cumulative Effects

The cumulative effects of Alternative 2 would be similar to those of Alternative 1, except there would be less grazing at the meadows used as pastures, so there would be fewer effects.

Grazing Resources – Alternatives 3 and 4

Analysis

All Analysis Units: The effects of implementing either Alternative 3 or Alternative 4 would be similar to those for Alternative 2-Modified. With Alternative 3 there could be increased direct effects in the meadows at Blayney Meadow, Jackass, Hellhole, Poison, and Double Meadow relative to Alternative 4. There would also be increased indirect effects such as increased trampling at localized sites within these meadows, stream bank trampling at favored watering and crossing locations, and a loss of riparian vegetation on instream bars. These effects may be visually noticeable, however, with frequent monitoring to ensure compliance with applicable standards the cumulative effects could be that resources at these locations meet or trend toward desired conditions, depending upon the effects of water diversion and flow regulation.

There would be approximately 5,549 stock nights of grazing available with implementation of Alternative 3 and 1,882 stock nights with Alternative 4. Overall, the effects of implementation of Alternative 3 and Alternative 4 would be indistinguishable from those predicted for Alternative 2-Modified. With Alternative 3 there would be increased risks of localized impacts to riparian vegetation at the meadows at Jackass, Hellhole, Double, Blayney, and Poison meadows relative to Alternative 4. With Alternative 3 There may be a localized loss of late-seral vegetation and decreased vegetative cover on in-stream bars and along stream banks over the long-term at these sites with inadequate vegetation to provide for watershed protection.

Over the long-term, there may not be adequate vegetation to provide for watershed protection in the meadows at Jackass, Hellhole, Poison, Double, and Blayney, especially when considering the chronic and synergistic cumulative effects of commercial pack stock grazing uses, other grazing uses, flow regulation, water diversion, and upstream private land uses with either Alternative 3 or Alternative 4.

Cumulative Effects

The cumulative effects of Alternatives 3 are similar to those of Alternative 2-Modified and those of Alternative 4 are similar to those of Alternative 2.

Grazing Resources – Alternative 5

Analysis

Most of the meadows assessed in the Florence/Bear exhibit well little or no altered vegetative species composition, these will continue in late-seral vegetative status. Approximately one-third of the key areas assessed have well defined alteration of vegetative species composition, including Hilgard, Rosemarie, and Shooting Star Meadows. There are also meadows with resource concerns such as poorly located trail crossings including Big Fen Meadow, Sallie Key Lakes to Boot Lake Meadows, the Lou Beverly inlet camp Meadow, Orchid Lake, and Rose Meadow.

All Analysis Units: With no grazing there will be decreased trampling of vegetation and an increase in vegetative cover at these locations, although continued hiker traffic will maintain existing conditions over most of the trail segments. There may not be recovery of the unstable banks and active headcuts at Hilgard Meadow and Rosemarie Meadow over the long-term to very long-term, even without grazing related impacts.

Overall, throughout this geographic area there would be adequate vegetation over the long-term to provide for watershed protection at most locations.

The increases in riparian vegetation will improve conditions such as at widened stream crossings and at trampled spring areas over the long-term, although continued use by private stock and hikers would limit recovery at these locations. There will continue to be localized alteration of vegetation species, and some reduced vegetative cover, especially near camps used by private stock parties at Rosemarie Meadows, Hilgard Meadows, Rose Lake, and to a lesser extent at Sallie Keys and Boot Lakes.

There may continue to be erosion and loss of vegetation along and on tributaries to the secondary trail at Rosemarie Meadow over the long-term to very long-term, with or without use by commercial stock. There would be localized impacts to riparian vegetation at the meadows at Jackass, Hellhole, Double, Blayney, and Poison meadows. There may be a localized loss of late-seral vegetation and decreased vegetative cover on in-stream bars and along stream banks over the long-term at these sites with inadequate vegetation to provide for watershed protection, depending upon water diversions and flow regulation. Cumulatively, over the long-term, there may not be adequate vegetation to provide for watershed protection in the meadows at Jackass, Hellhole, Poison, Double, and Blayney, especially when considering the chronic and synergistic cumulative effects of other grazing uses, flow regulation, water diversion, and upstream private land uses.

Cumulative Effects

The cumulative effects of Alternative 5 would be beneficial because there would be a higher chance of recovery of historic grazing effects.

Fens

Fens – Alternative 1

Italy AU: Upper Hilgard Meadow would be open for grazing, but grazing numbers would probably be very low, to the fen would continue to be in good condition.

Sallie Keyes AU: Big Fen Meadow would be open for grazing, but the fen would continue to be in good condition if the current lack of grazing continues.

Cumulative Effects

Historic livestock, hydropower facilities, and grazing current pasture use are major factors in the somewhat degraded condition of the meadows in this unit and commercial pack stock use could delay or prevent recovery in meadows not affected by the dams. In those meadows, the effect of commercial pack stock is minimal compared to the effects of the dams on hydrologic function.

Fens – Alternative 2 - Modified

Neither of the known fens in this geographic unit would be open to grazing use.

Italy AU: Upper Hilgard Meadow would be closed to grazing, so the fen would be protected from pack stock trampling impacts.

Sallie Keyes AU: Big Fen Meadow would be closed to grazing, so the fen would be protected from pack stock trampling impacts.

Cumulative Effects

Cumulative effects of Alternative 2-Modified would be similar to those of Alternative 1, although possibly slightly less intense.

Fens – Alternative 2

The effects to the meadows with fens or fen characteristics would be the same as Alternative 2 - Modified.

Fens – Alternative 3

The effects to the meadows with fens or fen characteristics would be the same as Alternative 2 - Modified.

Fens – Alternative 4

The effects to the meadows with fens or fen characteristics would be the same as Alternative 2 - Modified.

Fens – Alternative 5

There would be no risk of commercial pack stock impacts to fens.

Rare Plants

Rare Plants – Alternative 1

Of the ten populations of sensitive and watch list plants known from in or near this geographic unit, four are on or near trails open to all uses, one may have impacts from wandering grazing stock, three would not be affected by trails or stock (one may be affected by pipeline maintenance), and two would be in meadows open to grazing (one near a hot spring). Of the 51

meadows with habitat for sensitive species, 5 would have persistent or newly degraded conditions.

- **Hooper AU:** There would be no trail impacts to the Mono Hot Springs evening primrose near Jackass Meadow, but there may be stray pack stock from the grazing at there. The Hooper Diversion trail would be TC1, so there would be very little use or maintenance on the trail and risks to the population of Mono Hot Springs evening primrose would be very small. Any spread of cheatgrass from the around Florence Lake could have a negative impact on the habitat for the Mono Hot Springs evening primrose. There would be no change in the degraded stream and hydrologic function conditions, so there would be a risk to the population of Yosemite ivesia and habitat for the sensitive riparian species at Jackass and Hell Hole meadows. There would be no impacts to the population of gray-leaved violet because of its inaccessibility.
- **East Florence AU:** The Florence Lake Trail would be TC3 and continue to be used by pack stock, hikers, and 4WD vehicles accessing private property. Most use is probably after the flowering and seed set of the Mono Hot Springs primrose, but there is a small risk of trampling or spreading of cheatgrass seeds with use and maintenance of this trail. There are duplicate trails where hikers have developed routes away from the 4WD road/trail, so there is a very wide trail impact zone in this area. Impacts from the pack stock grazing Double Meadows and roaming through the primrose populations would be minimal because of timing. The populations of Mono Hot Springs evening primrose on the north side of Florence Lake would not be affected by any trail or pack stock activity, but could be affected by weed (cheatgrass) expansion.
- **Dutch/Boulder AU:** There would be somewhat less use of the Florence Lake trail than in East Florence AU, so there would be even less risk to the Mono Hot Springs evening primrose. The Thompson Lake Trail would be TC1, so the reported downed trees blocking the trail may prevent the trail from being used for a long time, protecting the population of Mono Hot Spring evening primrose. Any spread of cheatgrass from the around Florence Lake could have a negative impact on the habitat for the Mono Hot Springs evening primrose.
- **Ward Mountain AU:** The effects to the Mono Hot Springs evening primrose would be similar to those in Dutch/Boulder.
- **Sallie Keyes AU:** There would be no expected improvement in the vegetation composition at Shooting Star Meadow, which could maintain a degraded condition of the potential habitat for west side sensitive riparian species. There would be a risk of trampling to the population of Prairie wedge grass and the potential habitat of the west side riparian species at Blayne and Double Meadows due to continued use as a pasture, but no downward trends in meadow or stream function. At Blayne Hot Springs, there may be effects to the Prairie wedge grass from non-pack stock supported recreational use of the hot springs.
- **Italy AU:** The degraded conditions at Hilgard Meadow would continue, putting the potential habitat for veined water lichen at risk.

- There would be very few impacts to the potential habitat for Congdon's lewisia because it is rocky and would not receive much pack stock use. Trail impacts would mostly be limited to the tread, a minimal percentage of the habitat.

Cumulative Effects

In the area around Florence Lake, there are many sources of impact to Mono Hot Springs evening primrose other than commercial pack stock use, including 4WD access to private property, a pipeline on the north side of the lake, and most importantly, the construction of the dam itself. Possibly because it is an annual plant and blooms early, the populations appear to be doing well despite the additive effects of these activities and uses.

Historic livestock grazing, hydropower facilities and current pasture use have all affected the potential habitat of riparian sensitive species, and effects of current commercial pack stock use is minimal compared with the those existing effects.

Rare Plants – Alternative 2 - Modified

Of the ten populations of sensitive and watch list plants known from in or near this geographic unit, four are on or near a trail open to all uses, one may have impacts from wandering grazing stock, three would not be affected by trails or stock (one may be affected by pipeline maintenance), and two would be in meadows open to grazing (one near a hot spring). Of the 51 meadows with habitat for sensitive species, 5 would have persistent or newly degraded conditions.

- **Hooper AU:** The impacts to the Mono Hot Springs evening primrose near Jackass Meadow and gray-leaved violet would be the same as Alternative 1. The Hooper Diversion Trail would be TC2, so there would be a slightly higher risk of maintenance impacts to the population of Mono Hot Springs evening primrose on that trail. There would be significantly higher stock numbers allowed at Jackass Meadow in this Alternative, so the degraded conditions would possibly get worse, degrading the habitat of the Yosemite mousetail and the potential habitat for the west side sensitive riparian species. The degraded conditions would continue at Hell Hole Meadow. There would be a risk of wandering stock impacts to the Mono Hot Springs evening primrose.
- **East Florence AU:** The effects to the populations of Mono Hot Springs evening primrose would be the same as Alternative 1. The effects to the riparian habitat at Blayney meadows would be similar to Alternative 1.
- **Ward Mountain AU:** Impacts from the Florence Lake Trail to Mono Hot Springs evening primrose would be the same as Alternative 1.
- **Dutch/Boulder AU:** The Thompson Lake Trail would be TC2, so the downed trees would probably be removed, increasing the slight risk of trampling to the population of Mono Hot Springs evening primrose.
- **Sallie Keyes AU:** The impacts to the Prairie wedge grass would be the same as Alternative 1.
- **Italy AU:** The effects to the potential habitat of veined water lichen in Hilgard meadow would be the same as Alternative 1 (degraded conditions continue).

- The effects to the potential habitat of Congdon’s lewisia would be the same as Alternative 1.

Cumulative Effects

The cumulative effects of Alternative 2-Modified with historic livestock grazing, hydropower facilities, and current pasture use are similar to those of Alternative 1, but at slightly less intensity.

Rare Plants – Alternative 2

The effects to rare plants would be the same as Alternative 2 – Modified.

Rare Plants – Alternative 3

Of the ten populations of sensitive and watch list plants known from in or near this geographic unit, four are on or near a trail open to all uses, one may have impacts from wandering grazing stock, three would not be affected by trails or stock (one may be affected by pipeline maintenance), and two would be in meadows open to grazing (one near a hot spring). Of the 51 meadows with habitat for sensitive species, 5 would have persistent or newly degraded conditions.

- **Hooper AU:** The effects to the Mono Hot Springs evening primrose on the Hooper Diversion trail and the grey-leaved violet would be the same as Alternative 2 - Modified. The effects to riparian habitats at Jackass and Hell Hole would be the same as Alternative 2 - Modified.
- **East Florence:** The effects to the populations of Mono Hot Springs evening primrose would be the same as Alternative 1.
- **Dutch/Boulder AU:** The effects to the populations of Mono Hot Springs evening primrose would be the same as Alternative 2 - Modified.
- **Ward Mountain AU:** The effects to the populations of Mono Hot Springs evening primrose would be the same as Alternative 1.
- **Sallie Keyes AU:** The degraded conditions would continue at Shooting Star Meadow and could possibly worsen at Blayney Meadow because of an increase in the stock numbers, so the risks to the population of Prairie wedge grass and the potential habitat of the west side sensitive riparian species would continue.
- **Italy AU:** The effects to the potential habitat of veined water lichen at Hilgard Meadow would be the same as Alternative 1 (continued degraded conditions).
- The effects to the potential habitat of Congdon’s lewisia would be the same as Alternative 1.

Cumulative Effects

The cumulative effects of Alternative 3 with historic grazing, hydropower facilities, and current pasture use would be the same as Alternative 2-Modified.

Rare Plants – Alternative 4

Analysis

Of the ten populations of sensitive and watch list plants known from in or near this geographic unit, four are on or near a trail open to all uses, one may have impacts from wandering grazing stock, three would not be affected by trails or stock (one may be affected by pipeline maintenance), and two would be in meadows open to grazing (one near a hot spring). Of the 51 meadows with habitat for sensitive species, 5 would have persistent or newly degraded conditions.

- **Hooper AU:** Jackass Meadow would not be used as a pasture for commercial stock use, but some grazing would be allowed and Forest Service stock would probably continue to use it, so there would be a lower risk of impacts to the populations of Yosemite mouse-tail, the nearby population of Mono Hot Springs evening primrose, and the potential habitat for the west side sensitive riparian species than Alternatives 1, 2 – Modified, 2, and 3. Both Jackass and Hell Hole Meadows would continue to have degraded conditions, mostly due to hydrologic effects related to the Florence Dam. The impacts to the population of grey-leaved violet would be the same as Alternative 1.
- **East Florence AU:** The effects to the populations of Mono Hot Springs evening primrose would be the same as Alternative 2 - Modified.
- **Ward Mountain and Dutch/Boulder AUs:** The effects to Mono Hot Springs evening primrose would be the same as Alternative 1.
- **Sallie Keyes AU:** There would be no change to the degraded conditions at Shooting Star and Lower Blayne Meadows, continuing the risk to the population of Prairie wedge grass and the potential habitat for the west side sensitive riparian species.
- **Italy AU:** Although there would be a 30 percent utilization level and fewer stock nights at Hilgard Meadow, the degraded conditions of the meadow and the potential habitat for veined water lichen would continue.
- The effects to the potential habitat of Congdon's lewisia would be the same as Alternative 1.

Cumulative Effects

The cumulative effects of Alternative 4 with historic grazing, hydropower facilities, and current pasture use would be the same as Alternative 2-Modified.

Rare Plants – Alternative 5

Of the ten populations of sensitive and watch list plants known from in or near this geographic unit, three are in areas with no threats from pack stock or trail activities, although one is along a pipeline, four are on or near a trail open to all uses, one is near a meadow that may have pack stock use, and one is in a meadow near a hot spring. Of the 51 meadows with habitat for sensitive species, 3 would have persistent or newly degraded conditions.

- **Hooper AU:** Jackass Meadow would most likely still be used by Forest Service and private pack stock, so the risk of impacts to the populations of Yosemite mouse-tail and

nearby Mono Hot Springs evening primrose and to the potential habitat of the west side sensitive riparian species would be less than the other alternatives. The hydrologic condition of Jackass and Hell Hole meadows may not recover because most of the effects are from the Florence dam. The effects to the population of grey-leaved violet would be the same as Alternative 1.

- **East Florence AU:** The Florence Lake Trail would be TC3 and there would still be hiker, private pack stock and 4WD vehicle use, but overall, there would be slightly less risk of trampling or weed spreading to the populations of Mono Hot Springs evening primrose. There would be no risk of commercial pack stock impacts to the Prairie wedge grass population, although other recreational uses would continue.
- **Dutch/Boulder and Ward Mountain AU:** The impacts to the populations of Mono Hot Springs evening primrose would be similar to those in Hooper AU.
- **Sallie Keyes AU:** There could be slight improvement in the conditions at Lower Blayney, which would improve the habitat of Prairie wedge grass and potential habitat for the west side sensitive riparian species.
- **Italy AU:** There could be minor improvements to the stream condition at Hilgard Meadow, but no improvement in the hydrologic condition is expected, so there would be a risk to the potential habitat of veined water lichen.
- There would be no risk of commercial pack stock trampling to the potential habitat of Congdon's lewisia, but there would still be hiker and private pack stock use.

Cumulative Effects

The cumulative effects of Alternative 5 with historic grazing, hydropower facilities, and current pasture use would be the slightly less Alternative 2-Modified, since current use is fairly insignificant compared to the effects of historic and other current uses.

Weeds

See Wilderness Scale discussion.

Cumulative Effects

The cumulative effects of hydropower facilities, OHV use, and other recreational uses would be similar to that in Ansel Adams West Geographic Unit.

Campfires

See Wilderness Scale discussion.

Cumulative Effects

The cumulative effects of backpackers with commercial pack stock use would be similar to that in Mono Creek/Rock Creek Geographic Unit.

John Muir Southeast

Grazing Resources

Analysis

Current overnight use and grazing use is low throughout the John Muir Southeast geographic area. The majority of the use passes through the national Forest portion of the John Muir Wilderness Area for a few hours between the trailhead and the Sequoia Kings Canyon National Park Boundary. The majority of the riparian areas, while not assessed, are believed to be in good condition. These areas are currently not affected by commercial pack stock grazing and little difference is expected with implementation of any alternative.

Grazing Resources – Alternative 1

Analysis

There were 9 stock nights of grazing use reported in this geographic area between 2001 and 2003. There would be little change from current conditions with implementation of any alternative, with the possible exception of some increased trampling and related reductions in riparian vegetation at Anvil Camp with implementation of Alternatives 2, 2-Modified, and 3.

All Analysis Units: There is one known location, the Windy Gap area, with observable areas of altered vegetative species composition, due to trailing impacts such as trampling of vegetation and sod fragmentation and associated erosion along a trail that is along the meadow gradient at the south edge of the meadow. Overnight and grazing uses may also occur occasionally at Sawmill Meadow. Camping and grazing of pack stock is currently prohibited at Anvil Camp on the Shepard Pass Trail.

Little grazing use occurs in this geographic area and there would be little change and few noticeable effects regardless of the alternative selected. There would continue to be a prohibition of camping with stock and grazing at Anvil Camp. There could be limited and temporary trampling of riparian vegetation at Sawmill Meadow and other isolated locations in the Sawmill, Shingle Mill Bench, and Birch Creek areas associated with light use by either commercial or non-commercial pack stock users during hunting season some years. These effects are not likely to be repeated in any one year or to persist over the long-term at any one location.

At Windy Gap there would be decreased riparian vegetation over the short-term and then decreased riparian vegetation and decreased ground cover over the long-term to very long-term. At Windy Flat there would likely not be adequate riparian vegetation to provide for watershed protection over the very long-term unless a watershed restoration project was implemented.

There would likely continue to be adequate vegetation to provide for normal ecological processes and watershed protection such as providing for biodiversity, dissipation of energy, filtering of sediment, and retention of water at most locations throughout this geographic area.

Cumulative Effects

Because there are few areas with persistent historic effects and light commercial pack stock use, the cumulative effects of any alternative in this geographic unit would be slight.

Grazing Resources – Alternative 2-Modified

Analysis

There would be 45 stock nights of grazing available in this geographic area. Current reported grazing use is low throughout this geographic area. The majority of the riparian areas are believed to be in good condition. These areas are currently not affected by commercial pack stock grazing and little difference is expected with implementation of any alternative. There is one location, Windy Flat with observable areas of altered vegetative species composition and active erosion associated with trailing along the gradient of the meadow.

All Analysis Units: Little grazing use occurs in this geographic area and there would be little change regardless of the alternative selected. With resumption of pack stock camping there would be localized trampling and loss of riparian vegetation and decreased vegetative cover near Anvil Camp in the short-term. Over the long-term, there may be a decline in late-seral riparian vegetation and an increase in mid-seral and earl-seral vegetation at Anvil Camp as stock cross the small meadow to access the stream for drinking water. These effects of allowing camping with no grazing may eventually result in the need to require packing additional feed resulting in increased stock use and decreased vegetative cover near the designated stock holding area at Anvil Camp. There could be limited and temporary trampling of riparian vegetation at Sawmill Meadow and other isolated locations in the Sawmill, Shingle Mill Bench, and Birch Creek areas associated with light use by either commercial or non-commercial pack stock users during hunting season some years. These effects are not likely to persist over the long-term at any one location. At Windy Gap there would be increased riparian vegetation and ground cover over the long-term to very long-term; however, there would likely not be adequate vegetation to provide for watershed protection over the very long-term.

Grazing is not allowed at Windy Gap; however, the erosion and loss of vegetation would likely continue over the long-term unless watershed restoration work is accomplished. There could be some increased use and associated related direct and cumulative effects of trampling of vegetation at Sawmill Meadow and at Anvil Camp. Most visitors to this geographic area will not notice any difference in conditions, at any scale, including site-specific with implementation of Alternative 2 Modified relative to other alternatives.

There would likely continue to be adequate vegetation to provide for normal ecological processes and watershed protection such as providing for biodiversity, dissipation of energy, filtering of sediment, and retention of water at most locations throughout this geographic area.

Cumulative Effects

The cumulative effects of Alternative 2-Modified would be the same as those of Alternative 1.

Grazing Resources – Alternative 2

Analysis

There would be 45 stock nights of grazing available in this geographic area. Current reported grazing use is light throughout this geographic area. The majority of the riparian areas are believed to be in good condition. These areas are currently not affected by commercial pack stock grazing and little difference is expected with implementation of any alternative. There is

one location with observable areas of altered vegetative species composition, at the Windy Flat and Gap area. There could be increased use and direct effects near the designated campsite at Anvil Camp with implementation of Alternative 2.

All Analysis Units: Little grazing use occurs in this geographic area and there would be little change or few noticeable effects regardless of the alternative selected. With resumption of pack stock camping there would be localized trampling and loss of riparian vegetation and decreased vegetative cover near Anvil Camp in the short-term. There could be limited and temporary trampling of riparian vegetation at Sawmill Meadow and other isolated locations in the Sawmill, Shingle Mill Bench, and Birch Creek areas associated with light use by either commercial or non-commercial pack stock users during hunting season some years. These effects are not likely to persist over the long-term at any one location.

Over the long-term, there may be a decline in late-seral riparian vegetation and an increase in mid-seral and earl-seral vegetation at Anvil Camp. At Windy Flat there would be increased riparian vegetation and ground cover over the long-term to very long-term, but there would likely not be adequate vegetation to stabilize the headcuts and protect the watershed for the very long-term. Cumulatively there would likely continue to be adequate vegetation to provide for normal ecological processes and watershed protection such as providing for biodiversity, dissipation of energy, filtering of sediment, and retention of water at most locations throughout this geographic area.

Cumulative Effects

The cumulative effects of Alternative 2 would be the same as those of Alternative 1.

Grazing Resources – Alternatives 3 and 4

Analysis

There would be 45 stock nights of grazing available in this geographic area with implementation of Alternative 3 and none available with implementation of Alternative 4. Current reported grazing use is very light throughout this geographic area. The majority of the riparian areas are believed to be in good condition. These areas are currently not affected by commercial pack stock grazing and little difference is expected with implementation of any alternative. There is one location, Windy Flat with observable areas of altered vegetative species composition and active erosion associated with trailing along the gradient of the meadow. There could be some increased use and associated related direct and cumulative effects of trampling of vegetation at Sawmill Meadow and at Anvil Camp under Alternative 4. Most visitors to this geographic area will not notice any difference in conditions, at any scale, including site-specific with implementation of Alternative 3 relative to other alternatives.

All Analysis Units: Little grazing use occurs in this geographic area and there would be little change regardless of the alternative selected. With resumption of pack stock camping there would be localized trampling and loss of riparian vegetation and decreased vegetative cover near Anvil Camp in the short-term. Over the long-term, there may be a decline in late-seral riparian vegetation and an increase in mid-seral and earl-seral vegetation at Anvil Camp as stock cross the small meadow to access the stream for drinking water. These effects of allowing camping with no grazing may eventually result in the need to require packing additional feed resulting in increased stock use and decreased vegetative cover near the designated stock holding area at

Anvil Camp. There could be limited and temporary trampling of riparian vegetation at Sawmill Meadow and other isolated locations in the Sawmill, Shingle Mill Bench, and Birch Creek areas associated with light use by either commercial or non-commercial pack stock users during hunting season some years. These effects are not likely to persist over the long-term at any one location.

Grazing is not recommended at Windy Gap; however, the erosion and loss of vegetation would likely continue over the long-term unless watershed restoration work is accomplished. At Windy Gap there would be increased riparian vegetation and ground cover over the long-term to very long-term; however, there would likely not be adequate vegetation to provide for watershed protection over the very long-term. Cumulatively there would likely continue to be adequate vegetation to provide for normal ecological processes and watershed protection such as providing for biodiversity, dissipation of energy, filtering of sediment, and retention of water at most locations throughout this geographic area.

Cumulative Effects

The cumulative effects of Alternative 3 or 4 would be the same as those of Alternative 1.

Grazing Resources – Alternative 5

Analysis

Little grazing use occurs in this geographic area, and there would be little change in conditions with no pack stock use. At Windy Flat there would be increased riparian vegetation and ground cover over the long-term to very long-term; however recovery of the deeper incision and headcuts may not occur without watershed restoration work.

All Analysis Units: There may be some limited trampling of riparian vegetation at Anvil Camp, Sawmill Meadow, and other isolated locations primarily in the Sawmill, Shingle Mill Bench, and Birch Creek areas associated with light use by private stock parties during hunting seasons in some years. Cumulatively, over the long-term there would be adequate vegetation to provide for watershed protection.

Grazing is not recommended at Windy Flat; however, the erosion and loss of vegetation would likely continue over the long-term unless watershed restoration work is accomplished. At Windy Flat there would be increased riparian vegetation and ground cover over the long-term to very long-term; however, there would likely not be adequate vegetation to provide for watershed protection over the very long-term. Cumulatively there would likely continue to be adequate vegetation to provide for normal ecological processes and watershed protection such as providing for biodiversity, dissipation of energy, filtering of sediment, and retention of water at most locations throughout this geographic area.

Cumulative Effects

The cumulative effects of Alternative 5 would be similar to those of Alternative 1, since the effects are slight, although Alternative 5 would have the most beneficial cumulative effects of all the alternatives.

Fens

There are no known fens in this geographic unit and grazing use is very low, so there would be little risk to any unknown fens.

Rare Plants

Rare Plants – Alternative 1

Of the 31 populations of sensitive or watch list plants in this geographic unit, 10 populations are in remote locations and would not be impacted by pack stock or trails and 21 are along trails (17 open to pack stock use): 7 TC4 trails (4 are hiker only), 6 TC3 trails, 5 TC2 trails, 1 TC1 trail, and 2 use trails. This alternative has the highest trail classes of any alternative and so the use and maintenance impacts to populations on or near trails would be the highest. Even with these trail classes however, there would be very few impacts expected, since use stays mostly on the trail tread and most destinations are in the National Park.

Taboose and Sawmill AUs: The Taboose and Sawmill Trails would be TC3, so use, maintenance activities and the small risks to the populations of Raven's milkvetch, Inyo beardtongue, and alpine jewel-flower would be highest of any of the alternatives. There would be no effects to the Inyo beardtongue inaccessible to trails.

Kearsarge AU: There will continue to be access to Bench Lake via the Matlock to Bench Lake use trail, and on the Flower to Bench use trail. The populations of Mt. Whitney draba and Sharsmith's stickseed near Bench Lake would be at very minimal risk of impacts from client use of the area, but stock would not access the population. The other population would not be affected by pack stock use, regardless of alternative. The Grand Group Trail would be TC2 and there is very little current use, so there would be a low risk of impact to the population of Sharsmith's stickseed near the terminus of the trail. The Golden Trout Lake Trail would be TC2 and open for pack stock use, so the population of alpine jewelflower along the trail would be at a small risk of pack stock trampling and possibly some maintenance activity. The population of alpine jewel flower at Heart Lake is not directly accessible to pack stock, so there would only be a risk of hiker impacts. Camping could affect the populations of Mt. Whitney draba, alpine jewel-flower, and Sharsmith's stickseed near Bench and Heart Lakes, although most of the packer-supported and hiker use is accessing Sequoia-Kings Canyon NP. Since these plants grow in rock outcrops, the risk of damage is slight. The lower section of the Shepherd Pass trail would be TC2, so the populations of Dedecker's clover would be at a slight risk of pack stock and maintenance impacts. The marble rock mat population would not be affected by trail use or maintenance.

Shepherd AU: both sections of the Shepherd Pass trail would be TC2, so the populations of Father Crowley's lupine and Sharsmith's stickseed would be at a slight risk of pack stock and maintenance impacts.

Whitney AU: there would continue to be no commercial pack stock allowed, so the impacts to the populations of Mt. Whitney draba and Sharsmith's stickseed would be heavy hiker use and maintenance of the Mt. Whitney Trail at TC4.

North Fork of Lone Pine AU: There would be no pack stock or trail effect to the population of Sharsmith's stickseed.

North Fork of Big Pine AU: Both sections of the North Fork Big Pine Creek Trail would be TC4, with high levels of maintenance and use. The impacts to Father Crowley's lupine and Inyo beardtongue would probably be similar to the current situation and there would be a risk of some plants being trampled near the trail, but no risk to the populations as a whole.

South Fork of Big Pine AU: Both sections of the South Fork Big Pine Creek Trail would be TC3, probably with current use levels and moderate maintenance levels. There would be a minimal risk of off trail impacts to the Inyo beardtongue and Father Crowley's lupine populations

Baxter AU: The Baxter Pass Trail would be TC3 with some risk of pack stock use and trail maintenance activity effects on the population of Dedecker's clover along the trail.

Cottonwood AU: The Cottonwood Lakes Trail would be TC4, with high levels of use and maintenance. The trail ends near the populations of sweet-smelling monardella and Sharsmith's stickseed and there would continue to be social trails in the area of the population. No packing in of firewood would be allowed, so there would be no increased risk of disease, weeds, or damage to the subalpine vegetation. The populations of Sharsmith's stickseed on rock outcrops would not be affected by pack stock or trail actions. Camping and fishing use in the Cottonwood Lakes Basin may affect the populations of sweet-smelling monardella and Sharsmith's hackelia near Lakes 4 and 5.

Cumulative Effects

The Rex Montis Mine in Kearsarge AU operated for some years and there is currently a mine clean-up project at the site. These mining operations usually have only a local effect but it is long-term and the actual level of impact depends on the individual operation. There is very little commercial pack stock use near the mine, so there would be no cumulative effect.

Hiker and backpacker trampling would contribute to commercial pack stock effects in the Cottonwood Basin and along heavily traveled trails such as the Kearsarge Pass trail.

Rare Plants – Alternative 2 - Modified

Of the 31 populations of sensitive or watch list plants in this geographic unit, 10 populations are in remote locations and would not be impacted by pack stock or trails and 21 are along trails (14 open to pack stock use): 4 hiker only TC4 trails, 2 TC3 trails, 11 TC2 trails (2 NSCS), 1 TC1 NSCS trail, and 3 use trails.

Taboose and Sawmill AUs: The Taboose and Sawmill Trails would be TC2, so use, maintenance activities and the small risks to the populations of Raven's milkvetch, Inyo beardtongue, and alpine jewel-flower would be lower than Alternative 1, but higher than Alternatives 4 and 5. There would be no effects to the Inyo beardtongue inaccessible to trails.

Kearsarge AU: The risk to the Mount Whitney draba populations would be similar to Alternative 1, but the Flower to Bench use trail would not be used. Since this is duplicate access, there would probably be no change in use from Alternative 1. The effects to the population of Sharsmith's stickseed would be the same as Alternative 1. The Golden Trout Lake Trail would be TC2 and NSCS, so there would be no pack stock impacts to the population of alpine jewelflower, but there could be some maintenance activities. Impacts to the population of alpine

jewelflower at Heart Lake would be the same as Alternative 1. Impacts to the populations of Dedecker's clover and marble rock mat would be the same as Alternative 1.

Shepherd AU: Only the lower section of the Shepherd Pass trail would be TC2 and the last half mile would be TC1. There may be less pack stock and hiker use in this case, so the populations of Father Crowley's lupine and Sharsmith's stickseed would be at a slightly lower risk of pack stock and maintenance impacts than in Alternative 1.

Whitney AU: The effects to the populations of Mt. Whitney draba and Sharsmith's stickseed would be the same as Alternative 1.

North Fork of Lone Pine AU: There would be no pack stock or trail effect to the population of Sharsmith's stickseed.

North Fork of Big Pine AU: The lower section of the North Fork Big Pine Creek Trail would be TC3 and the upper 1.3 miles would be TC2, with moderate levels of maintenance, but probably use similar to the current situation. The impacts to Father Crowley's lupine and Inyo beardtongue would probably be similar to Alternative 1, but maintenance impacts would be less likely.

South Fork of Big Pine AU: The lower section of the South Fork Big Pine Creek Trail would be TC2 and the upper 1.2 miles would be TC1, possibly at somewhat lower use and maintenance levels than currently. The risk to Inyo beardtongue and Father Crowley's lupine would be marginally smaller than in Alternative 1.

Baxter AU: The Baxter Pass Trail would be TC1 and NSCS, so there would be no risk of pack stock impacts and maintenance would be unlikely. There could be some risk of hikers leaving the trail to avoid obstacles and trampling the Dedecker's clover, since there would be very little maintenance.

Cottonwood AU: The Cottonwood Lakes Trail would be TC3, but the use would probably remain similar to current use and the effects to the populations of sweet-smelling monardella and Sharsmith's stickseed would probably be similar to Alternative 1. However, the sweet-smelling monardella may be negatively affected by the increased illegal removal of downed wood that may result from non-packer supported users observing packer campfires, or by introduction of plant diseases or weeds carried in on the wood. The populations of Sharsmith's stickseed on rock outcrops would not be affected by pack stock or trail actions.

Cumulative Effects

Cumulative effects of Alternative 2-Modified would be slightly less than those of Alternative 1.

Rare Plants – Alternative 2

The effects of Alternative 2 would be the same as those of Alternative 2-Modified.

Rare Plants – Alternative 3

Of the 31 populations of sensitive or watch list plants in this geographic unit, 10 are in remote locations and would have no trail or pack stock impacts and 21 would be along trails: 4 hiker only TC4 trails 2 TC3 trails, 11 TC2 trails (2 NSCS), 1 TC1 NSCS trail, and 2 near use trails.

Taboose and Sawmill AUs: Effects to Raven’s milkvetch and Mt. Whitney draba would be the same as those described in Alternative 2 - Modified. There would be no effects to the Inyo beardtongue inaccessible to trails.

Kearsarge AU: The effects to the population of Sharsmith’s stickseed would be the same as Alternative 1. The effects to the population of alpine jewelflower along the Golden Trout Lake Trail would be the same as Alternative 2 - Modified. The impacts to the population of alpine jewelflower at Heart Lake would be the same as Alternative 1. The impacts to Dedecker’s clover and marble rock mat would be the same as Alternative 1.

Shepherd AU: The effects to Father Crowley’s lupine and Sharsmith’s stickseed would be the same as Alternative 1.

Whitney AU: The effects to the populations of Mt. Whitney draba and Sharsmith’s stickseed would be the same as Alternative 1.

North Fork of Lone Pine AU: There would be no pack stock or trail effect to the population of Sharsmith’s stickseed.

North Fork of Big Pine AU: The effects to Father Crowley’s lupine and Inyo beardtongue would be the same as Alternative 2 - Modified.

South Fork of Big Pine AU: Both sections of the South Fork Big Pine Creek Trail would be TC2, probably with use levels and maintenance levels similar to current use. There would be a small risk of off trail impacts to Inyo beardtongue and Father Crowley’s lupine.

Baxter AU: The effects to the population of Dedecker’s clover would be the same as Alternative 2 - Modified.

Cottonwood AU: The effects to sweet-smelling monardella would be the same as Alternative 2 - Modified. The populations of Sharsmith’s stickseed on rock outcrops would not be affected by pack stock or trail actions.

Cumulative Effects

Cumulative effects of Alternative 3 would be slightly less than those of Alternative 1.

Rare Plants – Alternative 4

Of the 31 populations of sensitive or watch list plants in this geographic unit, 10 are in remote locations and would have no trail or pack stock impacts and 21 would be along trails (9 open to pack stock): no TC4 trails, 6 TC3 trails (4 hiker only), 8 TC2 trails (4 NSCS), 4 TC1 NSCS trails, and 2 use trails.

Taboose AU: The Taboose Trail would be TC2 and NSCS, so there would be no commercial pack stock use, and maintenance activities would most likely be less often than with pack stock use. There would be very small risks to the populations of Raven’s milkvetch, Inyo beardtongue, and alpine jewel-flower. There would be no effects to the Inyo beardtongue inaccessible to trails.

Sawmill AU: The Sawmill Trail would be TC1 and NSCS, so there would be no commercial pack stock use, very little general use, and most likely no maintenance activities. The only risk to the population of Raven’s milkvetch would be hikers going around any trail blockages and possibly trampling the plants.

Kearsarge AU: The effects to the populations of Mt. Whitney draba would be the same as Alternative 2 - Modified. The effects to the population of Sharsmith's stickseed would be the same as Alternative 1. The Golden Trout Trail would be TC1 and NSCS, so the population of alpine jewelflower along the trail would have no pack stock impacts and probably no maintenance activity. The impacts to alpine jewelflower at Heart Lake would be the same as Alternative 1. The impacts to Dedecker's clover and marble rock mat would be the same as Alternative 1.

Shepherd AU: The effects to Father Crowley's lupine and Sharsmith's stickseed would be the same as Alternative 2 - Modified.

Whitney AU: The Mt. Whitney Trail would be TC3, so there would be less likelihood of trail maintenance impacts on the populations of Mt. Whitney draba and Sharsmith's stickseed, but hiker use would probably remain high.

North Fork of Lone Pine AU: There would be no pack stock or trail effect to the population of Sharsmith's stickseed.

North Fork of Big Pine AU: The effects to Father Crowley's lupine and Inyo beardtongue would be the same as Alternative 2 - Modified.

South Fork of Big Pine AU: Both sections of the South Fork Big Pine Creek Trail would be TC1 and NSCS, so there would be no pack stock effects and essentially no maintenance effects to the populations of Inyo beardtongue and Father Crowley's lupine along the trail.

Baxter AU: The effects to the population of Dedecker's clover would be the same as Alternative 2 - Modified.

Cottonwood AU: The Cottonwood Lakes Trail would be TC3, but the use would probably remain similar to current use and the effects to the populations of sweet-smelling monardella and Sharsmith's stickseed would probably be similar to Alternative 1. There would be no firewood packed in from outside the wilderness. The populations of Sharsmith's stickseed on rock outcrops would not be affected by pack stock or trail actions.

Cumulative Effects

Cumulative effects of Alternative 4 would be slightly less than those of Alternative 1.

Rare Plants – Alternative 5

Of the 31 populations of sensitive or watch list plants in this geographic unit, 13 are in remote locations and would have no trail or pack stock impacts and 18 would be along trails (none open to pack stock): 4 TC4 trails, 3 TC3 trails, 9 TC2 trails, and 2 TC1 trails.

- **Taboose AU:** Effects to the populations of Raven's milkvetch, Inyo beardtongue, and alpine jewel-flower would be the same as Alternative 4. There would be no effects to the Inyo beardtongue inaccessible to trails.
- **Sawmill AU:** The Sawmill Trail would be TC2 but without commercial pack stock, so there would be small risks to the population of Raven's milkvetch of hikers going around trail blockages, but they would be less likely to be removed than in Alternative 4.

- **Kearsarge AU:** There would be no pack stock impact to either population of Mt. Whitney draba. There would be no pack stock impacts to the populations of Sharsmith's stickseed. The Golden Trout Trail would be TC2, so the impacts to the alpine jewelflower along the trail would be the same as Alternative 2 - Modified. The impacts to alpine jewelflower at Heart Lake would be the same as Alternative 1. The impacts to Dedecker's clover and marble rock mat would be the same as Alternative 1, but there would be no pack stock use on Shepherd Pass trail.
- **Shepherd AU:** The effects to Father Crowley's lupine and Sharsmith's stickseed would be the same as Alternative 2 - Modified, except that there would be no commercial pack stock use.
- **Whitney AU:** The effects to the populations of Mt. Whitney draba and Sharsmith's stickseed would be the same as Alternative 1.
- **North Fork of Lone Pine AU:** There would be no pack stock or trail effect to the population of Sharsmith's stickseed.
- **North Fork of Big Pine AU:** There would be no pack stock effects to Father Crowley's lupine and Inyo beardtongue, and the trail maintenance effects would be the same as Alternative 2 - Modified.
- **South Fork of Big Pine AU:** There would be no pack stock effects to the Inyo beardtongue and Father Crowley's lupine, but the lower part of South Fork Big Pine Creek Trail would be TC2 and the upper TC1, so the risk of effects from trail maintenance is slightly higher than Alternative 4.
- **Baxter AU:** The effects to the population of Dedecker's clover would be the same as Alternative 2 - Modified.
- **Cottonwood AU:** The effects to the sweet-smelling monardella would be limited to hiker and trail maintenance on the Cottonwood Lakes Trail, which would be TC3. The populations of Sharsmith's stickseed on rock outcrops would not be affected by pack stock or trail actions.

Cumulative Effects

The cumulative effects of Alternative 5 would be less than the other alternatives since there would be no commercial pack stock use.

Weeds

See Wilderness Scale discussion.

Cumulative Effects

The presence of weeds at most trailheads (unknown source) is a source of weed seed for all vectors, including hikers and pack stock, both private and commercial. The effect depends on the total number of users.

Campfires

See Wilderness Scale discussion.

Cumulative Effects

Because much of the backpacker use in this geographic unit is travel into SEKI, there would be only slight cumulative impact with packer use of firewood above the existing closure, even though most of the campsites are above the closure.

John Muir Southwest

Grazing Resources

Analysis

Current reported grazing use is low throughout the John Muir Southwest geographic area. The majority of the riparian areas are believed to be in good condition. There are some meadows that have observable areas of altered vegetative species composition, including Big Maxson and Upper Falls. These areas are little affected by current commercial pack stock grazing, little to no changes in pack stock use is expected, and little difference is expected with implementation of any alternative. There would continue to be adequate riparian vegetation to provide for watershed protection in these areas.

Grazing Resources – Alternative 1

Analysis

The overall high reported grazing use was 212 stock nights between 2001 and 2003 in this geographic area.

All Analysis Units: There would be limited trailing related sod fragmentation and associated loss of riparian vegetation in the McGuire Lakes, Meadowbrook, Fall Creek, and Fleming Lake areas. These limited and localized effects would continue over the long-term. Most visitors would likely not notice these effects, which would not exceed standards, although the effects could be monitored over time at these locations.

There would likely continue to be adequate riparian vegetation to provide for watershed protection in these locations.

Cumulative Effects

Because there are few areas with persistent historic effects and light commercial pack stock use, the cumulative effects of any alternative in this geographic unit would be slight.

Grazing Resources – Alternative 2-Modified

Analysis

There would be 1,832 stock nights of grazing available in this geographic area with implementation of Alternative 2-Modified.

All Analysis Units: Current reported grazing use is light throughout this geographic area. The majority of the riparian areas are believed to be in good condition. There are some meadows that have observable areas of altered vegetative species composition, including Big Maxson and Upper Falls. These areas are currently not affected by commercial pack stock grazing and little

difference is expected with implementation of any alternative. There would be limited trailing related trampling and sod fragmentation and associated loss of riparian vegetation in the McGuire Lakes, Meadowbrook, Fall Creek, and Fleming Lake areas.

Overall, use will probably remain below the estimated capacity. Most visitors to this geographic area will not notice any difference in conditions, at any scale with implementation of Alternative 3 relative to other alternatives. Cumulatively, over the long-term there would likely to be adequate vegetation overall in most locations to provide for watershed protection.

Cumulative Effects

The cumulative effects of Alternative 2-Modified would be the same as those of Alternative 1.

Grazing Resources – Alternative 2

Analysis

There would be 1,832 stock nights of grazing available with implementation of Alternative 2 in this geographic area. Current reported grazing use is light throughout this geographic area. The majority of the riparian areas are believed to be in good condition.

All Analysis Units: There are some meadows that have observable areas of altered vegetative species composition, including Big Maxson and Upper Falls. These areas are currently not affected by commercial pack stock grazing and little difference is expected with implementation of any alternative.

There would be limited trailing related sod fragmentation and associated loss of riparian vegetation in the McGuire Lakes, Meadowbrook, Fall Creek, and Fleming Lake areas. This limited effect would continue over the long-term.

Overall, use will probably remain below the estimated capacity. Most visitors to this geographic area will not notice any difference in conditions, at any scale with implementation of Alternative 3 relative to other alternatives. Cumulatively, over the long-term there would likely to be adequate vegetation overall in most locations to provide for watershed protection.

Cumulative Effects

The cumulative effects of Alternative 2 would be the same as those of Alternative 1.

Grazing Resources – Alternatives 3 and 4

Analysis

There would be 1,832 stock nights of grazing use available in this geographic area with implementation of either Alternative 3 or 4. Current reported grazing use is light throughout this geographic area. The majority of the riparian areas are believed to be in good condition.

All Analysis Units: There are some meadows that have observable areas of altered vegetative species composition, including Big Maxson and Upper Falls. These areas are currently not affected by commercial pack stock grazing and little difference is expected with implementation of any alternative.

Overall, use will probably remain below the estimated capacity. Most visitors to this geographic area will not notice any difference in conditions, at any scale with implementation of Alternative 3 relative to other alternatives.

There would be limited trailing related trampling and sod fragmentation and associated loss of riparian vegetation in the McGuire Lakes, Meadowbrook, Fall Creek, and Fleming Lake areas. This limited effect would continue over the long-term but would not result in inadequate vegetation to provide protection to the watershed.

Overall, use will probably remain below the estimated capacity. Most visitors to this geographic area will not notice any difference in conditions, at any scale with implementation of Alternative 3 relative to other alternatives. Cumulatively, over the long-term there would likely to be adequate vegetation overall in most locations to provide for watershed protection.

Cumulative Effects

The cumulative effects of Alternative 3 or 4 would be the same as those of Alternative 1.

Grazing Resources – Alternative 5

Analysis

Current reported grazing use is light throughout this geographic area. There would be no grazing by commercial pack stock with implementation of Alternative 5. The majority of the riparian areas are believed to be in good condition.

All Analysis Units: There are some meadows that have observable areas of altered vegetative species composition, including Big Maxson and Upper Falls, likely due to historical impacts. These areas are currently not affected by commercial pack stock grazing and little difference is expected with implementation of any alternative.

There would be increased recruitment and establishment of vegetation in the long-term on the mid-stream and point bars at Big Maxson Meadow. There would be increased riparian vegetative cover in the short-term to long-term in the McGuire Lakes, Meadowbrook, Fall Creek, and Fleming Lake areas. These effects would continue over the long-term to very long-term.

Overall, use will probably remain below the estimated capacity. Most visitors to this geographic area will not notice any difference in conditions, at any scale with implementation of Alternative 3 relative to other alternatives. Cumulatively, over the long-term there would likely to be adequate vegetation overall in most locations to provide for watershed protection.

Cumulative Effects

The cumulative effects of Alternative 5 would be most beneficial of all, although only slightly different from the other alternatives, since historical effects are light.

Fens

Fens – Alternative 1

- **Big Maxson AU:** There would be no improvement in the stream condition at Meadowbrook, but the fens are in good condition with slight trampling impacts. If

grazing continues at the present low stock numbers, the fens would remain in good condition, but if numbers increase, there would be increased risks to the fens.

- **Spanish AU:** There is no current grazing reported from the area, so the fen (*Meesia uliginosa*) would continue in its current unknown but probably good condition. If grazing increased there would be trampling risks to the fen.

Cumulative Effects

The effects of historic grazing are a factor in meadow condition in this geographic unit, however there is very little commercial pack stock grazing use and few reports of degraded conditions, so any cumulative effect would be slight.

Fens – Alternative 2 - Modified

Approximately 12 percent of the meadows will be open for grazing, and inadvertent trampling and grazing impacts to any fens would be more likely in these meadows.

- **Big Maxson AU:** The effects to the fens at Meadowbrook would be the same as Alternative 1.
- **Spanish AU:** The meadow with the fen would not be open for grazing, so the fen would be at essentially no risk of pack stock effects.

Cumulative Effects

The cumulative effects of historic grazing with commercial pack stock use would be even smaller than in Alternative 1 because of the critical area protection standards.

Fens – Alternative 2

The effects to the meadows with fens or fen characteristics would be the same as Alternative 2 - Modified.

Fens – Alternative 3

The effects to the meadows with fens or fen characteristics would be the same as Alternative 2 - Modified.

Fens – Alternative 4

The effects to the meadows with fens or fen characteristics would be the same as Alternative 2 - Modified.

Fens – Alternative 5

The fen at Meadowbrook would continue to have private pack stock use, and the stream condition would not be expected to improve. At Spanish Lake, there would be no expected change in the fen (*Meesia*) condition.

Cumulative Effects

There would be no commercial pack stock grazing, so no cumulative effects with historic uses.

Rare Plants

Rare Plants – Alternative 1

Of the three populations of sensitive and watch list plants known from in or near this geographic unit, two are inaccessible with no threats and one is in a meadow with no reported use. There is habitat for six other sensitive and watch list plants of rock outcrop or upland habitats that is at very low risk of impacts. Of the approximately 178 meadows with habitat for sensitive species, 1 would have persistent or newly degraded conditions because of private pack stock use.

Pack stock use in this geographic unit is very light in general, so there is only a very slight risk to the riparian sensitive plants and potential habitat. No change in meadow conditions would be expected if grazing continued at current levels in the meadows with potential habitat for the west side sensitive riparian species.

- **Rodgers AU:** There would be no pack stock impacts to the population of Tulare County bleeding heart because of its remote location, not accessible by trails.
- **Spanish AU:** There would be very little risk of impacts to the population of *Meesia uliginosa* near Spanish Lake due to low use.
- **Crown Basin AU:** There would be no pack stock impacts to the population of Kettle Dome buckwheat because of its remote location, not accessible by trails.
- There is very low use in the potential habitat for the six species of sensitive and watch list plants in the Kings River watershed, and the risk of pack stock or trail impacts is low in the rock outcrop and upland habitats of these species. At Big Maxson Meadow, private pack stock but not commercial pack stock is using the meadow and the hydrologic condition would not improve as long as the private pack stock grazing continues. This puts the habitat for the west side sensitive riparian species at risk.

Cumulative Effects

Historic livestock grazing contributed to any degraded conditions in this geographic unit, but the current light pack stock use would probably not interfere with meadow recovery.

Rare Plants – Alternative 2 - Modified

Of the three populations of sensitive and watch list plants known from in or near this geographic unit, two are inaccessible and there would be no threats and one is in a meadow with no reported commercial pack stock use. There is habitat for six other sensitive and watch list plants of rock outcrop or upland habitats that is at very low risk of impacts. Of the approximately 178 meadows with habitat for sensitive species, 1 would have persistent or newly degraded conditions because of private pack stock use.

- **Rodgers AU:** The effects to the population of Tulare County bleeding heart are the same as Alternative 1.
- **Spanish AU:** There is no designated grazing zone, so there would be no risk of grazing impacts to the population of *Meesia uliginosa*.
- **Crown Basin AU:** The effects to the population of Kettle Dome buckwheat are the same as Alternative 1.

- The effects to the potential habitat for other sensitive species would be the same as Alternative 1. Only 4 of the 178 meadows with potential habitat for the west side sensitive riparian species would be in grazing zones and no downward trends in hydrologic function or stream conditions would be predicted.

Cumulative Effects

The cumulative effects of Alternative 2-Modified with existing historic livestock grazing effects would be minimal since grazing use is very light.

Rare Plants – Alternative 2

The effects of Alternative 2 would be the same as Alternative 2-Modified.

Rare Plants – Alternative 3

Of the three populations of sensitive and watch list plants known from in or near this geographic unit, two are inaccessible and there would be no threats and one is in a meadow with no reported use. There is habitat for six other sensitive and watch list plants of rock outcrop or upland habitats that is at very low risk of impacts. Of the approximately 178 meadows with habitat for sensitive species, 1 would have persistent or newly degraded conditions because of private pack stock use.

- **Rodgers AU:** The effects to the the Tulare County bleeding heart population, would be the same as Alternative 1.
- **Spanish AU:** The effects to the *Meesia uliginosa* population in Spanish AU would be the same as Alternative 1.
- **Crown Basin AU:** The effects to the population of Kettle Dome buckwheat would be the same as Alternative 1.
- The effects to the potential habitat for the other sensitive plants would be the same as Alternative 2 - Modified.

Cumulative Effects

The cumulative effects of Alternative 3 with historic grazing effects would be the same as Alternative 2-Modified.

Rare Plants – Alternative 4

- **Rodgers AU:** The effects to the population of Tulare County bleeding heart would be the same as Alternative 1.
- **Spanish AU:** The effects to the population of *Meesia uliginosa* would be the same as Alternative 2 - Modified.
- **Crown Basin AU:** The effects to the populations of Kettle Dome buckwheat would be the same as Alternative 1.
- The effects to the potential habitat of the other sensitive plants in the geographic unit would be the same as Alternative 2 - Modified.

Cumulative Effects

The cumulative effects of Alternative 4 with historic grazing effects would be the same as Alternative 2-Modified.

Rare Plants – Alternative 5

Of the three populations of sensitive and watch list plants known from in or near this geographic unit, two are inaccessible and there would be no threats and one is in a meadow with no reported use. There is habitat for six other sensitive and watch list plants of rock outcrop or upland habitats which are at very low risk of impacts. Of the 178 meadows with habitat for sensitive species, 1 would have persistent or newly degraded conditions due to private pack stock use.

- **Rodgers AU:** The effects to the population of Tulare County bleeding heart in would be the same Alternative 1, except that there would be no risk of pack stock impacts at all.
- **Spanish AU:** The effects to the population of *Meesia uliginosa* would be the same as Alternative 2 - Modified, except that there would be no risk of pack stock impacts at all.
- **Crown Basin AU:** The effects to the population of Kettle Dome buckwheat would be the same as Alternative 1, but there would be no risk of commercial pack stock impacts at all.
- There would be no pack stock impacts to the west side riparian sensitive species' potential habitat in this geographic unit.

Cumulative Effects

Since there would be no commercial pack stock grazing, there would be no cumulative effects with historic grazing uses.

Weeds

See Wilderness Scale discussion.

Cumulative Effects

There are some existing weeds at the pack station that uses this area, so pack stock could act as vectors for those weeds, however use is very light and the effect would be slight.

Campfires

See Wilderness Scale discussion.

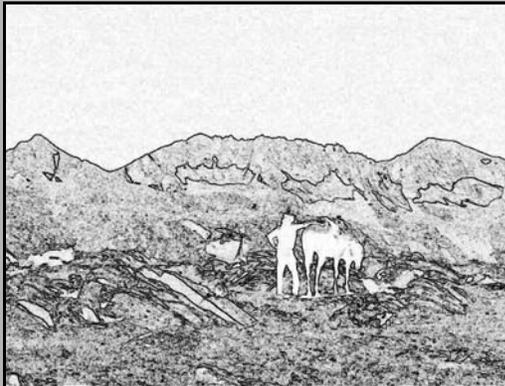

Cumulative Effects

Because commercial pack stock use is very light, the cumulative effect of allowing charcoal or firewood to be brought to locations above existing campfire closures would be minimal in this geographic unit.

Civil Rights and Environmental Justice

A specific consideration of equity and fairness in resource decision-making is encompassed with the concerns of environmental justice. As required by Executive Order 12898, all federal actions must consider potentially disproportionate effects on minority or low-income communities. Principles for considering environmental justice are outlined in Environmental Justice Guidance under the National Environmental Policy Act (Council on Environmental Quality 1997). Those principles were considered in this analysis. The Socio-Economic portion of this chapter considered the demographics of the affected areas of the project area, including minorities and low-income populations. There are no adverse environmental effects relating to an environmental justice issue.

There is no evidence to believe that minority or low-income groups will be adversely or disproportionately affected by the alternatives that have been presented in this document.

Trail and Commercial Pack Stock Management In the Ansel Adams and John Muir Wildernesses

**Final
Environmental Impact Statement**

Volume 3 – Appendices

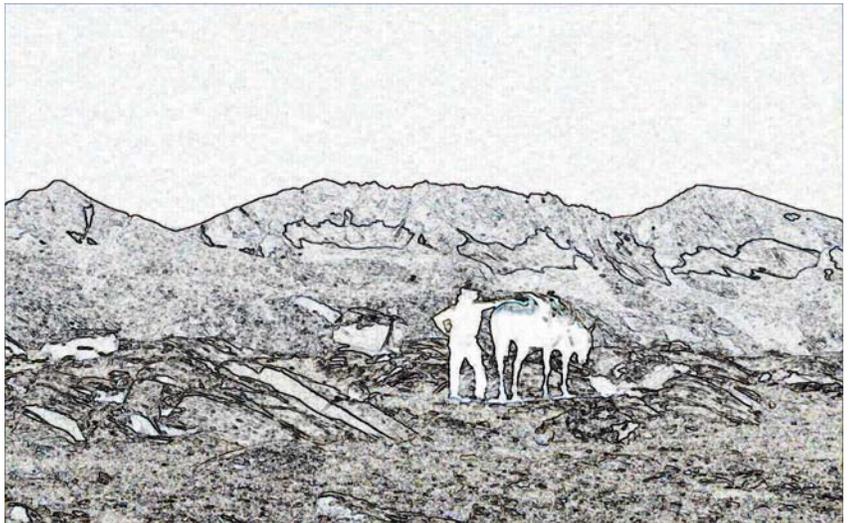

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, age, disability, and where applicable, sex, marital status, familial status, parental status, religion, sexual orientation, genetic information, political beliefs, reprisal, or because all or part of an individual's income is derived from any public assistance program. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at (202) 720-2600 (voice and TDD). To file a complaint of discrimination, write to USDA, Director, Office of Civil Rights, 1400 Independence Avenue, S.W., Washington, D.C. 20250-9410, or call (800) 795-3272 (voice) or (202) 720-6382 (TDD). USDA is an equal opportunity provider and employer.

Inyo and Sierra National Forests

Trail and Commercial Pack Stock Management in the Ansel Adams and John Muir Wildernesses

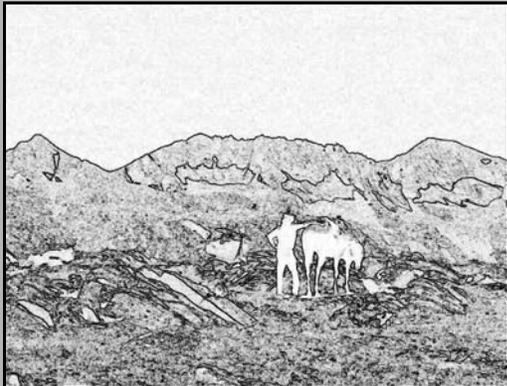

Final Environmental
Impact Statement

VOLUME 3 OF 3

APPENDICES

DECEMBER 2005

Appendix A Glossary

Appendix A – Glossary

Allowable Use: The degree of utilization considered desirable and attainable on various specific parts of a grazing area or zone considering the present resource condition, management objectives, and management level.

Area of Potential Effect (APE): The geographic area or areas within which an undertaking may directly or indirectly cause changes in the character or use of historic properties, if any such properties exist. The APE is influenced by the scale and nature of an undertaking and may be different for different kinds of effects caused by the undertaking (36 CFR 800.16[d]).

Beneficial uses: The natural and human uses of surface water defined in the Water Quality Control Board Basin Plans. These beneficial uses must be maintained and water quality objectives and best management practices (BMPs) are designed to protect beneficial uses.

Best Management Practices (BMP): A practice or combination of practices that are the most effective and practical means of preventing or reducing water pollution from non-point sources.

Biological Assessment: A “Biological Evaluation” specifically prepared for formal consultation with the U. S. Fish and Wildlife Service when a “May Affect” determination is concluded for a project on any Federally listed Threatened or Endangered Species per the legal requirements found in Section 7 of the Federal Endangered Species Act of 1976 as amended.

Biological Evaluation: A documented Forest Service review of Forest Service programs or activities in sufficient detail to determine how an action or proposed action may affect any Federally listed threatened, endangered, or proposed species, or Forest Service sensitive species.

Candidate Species: Plant and animal taxa considered for possible addition to the Federal list of Endangered and Threatened Species. These are taxa for which the U. S. Fish and Wildlife Service has on file sufficient information on biological vulnerability and threat(s) to support issuance of a proposal to list, but issuance of a proposed rule is currently precluded by higher priority listing actions.

Carrying Capacity: The maximum stocking rate possible without damaging vegetation or related resources. May vary from year-to-year on the same area due to fluctuating forage production.

Composition: The relative amount (usually percent) of one plant species or one community type in relation to other species or community types in a given area.

Consultation: The process of seeking, discussing, and considering the views of other participants, and, where feasible, seeking agreement with them regarding matters arising in the Section 106 process. The Secretary’s *Standards and Guidelines for Federal Agency Preservation Programs* provide further guidance (36 CFR 800.16[f]).

Consultation also takes place between federally recognized American Indian Tribes, groups, organizations, and individuals under Section 106 and a suite of other laws and executive orders. It is also a process used to determine whether a proposed action may affect listed species or critical habitat.

Council: The Advisory Council on Historic Preservation or a Council member or employee designated to act for the Council (36 CFR 800.16[g]).

Critical Area: An area that is evaluated separately from the remainder of the management zone because it contains special or unique values. Critical areas may be treated with special consideration due to inherent site factors, including size, location, condition, values, or significant potential conflict among uses. Critical areas in this analysis are unsuitable for stock entry, although some inadvertent negligible entry occurs.

Day Rides: Day rides involve clients riding stock, accompanied by a guide, for periods of a day or less. No overnight equipment is involved.

Dunnage Trips: Trips in which packers using pack stock carry equipment and supplies for clients who are hiking to a pre-arranged destination, and/or pre-arranged re-supplies for clients on long duration trips. The packer does not stay with clients.

Ecological (Seral) Status: The present state of vegetation of an ecological site in relation to the potential natural community for the site. Ecological status is independent of use. It is an expression of the relative degree to which the kinds, proportions, and amounts of plants in a community resemble that of the potential natural community. The four ecological status classes correspond to 0-25, 26-50, 51-75, and 76-100 percent similarity to the potential natural community and are called early-seral, mid-seral, late-seral, and potential natural community, respectively.

Effect: (Cultural resources) Alteration to the characteristics of a historic property qualifying it for inclusion in or eligibility for the National Register (36 CFR 800.16[i]).

Endangered Species: A Federally listed species which in danger of extinction throughout all or a significant portion of its range.

FAR: Functional at Risk Proper Functioning Condition rating, should include a trend indicator (upward, downward, or not apparent).

Fen: Riparian habitat where peat (undecomposed/partially decomposed plant material) accumulates faster than it decomposes in groundwater-fed, perennially saturated areas.

Full Service Trips: Full service trips involve a guide, cook, or other paid employees of the operator that accompany the clients for the duration of the trip. The full time packer or packers that stay with the party during the duration of the trip handle stock for the riders including saddling, packing the mules, trip planning, animal care, equipment repairs, safety briefings, and possibly trail work to clear trails of debris or obstacles.

Grazing Zone: An identified area of land in which grazing may be authorized.

Headcut: A break in slope at the top of a gully or section of gully that forms a “waterfall,” which in turn causes the underlying soil to erode and the gully to expand uphill. This scarp may migrate upstream (headward), leading to stream incision. In high elevation Sierra Nevada Meadows, these headcuts often migrate into trails or natural swales, creating new stream channels.

Historic Property: Any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the National Register of Historic Places maintained by the Secretary of the Interior. This term includes artifacts, records, and remains that are related to

and located within such properties. The term includes properties of traditional religious and cultural importance to an Indian tribe or Native Hawaiian organization and that meet the National Register criteria. The term eligible for inclusion in the National Register includes both properties formally determined as such in accordance with regulations of the Secretary of the Interior and all other properties that meet the National Register criteria. (36 CFR 800.16[l]).

Hydrologic Function (meadows and wetlands): Meadow hydrologic function is defined by the following factors: (1) The ability of the soil in a meadow to withstand intake, retain and transmit water (USDA Forest Service, 1995); (2) The ability of the meadow to dissipate energies associated with overland flow from adjacent sites and to improve flood water retention; and (3) The ability of the meadow to maintain a water table capable of supporting its Potential Natural Vegetation (PNV). PNV is defined as the plant community that would become established if all successional sequences were completed without human interference under the present environmental and floristic conditions, including those created by man.

Informal consultation: An optional process that includes all discussions and correspondence between the U.S. Fish and Wildlife Service and a Federal agency, prior to formal consultation, to determine whether a proposed Federal action may affect listed species or critical habitat. This process allows the Federal agency to utilize the Service's expertise to evaluate the agency's assessment of potential effects or to suggest possible modifications to the proposed action which could avoid potentially adverse effects. If a proposed Federal action may affect a listed species or designated critical habitat, formal consultation is required. (Except when the Service concurs that a proposed action is not likely to adversely affect listed species or designated critical habitat.)

Interdisciplinary Team: A team of varied land use and resource specialists formed to provide a coordinated, integrated information base for overall land use planning and management.

Key Area: A portion of rangeland selected because of its location, grazing or browsing value, or use. It serves as a monitoring and evaluation point for range condition, trend, or degree of grazing use.

Management Indicator Species (MIS): A wildlife species whose population and trend in a certain habitat type indicates the population and trend of other species that are also dependent on that habitat type.

National Register: The National Register of Historic Places maintained by the Secretary of the Interior (36 CFR 800.16[q]). This is a list of historic properties.

National Register Criteria: The criteria established by the Secretary of the Interior for use in evaluating the eligibility of properties for the National Register (36 CFR part 60). (36 CFR 800.16[r])

Nondegradation Objective (Water Quality): An objective in the Lahontan Regional Water Quality Control Board Basin Plan (1994). It requires that, "Whenever the existing quality of water is better than the quality of water established in the Basin Plan as objectives, such existing quality shall be maintained unless appropriate findings are made under the policy."

Not Recommended For Stock (NRFS): An advisory for private equestrians that the conditions of a particular trail may be notably awkward and/or especially risky for use by pack and saddle stock.

Not Suitable For Commercial Stock (NSCS): (See **Trail Suitability**)

Pathogen: An agent that causes disease, especially a living microorganism such as a bacterium, protozoa, or fungus.

PFC (Proper Functioning Condition): Protocol for assessing stream conditions. A stream is at proper functioning condition if it has adequate vegetative, landform or large woody debris present to dissipate stream energy associated with high water flow, with stable streams and ability to filter sediment.

Prehistoric Site: Physical cultural remains created by past activities of indigenous peoples.

Programmatic Agreement: A document that records the terms and conditions agreed upon to resolve the potential adverse effects of a Federal agency program, complex undertaking or other situations (36 CFR 800.16[T]).

Range Readiness: The state of relative soil dryness and plant development in a location at which soils will support the weight and movement of livestock without being displaced, compacted or otherwise damaged and the stage of plant development at which the plants will sustain grazing impacts without loss of vigor or productivity. Rangeland is generally ready for grazing when soil has become firm after winter and early spring precipitation, and when plants have reached the defined stage of growth at which grazing may begin under a specific management plan without long-lasting damage.

Rare Plants: Plant species listed as Sensitive or Watch List on the Sierra and Inyo National Forests.

Recreation Category: Refers to the strategy for managing recreation use in the Ansel Adams, John Muir and Dinkey Lakes Wildernesses. Three recreation categories describe the desired condition for these wildernesses. Recreation Category 1 is to be managed for low use and the most pristine conditions. Recreation Category 2 is for concentrated use along trail corridors and at popular destinations and dispersed use at low to moderate levels off the main trail corridors. Recreation Category 3 is for higher levels of use concentrated and managed intensively; these are typically popular destinations close to the trailheads. A full description of these categories can be found in the 2001 Wilderness Plan for the Ansel Adams, John Muir and Dinkey Lakes Wildernesses.

Resource Ratings or Overall Resource Rating (Trails): Refers to numerical rating assigned to a trail segment after field evaluation of current impacts and potential effects due to risk factors. Ratings are on a scale of 0-5, with 0 representing very low concern, highly stable with no notable effects; while a rating of 5 indicates severe/extensive concerns with severe resource impacts and high risk factors. Further definitions of each rating are in the project record.

Riparian: Referring to or relating to areas adjacent to water or influenced by free water associated with streams or rivers.

Riparian Conservation Area: Areas adjacent to water bodies and wetlands and have specific standards and guidelines established in the Sierra Nevada Forest Plan Amendment. These areas are usually defined as the area within 300 feet of a perennial stream, spring, or wetland, and within 100 feet of an ephemeral or intermittent stream.

Risk Factors (Trails): Refers to conditions on the ground—usually naturally occurring—which potentially affect the stability of the trail and associated resources. Common risk factors include

exceedingly steep slopes, loose soils, riparian or meadow habitat, proximity and connectivity to streams or surface water. Other risk factors have a human component, such as excessively steep trail grades, insufficient design and lack of structures, or high trail use.

Sedimentation: The process of depositing sediment. Here, the term indicates sediment deposition into surface water.

Sensitive Species: Those plant and animal species identified by a Regional Forester for which population viability is a concern as evidenced by: 1) significant current or predicted downward trends in population numbers or density and 2) significant current or predicted downward trends in habitat capability that would reduce a species existing distribution.

Seral-status: Plant community stage depicting the relative position on a classical successional pathway (see Ecological Status).

Sod fragmentation: Broken vegetative cover or soil. Minor sod fragmentation might remove some vegetation, while severe sod fragmentation would break the soil to the rooting depth of vegetation.

Soil compaction: An increase in the density of soil, usually as a result of humans or animals walking on the soil surface. Compaction alters the soil structure so that it has less pore space, lower infiltration rates, and lower permeability.

Soil productivity: The capacity of soil to support plant growth. Soil productivity depends on soil nutrient levels, soil structure, climate, and water availability.

Special Aquatic Feature: Water-related features other than streams or rivers, including lakes, wet meadows, fens, wetlands, vernal pools and springs (as defined in the SNFPA 2004).

Spot Trip: Trips in which clients ride stock to a destination with a guide, supported with pack stock for equipment and gear. The riding stock, pack stock and guide do not stay with the party.

Stabilizer Plants: Plant species that become established along edges of streams. Although they generally require wet conditions for establishment they may persist in drier conditions once firmly established. They have commonly have some combination of strong, cord-like, rhizomes, deep fibrous roots, coarse leaves, strong root crowns, and are effective in buffering streambanks against the erosive forces of moving water and trapping sediment to build stream banks. Examples include sedges (*Carex utriculata*, *Carex nebrascensis*) and Willow (*Salix spp*).

State Historic Preservation Officer (SHPO): The official appointed or designated pursuant to section 101(b)(1) of the National Historic Preservation Act to administer the State historic preservation program or a representative designated to act for the State historic preservation officer (36CFR 800.17[V]).

Stock Night: One horse or mule placed on a unit of land for the purpose of grazing available forage at any time during a 24-hour period. Expressed as a stock night because packers often place stock on a given grazing area overnight.

Stocking Rate: The number and types of animals placed on a unit of land for a specified period of time.

Stream bank sloughing: When a stream bank breaks vertically, and a portion of the bank falls into the stream. This process can occur naturally on outer bends of normally eroding streams, or

can occur as a result of stream bank trampling, vegetation loss, and soil compaction along the stream bank.

Stream incision: Erosion of either the stream bed or banks or both, where the stream is vertically separated from the former floodplain due to stream bed lowering. Where there is active erosion within the bed of a stream or river channel, the bed may be steadily lowered, creating relatively higher banks up onto the adjoining floodplain or terrace. The banks become increasingly steepened and unstable as this erosion is active at the toe of the slope. Streambed collapse and erosion occurs, and the channel commonly widens in conjunction with bed lowering.

Suitability: The appropriateness of applying certain resource management practices to a particular area of land as determined by an analysis of the economic and environmental consequences and alternative uses foregone.

Suitable Area: An area in which an interdisciplinary team has determined that grazing and or stock entry may be allowed with appropriate mitigations and standards.

System Trail: Trails that are wholly or partially within, or adjacent to and serving the National Forests, and that are included in the forest development transportation plan (Forest trail inventory).

Threatened Species: A Federally listed species which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.

Trail Classes: A designation assigned to each trail on the Forest trail inventory that defines the typical characteristics and intended development and management levels for each trail. Four classes are appropriate within wilderness areas. Trail Class 1 trails are the lowest development and typically the most lightly used managed trails. Trail Class 2 and 3 trails are increasingly developed on a continuum leading to Trail Class 4 trails, which are the most highly developed and typically serve extremely high numbers of trail users. These are further described in Chapter 2 of this document.

Trail Deferred Maintenance (Sometimes called “Backlog Maintenance): Maintenance that has not been performed—generally due to financial constraints—which leaves the trail in a substandard or degraded condition. Commonly refers to the added costs needed to return the trail to its intended standard.

Trail Maintenance (also Annual Maintenance): Recurring work performed to ensure the continued stability and availability of trails for use at the designated standard. May be performed annually or at intervals more frequent or exceeding annual. Typically includes clearing of obstacles, cleaning drainage structures, incidental repair and replacement of trail structures to ensure trail integrity and stability.

Trail Reconstruction: Major repairs and replacement of much of a trail’s infrastructure, to return a trail to its original standard or to improve a trail to its intended development level.

Trust Responsibility: Generally a set of principles and concepts outlining the responsibilities of the U.S. Government to act as the trustee of Indian people and Indian owned assets. The U.S. Government, through the President, has certain responsibilities to protect Indian property and rights, Indian lands, and resources. Fulfilling or redeeming a trust responsibility, can be reflected or demonstrated as a matter of action; a stream that was protected, a site that was maintained

intact, a property right that has been left unaffected by a Federal action. The writing of an environmental document is not an example of fulfilling a trust duty.

Trail Suitability: A determination of the appropriateness of commercial stock on individual system trails. This determination is based upon one or a combination of factors including the stability of the trail and associated resources, the presence of risk factors which would likely lead to instability without excessive trail development, considerations of destination capability, and desired conditions. Trails which are determined to be inappropriate for such use are designated “Not Suitable for Commercial Stock” (NSCS).

Unavailable Areas: Areas that are outside of grazing zones and are therefore closed to grazing.

Unsuitable Area: An area in which an interdisciplinary team has determined it is not appropriate for grazing or entry by any stock. All of these areas are closed to grazing.

Use Trail: A non-system trail (not on Forest trail inventory), either distinct and readily followed or intermittent, which provides access to lesser-used destinations, such as campsites, viewpoints, or remote areas not served by system trails. Use trails are most commonly formed by repeated travel by either hikers or equestrians. This can also refer to former trails or roads, of which use has decreased to the point that no management as a system trail is needed.

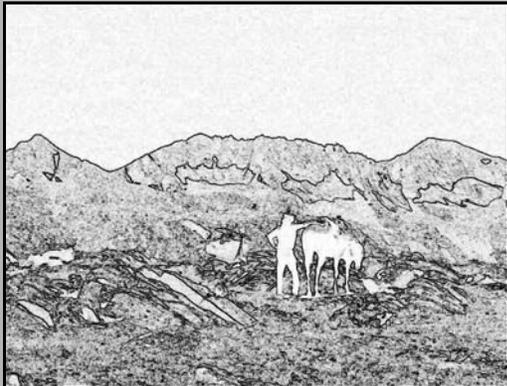

Watch List Plants: Species that are locally rare, are of special interest, such as cactus or orchids, are widely disjunct from the main distribution of the species, are largely endemic to the Forests, or species for which very little, if any, information is available but existing information may indicate some cause for concern.

Water Table (or Groundwater Table): The top surface of the zone where the soil is saturated with water. Above this surface, the pore space in the soil is filled mainly with air.

Weeds: Plants non-native to California, as listed in the Jepson Manual (Hickman, 1993).

Wetlands: Those areas that are inundated by surface or ground water with frequency sufficient to support, and under normal circumstances do or would support a prevalence of vegetation or aquatic life that requires saturated or seasonally saturated soil conditions for growth and reproduction. Generally includes swamps, marshes, bogs, and similar areas such as sloughs, potholes, wet meadows, river overflows, mud flat, and natural ponds.

* Grazing and rangeland related definitions are adapted for this project from the Glossary in the Rangeland Analysis and Planning Guide, (USFS, Pacific Southwest Region, 1997), and the additional Glossary contained in Chapter 3, Sampling Vegetation Attributes, Interagency Technical Reference, ITR, BLM/RSD/ST-96/002+1730, in the Rangeland and Analysis Guide, and “Monitoring the Vegetation resources in Riparian Areas” by Alma H. Winward (April, 2002).

Appendix C Response to Comment

Appendix C Response to Comment

Introduction

The Draft EIS was available for public review and comment from March 29, 2005, to June 15, 2005. During the comment period, the Forest Service heard from 429 individuals, agencies, interest groups, and elected officials. The agency received approximately 205 individual letters and 224 form letters. Organized response campaigns accounted for more than 50% of the responses received during the public comment period.

Public responses submitted on the Trail and Commercial Pack Stock Management in the Ansel Adams/John Muir Draft EIS were documented and analyzed using a process called content analysis. This is a systematic method of compiling and categorizing all of the public viewpoints and concerns submitted during the official comment period for the Draft EIS. Content analysis helps the Forest Service clarify, adjust, or incorporate additional technical information in preparation of the Final EIS.

All of the comment letters were numbered, read, and logged into a spreadsheet. Each letter was read with individual comments taken out of the letter and organized into a response to comment document. The comments were summarized into public concerns and forwarded to the appropriate specialist who provided a response to the concern raised. All of these public concerns and responses are reassembled into this final response to comment document. Over 300 public concerns were identified from the public's comment letters. In many cases, the public concerns below are summarized from the public's comment letters. In other cases, the public comment letter is directly quoted in the public concern statement. The project record also contains an annotated version of this response to comment including the full comment from the public's comment letter. Each comment also includes a response number or numbers. This number refers to the public comment letter that contained the comment. The project record contains a list of the names and addresses of the individuals, groups, and agencies that commented on the Draft EIS.

I. Process and Planning

Pack Stock Use in Wilderness

General, Continue pack stock use in the wilderness

Public Concern #1: *Pack Stock use in the wilderness should not be reduced/should continue:*

- *Because the damage the animals do to the trails is no more significant than the numbers of people coming in to the area or other uses on public lands. (response #10, 24, 244, 337, 351, 374, 375)*
- *Because there is a historic value to pack stock and stations in the wilderness. (response # form letter A, 10, 26, 27, 32, form letter F, 48, 80, 162, 240, 248, 286, 291, 374)*

- *Because the proposal discriminates against packers and the public that uses their services (response # form letter A, 32, 217, 320)*
- *Because wilderness should be open to all users, not just hikers (response #14, 18, 165)*
- *Because commercial packers are good at practicing leave no trace and often protect the wilderness better than other users. (response #17, 34, 39, form letter F, 43, 73, 217, 271, 277 309, 320, 418, 419)*
- *Because commercial packers help many people facilitate access to the wilderness that would otherwise not be able to make it on their own e.g., handicapped/elderly (response #1, 3, 7, 10, 19, 24, 26, 34, 39, form letter F, 43, 55, 71, 76, 78, 79, 80, 104, 154, 157, 162, 181, 188, 189, 190, 217, 228, 244, 248, 269, 271, 277, 281, 291, 295, 309, 331, 337, 351, 366, 415)*
- *Because commercial packers help to keep trails open for other wilderness users (response #23)*
- *Because most people can not afford to keep their own pack stock for these types of trips (response #23, 248, 382)*
- *Because commercial packers provide support for a number of activities in the wilderness including trail work/maintenance, scientific research, search and rescue, anti-poaching efforts, habitat restoration etc... (response #26, form letter F, 154, 190, 217, 290, 340)*
- *Because excluding commercial pack stock in some areas only leads to a concentration of use in other areas (response #26)*
- *Because restrictions on commercial pack stock will eventually lead to restrictions on private stock (response #27, 273)*
- *Because there should be room in the wilderness for various user groups. (response #form letter F, 43, 63, 283)*
- *Because all studies done in the John Muir, Ansel Adams, and Dinkey Lakes Wilderness areas have determined that the Wilderness as a whole are functioning ecologically better than as the time of the Wilderness designation in 1964. (response #form letter F)*
- *Because the Forest Service has not been able to directly attribute resource concerns to commercial pack station on and in trails, camps, and meadows closed to pack station use, but open for other use. (response #form letter F)*
- *Because there is a demand for these services (response #46)*
- *Because with the significantly changing ethnic and age related demographics, it is imperative that commercial packing remain alive and affordable to the American public. (response #form letter F)*
- *Because as the population increases, demand for packing services will also likely increase. (response #48)*
- *Because closing some areas to commercial pack stock will increase use in other areas, leading to more closures (response #73)*
- *Because commercial pack stock provide an important tie between people and the land. (response #75, 281)*

- *Because today's professional horse outfitters are our modern day guides still continuing the same traditions. (response #55)*
- *Because pack strings are responsible for much of the trails and infrastructure in the wilderness (response #156, 340)*
- *Because commercial pack stations allow several generations of a family to enjoy the wilderness (response #159)*
- *Because commercial operators can help to keep wilderness users safe (response #165)*
- *Because the DEIS provides no compelling evidence that would support the removal of commercial pack stock from the wilderness. (response #168)*
- *Because of the economic benefits of pack stations to the communities around the wilderness areas. (response # 190, 233)*
- *Because increased regulations will push the price of these trips to a level at which they are unaffordable to the average person. (response # 233)*
- *Because commercial packers provide an important educational service to the public in terms of teaching leave-no-trace, wilderness skills, wilderness ethics, and western heritage to clients. (response # 162, 277, 280, 295, 307)*
- *Because taxpayers have a right to enjoy the areas that are supported by their tax dollars. (response # 281, 388)*
- *Because the government has no right to restrict publicly owned property. (response # 288, 289)*
- *Because the restrictions are a violation of the Constitutional rights of the people of the United States. (response # 285)*
- *Because packing is a great recreational activity that improves physical and mental health. (response # 290)*
- *Because a vocal minority of the public should not dictate public land policy (response # 295, 326, 329, 348, 357, 397, 418)*
- *Because the needs assessment in Appendix D of the document has proven the need for commercial services in the wilderness (response # 423)*

Public Concern #2: *Commercial pack stock use of the wilderness should continue at current levels with the appropriate oversight (response #4, 308)*

Public Concern #3: *The Forest Service should work with the packers to develop a flexible and adaptive management strategy that will allow the continued operation of these historic businesses while protecting the resources which create the demand for this service in the first place. (response #44, form letter F)*

General, Discontinue/limit commercial pack stock use in the wilderness

Public Concern #4: *Commercial pack stock should not be permitted in the wilderness*

- *Because of the impacts of these animals to wilderness resources (response #2, 30, 96, 245, 261, 263, 319, 356, 398)*
- *Because the intention of wilderness is not to support for-profit businesses that cater to people unable or unwilling to meet wilderness on its own terms (response # 319)*
- *Because for those that want to use commercial packers to access the backcountry, there are other options already available (e.g., national parks) (response # 356, 371)*
- *Because a disproportionate amount of resources go to repairing trails that are damaged by stock (response # 356)*

Response to Public Concerns #1-4: Many comments were received that provided reasons as to why commercial packing should continue in the Ansel Adams and John Muir Wildernesses. Likewise, a number of comments were received that advocated a reduction or outright removal of these activities from the wilderness. The intent of the EIS is to disclose the environmental effects of the proposed project and display the trade-offs between the different alternatives.

Alternatives 1-4 analyze the effects of varying levels of commercial pack stock use with various control mechanisms. Alternative 5 analyzes the environmental effects of eliminating commercial pack stock in the Ansel Adams and John Muir Wildernesses.

Public Concern #5: *The number of commercial pack stock in the wilderness should not be allowed to increase over time. (response #36, 191)*

- *Because as the population of California increases, the demand on the wilderness will increase (response #65)*
- *Because commercial pack use is not compatible with other users (response #66, 93, 172, 254, 257, 284, 299)*
- *Because this use is damaging to resources in the wilderness (response #70, 99, 158, 171, 172, 178, 182, 187, 209, 211, 212, 215, 247, 249, 254, 257, 299, 305, 306, 313, 316, 368, 370, 386, 393)*
- *Because the overall wilderness experience is diminished by large commercial pack groups (response # 305, 306, 312, 386)*
- *Because stock animals damage trails and because of dust, smell, sight, and sound adversely affect the experience of other users (response # 312, 316, 353, 386, 393)*
- *Because water resources and meadows are damaged by pack animals (response # 305, 353, 370, 378, 381, 393)*
- *Because stock animals do far more damage to the wilderness hikers (response # 306, 400)*
- *Because commercial pack stations facilitate the access of large groups into areas that should be used only by smaller groups (response #99)*
- *Because wilderness areas should serve as refuges from civilization (response # 310, 312, 386, 390)*
- *Because future generations should have an opportunity to enjoy these wilderness areas undamaged (response # 313)*

- *Because the noise and accouterments associated with commercial pack parties are not compatible with wilderness (response # 316, 353)*
- *Because of the amount of debris left behind in the wilderness from these parties (response # 316, 353, 393)*
- *Because commercial packing is an ill-informed historical activity that should be (and mostly is) obsolete. (response # 367)*
- *Because the argument that commercial pack stock provide access for people who couldn't otherwise access the wilderness does not reflect reality. I (response # 367)*
- *Because stock are often left unattended to roam freely, both damaging the environment and adversely affecting the wilderness experience of others (response #370)*
- *Because horses are not natural to the High Sierra environment (response # 390)*

Response: The environmental document will analyze various levels of commercial pack stock along with different control mechanisms to help offset the environmental effects of this activity. The ideal use is that which meets the public need for the services and protects the wilderness character of the area. Whether this use level is more or less than some point in the past is not the issue we are examining, rather it is the extent that needed services can be provided while at the same time preserving wilderness character.

Public Concern #6: *Overnight holding of stock in the wilderness should not be permitted. (response # 201)*

Response: Analysis of the effects of overnight holding of stock can be found throughout Chapter 4. The wilderness, hydrology and vegetation sections describe effects to these resources at campsites and by grazing.

Public Concern #7: *Commercial pack stock services should only be made available to clients who truly need them (handicapped/other special populations). (response #form letter C, form letter E, 209, 257)*

Response: See response to Public Concern #5

Equity

Public Concern #8: *The commercial packers and non-commercial users should be treated equally in the wilderness areas. (response # form letter C, form letter E, 33, form letter B, 54, 65, 7098, 99, 105, 109, 175, 182, 209, 220, 247, 284, 417)*

Response: The Preferred Alternative in the FEIS allocates use to commercial pack stock operators based on destination quotas. They would no longer be a part of the daily trailhead quota. Consequently there will be no competition for access between the pack stations and other users. In addition several site specific restrictions will be implemented to manage commercial pack stock such as grazing limits, and designated stock camps. While these management controls may be perceived as treating users differently, they are deemed appropriate based on differential user impacts and necessary to meet wilderness objectives.

Public Concern #9: *The Forest Service should not let one user group degrade the wilderness experience (including the trail system) for other users (response # 178).*

Response: The Preferred Alternative and all the other alternatives in the FEIS comply with the goals and objectives set forth by law, regulation, Forest Plans and more specifically the 2001 Wilderness Plan. An analysis of the impacts of the commercial pack stock on the trail system is located in the Environmental Consequences section (DEIS pg. IV-30).

Public Concern #10: *The current permit/quota system unfairly denies noncommercial users access to particular trails through trailhead quotas while commercial users have rarely been denied. (response # 196)*

Response: Further analysis of the access equity issue and analysis of quota availability can be found in the Chapter 3 “Wilderness” section of the Final EIS. Data shows that commercial and non-commercial quotas fill at a comparable rate. There is no indication that since 2001 the general public has been turned away while the commercial pack station client has not. Wilderness Plan trailhead quota numbers were fully implemented in 2004. Therefore, it is only reasonable to compare quota numbers from 2004. In 2004, with few exceptions there were very few differences in access and availability. See discussion in Chapter 3.

Regardless of who gets turned away because of quota limitations, the objective laid out clearly in the preferred alternative is to maintain certain conditions. Amount of use is only one piece of maintaining conditions, and is arguably more of a social issue than a resource issue. The frequency or occurrences of filling quotas is one of many pieces of information that inform decision makers.

Legal Considerations

Public Concern #11: *The DEIS should address consistency with the ADA as any reduction or elimination of stock packing is a violation of the ADA. (response # 188, 267)*

Response: There is no additional information provided in the comment (case law, specific statutes in the law) that would indicate that the reduction or elimination of commercial pack stock is a violation of the Americans with Disabilities Act (ADA).

Furthermore, ADA does not directly apply to programmatic plans such as this. ADA or related statutes may apply to subsequent actions taken to implement the management direction.

Public Concern #12: *The Forest Service should recognize that RS-2477 is a valid claim to public right of way and that a pack animal or vehicle of any type merely passing over a long time existing route is considered minimum maintenance according to the law. (response #37, 259)*

Response: RS-2477 is a law from the mid-1800s and is quite complex. It involves the rights of individuals to use roads constructed prior to the reservation of lands for public purposes. This project is proposing to establish a trail system in the Ansel Adams and John Muir Wildernesses as well as set levels and locations for commercial pack stock use. The provisions contained in RS-2477 are not being violated by the actions proposed in this project.

Legal Considerations, Wilderness Act

Public Concern #13: *The Forest Service is violating the Wilderness Act*

- *Because these are designated wilderness areas, the Forest Service has the obligation to manage them in such a way that their wilderness character is not impaired. (response #102, 230)*

- *Because the very presence of stock animals in wilderness areas is a violation of the Wilderness Act. (response #169)*
- *Because outfitting and guiding are commercial activities and commercial activities are prohibited in wilderness except “to the extent necessary for activities which are proper for realizing the recreation or other wilderness purposes of the areas.” (Wilderness Act). (response # 172, 185)*

Response: The purpose and need (Chapter 1) clearly states the agency’s intention to follow the legal constraints of the Wilderness Act. It is clear that one of the public’s primary concerns associated with commercial pack stock in the wilderness is the consistency of this activity with the intent of the Wilderness Act. In light of this, Chapter 4 “Wilderness” examines the effects to wilderness character by alternative and concludes that only Alternative 1 “No Action” could be construed to not meet the legal threshold for wilderness character. The Record of Decision further clarifies how the decision-makers consider the legal requirements of the Wilderness Act and how their selected management direction will meet these legal requirements.

Public Concern #14: *The Forest Service should retain the historical uses of the 1964 and 1984 Wilderness Acts that preserve historical uses of the land especially packing and commercial grazing. (response #37, 80, 259)*

Response: The agency does not interpret the Wilderness Act to mean that 1964 conditions and uses will not be subject to management. Forest Service policy states “Each wilderness should be at least as wild in the future as at the time of classification. Resource impacts shall be decreased or held constant. Conditions shall always be improved in situations where degradation exceeds wilderness resource criteria as defined by the designating legislation.” (FSH 2309.19 21.1) The agency intends to “preserve wilderness character” provide an enduring resource of wilderness and protect these areas as wilderness over time. However, the agency, in formulating its alternatives has considered the values of historical uses. Many references to historical uses and baseline conditions in 1964 can be found in the “Commercial Pack Stock Operations” section in Chapter 3 and the “Wilderness” section of Chapter 4.

Public Concern #15: *The Wilderness Act does not allow a balancing of economic benefits and preservation of wilderness character. (response # 196)*

Response: The alternatives are not written with the intent of balancing the economic desires of commercial pack stations with the preservation of wilderness character. The formulation of alternatives is driven by the Purpose and Need for action and the public issues that are brought forward and significant to the decision. Alternatives provide different means to manage packstations: some more restrictive and some more direct. The underlying goal is to manage wilderness character, of which recreation use and enjoyment is one consideration. The public did identify economics as an issue that should be considered in the decision (see Chapter 1 – Issues), and for that reason it is considered and addressed in the analysis.

Public Concern #16: *The Forest Service is misinterpreting the definition of wilderness by claiming that the absence of pack stock will cause a loss in wilderness character. (response #196)*

Response: In Chapter 4, “Wilderness Resource” wilderness character is examined using four elements from the 1964 Wilderness Act (untrammled; naturalness; undisturbed; opportunities for solitude and primitive and unconfined recreation). The discussion addresses how one element

of wilderness character may be impaired while others are being met or achieved. This discussion of wilderness character qualities does not conclude that commercial pack stock categorically will create a loss of wilderness character. This comment takes the statement out of context. There are some elements, specifically “unconfined and primitive recreation”, that would be diminished or impaired as a result of some of the proposed management direction in the alternatives.

Public Concern #17: *The Wilderness Act does not allow for the elevation of solitude over other wilderness values (e.g., public recreational use of the wilderness). (response # 198)*

Response: See response to Public Concern #16. Four elements from the Wilderness Act were used to examine the effects to wilderness character. Opportunities for solitude were only one of these. The analysis does not value or weigh this quality over the others. The methodology section of Chapter 4 “Wilderness” has been modified to clarify how the analysis utilizes the concept wilderness character.

Public Concern #18: *The Proposed Actions violate the Wilderness Act by limiting the freedom and flexibility of commercial pack stations and their clients (response # 275)*

Response: The Wilderness Act specifically states that designated wildernesses are to be managed for “outstanding opportunities for solitude or a primitive and unconfined type of recreation” (Sec. 2(c)(2)). It does not specify that controls cannot be taken to preserve the other conditions specified in that same section. Forest Service policy on wilderness management is to “Maximize visitor freedom within wilderness. Minimize direct controls and restriction. Apply controls only when they are essential for protection of the wilderness resource and after indirect measures have failed” (FSM 2323.12 (1)). The Forests have identified unacceptable conditions where pack stations use occurs under many years of “indirect controls.” Research indicates that direct controls can be useful in managing the types of impacts that were identified in the planning area. Chapter 4 “Wilderness Resource” describes the research and the effects of direct versus indirect controls.

Public Concern #19: *To the detriment of commercial pack stations, the Forest Service is incorrectly interpreting the Wilderness Act (response # 273, 276, 278)*

Response: It is not clear from the comment how the Forest Service is incorrectly interpreting the Wilderness Act. See response to Public Concern #13.

Consistency with Forest Plan and Other Agency Direction

Inyo Forest Plan

Public Concern #20: *The Needs Assessment fails to mention direction regarding pack station permits in the Inyo National Forest Land and Resource Management Plan (1988; at p. 110) and should affirm that no new commercial packing operations will be permitted in the planning area. It also must demonstrate that the existing numbers are necessary and proper. (response # 196)*

Response: The Inyo National Forest’s LRMP was amended by the 2001 Wilderness Plan. The accompanying Needs Assessment analyzes the need for commercial services and the FEIS addresses the effects of the proposed service levels on the resource. The Record of Decision provides rationale, based on information and the analysis in the FEIS, to demonstrate the selected alternative meets the “extent necessary” standard.

2001 Wilderness Plan

Public Concern #21: *The 2001 Wilderness Plan provides adequate direction for commercial pack stock use. (response # 175, 262, 375, 423)*

Response: The District Court directed the Forest Service to examine the cumulative impacts of commercial pack stock operations prior to issuing permits, and to specifically address trail suitability, designated stock camps, stock numbers and group size. A two-step NEPA process was identified. This led the Forests to complete programmatic direction (this FEIS) first, which, by definition, re-examines the 2001 Wilderness Plan. The purpose and need (described in Chapter 1) narrows the scope of the analysis to additional standards needed for commercial pack stock operations and the development of a trail plan. This direction will amend portions of the 2001 Wilderness Plan.

Ninth Circuit Court Order

Public Concern #22: *The DEIS should acknowledge the entire scope of the Ninth Circuit Court of Appeals ruling in High Sierra Hikers vs. Blackwell including the Court's finding that the agency misinterpreted the Wilderness Act, and that its 2001 Wilderness Plan (and other proposals, including its June 2004 Proposed Action) were founded on those incorrect interpretations of the Wilderness Act. (response # 196)*

Response: The Needs Assessment and FEIS take into consideration the Ninth Circuit's ruling in *High Sierra Hikers v. Blackwell*. The FEIS "purpose and need" clearly identifies that preserving wilderness character is the agencies first and foremost responsibility.

Other Agreements

Public Concern #23: *We would hope that the decision reached by the Forest Service would build on and incorporate the discussions and agreement reflected in the MOU signed in February 2005 between the Forest Service and Eastern High Sierra Packers Association. A great deal of work went into that document and it is disturbing to see that it is not reflected in the DEIS. (response # 325)*

Response: The Forest Service has attempted to comply and address the commitments made in the Memorandum of Understanding (MOU). That MOU commits the Forest Service to planning process items but does not influence or affect the Forest Supervisor's decision-making authorities or responsibilities. The ROD is not influenced or directed by anything in the MOU.

NEPA Considerations

Public Concern #24: *The No Action Alternative (I) is flawed because it does not reflect the status quo of the 2001 Wilderness Plan modified by Court Order. The DEIS should have used the service day allocations that represent current actual use (not arbitrary past allocations), minus 20% as intended by the District Court, in addition to reductions in group size and other court-ordered modifications to the 2001 Wilderness Plan as the no action alternative (response # 196)*

Response: The No Action Alternative is correctly identified in the DEIS as implementation of the Wilderness Plan. NEPA requires that a no action be analyzed. The no action direction has been interpreted to mean that the proposed action does not take place and the environmental effects of taking no action are compared with the effects of permitting the proposed activity or

one of the alternatives to take place. We considered the options for the No Action Alternative and concluded that to assume the Court Order injunctive relief to be the existing programmatic direction was not justifiable. This is because the injunctive relief has a limited time and scope and ultimately it is the Wilderness Plan that is in place in the absence of new direction, not the court order.

Public Concern #25: *I have worked as an environmental professional for more than twenty years, and have reviewed literally hundreds of environmental documents, and authored dozens. Frankly, this one is nearly the worst I have ever seen, and possibly the worst. It is poorly organized, there are numerous typos that render its meaning unclear, and its conclusions are not clearly stated. It is shoddy work, and frankly, I would be embarrassed if it came out of my shop. I say these things not to criticize unconstructively, but to point out that the DEIS does not meet the intent of NEPA to inform decision-makers and the public about the issues, alternatives, and environmental consequences. It took many hours of careful study to decipher the document, and I'd bet a fair amount of money that your decision makers did not get through it. (response #346)*

Response: The Draft EIS fielded considerable comments that demonstrate that many people were able to understand the agencies proposed management direction and provide extensive input on the analysis. In the Final EIS, considerable effort has been made to clarify points of confusion, and enhance the analysis where staff and public have noted deficiencies. It should be noted that the size and complexity of the analysis area, combined with the specific requirements of the court have led to a more complicated document in order to comply with the court order.

Public Concern #26: *The DEIS does not comply with NEPA/Wilderness requirements because a number of relevant concerns are not addressed including: (all comments are from response # 275)*

- *Larger group sizes are not evaluated. The Forest Service has never looked at the environmental consequences of increasing group size. The Forest Service maintained that large groups are socially unacceptable. They never have studied the affect on the environment.*

Response: It is very difficult to demonstrate that larger party size has fewer impacts than smaller group sizes. Research indicates that although larger parties may, in some situations have less impact than multiple smaller parties, in most situations this is not the case. (Monz et al 2000 check)

In order to focus the analysis, NEPA requires the agency to address significant issues. The District Court had enough concern that existing party size was a source of environmental impact, that it did not seem prudent to expand the range of alternatives to include direction we felt would not meet the stated purpose and need. Chapter 4 – Wilderness discusses the social and environmental effects of party size.

- *The baseline is improperly defined. Fails to compare the past with the present and evaluate. The document should compare the conditions on the land today and compare that to the conditions of the land twenty to forty years ago.*

Response: There is little data on the conditions of these wildernesses from twenty to thirty years ago, so it was not possible to use this timeframe as a baseline. Chapter 3 – Wilderness includes what little published references exist on resource conditions from the past, including Snyder (1962) and Sierra Club Impact Study (1977). There exists many opinions, recollections, and anecdotal information but this would not meet any substantive standards for NEPA analysis.

- *Improper use of use numbers. We recommend that instead of using numbers for 2001, 2002, 200, you go back and include the numbers for the 1980's and 1990's. We have excellent data from the 1940's on that the Forest Service doesn't consider.*

Response: Accurate historical data from the 1980s and 1990s does not exist for the entire planning area. Historical records from one or two pack stations have limited value when looking at planning area-wide trends. The Final EIS brings in as much data on use from as far back as is possible to show trends. This does not allow us to do anything more than show trends.

- *Day use impacts are not analyzed. Throughout the document it states heavy day use is having impacts. Doesn't mention means to mitigate or prevent damage.*

Response: In areas where the impacts of day use is a relevant effect to consider in the analysis (such as Little Lakes Valley), it is considered as a part of the cumulative effects. Additional information on the level of existing day use (both hiking and riding) is provided in Chapter 3. The scope of the analysis and the proposed direction is on commercial packstock, and does not intend to provide management direction on all issue and all impacts (see Chapter 1 – Purpose and Need).

- *Elimination of service days is not adequately analyzed. Under the 2001 John Muir Wilderness Plan there was considerable historical background. The public and agency could compare and contrast proposed alternatives with a variety of service day allocations. This DEIS proposes use changes that I can't even figure out what numbers of people will be allowed in the three wildernesses.*

Response: The comment is correct, there is some difficulty in assessing different mechanisms of limiting use. There is no direct quantifiable comparison between the mechanism of service days and destination quotas. Each alternative clearly details what levels of use occur, but what is confusing is that the mechanism changes and has different effects. Chapter 4 – Wilderness explains the expected effects of the different mechanisms.

- *Improper analysis of the types of trips. The impact to the land and social effect may be as high of a dunnage trip as it is a full service trip. However, the Forest Service doesn't want to recognize the impact of increasing spot and dunnage trips. The proposed alternatives need to at least suggest the environmental effects of the proposed changes. Unfortunately, it just isn't done in this DEIS.*

Response: The analysis does distinguish the different impacts of spot, dunnage and traveling (all expense) trips. However the conclusions reached in the EIS differ from the conclusions reached by this commenter. All expense trips are considered to have more impact than other types of trips because these trips tend to include large stock numbers, use larger campsites for larger parties, and hold and graze stock overnight in the wilderness. For these reasons, the all expense trips are viewed to have more cumulative impacts than spot and dunnage trips.

- *Reducing grazing will cause increased amount of stock on the trail to haul in cubes. Fails to show that the campsites and surrounding areas will be thrashed and have considerable damage. Forest Service fails to disclose the advantages of loose free grazing instead of having stock tied to pickets.*

Response: This has been noted and is included in the Chapter 4 Wilderness discussion.

- *Permanent camps should be analyzed in the document. The Forest Service is allowing and will essentially be making designated campsite a permanent camp in the wilderness. This is not being adequately disclosed.*

Response: The designated sites proposed will not have any permanent structure associated with the camp. They are typically camps that have been used for these activities for years, and in many cases decades. Some of the camps will need to be set back from water or have access trails improved to meet standards. To the extent that this makes them “permanent”—in other words to be used on a regular basis—is disclosed in the Chapter 4 Wilderness and Physical Resources sections.

Needs Assessment

Public Concern #27: *The Needs Assessment is inadequate and does not provide an analysis of the extent necessary for these commercial services. (response #106, form letter B)*

Response: Additional data was collected and analyzed during the 2005 operating season to better document the public’s need for these services and the extent to which commercial pack stock services are necessary. The results and further analysis have been incorporated into the FEIS needs assessment. Protection of the wilderness character is addressed both in the FEIS as well as the needs assessment for all commercial use alternatives.

Public Concern #28: *The Forest Service indicates in the Needs Assessment that that the proportion of commercial packstock use relative to overall use in the AA/JM Wildernesses has been allowed to grow by fully 60 percent in the last 25 years. No rationale for this significant change in the use allocation among the different recreational user groups is provided in the Needs Assessment. Given that the presumption in the Wilderness Act is not to allow commercial uses of the National Wilderness Preservation System, and that an exception is made to allow commercial uses ONLY to the extent deemed necessary and proper for realizing the recreational purposes of wilderness, it would seem that the agency should be extremely vigilant so as not to allow the proportion of commercial uses to grow without clear justification. No justification is provided. Yet a number of studies by U.S. Forest Service personnel over the years have documented significant damage to wilderness resources due to packstock use of the Ansel Adams and John Muir Wildernesses, indicating that it may be appropriate to reduce proportionate levels of commercial packstock use, not increase it. (response # 106)*

Response: The comment on the proportion of commercial use of the total use illustrating a 60 percent increase in the last 25 years is inaccurate. Five percent of the total use in 1979 was based upon a higher total use number before general public trailhead quotas were implemented. The recent higher percent (8 percent) of commercial pack stock clients is based upon a relatively overall lower total wilderness use number. According to use data presented in the John Muir Wilderness Plan (1979), from 1972 to 1976, the total use averaged 84,873 people. Five percent of that number is 4,244 people, which would represent the average annual number of commercial pack stock clients during the 1970s. For the years 2001-2004, the average number of pack station clients for both the Ansel Adams and John Muir Wildernesses was 4,783. The John Muir Wilderness portion in 2001-2004 averaged only 3,319 clients. This is an average of 925 fewer clients or a 22 percent reduction between the 1970s and 2000, which supports the needs assessment and FEIS conclusions that pack station use has decreased following the 1964 Wilderness Act. This contention is further supported by the 1979 John Muir Wilderness Plan (page 6): “Nineteen commercial packers serve the John Muir Wilderness. Most of these operate

out of facilities located near the trailhead they use. Commercial pack stock use has not increased appreciably over the past two decades.” And, the 1979 Minarets Wilderness Plan (page 5) states, “Commercial pack and saddle stock use has remained static or has even declined slightly during the past decade.” There is no credible data to support the claim that commercial pack stock use has been allowed to increase significantly in these wildernesses, or to support that there has been a 60 percent increase from 1970s to present.

The Forest Service is unaware of a “number of studies by U.S. Forest Service personnel over the years that have documented significant damage to wilderness resources due to packstock use of the Ansel Adams and John Muir Wilderness.” Anecdotal wilderness ranger reports do not constitute studies or even credible resource impact reports, as these personnel are generally not qualified to professionally assess resource conditions. In fact, the only comprehensive or credible studies of commercial pack stock impacts in these wildernesses has been completed only recently by the Forest Service interdisciplinary team that prepared this DEIS and FEIS between 2001-2004. The conditions found are fully documented in the FEIS, and do not support the significant damage conclusion. The FEIS and ROD propose management actions to fully correct or mitigate any site-specific, localized impacts associated with commercial pack stock use. Use impacts by all wilderness users (commercial pack stock combined with the general public) at the wilderness and geographic scale is characterized from not measurable or adversely affecting the wilderness character according to the FEIS.

Public Concern #29: *The Needs Assessment does not adequately demonstrate a need for commercial services in the wilderness. Some of the need categories do not reflect a need at all. An example of this is people needing pack support because their equipment is too heavy. The Needs Assessment must also specify the need required for particular types of commercial horsepacking services (i.e., spot, dunnage, full-service, re-supply, day rides etc.). Each of these commercial enterprises is unique, and the findings required by the Wilderness Act must be made for each. (response # 196, 201, 347)*

Response: The “categories of need” in the needs assessment were developed based upon activities that are wilderness-consistent and dependent, and proper in a wilderness setting. Commercial packstock are needed to support visitors who have heavy equipment or persons poorly conditioned. They are also needed to allow persons to access and enjoy these areas that do not own or have access to packstock or possess the knowledge or skills to use or handle such animals in a wilderness setting. Segments of the public that need commercial pack stock support to realize their wilderness experience have day use, overnight spot and dunnage, and traveling trip needs. There is no requirement to establish that the use of heavy equipment is “necessary” or that poorly conditioned individuals are “necessary,” only that the activities are proper.

Data was collected on commercial packstock clients and packers during the summer of 2005 to help establish the “need” and “extent necessary” for commercial services; this data has been used in the preparation of the FEIS needs assessment and analysis.

Public Concern #30: *The Needs Assessment does not specify an operational definition of “necessary” for the analysis, and appears to assume that demand and desire equate to need. (response # 196)*

Response: The FEIS needs assessment contains a definition and discussion of “need” and “necessary.” The Forest Service agrees that demand and desire do not equate to need or necessary in the context of this needs assessment.

Public Concern #31: *The Needs Assessment unnecessarily advocates the historical importance of commercial horsepacking, and distorts the historical record in its attempt to promote commercial packstock enterprises. An egregious example of the bias demonstrated by the Forest Service is its attempt to portray John Muir as a supporter and user of horses. Muir was undoubtedly the greatest advocate of foot travel in his day. He despised horses, and also strongly believed in traveling alone in the wilderness. This should be noted alongside the photo.* (response # 196)

Response: The historical background of commercial pack stock using these two wildernesses is relevant to the needs assessment, as it establishes the history and past use practices for these areas. The history section of the needs assessment has been updated and revised in the FEIS.

The photograph of John Muir on horseback was used to illustrate that pack stock support was historically common in these wildernesses and adjacent areas, even by John Muir himself. And, while the comment takes strong exception with using this illustration, there is ample evidence to support retaining it in the document. Some examples to illustrate that John Muir regularly used horses and mules follow: “After his initial eight-day visit, he returned to the Sierra foothills and became a ferry operator, sheepherder and bronco buster” (“John Muir” from *Wikipedia, The Free Encyclopedia*, p. 1); “John Muir met me with a couple of packers and two mules to carry our tent, bedding, and food for a three days’ trip.” (“Theodore Roosevelt, *An Autobiography*” from *Outdoor and Indoors*, Chapter IX(1913)); “Here we made our first camp and arranged with Mr. Longmire, a farmer in the neighborhood, for pack and saddle animals.” (“An Ascent of Mount Rainier,” Chapter 20 of *Steep Trails* by John Muir (1918)); “All mules have their fear of bears before their eyes and are marvelously acute in detecting them, either by night or day”; (*South of Yosemite; Selected Writings of John Muir*, by John Muir, ed. Frederic R. Gunsky (1968)); and, “So it would seem that the big traveling trips through the wilderness such as initiated by the Sierra Club in that first annual outing, should be continued, by whatever organizations may be qualified to conduct them. The argument that John Muir presented remains essentially valid. If we want mountain wilderness—the spacious scenic wilderness that means something—we must make it known to the men who, knowing it will protect it. Those who like best the Spartan of wilderness trips—cross country backpacking—must make haste slowly in any attempts to impose such trips upon others, or there may be too few men in the wilderness to protect it.” (David R. Brower’s “Are Mules Necessary?” 1948 Sierra Club Bulletin Article). As illustrated in David Brower’s article, it is well documented that the Sierra Club annual outings started by John Muir commonly used several hundreds horses and mules to support several hundred members. This practice went well into the 1960s. These examples seem to refute the notion that, “He (John Muir) despised horses, and also strongly believed in traveling alone in the wilderness.” At a minimum, he apparently found packstock needed and necessary for wilderness travel from time to time. The agency has been unable to find any evidence to support the comment’s contention that “Muir was undoubtedly the greatest advocate of foot travel in his day.”

The commenter seems to be offended by the tone of some of the DEIS and needs assessment, stating, “...the Forest Service comes across as the foremost advocate of the commercial packers.” In fact, the Forest Service considers and attempts to treat permit holders authorized to provide outfitter and guide services to the public as “partners.” The Forest Service’s Outfitter-Guide Administration Guidebook states that “the reasons to allow outfitting in an area are to assure that the public has reasonable access to National Forest opportunities, that the use

resulting from it is of the highest quality, that the resources are protected, and that the client learns the unique attributes of the environment.” While there are sometimes disagreements, difficulties, or issues between the Forest Service and outfitter-guides, the fact remains that the two parties exist to serve the public and both have responsibilities for protecting the resources. The Forest Service is generally proud of the role of and services provided by pack stations; and, although work remains in terms of providing better wilderness protection in some areas of these wildernesses, it does not justify downplaying their importance to segments of the public that need their services.

Public Concern #32: *The Needs Assessment must analyze and determine what levels of commercial horsepacking use are truly necessary and proper, not attempt to justify existing levels of commercial pack stock use and the agency’s desire to allow expansion of that use. The fact that the Forest Service used the latter approach in the Needs Assessment is revealed on page 1: “[Part I of the Needs Assessment] provides the evaluation and rationale for why the selected commercial pack stock service levels decided upon meet the Forest Service’s overall wilderness management objectives to carry out the recreational and other purposes of the Wilderness Act.” (DEIS at D-1) This is putting the cart before the horse, it is not acceptable, and it is not legal. (response # 196)*

Response: The concern about the Part I (needs assessment) selected quote is well-taken; the wording can be misinterpreted. The statement was intended to explain that the use levels of the different DEIS alternatives were designed and developed to be consistent and compatible with wilderness management objectives. This wording has been clarified in the FEIS needs assessment.

Public Concern #33: *The Needs Assessment evaluates commercial pack stock operations in isolation, without consideration of how their use allocation affects that of other legitimate commercial and noncommercial uses. This does not conform with existing Forest Service guidance. (response # 196)*

Response: The Needs Assessment does “conform with [sic] existing Forest Service guidance.” The Forest Service used the Outfitter-Guide Administration Guidebook (1997) as a resource in developing the 2001 Wilderness Plan and 2005 Needs Assessment. Other Federal agency “needs assessments” were also reviewed and considered. The Forest Service is unaware of any needs assessment that has been prepared for outfitting-guiding that is more comprehensive or thorough than the Needs Assessments for this planning effort. It has attempted to address the Ninth Circuit Court of Appeals opinion, agency policies and directives, and public comment. Wilderness capacity considerations, social and resource considerations, other user considerations, as well as preservation of the wilderness character considerations have been included and addressed in the FEIS and Needs Assessment.

Public Concern #34: *The statement that the 1985 limits were intended to reflect historic or then-current use levels is completely unsubstantiated and unsupported. The truth is that no supporting documentation exists to show that the original (1985) service day allocations for eastside packers were related in any way to historical or then-current use. In fact, actual use never reached the levels allocated in 1985, and the 2001 Wilderness Plan reduced the allocations somewhat to rein in the inflated allocations. The available evidence shows that the 1985 allocations had no basis in historical use, but rather were substantially inflated from the*

beginning, did not actually cap use, and allowed for substantial growth in commercial pack stock enterprises all throughout the 1980s and 1990s. (response # 196)

Response: Commercial pack stock use and impacts have been thoroughly considered and evaluated in setting use and stock controls and restrictions in the FEIS. Commercial pack stations are allowed to provide public access to only nine percent of the total area of these wildernesses. They serve six to eight percent of the total current wilderness users. As documented in the FEIS and Needs Assessment, commercial pack stock use has not increased as claimed by some since the 1964 Wilderness Act. The use of percentages from the 1970s to the present is misleading. In fact, the total number of commercial clients is 22 percent less in recent years than 1970s (refer to the response to Public Concern #29.) Hence, the claim that, "...and allowed for substantial growth in commercial pack stock enterprises all throughout the 1980s and 1990s" is not supported by the documented client served records. The balance between commercial served and non-commercial served visitors is a reasonable and proper split according to the FEIS Record of Decision.

The focus of the three year data collection effort and preparation of the DEIS and FEIS was to consider and evaluate the impacts of the commercial pack stock operations in these two wildernesses. This analysis was done by considering past, present, and foreseeable future uses, actions, and activities of all users, not just commercial pack stations.

Public Concern #35: *Improper interpretation of data is prevalent in the Needs Assessment including: (1) the evaluation of historical trends in commercial horsepacking use in the planning area (in contrast to the unsupportable conclusions presented in the Needs Assessment, the Livermore and London studies actually indicate that current stock allocations in the John Muir and Ansel Adams Wilde); (2) the interpretation of Congressional intent related to the Wilderness Act; (3) the interpretation of work by Dr. Hendee and (4) data associated with the need categories. (response # 196)*

Response: The Needs Assessment (D-12) reference citing the Eastern Sierra Packers Association (2000) of evidence in the congressional record has been eliminated. Only congressional records themselves are cited in the FEIS.

The comment regarding the DEIS use of Hendee et al (D-12) appears to have misunderstood the intent of the citation. The needs assessment stated, "...it is generally supported in the wilderness management field; the conditions found in these areas when they were established as wilderness define the benchmark for uses and naturalness to be sought by management". Attachment I (Background) to the Needs Assessment in the DEIS contained a summary of some of Wilderness Management wilderness concepts and principles (D-48). The fifth selective citations was, "To a degree, under the non-degradation principle, the conditions prevailing in each area when it is classified established the benchmark of naturalness to be sought by management—unless conditions are deemed below standard and the objective is to restore naturalness." (Hendee et. al 1990 p. 145).

The Forest Service disagrees with the statements and conclusions of the commenter about how service days were established for commercial pack stations. And, as addressed in the response to Public Concern #28, the contention that the service days were substantially inflated and did not cap use, and actually allowed for substantial growth all through the 1980s and 1990s is not based in fact or evidence. The number of clients served today by commercial pack stations is 22 percent less than 1970s, that is the bottom-line and the evidence needed to substantiate the Forest

Service's conclusion that their use has been at least capped if not decreased. However, as acknowledged in Chapter 3 of FEIS, service days have serious limitations and value in accurately measuring and comparing use over time. Comparisons of "visitors" or "clients" served have significantly more validity than service days.

Additional clarification has been added to the comparison of number of pack stations and stock numbers over time. There is evidence to support the Forest Service conclusion that the number of pack stations and stock used within these wildernesses has declined over time, and more importantly that the clients served since 1970s to present has decrease by 22 percent. The comparison was merely attempting to show the historical trend in reduced pack stations, stock numbers, and clients served.

As stated in the response to Public Concern #29, additional data was collected and analyzed during the 2005 operating season to better document the public "need" and "extent" to which commercial pack stock services are necessary. The results and further analysis have been incorporated into the FEIS Needs assessment. The methodology for collecting the data and limitations of the results are fully disclosed.

Public Concern #36: *The DEIS does not analyze whether the number of commercial horsepacking operators (i.e., permits) is appropriate to the level of need. The Ninth Circuit made clear in their ruling that analysis of the number of permits granted by the Forest Service would be necessary, "...the Forest Service must show that the number of permits granted was no more than was necessary to achieve the goals of the Act." (response # 196)*

Response: The FEIS Needs Assessment discusses this issue in more detail. To a large degree, "the number of commercial horsepacking operators (i.e., permits)" is irrelevant when determining the necessary level of public need for wilderness horsepacking services. If, for example, one operator was granted a permit for a level of use that far exceeds the public's need, the intent of the Wilderness Act is not being met. Likewise, if fifty commercial operators were granted permits to operate in the wilderness, and the level of use authorized was less than what the public needed, again the intent of the Wilderness Act is not met. It is not the quantity of commercial operators that is important, but rather it is the level of use authorized to the commercial operators that must be examined.

To determine the extent necessary, the Needs Assessment looks at the current level of use and determines whether this level is appropriate and needed to meet the public's need for commercial horsepacking services. The Needs Assessment also considers other factors, including demographic trends, and arrives at a level of need for this service that is a range.

Public Concern #37: *The Forest Service should not consider eliminating or reducing commercial horsepacking services as the Needs Assessment clearly describes a need for commercial outfitting services. (response # 198)*

Response: The comment supports the conclusion of the Needs Assessment that commercial pack stock services are necessary in these two wildernesses. All of the action alternatives propose that commercial pack stock services will be authorized at levels and locations needed by the public but with conditions deemed necessary to protect the wilderness character. Only Alternative 5 proposes to eliminate commercial pack stock services. This alternative was included so that a full range of alternatives were analyzed and considered in this EIS. The Inyo and Sierra NFs agree that given the public need for commercial pack stock services and the EIS

analysis demonstrating that the wilderness is protected with the different control mechanisms and restrictions, there is no justification for “removing” pack stations.

Public Concern #38: *The Needs Assessment underestimates the true need or demand for commercial packing services in the wilderness. (response # 279, 348, 357)*

Public Concern #39: *The Forest Service should not decide who may or may not need the services of commercial pack operators. Rather, if a person desires the services of a commercial packer to access the wilderness, that should be sufficient evidence of the need for the service. (response # 279)*

Public Concern #40: *The need for commercial pack stock in the wilderness is driven by the demand by services from the public. This EIS fails to assess what is the desire of the public for service? What type of service does the public want? This draft plan and needs assessment fits the desire of a few special interest groups and ignores what is in the best interests of the public. (response # 275)*

Response to Public Concerns #38-40: The requirement to complete an amended Needs Assessment resulted from a U.S. Court of Appeals for the Ninth Circuit opinion filed August 25, 2004 and amended December 1, 2004, that concluded, “The finding of necessity required by the Act is a specialized one. The Forest Service may authorize commercial services only ‘to the extent necessary.’” That court further clarified, “Nowhere in the Wilderness Plan of the 2001 Needs Assessment does the Forest Service articulate why the extent of such packstock services authorized by the permits is ‘necessary.’”

It was not possible between December 2004 and February 2005 to collect data to fully answer this required finding in time for the release of the DEIS; however, data was collected during the 2005 pack station operating season and is incorporated in the FEIS Needs assessment. The appeal court clarified there is a clear distinction between “need” and “demand.” Demand is not a legitimate basis for authorizing commercial services in wilderness; instead, it must be based upon legitimate “need” for realizing proper wilderness purposes. The latter is what the Forest Service attempted to do in the amended Needs Assessment for the FEIS.

Methodology/Use of Science

Incorrect Assumptions

Public Concern #41: *The DEIS contains a number of false assumptions:*

1. *The public wants more dunnage trips and spot trips.*
2. *Wilderness can tolerate a lot more people either by spot trips, dunnage trips or day use.*
3. *Llama use is compatible with wilderness and is ok*
4. *Wilderness managers should impose their personal views over the direction of the Wilderness Act.*
5. *Giving operating areas to individual packers is in the public interest.*
6. *The Forest Service implies their economic analysis is ok. The Forest Service fails to look at net income and the ability of pack stations to stay in business.*
7. *More people and heavier concentrations of people in the wilderness is consistent with the Wilderness Act.*
8. *Designated campsites are consistent with the Wilderness Act*
9. *Eliminating free grazing is consistent with the wilderness Act.*

10. *The rights of those people who are on a spot trip or dunnage trip should have greater importance than those that travel through the wilderness on outfitted trips. (response # 275)*

Response: This list of disagreement with the DEIS are not “assumptions” but rather are issues and effects discussed in the NEPA in the DEIS and FEIS. The effects of spot and dunnage trips versus full service all expense and traveling trips; the capacity of the physical and biological resources for the various types of trips; the use of llamas; operating areas; designated campsites; grazing methods; are all relevant issues discussed in detail in Chapter 4 of the DEIS and FEIS.

Wilderness managers input and participation in the process reflect professional views based on agency policies, research findings education and experience. It is possible that other hold different opinions on issues.

Public Concern #42: *The document is clearly biased against commercial pack operations by not accounting for non-commercial pack stock (e.g., hiker) degradation in the wilderness. Commercial packers are unfairly blamed for all the damage in the wilderness (response #103, 168, 198, 275, 311, 348, 355, 357, 401, 428)*

Response: The analysis cites research published on relative impacts of stock and hikers along with the interdisciplinary team’s own findings. The team did find impacts that were associated with commercial stock use, though it is not the intent to determine cause, but rather determine an approach to managing the use. The focus of the analysis is commercial pack stock, as ordered by the District Court. The analysis intentionally narrows the focus and should not be construed as bias, as much as to respond to the court order.

Public Concern #43: *The document is clearly biased in favor of commercial pack operations and relies too heavily on unconfirmed data and anecdotal observations provided by commercial enterprises. (response #105, 196)*

Response: See response to Public Concern #42. A number of comments were received that asserted that the document was favoring pack stock interests; an equal number were received that stated that the document was bias against commercial packing activities. That these comments came from both sides of the issue probably indicates that the document is a fairly objective analysis of the effects of commercial packing on wilderness resources.

In terms of packer-supplied data and anecdotal observations, the FEIS attempts to independently verify any data or observations used in the analysis. This, however, is not always possible. Often times, the commercial packers have the most accurate and comprehensive information for a particular topic. When this type of data or observation is used in the FEIS, the source is disclosed.

Cumulative Effects

Public Concern #44: *The potential cumulative effects discussion includes a number of impacts that do not even exist in the field. Mixing science, fact, hypothetical scenarios with desired future conditions is based on subjective interpretations of the Wilderness Act. Only the known specific cumulative effects and impacts attributed by proof to commercial pack stations should be analyzed in this document. (response # 311)*

Response: It is not clear from the comment what effects are discussed “that do even exist in the field.” NEPA requires a cumulative effects discussion in the EIS. By definition, a cumulative effect is the impact on the environment which results from the incremental impacts of the action

when added to past, present and reasonably foreseeable future actions (CEQ 1508.7). The analysis in the FEIS considers whether there are any cumulative effects associated with the proposed project when combined with relevant past, present, and reasonably foreseeable actions in the project area.

Public Concern #45: *Since the USFS does not currently document or consider the cumulative impacts of clearcut logging on public lands, which is obviously much more devastating to forests, wildlife, water resources and our quality of life, the USFS should not be able to require a Cumulative Effects Analysis EIS for other groups that impact public lands. (response # 72)*

Response: Under NEPA, a cumulative effects analysis is required for any federal action, including any analysis of timber sales.

Public Concern #46: *The catalog on page IV-4 does not include historic or present grazing by commercial pack stock. There are no records included for private or administrative use. (response # 311)*

Response: The effects of historic or current commercial pack stock grazing is disclosed in the direct and indirect effects discussions in the FEIS.

Public Concern #47: *Unfortunately, this EIS does a poor job of looking at the cumulative effects of pack stock in areas where packers overlap services. Instead, the Forest Service proposes to eliminate multiple packers using the same area and give exclusive rights to certain packers. (response # 275)*

Response: One action that is proposed in two of the alternatives is “primary operating areas.” This concept does not give exclusive rights to certain packers. In fact it allows for a number of areas of overlap where that overlap has occurred in the past and there are no resource concerns that need to be addressed. Measures have been proposed (and primary operating areas is one of them) to reduce or eliminate impacts where overlap of operators occurs and there are documented resource concerns. Chapter 4 – Wilderness describes the effects of overlapping operations. More specifically, a number of sections discuss the Silver Divide area and describes the effects of overlapping operations.

Other Methodology Issues

Public Concern #48: *The methodologies section of the DEIS is seriously flawed because it takes the liberty to determine the amount of impact that is acceptable: “The intensity of the impact considers whether the impact to wilderness character would be negligible, minor, moderate, or major.” There is no reference to the condition that existed when the areas were designated. The effect of this inappropriate methodology is evident in statements found throughout the DEIS, for example, “the higher development trails have characteristics and management intrusions which adversely affects visitors’ experience of wilderness.” (response # 276, 278)*

Response: There are references to the condition that existed when the area was designated wilderness in the Chapter 3 Wilderness section. Unfortunately there is a lack of data on the conditions, and very little other than anecdotal evidence of conditions.

The subjective statements on wilderness character are consistently used in order to provide some response to accusations that the proposed uses are violating the Wilderness Act and having an impact on wilderness character. A full description of the methodology of using wilderness

character can be found at the beginning of Chapter 4 – Wilderness, and may help put these statements in context.

Public Concern #49: *Why are some resources in Chapter 4 described at the wilderness scale (trails, social, economics, and heritage) while others are given a more thorough examination at the geographic scale. Some of these resources may have important implications for a pack station but are only given a quick review at the wilderness scale. (response # 311)*

Response: Chapter 4, page 1 of the DEIS explains that some resources are only described at the wilderness scale as this is the relevant scale to analyze the effects on those resources”.

Public Concern #50: *The Forest Service fails to look at the historical baseline. We again ask that the Forest Service include data and assess the environmental condition at beginning of the 1979 John Muir Wilderness Management Plan and compare it to the conditions of the late 1990’s. (response # 275)*

Response: Additional data has been brought into the analysis to try and display use levels at different points in time. However as mentioned a number of times, the quality of data is very poor prior to 2001. Data is incomplete across the planning area in 1979.

Public Concern #51: *The EIS is good in that it tries to show the various impacts and use patterns throughout the wilderness. For a quick study.....it should be a considered a good start. A major deficiency is not putting down on paper those areas that have received great use and show little impact. The EIS should do a better job of showing areas where there is a lot of use but the impact is not very high. (response # 275)*

Response: Comment noted. There are a few locations, such as North Fork of Big Pine, that receive very high level of use and resource impacts are considered low-to-moderate. Areas such as these are noted where they exist and are mostly the result of on-going management or the durability and resilience of the particular ecotype (i.e. granite).

Public Concern #52: *The differences in type and magnitude of impacts caused by recreation pack stock compared to other uses must be fairly and equitably analyzed in the DEIS. The Forest Service should acknowledge the disproportionate amount of resource impacts caused by stock-supported visitors, compared to non-stock-supported visitors, and that from a resource carrying capacity perspective, use allocations for non-stock-supported visitors could be substantially increased if commercial pack-stock use were limited to the extent truly necessary. (response # 196)*

Response: A number of research papers have been cited throughout Chapter 3 and 4 that note the differential impacts associated with pack and riding stock. The planning team does acknowledge the disproportionate amount of resource impact that can occur with packstock. We cannot, however, look at a condition and definitively state that something has been caused by stock. Allocations to commercial uses will be made with many considerations given to the extent necessary of this use. Non stock-supported visitors can also be the source of impacts that affect the recreational carrying capacity, but this analysis is focused on the commercial stock portion of the allocation and insuring it meets the intent of the Wilderness Act’s specialized requirement.

Public Concern #53: *While we are sure the DEIS represents a lot of hard work on the part of the USFS, we must question the intent of the authors and their proposed actions. The 1,000 page document is unwieldy and unclear in its format. It does not support any of the proposed alternatives nor does it include any clear scientific evidence that documents serious resource*

concerns. *If at all, it supports an increase in commercial pack stock use in certain areas.* (response # 279)

Response: To aid readability, the Final EIS has reorganized and clarified some of the analysis. Although some readers may read that there is a need for more commercial pack stock, it is the decision makers that will take the information provided and make a determination as to the extent of commercial pack stock that is necessary given this document's analysis of the factors.

Public Concern #54: *It appears as if Data significance changed - ie. data collection taken earlier in the study vs. later. If the ID team did not have objective data interpretation from start to finish, then there are some highly questionable outcomes. (For instance Lee and Cecil lakes areas seen the first year of data collection) (Chap. III - 1, Data Collection and Analysis Process).* (response # 355)

Response: It is true that the first year of data collection was prior to the court order. Data collection methods changed and were improved over the course of the four years of data collection. However, data interpretation and consistency reviews of data took place after each field season, with particular attention to the first year of data. The above mentioned Lee and Cecil Trail had additional visits over the course of the data collection and both still and video photos were taken that were used throughout the alternative formulation and effects analysis. There no indication that new information collected would change the outcome of this highly impacted trail.

Public Concern #55: *The DEIS did not use objective standards to determine wilderness character as defined by Congress in Wilderness legislation. (Re: Chapter 3, Affected Environment, Data Collection and Analysis Process)* (response # 355)

Response: The effects analysis used four elements of wilderness character (see response to Public Concern # 16) that come directly from the Wilderness Act. This approach is supported by a technical report (Landres et al. 2005) as an objective approach to what could be considered the very intangible goals of the Wilderness Act. Chapter 3 includes the same elements of discussion of wilderness character in the context of the existing condition.

Public Concern #56: *At IV-140, the DEIS states, "The Science Review acknowledges that the available literature is replete with statements about the probable effects of grazing, many of them observational or anecdotal, but rarely is there controlled studies from which to accurately assess different levels of grazing. Most studies refer to heavy grazing without actual forage use quantification by cattle or sheep, and do not examine moderate grazing intensities that are proposed in this EIS." Again, pack stock users have modified their methods to protect grazing areas, which are important to their livelihood, and again there is less stock grazing now than in years past. Additionally, horses and mules graze differently than cattle and sheep since they do not pull out the grasses by the roots and they favor the tops of the grasses. Further, the meadow monitoring methods used by the Forest Service are quasi-scientific and as such are subjective and can, and indeed are (as admitted to me by a Forest Service employee) slanted to fit the anti-pack stock bias of the person doing the monitoring.* (response # 348)

Response: The referenced quotation in IV-140 of the Science Review that was part of the Sierra Nevada Ecosystem Project was meant to demonstrate the difficulties in assessing impacts of all classes of livestock grazing impacts on wildlife populations and habitat across the Sierra Nevada. The quotation is not applicable for all aspects of grazing impacts on resources that were analyzed

in the DEIS (e.g., range condition and trend, suitability, range readiness, and proper functioning hydrologic condition). These management factors were used in many cases to develop grazing recommendations.

Public Concern #57: *The Forest Service should reduce user conflicts between hikers and stock users by giving notice where stock are likely to be. The agency estimates that pack stock utilize 9% of the land. Surely those on foot can find somewhere to travel in the remaining 91%. User conflicts can also be reduced by educating members of all user groups regarding the historic values, public service values and mutual responsibilities of all who seek to experience the wilderness. (response #277, 362)*

Response: Improving information to help with visitor expectations is an excellent approach, and one tool which the agency has and will continue to use. Such a tool is not subject to NEPA compliance and can be applied regardless of the alternative that is selected.

Public Concern #58: *Positive impacts of pack stations and pack stock are not mentioned or collected as part of this analysis. (response # 311)*

Response: Chapter 3 describes the existing condition of the resource with specific mentions of areas where pack stock operate that have low or no impact. This information was then used in assessing the effects of alternatives in Chapter 4. The environmental document discusses many locations where continued use would have minor or negligible effects.

Public Concern #59: *The Forest Service should clearly explain the source of the direction for many of the management actions they are proposing. Is it direction from the 2001 John Muir Wilderness Management Plan and Record of Decision? Or, is it from standards from the Sierra Nevada Framework? Or, is it a new direction that is included in this set of decisions to be made. There is little effort by the writers of the plan to disclose why they are making choices. It appears that the EIS studies past actions and assesses future actions as a result of:*

1. *Sierra Nevada Framework*
2. *Record of Decision of the John Muir Wilderness Management Plan*
3. *Permit Renewal Process for the various pack stations.*
4. *Court imposed sanctions on the Forest Service to correct NEPA and Wilderness Act Violations for current and past actions.*
5. *Settlement and lawsuits from the HS Packers Association*
6. *Personal vision of a few Inyo National Forest employees who want “their goals” imposed on the public. (response # 275)*

Response: There are many sources of the direction contained in Chapter 2, including the 2001 Wilderness Plan, Sierra Nevada Framework, and the court-ordered analysis of commercial pack stock in the wilderness. The direction also comes from the conditions found on-the-ground during the years of data collection.

Personal goals of Forest Service staff have no bearing on the ultimate decision to be made by the Forest Supervisors, nor the formulation of alternatives. Alternatives come from public issues raised during the scoping period. These issues must meet the stated purpose and need of the analysis as identified in Chapter 1.

Public Concern #60: *The Forest Service is eliminating the rights of the public to use less traveled areas because a particular official says it isn't ok. Not because of a resource*

concern...primarily because it wasn't used between the time studied by the Forest Service. This is wrong and goes way beyond the authority of the Forest Service. (response # 275)

Response: Determinations of trail suitability took into consideration of management objectives, resource concerns, and use allocations (see Purpose and Need, Chapter 1). Pack stations had the opportunity to provide historical information on trails they have used (and most utilized this opportunity). All of these factors were considered within the above criteria to make a determination, and was not solely based on how much the trail has been used in the past few years.

Use Data

Public Concern #61:: *The Forest Service provides no credible data or analysis in the DEIS to support its conclusion that actual commercial pack stock use after the injunction has been significantly lower than actual use that occurred prior to the injunction. In addition, the historical use data is not reliable, because the commercial packstations self-reported their service days using tally sheets, and issued all wilderness permits to their clients during that period. We also believe that the revenue of the commercial outfits has increased in the period after the injunction, further indicating that the restrictions imposed by the district court did not negatively impact their operations and that no significant reduction in actual use has been achieved. When comparing gross revenue for the years 2000-2001 (prior to the injunction) to 2002-2003 (after the injunction), gross revenue increased an average of 17 percent. (response # 196)*

Response: There is no evidence that pack stations regularly inflate their use numbers. Further, there is no evidence that data prior to 2002 is invalid. Existing data shows that use has decreased since the court-ordered injunction. Chapter 3 shows number of people serviced, not service days, to show that this very basic measure of use clearly is declining. Using gross revenues to draw conclusions on use is illogical. As discussed in the DEIS, the prices of trips have increased over the last few years. This alone could account for the increased gross revenue figures. It appears as though additional regulations have increased the cost of doing business. Over the last four years, commercial packers have increased the price of their services and experienced increased gross revenue although use has decreased.

Public Concern #62: *The 2001 Wilderness Plan allocations do not accurately represent average historical use. The pre-2001 service day allocations, first established in the mid-1980s, were never based on actual use levels. They were illegally established without public involvement or proper NEPA analysis, and they were arbitrarily established at highly inflated levels (i.e., to allow substantial growth in commercial pack stock enterprises). The 2001 Wilderness Plan service day allocations simply reduced those inflated allocations, for the first time, to reflect the high end of then-current use levels. And the 2001 Wilderness Plan then allowed for significant growth above the then-current levels. (response # 196)*

Response: No data supports this theory. All existing use data shows a very definitive decline in commercial pack stock use in the past twenty years.

Public Concern #63: *The 20% reduction in allocated service days to commercial pack stations has not resulted in a 20% reduction in use, as intended by the District Court. The Forest Service has provided no credible evidence to demonstrate that the 20% service day reduction ordered by*

the District Court in 2002 has had any significant effect on actual commercial pack stock use levels.

On average, these packstations utilized only 74% of their reduced allocation in 2002, 2003, and 2004, and only three of the twelve packstations utilized over 90% of their allocation. In other words, these data indicate that the court-ordered reduction in service days did not limit use for the vast majority of these packstations, because the actual use levels did not even approach the service day levels ordered by the court. The most likely explanation is that the self-reported use figures (upon which the 2001 service day allocations were based) were inflated, and that the current use under the injunction is not significantly different from past actual use levels. (response # 196)

Response: Considerably more work was done in the Final EIS in analyzing data to assess trends. The Wilderness section in Chapter 3 was revised to provide a clearer picture of the data available to substantiate the trends. We do not believe service days to be a very accurate measure of trends. Number of clients served has gone down over the past 5 years and total. That is an indicator of commercial use levels actually declining.

A full discussion of types of data and interpretations of data can be found in Chapter 3. They do not support the theory that commercial use is increasing.

Public Concern #64: *The DEIS fails to analyze and disclose the fact that commercial pack stock use has never been meaningfully capped. Until the 2001 Wilderness Plan was adopted, 29,623 service days were allocated to commercial horsepacking stations in the planning area (DEIS at D-26). According to the 2001 FEIS Needs Assessment (at D-9): “Little documentation exists on how these allocations were determined or originated. However all indications show that historic use levels were intended to be authorized.” It was this inflated allocation that the 2001 Wilderness Plan sought to address, reducing the total service day allocation to 21,900 (DEIS at D-26), not including the 20% injunctive relief reduction. However, by allocating service days based on the two highest-use years of the previous five, this did not amount to a meaningful cap, especially since the Plan provided for a pool of 3,000 additional service days. As demonstrated above, the commercial packstations have been using only 74% of their allocated service days during the past three years, even with the 20% reduction and without the discretionary pool of service days. The fact is that commercial pack station clients are almost never turned away because of these restrictions, while the non-outfitted public is turned away in droves. (response # 196)*

Response: The environmental analysis is conducted to determine the effects of pack stock and to arrive at a level of use that is compatible and consistent with the purpose and goals of the Wilderness Act. It is not a stated goal to “meaningfully cap” packers. It continues to be the agency’s position that it is not only the amount of use that is meaningful to managing impacts, but the type and timing and management of the use. See response to Public Concern # 63 for discussion of the reliability of service days as an indicator of use levels.

Public Concern #65: *The DEIS uses methods and determines use numbers based on historic highs. In reality, the numbers that were used were taken from the past three years – years in which pack stations operated under a Court injunction and a new management plan which both served to reduce use anywhere from 20 to 50%. Historic Use should include at least 10 years pre-Court injunction. (response # form letter F)*

Response: Nowhere in the document does it state that use numbers were determined based on historic highs. Use numbers from the last five years have been used as a baseline because data prior to 2001 prior data is inconsistent, inaccurate and not complete. However, in preparing the Final EIS all available data dating back the last fifteen years was reviewed and brought into the analysis. The results of this are documented in project record.

Adequacy of Comment Period

Public Concern #66: *The comment period for the DEIS should be extended. (response # form letter E, 196, 198, 275, 339, 364)*

Response: The Trail and Commercial Pack Stock Management DEIS is a long, complex document. The agency provided more than the minimum required comment period for a Draft EIS. Forest Service Handbook 1909.15, Chapter 20 requires a minimum of 45 days for comment on a Draft EIS. For this project, the Draft EIS was mailed out to the public on March 29, 2005. The document was also placed on the Inyo and Sierra National Forests' websites on this date. The comment period ended June 15, 2005. The comment period was open for nearly 80 days, more than a month longer than the minimum 45-day requirement.

Implementation and Monitoring

Public Concern #67: *The DEIS does not consider the implementation of the proposed alternative. Analyses in the document assume that full compliance with the proposed actions will be achieved. Relevant issues and factors related to enforcing the proposed management actions are ignored. Clearly, the proposed management actions will not achieve the desired outcome unless compliance can be ensured. Thus, the Forest Service should develop management schemes that take into account the agency's ability to monitor and enforce compliance, and consider the historical degree of compliance with management decrees by the commercial outfits. (response # 196)*

Response: The Final EIS cannot assume non-compliance with proposed management direction. Nonetheless, given the concerns expressed over compliance and monitoring, the FEIS includes a very descriptive implementation plan (Appendix A) to guide the implementation of the selected alternative.

Public Concern #68: *Overall use needs monitoring to see how it is working and whether special problems develop. This is especially true for marginal meadows. The document does not contain adequate concern for continued monitoring. (response # 195)*

Response: See Response to Public Concern #67.

Funding

Public Concern #69: *The forest service does not have the funds to micromanage designated destination camps and other aspects of the proposed project (response # form letter A, 35)*

Response: See Response to Public Concern # 67.

Public Concern #70: *The fees generated by a substantial increase in commercial pack stock activity would undoubtedly result in significantly greater income to the Inyo and Sierra National Forests. Given the greatly diminished receipts from timber sales over the last fourteen years, it is understandable that the agency is looking for ways to offset that loss of income. But that is not*

an excuse to abandon environmental ethics or to ride roughshod over the sensibilities of the self-propelled hiker. (response #166)

Public Concern #71: *The Forest Service's Preferred Alternative in the DEIS is a horrible example of the privatization and commercialization of wilderness. Do not give these outfitters a property right (through a 20-year permit) which permits them to commercialize and privatize wilderness. Retain the ability to regulate these non-conforming Wilderness uses and to limit them, when and as required. (response # 185)*

Response to Public Concerns #70 & 71: The proposed project does not represent an attempt by the agency to replace timber receipts nor does it privatize or commercialize the wilderness.

Public Concern #72: *Commercial pack stock enterprises should be required to post bonds to cover the costs to repair damage that they cause. The Forest Service has long known that commercial pack stock enterprises can and do cause substantial damage to natural resources in these wildernesses. The Forest Service's own files are replete with evidence of harm to the wilderness character that is caused by these businesses. The District Court found disturbing evidence of environmental degradation from stock usage in these wildernesses, and the appellate court upheld that finding. In response, all commercial pack stock enterprises permitted to operate in these wildernesses should be required to post bonds sufficient to cover costs to repair damage, as is required of miners who operate on public lands. This is not a new concept. (response # 196)*

Response: Currently under the "Guidebook on Outfitting and Guiding 1997" all O/G and Resort Permit pay a scheduled fee adjusted to the gross revenue reported at the end of the season to supplement the cost for use of the national forest land.

Chapter 4 includes environmental consequences and limitations associated with implementing each alternative. Where appropriate, the environmental document, discloses limitations and risks of inadequate funding, in particular when this funding is essential to effectively manage trails and commercial pack stations.

Adjacent National Parks

Public Concern #73: *The Proposed Action would cause significant impacts in the surrounding national parks. The proposal would eliminate service days, and replace those limits with new limits on the number of trips that commercial pack stock outfits based on National Forest System lands may operate into the adjacent national parks (e.g., Sequoia, Kings Canyon, Yosemite). The service day limits currently act as a governor on the number of trips that Forest Service-permitted outfits may run in the national parks. We oppose the elimination of service days, and any action that may increase the impacts of commercial operations in the fragile high country of the Sierra Nevada national parks. At minimum, the EIS must carefully evaluate the impacts of increased use in the national parks due to the elimination of service days and/or the adoption of limits on number of trips. (response # form letter D, 196)*

The Forest Service and National Park Service should, to the extent possible, manage wilderness uniformly. This includes evaluating the impacts of approving commercial trips that travel into the parks and coordinating grazing start dates with NPS administered parks. (response # 343).

Response: The Inyo and Sierra National Forests have worked closely with the neighboring parks throughout this environmental analysis. Both Parks have responded to the Draft EIS and a close working relationship is in place to insure as much consistency as possible given the issues and

the situations. The Final EIS incorporates many of the requested restrictions on commercial pack stock operations as outlined by the Parks.

Yosemite National Park

Public Concern #74: *If destination quotas and seasonal stock thresholds are used we would appreciate further discussion regarding the numbers provided for Yosemite access. Although excellent work was done to develop these proposals, there are some inconsistencies which may either be typos (for instance, no Yosemite trips are shown for Reds Meadow), or some numbers may be different than thresholds already established in the park for people and stock nights. Yosemite capped commercial stock use at its historic high in 2002, and will be continuing to monitor to assess proper levels of use. Some of the numbers given in the DEIS for quotas or thresholds are lower than use currently allowed in Yosemite. As an example, Yosemite Trails has an annual Yosemite stock use threshold of 457 animals, but the seasonal stock threshold in Alternative 3 is 245 animals. Their Yosemite use has been both higher (317 in 2003) and lower (191 animals in 2004) than the 245 animal threshold. We feel that because the pack stations need to travel through the Forests to access Yosemite, the park should honor the numbers given by the Forests if those numbers are based on research, best management practices, and/or ongoing monitoring. It will be important to review those numbers if this alternative is chosen. (response # 426)*

Response: Destination quotas for Yosemite National Park have been recommended in the preferred alternative in the FEIS that are reflective of the limits set in the Park. Thresholds already set by the National Park Service (NPS) and included in the Incidental Business Permits issued to the commercial pack stock operators by the NPS will be honored as appropriate use in the Park.

Public Concern #75: *We are uncomfortable with the standards given for trails entering Yosemite. Although we do not use the trail standards given in the document, the descriptions seem to imply a much more developed trail on passes leading into the Park. To be consistent with the level of development on the park side, each of those segments leading to the park boundary (Chiquito, Quartz Mt., Isberg, Fernandez, and Post Peak) would be more consistent if maintained to the level 2 standard rather than 3. Donahue Pass would be consistent at a level 3 rather than level 4. We felt the trail standards given were generally very ambitious. Additionally, it is highly unlikely we would allow sanding on any pass within the park, so would ask it not be allowed on the trails listed above to prevent hazardous conditions and resource damage from those accessing the Forest side earlier due to the sand. (response # 426)*

Response: In the FEIS, Alternative 2 – Modified proposes to manage Donahue Pass as Trail Class 3. For the remaining four passes that access Yosemite National Park (Chiquito/Quartz, Post Peak, Fernandez, and Isberg) we feel the proposed management classes in the Preferred Alternative of the FEIS are appropriate for the landscape, resource protection, and use. In particular field surveys indicate the Chiquito/Quartz, Fernandez and Post Peak trails appear to receive very similar management on each side of the boundary.

In Alternative – Modified, early season access over passes will be assessed by the proposed destination readiness criteria. One specific decision point in the process is consultation and concurrence with the National Park Service for trails that enter the Parks. The readiness criteria is designed to evaluate requests from the commercial pack stock operators based on the impacts created by altering natural snow pack conditions by shoveling, sanding or any other methods that

might be proposed. Annual approval is based on site-specific conditions on a case-by-case basis. This means that the National Park Service would be consulted each time a request is received, so that the specifics of that request would be considered.

Sequoia and Kings Canyon National Park

All comments are from response # 425

Public Concern #76: *Some specific aspects that we [Sequoia and Kings Canyon National Park] do not support are:*

- *The non-treatment of commercial stock use over Cottonwood Pass. With the controls proposed in all alternatives, we fully expect that commercial stock operators will at times seek other areas in which to operate. This will have an effect on SEKI, specifically in the area of Cottonwood Pass in the Golden Trout Wilderness.*

Response: Cottonwood Pass is subject to the subsequent analysis which includes the Golden Trout Wilderness.

- *The absence of analysis for commercial stock use over New Army Pass. Currently operators leaving the Horseshoe Meadow area prefer utilizing Cottonwood Pass, but if controls were put on Cottonwood Pass, some operators may seek to enter SEKI via New Army Pass. New Army and Cottonwood passes should be considered together to assure appropriate levels of use are determined. This is more of an issue if Alternative 3 is chosen which controls the area via a general trailhead quota, and less of an issue if Alternative 2 is chosen. It appears that if Alternative 2 is chosen, no commercial use would be permitted over New Army Pass as the destination is Cottonwood Basin. We would support only a very small amount of commercial use over New Army Pass.*

Response: The Final EIS includes specific discussion and direction for New Army Pass. This had been not specified as “New Army” in the Draft and is corrected in the Final.

- *The holding of exit quota spots, from Trail Crest east, for commercial operator clients as specified for Alternative 3. We feel that all visitors should compete equally for exit quota spots.*
- *Daily party sizes and yearly totals for these select passes:*
- *Taboose Pass in Alternative 3 – A single quota with 10 people/day and 50 stock/year allowed is proposed. We feel that the narrow and rocky condition of the trail, does not allow for safe passage of large stock groups and hikers and would encourage you to place a limit of 10 head/day on this trail. The annual limit as specified is acceptable.*
- *Shepherd Pass in Alternative 3– A single quota of 15 people/day and 100 stock/year allowed is proposed. We feel the narrow, rocky condition of the trail does not allow for safe passage of large stock groups and hikers, and that the fragile nature of the high country accessed does not support this level of stock well and would encourage you to place a limit of 10 head/day and a seasonal limit of 80 stock/year. The high meadow areas accessed by this trail have seen a notable increase in use in the past three years and they will not be able to sustain this level of use.*
- *Shepherd Pass in Alternative 2 – A destination quota of 18 trips per season is allotted. Due to the reasons stated above, we would encourage you to set the quota at 10 trips in order to assure that meadows in the area do not become overused.*

(NOTE: we feel the other quotas and use numbers as delineated in Alternatives 2 and 3 are acceptable at this time. We will continue to enforce our group size limits of 15 people and 20 stock as well as our monitoring efforts and may need to enact further control of use in these parks if impacts to resources and experiences so warrant.)

Response: Further communications with Sequoia-Kings Canyon have taken place to resolve inconsistencies and address their concerns.

Devils Postpile National Monument

Public Concern #77: *Some specific aspects that we [Sequoia and Kings Canyon National Park] do not support are:*

- *It does not appear that a thorough evaluation of the carrying capacity and impacts of the 1500 annual day use riders to Rainbow Falls has been conducted. The use of this area by commercial stock operators has been conducted via the NPS's Incidental Business Permit system. DEPO will be developing a General Management Plan in the upcoming years, and will address carrying capacity and resource impact issues in connection with this use. We are willing to accept the use numbers as allotted in the DEIS and Plan, but reserve the right to control and regulate use in DEPO pursuant to resource impacts determined through future monitoring and analysis.*
- *We also feel that trails which lead into DEPO, specifically those sections of trail number 2000.3 (Ref. #'s I-24 and I-25) should be classified no higher than Trail Class 3. These are classified as Trail Class 4 in Alternatives 1 and 2. These trails are in wilderness, and the higher level of trail class has conditions that we feel are not appropriate in wilderness. Trail Class 3 more accurately reflects the current condition and the maintenance level that we work to accomplish.*

Response: Proposed Day Ride allocation remains the same throughout the alternatives at 1500 (this includes rides at Agnew Meadow and on the River corridor). In the Final EIS, Alternative 2 – Modified designates Trails I-24 and I-25 as Trail Class 3.

Other Planning/Document Issues

Public Concern #78: *The Forest Service should allow people to help on the ground with the repair, relocation, and realignment of campsites and trails. If improvements or mitigation efforts are needed, there are a lot of people, including commercial pack operators who want to be of service. (response # 277)*

Response: The Forest Service currently utilizes many volunteer groups and organizations, including the Pacific Crest Trail Association, Sierra Club, American Hiking Society, Friends of the Inyo, Students Conservation Association, and the Eastern Sierra Backcountry Horseman to assist with trail maintenance, camp site relocation, logging out, brushing and general maintenance at trailheads. Packers are also required to help “log out” and repair trails prior to entering the wilderness in the spring.

Public Concern #79: *The Forest Service should address the issue of uncontrolled dogs in these wilderness areas (response # 346, 347)*

Response: This topic is outside the stated Purpose and Need (Chapter 1) and scope of this project.

Public Concern #80: *Noncommercial recreational pack stock should also be removed from the wilderness. Private stock is essentially unregulated. Private stock users are often untrained and unprepared for the task of handling and caring for stock in the mountains.*

Removing pack stock from the wilderness or reducing pack stock use might result in an increase in the number of backpackers. To realize the benefits of removing stock from the wilderness, measures must be taken to ensure that increases in other forms of recreational use does not result in increased negative impacts. (response # 392)

Response: Analysis of non-commercial pack stock is outside the scope of this document. As stated in the Purpose and Need (pg. I-1) this analysis responds to two needs: 1) establishing additional management controls for commercial pack stock operations, and 2) a trail plan that accurately identifies a system of trails for all users and appropriate trail management objectives.

Public Concern #81: *The FEIS should include a glossary and acronym list that describes and explains specific terms such as trail class, recreation category, spot trips, dunning trips, full service trips, service days, grazing night allocations, and properly functioning conditions. (response # 427)*

Response: The FEIS includes a glossary of terms.

Public Concern #82: *The FEIS should provide a one to two page comparative chart highlighting the differences between the impacts of each alternative on key resources and management issues. Include a comparison of the temporal, spatial, and intensity of effect of each alternative. For example, while Alternative 4 may reduce the spatial effects of commercial pack stock use, it could increase the intensity of adverse effects by concentrating use into smaller high use destinations. The goal should be to highlight environmental and management tradeoffs between alternatives. (response # 427)*

Response: Unfortunately, given the nature and complexity of the project it is difficult to summarize the effects of the (now) six alternatives in one or two pages. Table 2.25 at the end of Chapter 2 summarizes the effects of the six alternatives on the relevant resources analyzed in the document.

II. Alternatives

Alternatives, Components

Quota, General

Public Concern #83: *Commercial pack stock management quotas should include caps on both the total number of stock animals and the number of customers served. (response # form letter C)*

Response: This concept was analyzed in Alternative 3. For each trailhead quotas there was identified seasonal thresholds on stock and clients.

Public Concern #84: *No rationale and/or methodology is explained or referred to for the calculation of use levels and stock numbers which vary greatly from Alternatives 1 through 4. (response # 248)*

Response: The methodology for calculation of use levels in each alternative exists in the project record. The FEIS includes additional summary language in each of the alternatives' "Quota" section to help readers understand the differences between the alternative use levels. Alternative approaches generally respond to issues, which is how the DEIS attempted to explain the differences between the alternatives.

Public Concern #85: *There should be only one packstock group allowed per trailhead per day, with a limit of four clients, and eight horses/mules. The group can be either a day trip or overnight trip, with a limit of five days. They must carry in all their feed. (response # 316)*

Response: The DEIS/FEIS analyze a range of alternatives that propose a variety of mechanisms to control commercial pack stock use. The consequences of each of these are disclosed in the Environmental Consequences. There does not appear to be any rationale for the limits suggested above. The Preferred Alternative (Alternative 2 – Modified) proposes a destination quota system that regulates use on a very site-specific basis, which provides more direct internal controls than a daily trailhead quota. In addition, there would be daily and seasonal limits on the number of stock that could be used. The approach for managing pack stock suggested above does not meet the purpose and need for the project.

Public Concern #86: *Given the unused quota space over the last several years, it is obvious that demand does not exist at a high level for some commercial pack services. Quotas should be lowered to levels much nearer present levels. (response # 399)*

Response: Information on quota space ('quota availability') has been added to Chapter 3, "Wilderness Resource." This shows that quotas are filling at a similar rate for commercial quotas as non-commercial quotas. Quotas are in place as an overall regulator of capacity for the general public, while the commercial operator's capacity is regulated with service days (currently) and quotas act as a temporal control to reduce spikes in use. The various alternatives provide a range of commercial use levels and mechanisms to limit use. Alternative 4 proposes lower quotas where resource concerns exist. It should be pointed out that demand and use changes over time and the agency's objective with commercial use levels is to provide the level of commercial use that is necessary to meet the goals of the Act and preserve wilderness character. It is not the

objective (see Purpose and Need, Chapter 1) to reduce use to current need levels unless there is a resource need.

Public Concern #87: *Alternative 3 allows an option for “adjusting” allowed use downward if use is “low”. This is not reasonable - it is an outfitter/guide policy and should not be applied to Pack Stations. It does not account for economic trends, weather conditions or any myriad of factors. (response # 38, 355)*

Response: Alternative 3 does not have any direction to reduce stock and client thresholds simply because use is low or below the established thresholds. Any adjustments to the thresholds are based on an assessment by the Responsible Official regarding the condition of the resource conditions. “If any evaluation indicates that conditions do not meet standards and guidelines or desired conditions corrective actions including reduced thresholds, additional destination quotas and/or campsite or other site specific closures will be considered.” (DEIS pp. II-42)

Public Concern #88: *The Forest Service should not allow for the adjustment of quotas as is suggested on page 11-18 of the DEIS. There should be defined, effective limits on the seasonal and daily number of persons and stock animals, and effective controls (i.e., either daily trailhead quotas or daily destination quotas) to prevent spikes in use. (response # Form Letter C, 36, form letter B, 65, 196)*

Response: The analysis of this management direction is found in Chapter 4. The Final EIS improves this language to make it clear that proposed use levels are intended to be an estimate to reach certain conditions. Our emphasis is on the conditions, not the tool (quota) or mechanism.

Public Concern #89: *Pack Stations that merely pass through the John Muir and Ansel Adams Wilderness Areas without staying overnight or without dropping a party off as a spot camp should not have their use categorized as “overnight” as there is no overnight use taking place. No campsites are being used, no stock grazing or holding areas, and no firewood being used. It is merely day use of trails. (response # 428)*

Response: The classification of use as “overnight” was used when the allocation system is based on service days, as prescribed by the 2001 Wilderness Plan (ROD pg. 12) and the No Action, Alternatives 1 and 4 in the DEIS. With service days a certain number were allocated to “overnight” use as well as a specific number to day rides. However the Alternative 2 – Modified in the FEIS and Alternative 2 and 3 does not use service days as a use allocation method, so the classification no longer applies in these alternatives. The Selected Alternative implements a system of destination quotas. For trips passing through the John Muir and Ansel Adams into the National Parks, the number of trips, or other appropriate mechanism, will be set by the National Park Service. While it may be true that there are few impacts on the John Muir and Ansel Adams Wildernesses the impact will occur where the party does camp and the FEIS incorporates the appropriate direction in cooperation with the National Park Service to meet the objectives of both agencies.

Quota, Trailhead Quotas

Public Concern #90: *A separate quota should be established for each trailhead in the vicinity of any pack station that is specifically for commercial pack stations. For trailheads not frequently served by the pack stations, there should be another quota for all commercial users. (response # 428)*

Response: This approach is used in Alternative 3 (Chapter 2) and analyzed in Chapter 4.

Public Concern #91: *Non-commercial user quotas should be 95% reserveable and placed on the National Recreation Reservation System. First come, first served quotas are not fair to visitors from out-of-town. (response # 428)*

Response: Reservable quota and the National Recreation Reservation Contract are both outside the scope of NEPA and the Purpose and Need (Chapter 1).

Public Concern #92: *Trail Crest should not be considered an entry trailhead. Controls should be instituted on the uncontrolled, unlimited, and unregulated day use that currently tops 300 persons a day on the Mt. Whitney Trail. (response # 428)*

Response: Use entering Trail Crest comes through Sequoia and Kings Canyon National Park. The Park and Forest Service have indicated concerns with this use and determined management of it is important. Alternatives in Chapter 2 address these concerns by providing alternative approaches to a Trail Crest quota. Current levels of day use on the trail are outside the scope of this project and are not analyzed in the environmental document.

Public Concern #93: *Daily trailheads quotas should be implemented:*

- *To prevent “spikes” in use and overcrowding of popular areas. (response #Form Letter D, 33)*
- *To prevent overcrowding and in order to be fair to other users who have to abide by these quotas (response # form letter C, form letter E, 35, form letter B, 318, 399)*

Response: The FEIS presents various alternatives for managing commercial pack stock use, including daily trailhead quotas. Alternatives 1, 3, and 4 continue to use a quota system while Alternative 2 and the Alternative 2 – Modified use a destination quota method in place of the daily trailhead quotas.

Quota, Destination Quotas

Public Concern #94: *Some areas should be subject to destination quotas. Trailhead quotas will not be adequate to control use of some popular areas. The listed provision of trip limits for some areas is not sufficient protection. (response # 195, 277)*

Response: The effects of destination quotas and trailhead quotas are described and compared in Chapter 4 “Wilderness”. Chapter 4 analyzes the environmental effects of different control mechanisms (including trailhead and destination quotas).

Public Concern #95: *The Forest Service should give careful consideration and attention to the concept of destination management. Destination management can become a management tool which would provide a single focal point into which the myriad forms of restrictions or management contained in the DEIS can be integrated into a streamlined, destination specific form of site-specific management. (response # 325)*

Response: The Final EIS analyzes the environmental effects of destination a destination management approach to managing commercial pack stock. The concept has been incorporated into the selected alternative and the implementation /monitoring plan. The Record of Decision provides the rationale for adopting this approach.

Public Concern #96: *Destination quotas (Alternative 2) may ultimately be an excellent way to manage commercial use because they may allow the agency to more specifically target the areas of concern. However, trailhead quotas provide the value of freedom of movement. The unconfined nature of the wilderness experience is something to strive for in management as long as the behavior of the user is such that the resource is protected. There will be effects to Yosemite with either management direction. Trailhead quotas are consistent and generally preferred within the Central Sierra Wilderness Group due to the inherent flexibility and existing system, but the destination quotas may be a new and effective tool we should consider particularly with respect to commercial operations. (response #426)*

Response: The DEIS analyses both approaches to managing commercial pack station use. Daily trailhead quotas are a component of Alternatives 1, 3, and 4 while destination quotas form the basis for Alternative 2 and Alternative 2 – Modified. Destination quotas for Yosemite National Park have been removed in the selected alternative in the FEIS. Thresholds already set by the National Park Service (NPS) and included in the Incidental Business Permits issued to the commercial pack stock operators by the NPS are sufficient and there is no need for the Forest Service to interpret or duplicate them.

Public Concern #97: *Destination Quota – there is no impact when a party comes out of the mountain. Numbers should not be counted for stock just dropping people in the mountains nor should they be counted when picking up a party. There is no impact from this. (response #38)*

Response: There are impacts to the environment each time a group travels in the wilderness. Impacts to the trails are described in the Environment Consequences (DEIS pg. IV-30). Impacts to the wilderness character (opportunities for solitude; naturalness; undisturbed; and primitive and unconfined recreation (DEIS pg. IV-6)), also occur whether a party is traveling in or out of the wilderness, or is dropped off.

Public Concern #98: *Destination quotas should only be used in areas with no trailhead quotas. They should not be used in conjunction with trailhead quotas. (response # 428)*

Response: In Alternative 2, destination quotas replace both daily trailhead quotas and service days (p. II-17) for commercial pack stock operators. Destination quotas are not used in conjunction with daily trailhead quotas for commercial pack stock operators. In Alternatives 1 and 4 there are no destination quotas. In Alternative 3, destination quotas are implemented on a few sites (27 total) to provide site-specific management controls where daily trailhead quotas will not meet the desired objectives (p. IV-22)

Quota, Thresholds

Public Concern #99: *The proposed action relies heavily on thresholds. Implementation of the thresholds would require intensive efforts and a large investment of Forest Service staff time and resources at the end of each season. Any proposed reductions in thresholds would be vigorously contested by packers. Alternative 3 does not give any explanation on how thresholds have been determined. Thresholds would not be effective limits on use and should be abandoned. (response # 399)*

Response: Currently all pack stations are required under the annual operating plan to submit monthly, tally sheets of all use inside and outside the wilderness. The tally sheets record provide historical records to track use to monitor the threshold. Thresholds are another proposed tool to

monitor and control use in the wilderness. Alternative 2 – Modified (the Selected Alternative) does not include the threshold concept as outlined by Alternative 3.

Public Concern #100: *With regard to Seasonal thresholds - yearly assessments - this will be subjective and arbitrary. There are no guarantees that the public need will be met. It is also highly inefficient. (In Alt. 3 is borrowing still allowed?). The means for approving use is subjective. It would subject the clients of the Pack Station to the biases of various Forest personal, in the present or in the future. (response # 355)*

Response: These thresholds provide general guidance for total use in a season. Single quota trailheads will only have a seasonal stock threshold and will regulate number of clients through the daily trailhead quota (see DEIS, Chapter 2 C. Quota-trailhead Quotas). By utilizing the threshold, once packers meet their quotas, all trips will be discontinued. Packers will be responsible to monitor their operations and inform their clients of the possibility that they may not be able to complete their trip and another area will need to be selected.

Public Concern #101: *There should be no caps on the annual number of trips. There is no need to curtail trips in September or October, when use is generally far below the capacity of the area. (response # 428)*

Response: The packer will have the discretion to disperse trips throughout trailheads to prevent hitting the cap. Caps are also place in areas where evaluations have shown a need to control capacity to prevent resource damage and social impacts.

Primary Operating Areas

Public Concern #102: *The Forest Service should not implement the Primary Operating Area concept. (response # 38, 355)*

Response: Primary Operating areas will be deferred and developed when the pack station permits are reissued under the SUP EIS document. In the FEIS, destination areas will be analyzed.

Public Concern #103: *There are two major problems associated with the concept of POAs [Primary Operating Areas]. The first is that there is a potential to dramatically change the basic capital value for individual pack stations whose value was previously established through the purchase of a volume of use days. A restriction to a primary operating area which is not consistent with this level of use would have the effect of diminishing the value of the business asset through administrative regulation.*

The second problem relates to traveling trips. The MOU recognizes that there is a fundamental difference between traveling trips and spot and dunnage. A restrictive POA would compromise the viability of traveling trips or result in a significant concentration of use. As the DEIS indicates, traveling trips account for a smaller percentage of overall use than spot and dunnage trips. There are operators, including Frontier who have the ability and desire to offer this service to the public. Operators should have the flexibility to offer this service. We note that the discussion of POAs does not mention the use of such a management tool in connection with traveling trips and do not, therefore, believe that this is intended to apply to such trips. (response # 325)

Response: Identifying POA's will not restrict the operators from offering traveling or all expense trips to their clients. POA's could increase the value of the business once the packer can

show an area as part of the permit. The level of use allocated will be consistent with the historically recorded use by each pack station and not reduce use.

Under the DEIS Alternatives 2, 3, 4, traveling trips will not exclude packers from traveling outside the POA and, therefore, would not compromise the viability of traveling trips. Primarily spot and dunnage trips are directly affected by the DEIS.

Unassigned Trips

Public Concern #104: *We strongly oppose the proposal to allow five unassigned trips per year for each pack station (at II-17 & 18). These trips could occur essentially anywhere, at any time, presumably without specialist review, further NEPA analyses, or public involvement. The proposal would allow up to 100 commercial pack stock trips per season to areas in these wildernesses that have not been analyzed B and probably will not be analyzed or monitored in any meaningful way. Because commercial packers often hire young, inexperienced guides, and because the commercial outfits have a clear track record of disregard for wilderness protection regulations, the unassigned trips are likely to have significant adverse effects on the wilderness character. (response # 196, form letter D)*

Response: Alternative 2 – Modified (Selected Alternative) responds to this concern by not permitting “unassigned” trips. Unassigned trips are analyzed in the FEIS in Chapter 4, Wilderness for Alternative 2. While the analysis does indicate the difficulty in predicting the exact effects of unassigned trips, it is not entirely fair to make the assumption that commercial outfits have disregard for wilderness protection regulations.

Designated Stock Sites

Public Concern #105: *Loopholes render the proposed designation of stock camps ineffective. The DEIS proposes for Alternatives 2 and 3 that, (at p. II-33 and II-49), “All overnight holding of stock by commercial operators would only take place at a designated stock camp.” This key requirement would limit the magnitude and extent of stock impacts, and is long overdue. However, the proposal quickly adds loopholes that would render this direction essentially meaningless:*

If a stock camp has not been identified, and an operator requests use of an area where overnight holding of stock is needed, the Authorized Officer may approve that use. If an operator plans to use sites repeatedly through the term of the permit, the site should be approved and designed in accordance with the guidelines above. (DEIS at II-33 & II-49)

Despite the clear initial language (i.e., All overnight holding of stock by commercial operators must take place at a designated stock camp) exceptions can be obtained for overnight holding of stock anywhere and anytime as long as the operator receives approval from the Forest Service. There is no requirement for specialist review, NEPA analysis, or opportunity for public involvement as new sites are created and used as stock camps. There are no limits on the number of exceptions that may be granted, and no objective criteria to limit where or when such exceptions may be granted. Also, the words needed, repeatedly and should are undefined, open to wide interpretation, and essentially have no regulatory meaning at all.

In order for this proposed action to be meaningful, the provisions for exceptions must be removed, to require (with no exceptions) that all overnight holding of stock must occur at locations that have been: (1) evaluated and cleared by resource specialists, and (2) designated as stock camps in a public NEPA process.

Five years is too long to install BMPs at designated stock camps. It has long been known that stock holding areas pose the potential to cause significant nonpoint source water pollution. The Forest Service's own Best Management Practices Evaluation Program has shown backcountry stock holding areas to have among the lowest implementation and effectiveness scores of any nonpoint source pollution category. The DEIS states (at II-33 & II-49) that under Alternatives 2 and 3 the Forest Service and/or permittees will prevent nonpoint source water pollution from stock camps by installing Best Management Practices (BMPs) within five years of permit issuance (the BMPs are to include designated stock holding areas, designated access into and out of the camp, and other erosion control measures as needed). The Forest Service cannot legally put these problems off for up to five years. The DEIS (at B-13 to 15; Table 5) indicates that approximately 40% of commercial horsepacking campsites evaluated by the Forest Service have "substances entering water." These evaluations were begun in 2002 or earlier and little has been done to remedy these situations. The Forest Service must move more expeditiously to prevent water pollution from stock holding areas. (response # 196, form letter D)

Response: The Forest Service believes that placing the responsibility for approval of additionally requested stock camps with the Authorized Officer is appropriate. The Authorized Officer is bound by law, regulation, and policy to conduct an analysis appropriate to the magnitude of the request. The DEIS identifies the issue of allowing discretion for case-by-case decisions as non-significant (DEIS pg. I-10) since it is "conjectural and not supported by scientific or factual evidence." There is no evidence to suggest that future decisions would necessarily "lead to a deterioration of wilderness value and resources and an inconsistent approach to management overtime."

A five year target to implement BMPs at designated stock camps is appropriate. Table 5 (DEIS pg. B-13) does not differentiate proposed stock camps from campsites used for spot/dunnage, unknown uses or stock holding camps that are not proposed, so the percentage of proposed stock camps that have substances entering the water cannot be quoted from the data presented.

Public Concern #106: *Commercial packers should not be limited to designated sites*

- *Because according to the DEIS "impacts reach a peak with light to moderate use and beyond this point decreases significantly." (D-54) Much of any increased impact could be attributable to the increase in hiking activities, since pack stock use has actually decreased. Additionally, pack stock users have improved their methods for containing stock at camp sites, and have limited further deterioration of those sites. (D-55) By contrast, hikers will often seek new, untrammled sites on the edges of established camp sites in which to camp. Thus, attributing campsite degradation to pack stock appears to be misdirected. (response # 357)*
- *Because this is restrictive, demonstrate micromanagement of the forest and do not allow the public to visit the areas they choose. Flexibility and the freedom to travel within the wilderness are important values to the public, and are referred to in the Congressional Record for the Wilderness Act as being necessary for a wilderness visit. (response #34, 40, form letter F, 154, 281)*
- *Because designated campsites are terrible for the public and not consistent with the Wilderness Act. And the closure of camping from Third Recess to Second Recess is even worse than having a few camps. The Forest Service proposes a few designated campsites for Rock Creek Pack Station and fails to tell the public what that impact will have when they go to take a pack trip. (response # 275)*

Response: At the conclusion of this planning effort, the packers will be limited to existing established sites to prevent additional resource damage to the wilderness. The sites selected are sites historically used by packers and new sites are generally not necessary. Commercial pack stock use has been on the decrease for the last five years. The existing sites will accommodate the demands by the pack station and still provide additional sites for other users without adding pressure on the existing wilderness. There are no restrictions for foot travel off trails to visits the area they chose.

Public Concern #107: *To reduce the potential for user conflicts, the Forest Service should ensure that designated sites are adequately signed. (response # 198, 362)*

Response: The National outfitting/guiding regulation permits the Forest Service and the packers to post signs at the designated sites to inform the public that the site is under a fee for use (also known as Assigned Sites O/G Handbook p. IV-20 item V). The packer would have the right to request the other user to move to another site. In addition, more than one site will be identified in a geographic location to minimize the conflict of multiple users.

Public Concern #108: *The DEIS states that the designated campsites by alternative are as follows: Alternative 2 - 94 sites, Alternative 3 - 101 sites, and Alternative 4 - 59 sites (p. IV-116). The FEIS should provide the justification and rationale for the number and location of designated sites for each alternative. (response # 427)*

Response: The FEIS contains a range of alternatives to meet the purpose and need for the project. Imbedded in each alternative are specific components, including designated campsites. The components included in each alternative are generally developed to be consistent with the intent of the individual alternative. The effects of all the alternatives are analyzed and disclosed in Chapter 4 of the EIS.

Campfires, Restrict/Prohibit

Public Concern #109: *Commercial pack outfits should not be allowed to haul firewood into areas that are closed to campfires.*

- *Because this absurd proposal would constitute unfair favoritism to commercial businesses, it would result in increased impacts to trails and meadows (from the extra animals needed to haul firewood), it would invite abuses (i.e., packers would certainly use local firewood after their imported wood is gone, and other visitors would see the smoke/fires and think it's okay to build their own campfires). And, it would be impossible to enforce. (response #form letter C, form letter D, 33, 35, 36, form letter B, 65, 78, 97, 175, 209, 212, 230, 310, 318, 372, 390, 399, 406)*
- *Because this would set up a serious inequity perception, and confuse and compromise campfire regulations for other users. We are also concerned about the very disturbing potential of introducing pathogens and/or weed seeds by allowing wood to be imported. (response # 426)*
- *Because this practice would pose a myriad of problems and will not be allowed in SEKI. The practice takes significant risks with minimal rewards at best. By bringing in firewood, there is a risk of importing non-native, and potentially harmful, pathogens and materials, e.g. weed seeds. There is also a compliance issue in that coals/ashes may be dumped counter to instructions to remove these materials. We believe that ecological values should not be subservient to economic values. This practice would have other effects as well, including requiring additional stock to carry the wood/charcoal (which would increase impacts and costs to clients), the false*

impression that fires are allowed in what are supposed to be “closed” areas to other user groups, and the potential dissatisfaction of those other user groups who subject themselves to citations and may feel that a double-standard exists for the benefit of a commercial entity. On page D-37 of the DEIS, a US Forest Service policy states: “Where a choice must be made between wilderness values and visitor or any other activity, preserving the wilderness resource is the overriding value. Economy, convenience, commercial value, and comfort are not standards of management or use of wilderness.” We feel that the packing in of wood or charcoal is not in the best interest of preserving the wilderness resource and urge you to continue with the decision made in the 2001 Wilderness Management Plan to “Prohibit. . . packed in firewood, or fire pans within areas closed to wood campfires.” (response # 425)

- *The Forest Service should reconsider the decision providing an exemption for commercial pack stock operators to the elevation fire closure zone. The FEIS should describe the actual and perceived importance of campfires to clients’ experience of the wilderness. If exemptions to the elevation fire closure zone are provided, the FEIS should describe and commit to specific monitoring and mitigation measures to reduce potential adverse effects. (response # 427)*

All of these comments are from response #196

- *Because this apparent deference to political pressure by commercial outfits to weaken the campfire restrictions is inappropriate in light of the Ninth Circuit’s ruling in High Sierra Hikers v. Blackwell.*
- *Because the 2001 Wilderness Plan clearly stated the problems associated with allowing the packing in of charcoal or wood and to allow only gas stoves in the closed areas.*
- *Because the Forest Service should promote these wilderness areas for what they have to offer, not cater to incompatible desires and expectations of users.*
- *Because there is no valid reason to allow commercial outfits to have fires in areas that are closed to campfires.*
- *Because scientific research also clearly demonstrates that the Forest Service must ban campfires at high elevations in order to prevent significant adverse impacts to the environment.*
- *Because it would be nearly impossible to enforce a fire closure if commercial outfits were allowed to import firewood. In addition, campers who see the fires, smoke, and/or fire scars from imported wood or charcoal would be tempted to build their own fire, resulting in additional significant ongoing impacts.*
- *Because there is no evidence that the current campfire closure has caused lower elevation wood depletion.*
- *Because the full impact of allowing packers to bring in their own wood is not fully analyzed.*

Response: The inability of the packers to provide a desired service (campfires) to their clients was identified as an issue, and the determination of appropriate campfire limitations is part of the purpose of this analysis. The issue of inequity for users is addressed in Alternative 2 – Modified which allows any wilderness user to pack in charcoal and a fire pan and requires that the ashes be packed out. The use of charcoal would also eliminate the concern about weed or pathogen introduction. The environmental effects of the campfire policy are fully disclosed in Chapter 4 of the Final EIS.

Public Concern #110: *The elevational campfire closures established by the 2001 Wilderness Plan (i.e., 10,000 feet in the north; 10,400 feet in the south) are too high, and must be re-analyzed in light of the Ninth Circuit's ruling. Specifically, the Forest Service must regulate wood-gathering and campfire building by the commercial pack stock industry to fully protect the wilderness character. The Forest Service cannot continue to allow impairment of the wilderness character because commercial outfits desire to build campfires in areas where campfires are inappropriate.*

The inadequate campfire elevations established in the 2001 Wilderness Plan (i.e., 10,000 feet in the north; 10,400 feet in the south) were selected by the Forest Service based on political pressure exerted by the commercial pack stock businesses. (response #196)

Response: A range of alternatives has been analyzed in regards to campfire building. We do not believe the 9th Circuit ruling can be interpreted to include lowering the elevational closure based on an allegation that the 2001 elevations were selected based on pressure from the commercial pack stock business. The elevations were based on the approximate elevations of white bark pine forests.

Public Concern #111: *The Forest Service should consider dropping the fire closure to 8000' to 9000'. (response # 230)*

Public Concern #112: *Campfires should not be allowed anywhere in the wilderness (response # 316)*

Response: Consideration of campfires in general is outside the scope of the FEIS. The decision related to campfires and campfire closures was made in the 2001 Wilderness Plan (ROD pg. 4).

Campfires, Allow

Public Concern #113: *Campfires should be allowed above the current closure.*

Comment: *The firewood closure in areas where there is plenty of available and down firewood is wrong. A good alternative not discussed is to allow fires in those areas where the firewood is available. For example, the Tamarack/Dorothy Lake area has tremendous amounts of firewood available for campfires. However, the camping areas are between 10,000 and 10,400 ft. There should be alternatives that particular regions or lakes could have fires. The 10,000 ft fire closure for Tamarack and Mono Creek is inappropriate. This EIS should have shown the environmental consequences from the Fire Closure of 2002. Now camps are moving and there are all sorts of new impacts. (response # 275)*

Comment: *Campfires – All areas should be open to fire plans with charcoal. There are no other forests in the nation with this restrictive policy of no charcoal. In addition, there is no reason to not have a campfire as long as it is in a firepan, using packed in wood, and packing out the ash. It is all contained, everything is removed. This is highly desired by the public, and they should be allowed to have this option. (response #38)*

Comment: *There should be no elevational closures for campfires as this forces the public into concentrated areas leading to overuse and ultimately elimination of campsites. Mitigation measures can be used to allow contained campfires, including packing in wood, packing out ashes, and using fire pans. Campfires should be allowed in all areas with the mitigation measures in place where firewood is scarce. (response #34, 37, form letter F, 257)*

Comment: *Campfires are an important traditional aspect of the wilderness experience as well as a health and safety matter in a high elevation where nights and even days can be very cold. Campfires are a historical practice since the dawn of mankind and were in common usage when the Wilderness Act was enacted. Campfires are part of the wilderness character. If the area does not have sufficient firewood available, the visitor must be allowed to bring in fuel from elsewhere if they so choose. The elevational fire closures forest wide make no sense. The tree line is different in various basins and there are many avalanche slides with a jungle of fallen dead trees that can't be utilized and pose a fire danger, because of a no campfire regulation. Pack station customers have been shown to be in compliance with this regulation but backpackers are more difficult to regulate, and the majority are unaware of the regulations as evidenced by illegal campfire rings. (response # 198)*

Comment: *We believe that all wilderness users, regardless of their method of transportation should be able to enjoy the experience of a campfire if they are willing to pack in a fire pan and remove the resultant ashes. We strongly believe that management policies should not create categories or tiers of rights among wilderness users. Such disparities generate misunderstanding about what people can do and conflict between people who are subjected to different rules at the same location. We would propose that the campfire rules from the 2005 MOU be adopted. (response # 325).*

Response: The concerns of inequity for users, use of charcoal, and areas above the closure with adequate firewood are responded to in Alternative 2 – Modified. This alternative allows any wilderness user to pack in charcoal and a fire pan and requires that the ashes be packed out, and modifies the elevational boundary where adequate firewood is available. It also allows for some case by case exceptions for packers upon request, with established criteria for the approval process. Monitoring controls and responses are identified.

Group Size

Public Concern #114: *Group size should be lowered*

- *To no more than twelve animals should be allowed per group, maximum. (response #form letter D, 406)*
- *To ten animals per group, following the recommendations of the best available science. (response #form letter B, form letter C, form letter E, 35, 65)*
- *Because of the excessive manure, urine, and dusty conditions that large groups lead to. (response #30, form letter B, 78)*
- *Permanently to 12/20 limit on livestock party sizes to reduce environmental impact. (response # 175)*
- *To 15 animals. (response # 318)*

Public Concern #115: *Group size should be increased*

- *To accommodate the additional needs of handicapped individuals. (response # 188)*
- *To accommodate larger groups such as girl scouts, boy scouts, YMCA's, church organizations, youth groups, and large family reunions. (response # 355)*

Response to Public Concerns 114 & 115: Analysis of non-commercial pack stock group size limits is outside of the scope of this FEIS. In addition, the 2001 Wilderness Plan (FEIS pg. I-15) identified that consideration of party size limits was outside the scope of that planning effort: “Existing limits have been reviewed and determined sufficient for this planning effort.” In the FEIS, consideration of group sizes larger than the current limit of 15 people for clients of commercial pack stock operators would create an equity issue where some selected groups would enjoy privileges not afforded other users. Also, use data shows that with the current 15 person limit, only 7% of pack station trips exceed 12 people (DEIS pp. III-8, IV-14). There is no compelling reason to alter the upper limits that have been in effect throughout the entire central Sierra Nevada wildernesses for the past 15 years. Consequently, party sizes above the established 15 for commercial pack stock operators are outside the scope of the FEIS.

Public Concern #116: *The DEIS illegally fails to consider group sizes smaller than the court-ordered limits of 12 persons and 20 animals per group for commercial pack stock groups. There is no indication in the District Court’s rulings that it intended the Forest Service to limit its consideration of group size limits to 12/20 or larger, and there is every indication in the scientific literature that lower limits are needed to protect wilderness resources. During the scoping phase for this EIS, a large number of respondents asked the Forest Service to evaluate lower limits on group size for commercial pack stock. And our representatives made clear on several occasions throughout the process that the Forest Service must evaluate smaller group size limits as recommended by scientists.*

The DEIS is deficient because it fails to evaluate and disclose the impacts of allowing such large parties to use these wildernesses. Alternatives 1 through 4 are deficient and non-viable because they fail to evaluate or propose group size limits that will protect the wilderness character from significant impacts that have been documented in the record throughout this planning process. The scientific literature clearly indicates that group size limits for stock animals should be no larger than 10 in order to protect physical, biological, and social values (Cole 1989a, 1990; Watson et al. 1993). (response # 196)

Response: The Forest Service considered a reasonable range of alternatives (DEIS Ch 2) and displayed the environmental consequences of those various actions (DEIS Ch 4). Party size was identified as one of the significant issues (DEIS pg. I-8) and the indicator for that issue is “Locations where party size is less than wilderness-wide standard of 15 persons and 25 stock” (DEIS pg. I-8). Alternatives 1, 2, and 3 analyze a wilderness-wide party size of 15 persons and 25 head of stock, contrasted with Alternative 4, which analyzes 12 people and 20 head of stock, and Alternative 5 where no commercial stock would be allowed and party size not applicable. In Alternatives 2, 3 and 4 low use and low capacity site-specific locations are identified for less than the wilderness-wide party sizes. In Alternative 2 and 3 fifteen sites are identified with party sizes ranging from as low as 6 people/6 stock to 10 people/10 stock. In Alternative 4, 70% of the trailhead quotas would limit party size below the maximum of 12 people proposed in this alternative. The DEIS fully discloses the impacts of these actions for each alternative (DEIS pg. IV-19, 26).

Public Concern #117: *The DEIS is also inadequate in failing to consider that a lesser number of packstock is “necessary” today than in the day when 25 pack animals was deemed a reasonable upper limit (many years ago), because of recent significant reductions in the weight of necessary camping equipment and food. (response # 301)*

Response: see response to Public Concern #116

Permits

Public Concern #118: *All permits for outfitter/guide (O/G) operations within wilderness should be subject to the Forest Service's outfitter/guide regulations, and have a maximum term of ten years. The Forest Service has signaled that it is considering issuance of long-term resort permits for commercial pack stock enterprises that operate in these wildernesses. Resort permits are not appropriate for most/all of these operations because most/all pack stations are not a complex of enterprises, but are instead a single enterprise: stock packing. The base facilities (improvements) for the majority of these operations are not significant. They tend to have a few rustic cabins/shacks, corrals, hitching rails, loading docks, and trailers. They are not resorts as defined by Forest Service policy and regulations. (response # 36, 196, form letter B, form letter D)*

Response: Decisions regarding the appropriate type of permit and term are outside the scope of this EIS, which does not include the type or term of permits authorizing use. The scope of this analysis is displayed in the DEIS (pg. I-7).

Public Concern #119: *Commercial packers should not be allowed to write their own permits (response #97)*

Response: No alternative allows for the packers to write their own permits. This decision was made in the 2001 Wilderness Plan and is not subject to reconsideration (see Purpose and Need – Chapter 1).

Public Concern #120: *Commercial packers' permits should be phased out as they expire, allowing owners and employees an economic transition. (response # 171)*

Response: Decisions regarding reissuance and administration of the Special Use Permits that authorize commercial pack stock use are outside the scope of this analysis. The scope of this analysis is displayed in the DEIS (pg. I-7).

Public Concern #121: *Commercial packers should be liable to citation and made to clean up their messes left behind; requiring records of where trips went and when camps were used would allow post hoc assessment of how particular packers treat the wilderness. (response # 305)*

Response: Commercial pack stock operators are required to prepare detailed reports of their use within the wilderness and the “reports will include as a minimum: number of clients, number of employees, number of stock, trailhead entry, trailhead exit, destinations of the service provided, stock or designated camps used and grazing activity by grazing zone or meadow” (DEIS pg. II-4). This direction is common to all alternatives. In addition, all wilderness permits will be written by the Forest Service (or designated contractor), thereby, providing an independent crosscheck on the packer reports.

Public Concern #122: *The Forest Service should/should not issue resort special use permits to commercial pack stock operators.*

Comment: *Pack Stations operate with “Resort Special Use Permits” from the Forest Service. These permits recognize the substantial investment made by individuals to provide service to the public. With regard to controls or allocation methods Pack Stations should be treated like other Resort Special Use Permits nationwide, where the permit holders are encouraged to operate as long as possible to make the best use of the public lands. (response # form letter F)*

Comment: Term Special Use Resort Permits are not given their due anywhere in the document. Pack Stations continue to be considered as outfitter guide permittees when this is clearly not the case. We believe this leads to numerous errors and faulty conclusions. (response # 355)

Comment: The Forest Service should be strongly encouraged to utilize national standards of 'allocation' for this type of Permit - use can be limited by limiting the number of livestock allowed by the Permit. In this case, a business can balance cost with demand. (response # 355)

Comment: The pack station permits are resort permits, different from O/G permits, yet much O/G administration methodology etc. is applied to them incorrectly and adversely. These term permits, often 20 year terms allowing 365 days of use, if available due to natural land conditions etc.. were traditionally renewed under the authority of NEPA using the categorical exclusion method. (response # 311)

Response: Decisions regarding the appropriate type of permit and term are outside the scope of this EIS, which does not include the type or term of permits authorizing use. The scope of this analysis is displayed in the DEIS (pg. I-7). The mechanisms presented in each of the alternatives comply with current policies regarding commercial pack stock management within the wilderness. The 2001 Court Order specifically ruled out Categorical Exclusions in reissuing Special Use Permits for pack stations operating in wilderness and "determined that in authorizing the special use permits for the pack stations, the Forest Service failed to adequately document environmental impacts as required by NEPA (DEIS pg. I-1)."

Drift Fences

Public Concern #123: *The Forest Service should allow/remove drift fences in the wilderness.*

Comment: *All of the drift fences in the John Muir and Ansel Adams exist primarily for the convenience of the commercial packers. All of the drift fences should be removed. (response #form letter D, form letter B)*

Comment: *Existing drift fences should remain in place and be maintained. These fences are effective tools for stock and meadow management and have the ability to minimize conflicts among users. The Forest Service should have more drift fences and should let the public know the advantages. Fails to be an adequate document without offering the various options. (response # 325, 275)*

Response: The six alternatives provide various strategies for the management of drift fences in the wilderness (see FEIS, Chapter 2, Table 2.34 for a comparison of these strategies). The FEIS also contains an analysis of these strategies.

Sanding of Passes

Public Concern #124: *The Forest Service should not permit the sanding of passes.*

Comment: *Some specific aspects that we [Sequoia and Kings Canyon National Park] do not support are: The practice of "sanding." This activity poses several risks, including the introduction of materials to areas where they are not found, and the potential for excavation of materials from "borrow" areas. In other words it is not environmentally sound to bring in outside material or to "borrow" and displace local material to simply speed up accessibility. (response # 425)*

Comment: *Proposals in the DEIS to allow sanding of snowbound passes will irreparably harm the wilderness resource and character and are unacceptable.*

There are myriad significant negative impacts associated with sanding snowbound trails. Sanding facilitates earlier access to system or use trails and destinations beyond the snow blockage that are still either very wet from snow runoff or have other snow blockages. The DEIS also recognizes that importing sanding material, [C]ould possibly be a source of weed seed introduction.

An additional concern is that the Inyo National Forest has authorized the caching of sand in wilderness by commercial horsepackers in the past (i.e. sand is cached in the fall for use the following spring). Caches in wilderness are in violation of the Wilderness Act (16 U.S.C. 1133c) and inconsistent with the direction in the Forest Service Handbook.

Given the known adverse effects, the Forest Service can only conclude that the practice of sanding (or manuring) trails would create significant adverse effects on the environment. And given the negative impacts associated with sanding, and that the practice of introducing foreign material into wilderness for the convenience and economic benefit of commercial operators is antithetical to the Wilderness Act, the Forest Service should not permit the sanding of any trails, as in Alternative 4. (response # 196)

Public Concern #125: *IV-122 it says that passes would be allowed to be sanded are Piute and Pine Creek. Almost all passes will be sanded in the John Muir and Ansel Adams Wildernesses. Sanding reduces erosion because hikers follow the sand.*

Sanding is a traditional practice and has been used for over a hundred years and is necessary for livestock use in the Sierra. (response # 275)

Response: In the FEIS selected alternative, access over passes – including the use of sanding and/or shoveling, is governed by certain criteria at destination camps, use trails, and system trails, in addition to range readiness standards.

Day Rides

Public Concern #126: *The Forest Service should reduce or eliminate day rides in the wilderness*

Comment: *In Alternative 4, eliminate “day rides” in the wilderness. Commercial day use of wilderness resources adds to excessive trailhead area congestion and resource impact (including dust). Day rides should be accommodated outside wilderness; it seems only prudent to allow overnight commercial activity only. (response #form letter B, Form letter C, form letter E, 310)*

Comment: *The Forest Service should not allow day rides to increase above current levels. The USFS should expand horse riding opportunities outside of wilderness areas, and decrease or eliminate day rides in these wildernesses to reduce dust, trail erosion, and crowding on trails. (response #33, 35, 318,)*

Comment: *All limits on commercial outfitter use of these wilderness areas must include the impacts of day rides. Day rides must be included in outfitter use limits. (response #36)*

Comment: *Day rides should be limited to ten animals. (response # 194)*

Comment: *Alternatives 2 and 3 propose a substantial increase in the day ride allocation for commercial pack stations. There is no accurate data available on day rides historically, a deficiency identified in the 2001 Wilderness Plan ROD (at p. 15).*

There is no rationale given in the DEIS for substantially increasing the day ride allocations in Alternatives 2 and 3, by 39% and 34% respectively. The DEIS also fails to disclose the non-wilderness day ride allocations and recent use data for the numerous operations that provide that service. For example, the 2003 operating plans for Frontier Pack Train and Mammoth Lakes Pack Outfits allocate 1,850 and 7,000 non-wilderness day ride service days, respectively. There is no justification, aside from economic benefit to the commercial pack stations, for increasing the number of day rides in these wilderness areas, as most of these rides are of short duration and are not wilderness-dependent. We believe that most people take these rides because they want to ride a horse, and not because they want to visit the wilderness. Wilderness day rides are thus not necessary, and should be reduced or eliminated, and the Forest Service should strive to provide day-ride opportunities outside of these wildernesses.

The DEIS contains little discussion of the impacts associated with day rides. In discussing Alternative 1, it does state, “Opportunities for solitude will not be high in first six miles from trailheads. . . .” (p. IV-15) However, the DEIS fails to disclose that day rides would be a major factor; day rides occur predominantly, if not entirely, within the first six miles of a trailhead. Furthermore, the DEIS does not express this same concern with Alternatives 2 and 3, which would both substantially increase the day ride allocations compared to Alternative 1. The DEIS must analyze and fully disclose the impacts associated with the proposed day ride allocations in each of the alternatives.

The DEIS fails to evaluate the impacts to trail condition of increasing day rides, and it fails to evaluate the increases in dust (a human health concern) in the heavily used trailhead areas. The only two legal approaches to this issue would be to eliminate day rides, or to reduce day rides in these wildernesses to those that are truly necessary under the Wilderness Act. Day rides could be increased outside of the wildernesses to provide horse rides for those who want them, and to provide replacement income for the commercial outfits. (response # 196)

Response: The 2001 Wilderness Plan Needs Assessment identified that the general public does not possess the skills or equipment/stock to day ride in the wilderness. Day riding is a proper wilderness activity. As general public use trends change (2001 Wilderness Plan Appendix D-12, E) towards shorter duration outings, there is increased interest in day ride services. The Forest Service is of the opinion that a large segment of pack station clientele are aware of designated wilderness and wish to experience the wilderness from horseback. A team of resource specialists assessed the amount of day ride activities by alternative looking at many different aspects including current trail condition, risk factors, maintenance considerations, resource impacts and past use reports.

Day use is proposed in Chapter 2 and varies by alternative. Day use is described and environmental consequences are disclosed and compared in Chapter 4.

The comment regarding appropriate levels and types of use is an opinion. The analysis of use levels in the DEIS/FEIS focuses on the conditions or effects of the use levels, as much, if not more, than the use levels themselves. Use levels themselves are arguably more of a social/experiential consideration and in that regard they are considered. But the analysis of use levels is directed towards specific and identifiable effects on the resources. The Forest

Supervisor's Record of Decision describes the rationale in making the final determination of use levels standards and guidelines for commercial pack stock operations.

Spot/Dunnage Trips

Public Concern #127: *Return trips by outfitters to pick up guests that they previously dropped off must be also included in the limits. (response #345)*

Response: Return trips for spot and dunnage are included in Alternative 2 and Alternative 2 – Modified. They are not considered when using trailhead quota mechanisms for managing use. This difference is covered in the analysis and comparison of alternatives (Chapter 4 – Wilderness).

Grazing (grazing comments are in the vegetation section)

Recreational Categories

Public Concern #128: *The Forest Service should not implement the Recreation Categories concept*

- *Because the concept of zoning in the recreation categories is not in the Wilderness Act. Wilderness is to be managed as wilderness or a primitive area and not divided up into many little zones with different regulations about who can be there and under what circumstances. (response # form letter A and F, 34, 275, 355)*
- *Because any deliberate use concentration should be made because it is consistent with appropriate site specific destination management. Beyond this, all members of the public should have free access to the wilderness. (response # 325)*
- *Because the provisions of the Wilderness Act are meant to apply to the entire wilderness. Of the three categories of desired conditions described, only the first would be likely to maintain natural conditions in the wilderness. Wilderness values will not be protected in the Category 3 zones. (response # 392)*

Response: The three Recreation Categories were established in the 2001 Wilderness Plan (ROD pg. 3). Reconsideration of Recreation Categories is outside the scope of this FEIS, which deals with the allocation of use to commercial pack stock operators and trail management in these wildernesses. Alternative 3 does propose some minor adjustments to Recreation Category classifications as a result of field visits by the Interdisciplinary Team. In those Analysis Units changes proposed better match ground conditions with Recreation Category objectives.

Range of Alternatives

Public Concern #129: *The DEIS does not contain a range of alternative capable of complying with the Wilderness Act. Alternatives 1 (implementation of the 2001 Wilderness Plan), 2 (June 2004 Proposed Action), and 3 (Forest Supervisors' currently "favored" action) all would be illegal because they would violate the Wilderness Act's mandate to preserve the wilderness character of the John Muir and Ansel Adams Wildernesses.*

The Proposed Action (Alternative 2) and the "favored" alternative (Alternative 3) would allow substantial increases in commercial pack stock uses, and are so full of loopholes, invalid assumptions, and long-discredited practices that, on whole, the current Wilderness Plan would

be substantially weakened, and the wilderness character would be significantly degraded. The record shows very clearly that current levels of commercial pack stock uses are degrading the wilderness character in the John Muir and Ansel Adams Wildernesses, and Alternatives 2 and 3 in the DEIS would allow for significant, even substantial further growth of these commercial enterprises. The appeals court, in High Sierra Hikers v. Blackwell, has already ruled that such outcomes would be illegal.

These radically irresponsible proposals (Alternatives 2 and 3) are not even suitable as “fringe” alternatives, let alone preferred alternatives. Because they would not adequately protect the wilderness character to meet the mandates of the Wilderness Act, these alternatives should not have been evaluated in detail in this DEIS. In sum, the Forest Service must scrap both of these alternatives, and honestly evaluate a range of reasonable alternatives that can at least minimally meet the mandates of the Wilderness Act to preserve the wilderness character. The Forest Service should develop a range of reasonable alternatives, and re-circulate another Draft EIS for public review. (response # 196)

Response: We believe the four action alternatives (Alternatives 2, 3, 4, and 5) in the DEIS adequately respond to a reasonable range of alternatives. The Final EIS includes another alternative, a modified version of Alternative 2. The range of alternatives and scope of analysis is determined by the Purpose and Need (Chapter 1) and to look at lower use levels and party size than Alternative 4 (or 5) would be beyond the reasonable analysis expected from NEPA. The stated position related to appropriate levels and types of use reflect opinions. The analysis of use levels in the DEIS/FEIS focuses on the conditions or effects of the use levels, as much, if not more, than the use levels themselves. Use levels themselves are arguably more of a social/experiential consideration and in that regard they are considered. But the analysis of use levels is directed towards specific and identifiable effects on the resources. The Forest Supervisor’s Record of Decision considers the legal requirements of the Wilderness Act in making the final determination of use levels standards and guidelines for commercial pack stock operations.

Public Concern #130: *The DEIS does not contain an adequate range of alternatives because the Forest Service fails to provide an alternative that optimizes the public the opportunity to enjoy the wilderness with livestock in a manner that is consistent with the Wilderness Act.*

Congress passed the Wilderness Act for many reasons. A significant goal is to allow man to travel in the mountains for days on end to experience land not significantly altered by man’s modern civilization. Our wilderness areas, and for those of us in California, the John Muir and Ansel Adams Wildernesses, provide us the land so that we may experience the thrill and exhilaration of those original explorers who traveled in the West in the 1800’s. Native Americans had the good fortune to live everyday in that environment before the European migrants forced them off their land.

The Forest Service fails to provide an alternative that allows the wilderness traveler to have freedom of movement and to travel in the wilderness in a manner that Congress intended when passing the Wilderness Act. Alternatives 1-5 fail to adequately give the public an option that permits wilderness travel consistent with the values of the Wilderness Act. A separate and new, Alternative 6 needs to be proposed that relies on primarily external controls and uses site specific management to provide resource protection. (response #275)

Response: An analysis of the effects of internal versus external controls is found in the Wilderness section of Chapter 4. This information is used by the decision-maker to select a management direction that responds to resource protection and visitor access. The analysis has addressed these issues in Chapter 4.

Public Concern #131: *The DEIS does not contain an adequate range of alternatives because the DEIS fails to consider an alternative which is consistent with the protection and devotion of the area to historical uses such as pack and saddle stock and also considers alternatives which are inconsistent with this goal. In addition, the DEIS fails to consider alternatives which propose and evaluate variations to the Forest Service's draft National Trail Management Classes. Given the significance and very concrete impact with these trail management classes will have on the Wilderness Areas, this failure constitutes a violation of law. (response # 401)*

Response: In response to various comments, Trail Class definitions in the FEIS have been slightly modified and clarified to better meet the intended travel management of trails in the AA/JM Wildernesses. These definitions rely on the concepts of the Draft National Trail Classes and the Draft National Design Parameters so that they should be consistent with any future final national Forest Service concepts. The definitions are designed to be specific as to how the Inyo and Sierra National Forests intend to manage trails in these areas.

Public Concern #132: *The DEIS should analyze an alternative that requires that all users travel with a commercial provider, as this will provide the highest level of environmental protection. (response # 428)*

Response: Under the National Environmental Policy Act (NEPA), environmental analyses must consider a range of alternatives that address the significant issues and meet the need for the proposed action. The alternative suggested by the commenter does not meet the purpose and need and is outside the scope of the project. Further, this alternative is not consistent with the Wilderness Act which limits commercial services in the wilderness to the extent necessary for realizing the purposes of the Act.

Alternatives, General/Multiple Alternatives

Public Concern #133: *I believe strongly that the Eastern High Sierra Packers Association's Alternative should be included and analyzed in the Final EIS. (response # 248)*

Response: The Eastern High Sierra Packers Association's alternative was reviewed and considered; however, it was not evaluated in detail, as it was determined it does not meet the Purpose and Need (Chapter 1).

Public Concern #134: *Action alternatives are made up of discrete management elements including destination quotas, daily and seasonal quotas on stock and people, trailhead quotas, trail class and use designations, grazing use levels, campfire closures, and campsite locations. The criteria used for determining the parameters of the elements of each alternative is not well described in the DEIS. For example, the reason for allowing trail sanding on only one pass in Alternative 2, while it is unrestricted in Alternative 3, is not provided.*

The FEIS should describe each management element, its role in the use authorization action, and the environmental effects of the specific element. For instance, describe each type of quota and the likely effect of the specific quota on operator use patterns and operations, client experience,

and on-the-ground impacts. Describe how the parameters of each element in each alternative were developed and chosen. Also explain how internal and external use controls affect use patterns and environmental effects. (response # 427)

Response: The effects of the alternatives, including the effectiveness of internal versus external controls are discussed in some detail in the Wilderness section of Chapter 4. The rationale for why certain elements are in each alternative has been improved in the final EIS. This is not a requirement of NEPA; however, we felt given the complexity of the alternatives, there should be a limited explanation of rationale. The selected alternative (Alternative 2 – Modified), complete with the rationale, is found in the Record of Decision.

Public Concern #135: *The Forest Service should/should not implement a certain alternative.*

Comment: *We cannot recommend or urge adoption of any of the five alternatives. Four and five are absolutely NO. But we find unacceptable provisions in the other three including the Forest Service preferred alternative #2. A plan that would permit and support the continued availability of commercial pack stock operations in the Sierra to service the public who desires and needs their services is the only acceptable action. In the Needs Assessment portion, the writer does conclude that there is a need for commercial pack stations, that it is legal in the Wilderness Act and that it is appropriate. Perhaps a new alternative of the best and least discriminatory aspects of 1, 2, and 3 could be crafted together. (response # 198)*

Comment: *Alternatives 1, 2 and 3 are totally unacceptable as these drafts allow a large increase in commercial pack stock use as compared to present levels. Pack stock use causes documented impacts to the resource far exceeding that which is caused by muscle powered wilderness compatible recreation. The Forest Service must decrease wilderness use by commercial pack stock and mitigate the documented impacts caused by these activities. (response #form letter B, form letter D, 25, form letter B)*

Comment: *I strongly favor modified versions of either Alternative 5 or Alternative 4. Given that horses can have more erosional impact than motorcycles (Wilson, J. P., and J. P. Seney. 1994. Erosional impact of hikers, horses, motorcycles, and off-road bikes on mountain trails in Montana. Mountain Research and Development 14:77-88), stock use in all but a few exceptional circumstances should be prohibited immediately rather than phased out slowly, although I understand that the political realities may require more gradual change. Ongoing exceptions to the ban might include rescue operations, Forest Service work (especially trail maintenance work), and disabled access. These uses are likely to require a low and limited level of use, unlike able-bodied parties paying commercial outfits for special privileges while pummeling the trail and littering it with feces. (response # 367)*

Response: As directed by NEPA, the DEIS and FEIS analyze a range of alternatives with various effects that respond to the significant issues (DEIS pg I-7). The Responsible Officials have selected the alternative they believe best fulfills the Purpose and Need of this planning effort. Comments that state a position for or against a specific alternative are appreciated as this gives the Forest Service a sense of the public's feeling and beliefs about a proposed course of action. Such information can only be used by the Responsible Officials in arriving at a decision and not for improving the environmental analysis or documentation.

It should be noted that the selected alternative (Alternative 2 – Modified) draws on many of the elements of Alternative 2, utilizing the conclusions of needed commercial operations from the Needs Assessment with an articulation of the extent needed in the Record of Decision.

The effects of stock and hiker use on trails are described in the Environmental Consequences section of the DEIS (p. IV-30)

Alternative 1

Public Concern #136: *The DEIS is flawed in its characterization of the environmental impacts of Alternative 1, the implementation of the existing Wilderness Plan (i.e., no action alternative). The DEIS consistently presents arguments that attempt to discredit the existing Wilderness Management Plan, in favor of management direction in Alternatives 2 and 3 that would be even less protective. We in no way endorse Alternative 1 or the existing Wilderness Plan, indeed we appealed many aspects of it. But, we wish to point out this pattern in the DEIS of discrediting the existing Wilderness Plan, while the true implications of the management actions proposed in Alternatives 2 and 3 are never adequately analyzed or disclosed in an objective manner. (response # 196)*

Response: An explanation of the No Action is included in the beginning of the description of Alternative 1 in Chapter 2. The purpose of the No Action alternative is to provide a baseline from which to compare alternatives. We choose to describe the No Action in terms of “status quo,” disclosing that all the potential management direction from the 2001 Wilderness Plan has not yet occurred due to the intervention of the court and limited resources to achieve the court order and implement all aspects of plan implementation. This is not to say that we had never any intention to implement the plan. It is merely a description of what is the status quo. The No Action Alternative is a required alternative and provides the baseline to compare the alternatives to.

Public Concern #137: *Alternative 1 should be implemented:*

- *For the following reasons: a) alternative 2 and above are so restrictive that they will completely remove the opportunity to travel to little used areas. b) The reduction in travel opportunities will require the commercial packers to raise rates to the point it will be impossible to afford to employ a packer. c) Any other alternative will financially eliminate commercial packers from the Sierras. d) The elimination of the commercial packers will make it impossible to make an extended stay camp experience. (response # 363)*
- *With some site-specific controls. (response # 168)*
- *With no reductions in issuing permits. (response # 423)*

Response: The DEIS and FEIS analyze a range of alternatives with various effects that respond to the significant issues (DEIS pg I-7) as directed by NEPA. Various comments on the DEIS express support for one alternative or another. Comments that state a position for or against a specific alternative are appreciated as this gives the Forest Service a sense of the public’s feeling and beliefs about a proposed course of action. Such information can only be used by the Responsible Officials in arriving at a decision and not for improving the environmental analysis or documentation.

- *Because Alternative 1 represents the current level of mitigation and subsequent restriction on commercial pack stock operations in the Ansel Adams and John Muir Wilderness. This status quo, which represents an increase in restriction of commercial pack stock operations over historical activity levels, is the result of a previous environmental analysis performed in 2001 during the development of the Ansel Adams, John Muir and Dinkey Lakes Wilderness Plan Environmental Impact Statement. The Board believes that the 2001 analysis and subsequent mitigation accomplished its purpose. Of the alternatives presented the Board is supportive of Alternative 1, however, it is important that all concerns identified in this letter are addressed in whatever alternative is developed. The Board believes the additional restrictions to commercial pack stock operations, as proposed by the remaining alternatives outlined in the DEIS, to be unnecessary. These additional restrictions would result in significant economic impacts to commercial pack stock activity, an important historical and cultural pastime and a healthy segment of the local economy. Such impacts to the local economy could also result in a significant "ripple effect," thereby negatively affecting the county economy as a whole and impacting individual livelihoods outside the commercial pack stock industry and tourist economy of Inyo County. (response # 354)*

Response: Comment noted. The economic effects of each alternative are disclosed in the Final EIS.

- *Because the Snow Survey Program depends on having sufficient access to conduct these field observations. Summer and fall access is actually more critical than in winter because that is when we can perform infrastructure maintenance on our electronic and manual data collection sites. To that end, we are generally not in agreement with increasingly restrictive limitations on livestock and helicopter use which could adversely affect timely and feasible access to our data collection sites. We favor the "No Action" alternative in the absence of assurances that reasonable and feasible access for our program activities is safeguarded. We have observed through the years that there is a trend in wilderness management that "ratchets" in favor of restrictions, but does not allow for any loosening of restrictions if justified by objective criteria. (response #15)*

Response: None of the alternatives presented would affect access for the Snow Survey Program. Access to infrastructure would be considered administrative use and not subject to the management controls placed on public use of the pack stations. Helicopter use is outside the scope of the FEIS, and current policies are not affected.

Alternative 2

Public Concern #138: *Alternative 2 would allow a substantial increase in commercial pack stock use, and it would eliminate the existing caps on commercial pack stock use. The proposal to eliminate current service day limits and trailhead quotas in favor of quotas on the number of trips is radical, untested, unproven, and unlikely to succeed. Furthermore, the quotas on number of trips are proposed at levels that would allow a significant growth in commercial pack stock use.*

We strongly oppose the proposal to eliminate trailhead quotas and service day limits for commercial pack stock outfits operating in these wildernesses, as proposed in Alternative 2. The trailhead quotas are needed to prevent spikes in use that were identified by the 2001 FEIS (and

the district court) as being a significant concern. The service day limits are needed to ensure that the number of commercially supported wilderness visitors does not increase over time.

Elimination of service day limits would also cause many indirect problems. For example, certain provisions in the outfitter/guide regulations (i.e., Forest Service Special Uses Handbook) regarding service days may no longer apply if service days are eliminated.

The proposed quotas on number of trips per season would allow a substantial increase in commercial pack stock use compared to recent levels. The DEIS does not include a disclosure or credible analysis that compares Alternative 2's commercial pack stock regulatory scheme with past use. (response # 196)

Response: Alternative 2 and the FEIS selected Alternative 2 – Modified both use a destination quota to limit the number of trips. Our analysis shows that it is the number of stock, more than the number of visitors that contributes to the environmental concerns brought forward by the District Court. While we do not believe Alternative 2 – Modified will substantially increase use, we have identified a need for that level of use (Appendix D) that is consistent with maintaining wilderness character in these wilderness. Both the Record of Decision and Chapter 4 of the Final EIS contain an analysis of the effects of Alternative 2 – Modified on wilderness character. It is our conclusion that environmental and social concerns are significantly and sufficiently mitigated by limits on number of trips to destinations and that this mechanism, along with the other regulatory mechanisms in the alternative allow for a level of use that both meets identified need and preserves wilderness character.

Public Concern #139: *Alternative 2 should not be implemented:*

- *Because it seems to be very restrictive to the operator and users of commercial pack stock. This is a very bureaucratic alternative that will be difficult to enforce, monitor, and implement. (response #40)*
- *Because it has not been shown that the changes proposed in this alternative will reverse the downward trend of meadows, watercourses, trails, and campsites utilized by stock. There are no definite limits on stock in this alternative. It appears as though an increase (even a considerable increase) in stock numbers and resulting resource damage (at particular locations) seems possible under this alternative. (response # 392)*

Response: See response to Public Concern #137.

Alternative 3

Public Concern #140: *Alternative 3 should be modified:*

- *So that there will not be a financial incentive for the packers to add unneeded animals to our type of trip. It seems to me that it would be in the interest of the forest to limit the number of animals required for a given number of users. The seasonal client limit in Alternative 3 may lead to the same problem that the Service Days have: groups with small numbers of stock are placed at a disadvantage. I encourage you to simplify the complex system in Alternative 3. (response #13)*
- *By removing the seasonal client threshold from all trails, not just those with single quotas. Although I recognize that people also have an environmental impact, the seasonal client quotas*

seem redundant and entirely unnecessary when group size limits, trailhead quotas, and destination trip quotas are in place to limit the number of people entering the wilderness. In Alternative 3, some trails have daily trailhead quotas that are less than the group size limit. This Alternative does not discuss whether split quotas will be permitted on these trails. I urge you to permit this practice. Since the management plan is concerned with the impacts of pack stock, the plan that is adopted should encourage more trips with low numbers of stock and fewer trips using large numbers of stock with few people. (response # 333)

Response: Comments that state a position for or against a specific alternative are appreciated as this gives the Forest Service a sense of the public's feeling and beliefs about a proposed course of actions. Such information can only be used by the Responsible Officials in arriving at a decision and not for improving the environmental analysis or documentation.

The practice of split quotas would continue in all alternatives except for Alternative 4, unchanged from its current application.

Direction regarding application of the Client and Stock Thresholds in Alternative 3 is described in the DEIS pg. II-42. "At the conclusion of each season actual use will be compared to the established thresholds. If thresholds are reached or exceeded, the responsible officer will make an assessment of the causative factors and potential resource implications. If conditions are within standard (sic) and guidelines, the responsible officer can allow the threshold to be raised with definitive monitoring goals and objectives identified. If any evaluation indicates that conditions do not meet standards and guidelines ore desired conditions corrective actions including reduced thresholds, additional destination quotas and/or campsite or other site specific closures will be considered." Quotas, on the other hand, are limits that cannot be exceeded.

Public Concern #141: *Alternative 3 should/ should not be implemented.*

Comment: *Alternative 3 should not be implemented:*

- *Because it will only allow increased degradation of the wilderness by profiteering commercial outfitters. (response #30)*
- *Because it will allow a substantial increase in commercial pack stock on the trails and it would fail to address the many impacts of commercial pack stock on the trails and pathways of our wilderness areas. The alternative does not set an upper limit on the number of commercial pack trips in the wilderness and increases the group size from 20 animals per trip to 25. (response #33, 36, 145, 166, 179, 230, 396)*
- *Because implementation of the alternative is left to the judgment of the Forest Supervisors who will be expected to rely on future studies and evaluations which may not even occur (response # 166)*

Comment: *Alternative 3 should be implemented:*

- *With the camping restrictions of Alternative 1. (response #40)*

Because it seems to represent a fair compromise, employing trailhead quotas, combined with a limited number of destination quotas, depending on local conditions. We presume that quotas would be altered season-to-season, as a result of monitoring. (response # 175).

Response: See response to Public Concern #137.

Public Concern #142: *Alternative 3 would allow a substantial increase in commercial pack stock use, and eliminate the existing caps on commercial horsepacking use. In this alternative, service days would be eliminated and replaced with non-binding thresholds on commercial stock numbers and clients, which are characterized in the DEIS (at II-42) as general guidance. Besides no longer mandating any binding cap on use, the principal significance of this change is that instead of a service day cap that applies to a particular pack station, the seasonal thresholds apply to particular trailheads, which may apply to multiple packstations. Elimination of service days would have the same adverse effects as described above for Alternative 2. Further, the DEIS does not make a credible attempt to compare the proposed guidance thresholds to historical levels of use, or to the existing service day allocations. Such a comparison is difficult to make, as some destinations in the interior of the planning area may be accessed from multiple trailheads, and by multiple packstations.*

Alternative 3 apparently relies on setting client threshold guidance that exceeds average historical use by an even greater percentage (an average of 73% for these six trailheads) than the stock threshold (32%). But, given that these thresholds are non-binding, and that the allocations are substantially inflated compared to past use, it is not likely that they will result in any limitation on use, either to the number of clients, or the number of stock. (response # 196)

Response: The respondent's comparison uses a mean of three years of data, and two years are at reduced use levels, and then uses the mean to compare proposed stock numbers which indicates a considerable increase. First, this is misleading, as the mean is not a valid approach to measure increases. But more importantly, the objective of the proposed management direction is to manage stock impacts, not to "hold the impacts static." In addition, the objective is to improve conditions where they need to be improved and manage for a range of settings and experiences and conditions that is consistent with the purposes of wilderness and the desired conditions established in the 2001 Wilderness Plan. It is misleading and simplistic to assume that simply an amount of stock relates directly to an amount of impact and that maintaining use maintains a condition. Our selected alternative employs many tools to achieve goals and conditions, and stock controls are only one of the tools we are using to manage for conditions.

Public Concern #143: *There is no explanation in the DEIS as to how the daily quotas and seasonal thresholds are determined and whether any objective criteria are used in calculating these limits. Also, despite the assurance on page IV-27 of the DEIS that impacts to new areas will be reduced over the short and long-term some experts maintain that these impacts to new areas are the most serious impacts. (response # 392)*

Response: See the response to Public Concern #134 above regarding rationale and justification. We have provided more rationale for the derivation of quotas and thresholds in each of the alternatives in the FEIS.

Alternative 4

Public Concern # 144: *Alternative 4 should/should not be implemented.*

Comment: *Alternative 4 should be implemented:*

- *Because this alternative better limits the number of pack stock and impact to the environment (response #153, 305, 313)*

- *Because it follows the letter and spirit of the Wilderness Act. Wilderness belongs to all Americans, and commercial users should not have the right to excessively impact it. (response #110)*

Comment: *Alternative 4 should not implemented*

- *Because it is too restrictive and it reduces service levels (response #40)*

Response: See response to Public Concern #137.

Public Concern # 145: *Alternative 4 should be modified:*

- *With changes to better protect these magnificent wilderness areas. In particular, Alternative 4 needs limits on stock numbers, lower group size limits for stock, fewer (or no) day rides (to protect trailhead areas from overcrowding and trail deterioration), later grazing start dates (to protect meadows and lakeshores from trampling damage), lower “service day” allocations for pack outfits (to address chronic resource impacts), and lower campfire elevations for commercial outfits (i.e., 9,600 feet north and 10,000 feet south, with no exceptions) to protect soil and vegetation. (response #form letter D, form letter G, form letter B, 100, 299, 306 328, 359, 360, 367, 368, 369, 378, 381, 389, 391, 393, 394, 395, 400, 406, 409, 414, 422)*
- *By decreasing the “service day” allocations for pack stock outfitters (from current levels). Allocations for both the number of commercial participants (including crew) and pack stock must be lowered to a level that does not impair the wilderness resource. (response #form letter B, form letter D, form letter E, 36)*
- *By setting clear upper limits on the total number of stock animals that may be used in a group. 25 is too many as is 20. Grazing start dates must be changed to better reflect the cycles of the environment. There are months when soil and lakesides are more vulnerable. High elevation campsites should not have campfires as they are quite fragile and cinder piles leave an ugly mark upon the landscape. Trails without the infrastructure and capacity for stock animals should not be used for stock animals. (response #25)*
- *With maximum allocation numbers identified. An allocation ceiling must be identified for both commercial participants (including crew) and pack stock. Both people and livestock impact the resource, and both must have an identifiable use limit. The identified allocation maximums must protect the wilderness from impairment. Wilderness as a resource should not be sacrificed for the profit margin of commercial activities in wilderness. Identifying maximum use limits assures that the resource will be protected while still allowing commercial Activities. Daily use limits must be established. Commercial activities must be limited by a maximum daily use limit to decrease weekend and holiday crowding. This is only fair as such limits apply to the general public who do not use commercial services. (response #form letter B)*
- *With changes to strictly limit stock numbers and the places they go. One head of stock for two people is adequate in the wilderness; for a group of six, a decent maximum that is three mules, six horses to ride if they must and one for the packers, ten head of stock (response #93)*
- *By reducing the current limit of 20 animals per group. (response #145)*
- *With no increase in use above prevent levels. This includes present day rides groups, size of overnight parties (both customers and stock animals), daily trailhead quotas (like those imposed on backpackers), no campfires where fires are not presently allowed, and no stock cross-country*

travel. There are also good reasons to lower items such as party size and trail quotas. (response #98)

- By reducing the service day allocation to address degradation of the wilderness character that has occurred, and is occurring (and being exacerbated) by current levels of commercial pack stock use. The DEIS incorrectly assumes that the service day allocations proposed in Alt. 4 represent a reduction in actual use. The DEIS fails to acknowledge that the service day allocations in Alt. 4 would result in significant growth (approximately 36% growth) of commercial pack stock enterprises over time, and it fails to acknowledge the resulting impacts associated with that growth;

Add controls on the number of stock, not just people. The DEIS identifies the following concern with Alternative 4: "With a reduction in people serviced and controls on people, not stock, there is a potential for stock numbers to increase. (IV-27)." The obvious remedy for this concern is to limit the number of stock animals, as well as people. This is the only way to achieve the goal of reducing the stock/client ratio, which would optimize the number of commercial pack stock-supported visitors that could visit the wildernesses, for a given level of impact;

Allocate commercial horsepacker service day allocations by type of service (i.e., spot, dunnage, full-service, day ride, re-supply). Each type of service impacts the resource and wilderness character to a different extent. Thus, the most effective means to manage these impacts would be to establish limits for each type of service;

The Forest Service must take a more conscientious and reasonable approach to the approval of user trails. Scientists have long recommended that stock animals should not be allowed to travel off of designated, maintained trails, except in rare cases where site-specific environmental analyses demonstrate that a specific route can be open to stock use without increasing erosion rates or otherwise adversely affecting the wilderness character. Yet the Forest Service simply approved most of the off-trail travel routes requested by the commercial packers, without even surveying the routes and surrounding environmental conditions. (This is a clear violation of the District Court's injunction, which required the Forest Service to follow specified criteria for approving off-trail use by commercial packstock. One of those criteria is that such routes must be existing, visible trails;

Reduce the elevational campfire closures to 9,600 and 10,00 [sic] feet north and south of the San Joaquin River, respectively, with no exceptions;

Reduce the group size limits for travel on designated trails to maximum 12 persons-per-group, maximum 10 stock animals-per-group, and for off-trail (cross-country) travel a maximum of 8 persons-per-group, with no stock animals allowed off-trail, except for grazing at approved forage areas;

Eliminate day rides within the wilderness areas;

Alternative 4 lowers some commercial trailhead quotas so that many are less than 15 on major trails and does not allow split quotas (borrowing). This latter provision removes a loophole that allowed large groups to gain access to a low use/quota trailhead by seeking the services of a commercial packer.

Without these modifications to Alternative 4, it fails to preserve the wilderness character. (response # 196)

- *By reducing the commercial packstock service days to eliminate day rides, eliminate 1-way dunnage trips, and eliminate full-service trips for all but truly disabled folks. (These just aren't necessary. Focus necessary commercial stock use on spot/dunnage trips to allow wilderness access for people who can't hike or carry a pack; such trips are the lowest impact); reduce the maximum group size limit for commercial outfits to 12 persons and 20 heartbeats, maximum (on designated system trails), with 8 persons and zero stock animals off of system trails; include limits on stock days to prevent commercial stock use from increasing over time; do something to require dogs to be under control. (I am so tired of being harassed by dogs on Forest Service lands. Take a look at the rule in the Emigrant Wilderness, which is a good, fair approach); lower the campfire elevation to 9,600 feet (north) and 10,000 feet (south) to be more consistent with the surrounding parks & protect high-elevation ecosystems. (The existing fire elevations are bogus & were established based more on politics than wilderness protection); remove all drift fences from the wilderness. (They're just for packers' convenience, and aren't necessary); come up with a more realistic plan for regulating grazing (i.e., don't allow grazing where stock can drift into sensitive "closed" areas).*

Maybe if you do these things you will regain the public trust as well as make progress toward proper wilderness stewardship. Alternatives 1-3 are bankrupt bad ideas and/or business as usual. It's time for the Forest Service to rein in the packers, take control, and make some decisions that protect the wilderness character, instead of the commercial packers' wallets.

Oh, and by the way, the idea of allowing packers to haul firewood into closed areas is ridiculous. It's unenforceable. They won't follow the rules. You'll have on-going problems forever. Just forget about granting special exceptions to the commercial outfits. It won't work, and it's not fair. (response # 346)

Response: These suggestions for modifying Alternative 4 are addresses in Chapter 2 of the FEIS in *Alternatives Considered, but Eliminated from Detailed Analysis*. This alternative was not considered in detail because we believe that merely reducing commercial services to arbitrary levels below Alternative 4 does not demonstrate a corresponding improvement to the condition of the wilderness and justify the draconian reduction in public access to these wilderness areas. In effect, "Modified Alternative 4" is the same as Alternative 5 in that the severe restrictions proposed for this alternative would likely result in a number of the commercial operators going out of business and quite possibly the eventual elimination of commercial packing services in these wilderness areas.

Alternative 5

Public Concern # 146: *The Forest Service should/should not implement Alternative 5.*

Comment: *The Forest Service should implement Alternative 5.*

- *Until the agency can regain its regulatory independence and, by protecting wilderness for future generations, serve the public. (response #100)*
- *Because given the dishonest treatment of history, the clear bias in favor of commercial companies, the poor analysis, and the generally useless nature of the document to allow a true understanding of the current situation, Alternative 5 is the only alternative that will address the ongoing harm being caused by these companies. (response #105)*

- *Because of the negative impacts related to pack trains. (response # 319, 353, 356, 371)*
- *In a manner that phases the pack stock operations out over a couple generations as these operations are usually family-owned. (response # 396)*
- *Because Alternative 5 is the only alternative that is in accord with the purpose of the proposed action and the requirements of the Wilderness Act. (response # 392)*

Comment: *The Forest Service should not implement Alternative 5.*

- *Because stock has always been a part of the wilderness. (response #40)*
- *Because the Forest Service has shown a need for these services in the Needs Assessment (response #277)*
- *Because there is nothing in the DEIS that would support this draconian alternative (response #277)*
- *Because closing down commercial pack operations is not appropriate. I think that the Forest Service should continue to work with the parties involved including the packers, find areas of concern, and do what's needed to mitigate those concerns in order to come to an agreed upon solution. (response #44)*
- *Because it is unnecessarily draconian. With proper limits, it seems that pack stock led by responsible commercial outfits can be accommodated in the wilderness along with those entering on foot. (response #145)*

Response: See response to Public Concern #137.

Public Concern # 147: *The DEIS's evaluation of Alternative 5 does not have rational validity. In discussing Alternative 5, the DEIS states that, "Campsites will likely not improve since they will continue to receive use and impacts have already taken place. Only with additional management would campsite rehabilitation, containment, and improvement to the site take place. It is likely that without the commercial use, this work would have less of a chance of getting done, whereas if commercial use were to continue the improvements to campsites, access, size and proximity to water would occur under Alternatives 2, 3 and 4." (IV-29) These statements do not make sense. Conditions at campsites would improve significantly without the holding of stock, etc., as the sites recover over time. And there is no valid reason to conclude that campsite rehabilitation would be more likely to take place if commercial pack stock impacts continued to degrade them. (response # 196)*

Response: Research does indicate that once an impact reaches a point, unless there is significant mitigation, the impact will persist and recovery will be very slow. Specifically, forested environments where soils has been severely compacted, will take some time to recover regardless of use. Sites that have moisture and do not get continued use, may recover quicker. But the campsites that commercial pack stock has frequently used will continue to get use from backpackers, private stock, just at a lower use level.

Public Concern #148: *In discussing Alternative 5, the DEIS states that, "It is also possible that with the removal of stock there may be an increase in backpackers. Those hikers and backpackers that have avoided areas where pack stock use is high may plan more trips than they currently do." Thus the Forest Service acknowledges that current levels of commercial stock use displace noncommercial visitors. However, they inaccurately portray the situation, in that there*

cannot be an increase in backpackers without an adjustment to the non-outfitted trailhead quota. Alternative 5 does not provide for re-allocating the excess capacity formerly used by commercial operators to the non-outfitted public, which has a demonstrated need and demand for it. Thus, the DEIS omits a significant implication of Alternative 5, and fails to disclose its true impact to the public. (response # 196)

Response: It is correct to say that Alternative 5 does not provide for re-allocating the commercial pack stock use. There is no indication that the non-outfitted public has demonstrated a need and demand for additional use or that capacities have been reached. Chapter 3 shows the number of days non commercial quotas are being filled, which do not show that many days are currently filled (one exception is the North Fork of Lone Pine which is a hiker only and the commercial quota is non pack stock). And, even if quotas are being filled, it does not constitute a need to raise the quota just to meet demand, as the ultimate objective is to preserve wilderness character which includes environmental and social considerations. The alternative does not address future public allocations, primarily because the purpose of this alternative is to demonstrate the effects of eliminating this user group, not replacing that use with additional non-public use of a different kind. It is not even considered a reasonably foreseeable action in this alternative to increase the non-public use, since, as stated above, there is not a significant demand for that use.

III. Environmental Consequences

Commercial Pack Station Operations

General

Public Concern #149: *The Forest Service should encourage packstock operators to invest in and use lightweight equipment that reduces the number of packstock required and the consequent environmental effects. (response # 399)*

Response: The Forest Service does encourage the packstock operators to invest in lightweight equipment, and other minimum impact techniques, as required of the *Annual Operating Plan, Appendix E, Resource Protection/Leave No Trace Practices for Stock Management*, and is considered part of the administration of the special use permits. The Forest Service also encourages permittees to view the video *Caring for the Land, Stockpacking in the Sierra* for minimum impact stock use in the wilderness and to attend Leave No Trace, Stock Masters training.

Public Concern #150: *The Forest Service should not micromanage commercial pack stock campsites, campfires, and grazing. (response #32)*

Response: The Forest Service is engaging in site-specific management of wilderness resources, not commercial pack stock. The site-specific nature of the destination management strategy allows the agency to pinpoint resource concerns and apply the appropriate measures to remedy the problem.

Public Concern #151: *Packers should be required to use dung-catchers on their animals and to pack out their excrement. (response # 318)*

Response: The use of dung-catchers is not practical, nor safe, for the animals on steep mountainous terrain. The Forest Service does not consider this a practical means of operations, nor is it identified as a significant resource issue.

Public Concern #152: *The pack trains should stop at the wilderness border. The commercial outfitters should be given an additional permit only when they can show proof that they went out and spent a week repairing damage to trails, meadows, streams and trees that they caused. That seems fair—one week of repair for each new permit and no access to areas designated as Wilderness. (response #12)*

Response: As demonstrated in the Needs Assessment and the analysis in the Final EIS, commercial packing is a legitimate use in these wilderness areas. It should also be noted that commercial packers already assist with trail maintenance.

Public Concern #153: *If the Forest Service is serious about reducing the stock/client ratio, then they should propose a real mechanism for doing so. Currently, the billing practices of commercial packstations, whereby clients are charged based on the number of employees and pack stock utilized, favor maximizing the stock/client ratio. Commercial horsepacking is not operated in the same way as a freight-hauling business, where the hauler charges based on the*

quantity of freight, and the hauler has an incentive to minimize the amount of equipment used and maximize its efficiency. (response #196)

Response: Forest Service did consider and evaluate control mechanisms that directly or indirectly affect business practices and number of stock used by pack stations. However, control mechanisms were generally designed to protect wilderness resources and not specially to provide “incentive to minimize the amount of equipment used and maximize its efficiency.”

Public Concern #154: *The DEIS does not adequately disclose the effects to operations including: (all comments from response #275)*

- *Sawmill Pass will be closed to commercial stock. Essentially wipes the option away in the future for pack stock to take a trip into Kings Canyon. And, the way the alternatives are written, commercial pack stock probably won't be able to exit either.*

Response: Based on the Table 2.3.1, page II-85, DEIS, Alternative 1 proposes the Sawmill Pass trail as trail class 3. Alternatives 2 and 3 designate the Sawmill Pass trail as trail class 2. Both designations allow access by commercial stock. Alternative 4 proposes trail class 1, “Not suitable for Commercial Stock.” All trails were assessed using various standards by the Interdisciplinary Team. The Forest Service understands this difference in opinion and considered this comment while developing the FEIS.

- *Red's Meadow Pack Station won't be able to originate trips and head south on the Muir Trail. No allocation for stock headed on the John Muir Trail from Red's Meadow.*

Response: This was an omission in the DEIS and will be corrected in the FEIS.

- *Operating areas will give each operator a monopoly. Rock Creek Pack Station will not have the ability to operate trips on the John Muir Trail. Possibly 2 trips per year from Rock Creek to Yosemite. Who is going to get to do those trips?*

Response: Alternative 2 – Modified has removed the concept of operating areas.

- *Stops most traveling trips. The document does not disclose that campsites on Mono Creek where you can graze and have a nice camp have been closed. There isn't enough grazing to support less than three or four trips per year;*

Response: Traveling trips will be allowed. It will be the pack station's responsibility to work within the decision parameters.

- *Grazing going from Mono Creek to the Fish Creek area has been closed off; Once you get to Fish Creek area you can't spend more than one night since there is a one night stay (essentially won't be able to fish any of the lakes unless it is a spot trip).*

Response: comment noted

- *Cost of any traveling outfitted trip will increase significantly. The document indicates cost will increase 25%. The document does not disclose that with only two trips a year, the cost will rise to the highest bidder.*

Response: The Economics section of Chapter 4 discloses that there is potential for the cost of some trips to increase as a result of new restrictions and regulations. Exactly how expensive these trips will become is somewhat speculative.

- *Hiking with stock trips will be unable to go down the Muir/PCT trail because of designated campsite and controlling operating plan areas.*

Response: The DEIS analyzed campsites, as identified by the packers. The Forests believe enough campsites will be designated in appropriate places to allow hiking with pack support to continue. If clients wish to stay at a site that has not been designated as a stock camp, the stock and staff can continue on or return to the designated stock camp.

- *Alternatives 2 and 4 substantially increase wilderness use for dunnage and spot trips. The Wilderness Act was supported and promoted to protect the continuous traveling trips like the Sierra Club trips.*

Response: The agency's interpretation of the Wilderness Act does not include this contention that the Act was passed to protect traveling trips.

- *The trail system in Hilton Lakes and Tamarack Area has been closed. (response # 275)*

Response: Although commercial pack stock use is managed, the trail system in the Hilton Lakes and Tamarack Area has not been closed.

Public Concern #155: *The DEIS does not describe existing environmental conditions at the Pack Stock Stations. Nor does the DEIS evaluate potential environmental effects of these Pack Stock Stations or the effect of commercial pack stock use authorizations on the environmental conditions at the Pack Stock Stations. The FEIS should include a description of existing conditions at Pack Stock Stations, especially those located on Forest Service land. Evaluate the potential environmental effects of action alternatives and use authorization on existing conditions. For example, describe existing conditions and potential effects of reduced or increased use authorization on water quality, meadow conditions, and threatened and endangered species habitat at Pack Stock Stations locations. (response # 427)*

Response: Analysis of the pack station operations and facilities not in the Ansel Adams and John Muir Wilderness are outside the scope of this EIS. The scope of the analysis is displayed in the DEIS (pg. I-7). Impacts at the base stations and in areas outside the AA and JM will be appropriately considered in the analysis to reissue the authorizing Special Use Permit for the entire pack station operations.

Operations, Llamas

Public Concern #156: *The Forest Service should not be allocating use to llama operators.*

Comment: *There is no historical precedent and llamas are not part of the historical pack stock use nor are they heritage resources of this John Muir Wilderness, nor the Inyo and Sierra National Forests' trails, and use. Why is this proposal even included in the document? Why take use from our established pack stations that are suffering from the 2001 Wilderness Plan and Court ordered reductions. This particular llama user has illegally used the Inyo and Sierra National Forests and Sequoia/Kings Canyon with no permit. Even after operating illegally, the operation is assigned twice as many service days than an established, legal outfit such as Sequoia Kings Canyon Pack Outfit. (response #279)*

Comment: *Llamas have a greater impact on the landscape compared to mules; for example, they can't carry as much weight, tend to browse brush and trees and transmit diseases to Bighorn Sheep. (response # 311)*

Comment: *IV-20 Chapter IV - third paragraph to say that 500 more service days for commercial llamas will have no additional effect on resources is wrong.*

It is the duty of the Forest Service to state what the impacts of llamas and 500 more service days of people will have on the environment.

- 1. Where do the llamas graze?*
- 2. What is the impact on llamas on water quality?*
- 3. Which areas of the wilderness will llama groups travel to in the wilderness.*

One needs to look at the impact of commercial llama parties because the llamas traditionally only go five to seven miles per day. That means that llamas in the Rock Creek area will be going to Little Lakes Valley, Hilton and Ruby Lake if they are going over Mono Pass.

And, by allowing llama packers to compete with the commercial quota of a regular packer you will have commercial mule and horse packers utilizing other areas that they wouldn't have used prior to competition with llama trips.

Llamas are a new use and inconsistent with the Wilderness Act. It is a new use and the needs assessment in the EIS for the John Muir and Ansel Adams Wilderness area fails to show they are needed. (response # 275)

Comment: *The USFS proposes to add llamas to the trail and allot high use levels to them. There has been little demonstrated need for llamas and it appears as though the agency is creating demand where none currently exists. (response # 279)*

Response: The 2001 Wilderness Plan identified a need for a small amount of llama packing services in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. Alternative 2 – Modified modifies that direction by reducing the allocation from 500 to 250 service days from the 2001 Plan.

Pack Station Specific Comments

Cottonwood

All comments are from response #38

Quota

Public Concern #157: *Alternative 2, Quota: While I disagree with this type of regulation completely, I will comment on the specifics: 50 trips to Cottonwood – one spot trip has always been considered “a trip.” It was never thought of as two trips. Further, since I am limited to 25 round trips, I will be forced to take only spot trips (since I can rent more stock on this, with clients riding and all clients taking at least one pack mule). Also, I will be forced to sell as many as all-expense trips as I can. This makes no sense! It discriminates against the dunnage trips/hikers who want help carrying their gear. This is just reworded service days will the same problems.*

Response: The number of trips assigned was determined using the packer reported use in recent years. Reported use summaries are part of the planning record. Reported two way spot and dunnage trips were split out as two trips, in and out, in the analysis data. Hence, the high reported reflects a two way service as two trips. Refer to table in App B. of the FEIS, page B-1, Table 1 Pack Stations Use by Analysis Unit for summary of reported use.

Spot and dunnage services are considered separate and have a separate allocation of trips from all expense services. Although it is possible to wait for large parties, or for spot trips instead of dunnage, it is probably not practical or probable from a business standpoint. But, the more important point is that this is the same level of use that has been occurring. If currently businesses are not waiting for larger groups or spot instead of dunnage, it is likely that will not start happening with a different mechanism, however monitoring and adaptive strategies are built into this alternative in order to respond to unintended consequences or unacceptable impacts.

Public Concern #158: *Alternative 2, Quota: Trail Crest – 10 trips – what does this mean? What if the trips are continuous hire? The EHSPA MOU agreed there would not be a limiting number on one way dunnage where the clients hiked over Trail Crest.*

Response: The ten trips identified for Trail Crest include one-way services provided, including spot or dunnage, where the client hikes out to the Whitney Portal unguided by the pack station.

The allocation of 10 trips for Trail Crest reflects the Wilderness Plan established reservable quota of 25. Chapter 2, Alternatives 2 and 3 propose a maximum of 10 trips. This use is analyzed in Chapter 4. There are relevant issues raised by Sequoia Kings National Park that affected the selected alternative quota. The EHSPA MOU does not direct the decision.

Public Concern #159: *Alternative 2, Quota: Seasonal and Daily Stock Limits: 35/day; 300 season: this is an unreasonable number. If I had to use 35 head/day – this would be less than 75 clients round trip (when you include packer horse) – there is no way I can maintain a viable business with this number. It could mean less than 50 people per season based on the number of stock/party and the necessary packers needed. This is unworkable, with 300 head of livestock per season, I could hit my quota in less than 9 days of operation.*

Response: Stock numbers per day and season were determined using recent reported use data which is part of the planning record. Refer to the table in Appendix B., page B-1 for a summary of use in the Cottonwood Analysis Unit. The high stock use reported into the John Muir Wilderness was 296 in 2001. Based on historic use patterns, it is unlikely that use will be maximized as described. This analysis considers use only in the John Muir Wilderness. Service provided into the Golden Trout Wilderness is a large component of Cottonwood Pack Station's total business. Comment noted and considered in developing the FEIS.

Public Concern #160: *Alternative 3, Quota: There is no way with a 300 seasonal stock that I can accommodate 200 clients. In reality, the client threshold is less than 75 (when packer stock are counted). To overlay this with 15 daily quota is overly restrictive. This is flawed math. I cannot remain viable with this kind of restricted number. It is apparent that the only type of wilderness user the Forest Service desires us to cater to is the backpacker/hiker.*

Response: Reported use data for the Cottonwood Lakes Basin is part of the planning record. Stock numbers per day and season were determined using reported use data. Refer to table in Appendix B., page B-1. Forest Service considered this comment when developing the FEIS.

Trails

Public Concern #161: *South Fork Cottonwood Creek, Ref #148 – there is no reason to close this trail, especially if I want to use it for day and ½ day rides to make a loop trip. This trail is not user created – it was built by a Forest Service crew, it has rock structures and layout. It was rumored to have been built about the same time as New Army Pass by the Army Corps of Engineers. It was the main trail to Lower South Fork Lake and Cirque Lake.*

Response: Some segments of this trail show some very simple trail structures, and it is likely that some basic design was incorporated at one time; however parts of the trail are located in some sensitive areas with risk factors, and would be hard to maintain under recurring use. If this route were used frequently as a loop trail—either for day rides or for traveling between South Fork Meadow camps and the Cirque Lake and Cottonwood Lakes Trail—it would need to be maintained at a much higher level to maintain stability. The Cottonwood Lakes Trail is a well-built and maintained trail which accesses the same destinations, so access to these areas is provided on a stable route.

Public Concern #162: *UT 140 and UT 141 – This should not be closed. Nobody camps here. This is very necessary for my ½ day and all day rides. This is where fisherman like to be dropped off. If these trails are closed, the fisherman and hiker will still be there. Fish and Game’s employees spawn fish in these lakes and this will continue. Chapter 4 claims that these trails should be closed to reduce foot traffic around the lake, closing the trail to commercial stock will not change this. This is discrimination.*

Response: The Cottonwood Lakes System Trail provides access to the outlet of Lake 4 and Lake 5, where clients can be dropped for angling. UT 140 is a trail that leads to and along the back sides (west shores) of Lakes 4 & 5. Clients can still walk this trail, but commercial pack and saddle stock will be prohibited.

System trails or approved use trails provide access to the same destinations that UT 141 would, along Lake 2 and Lake 3. The location of UT 141 on the map may be in error, as no stock-used route is visible west of Lake 2. In either case, the use trail duplicates access with system trails.

Day Rides

Public Concern #163: *There should not be any limit on day rides as long as there is no limit on day hikers. 200 is the number used in Alternative 2 for Cottonwood. While that number is workable, there should not be a number. Alternative 3, day rides: There should be no numbers counted on day rides. This is discriminatory. While 200 is a nice number (better than 41), it is unreasonable to limit this use. The service is supplied to visitors in Lone Pine, there will never be an overuse. There is no reason for this number and it restricts my ability to maintain a viable business as day rides provide needed cash flow especially as wilderness use is restricted.*

Response: This EIS is concerned with disclosing the environmental effects of commercial pack stock not day hikers. The day ride allocations in Alternative 2 and Alternative 3 represent the average day use over the last three years. Alternative 2 – Modified (the selected alternative) does not include a specific limit on day rides, but rather relies upon a total number of stock in the wilderness cap to provide maximum flexibility to the commercial operator.

Designated Camping

Public Concern #164: *Camping Limitation: My historic camp at Muir Lake has always been at the east end of the lake. This is my historic all-expense camp. There is a trail to this camp, it should be mitigated to allow this use as I have very few options. The public does not desire to stay at the west side camps. Many hiking groups use the camp as the east end.*

Response: The selected alternative does not limit access to historic pack stock camps on the east at Muir Lake, II-37. The current route to the camp has some resource concerns and risk factors, so access will be allowed via a designated alternative route. If no practical alternative exists, some stabilization of the current route may occur.

Public Concern #165: *The DEIS does not adequately disclose the implications of allocating several more trips-per-year to SEKI, and several trips to locations in the planning area for which there are no records of permitted historical use.*

Alternatives 1, 2, 3, and 4 would allocate overnight service days to Muir Trail Ranch for the first time, despite stated concerns about resource impacts, overlapping operators, and conflicts with other wilderness users. There has never been an official allocation of overnight service days for the Muir Trail Ranch, which the DEIS fails to acknowledge.

We are adamantly opposed to any overnight service day allocation to Muir Trail Ranch. The Florence Trailhead, from which Muir Trail Ranch operates, was assigned a resource rating of Red-Yellow in the 2001 Wilderness Plan. (response # 196)

Response: The current permit for Muir Trail Ranch authorizes a total of 319 service days of use consistent with the 2001 Wilderness Plan allocation. Prior to this permit, they had been authorized a total of 500 service days. The use recorded for the “high two” as shown in the 2001 Wilderness Plan was recorded by the permittee as day use. This was based on the definition found in the Outfitter-Guide Administration Guidebook which states that day use is “Outfitting and guiding involving no overnight use of National Forest System Land.” Muir Trail Ranch has guided clients to the SEKI Park for many years. Although the clients remained in the park overnight, it was still recorded as day use because the park was not National Forest System Land and they did not spend the night on the Forest. However, under the 2001 Wilderness Plan this same use was defined as Packstock Supported Overnight Use. Based on this new definition the use into SEKI should have been converted to Packstock Supported Overnight Use in the 2001 Wilderness Plan. It was not changed because the Sierra NF was either not aware or did not understand the difference in definitions. This is corrected in the DEIS – Alternative 1 by splitting their current 319 service days between day rides (184) and overnight use (135). The total service days have not changed and this merely brings the Muir Trail Ranch service day allocations into alignment with current definitions. These mistakes were discovered when the 2001 Wilderness Plan was implemented in 2002.

Use figures based on tally sheets for Muir Trail Ranch show the following totals: 2001 was 185 day rides with one trip to Evolution Valley in SEKI for 2 service days with 3 head of stock (This trip in 2001 was prior to implementation of the 2001 Wilderness Plan and understanding that this would be considered Packstock Supported Overnight Use by the Wilderness Plan definition), in 2002 there were 150 day rides, 2003 there were 115 day rides and one trip to Evolution Valley in SEKI for 10 Service days with 5 head of stock (Packstock Supported Overnight Use using the Wilderness Plan definition). This trip to Evolution was previously recorded on the spreadsheet as day use, 2004 was 115 day rides with no trips into SEKI.

The “Red, Red/Yellow Trailhead Evaluation” from the 2001 needs assessment was not specific to commercial uses. Some areas, such as Blayne Hot Springs were given these concern ratings yet had little or no relationship to commercial pack station use. The use levels proposed for Muir Ranch were considered and evaluated in the FEIS, and found to be compatible with preserving the wilderness character.

Public Concern #166: *The DEIS fails to document or demonstrate that there is need for an additional packstation to offer overnight services in the Florence area when High Sierra Pack Station and Lost Valley Pack Station already offer these services.*

In 2004, High Sierra Packstation utilized only about one-third of their service day allocation, while Lost Valley Packstation substantially exceeded their allocation. Florence is one of the busiest, if not the busiest trailhead on the west side. The Forest Service should be proposing ways to limit use, reduce conflict, and protect the resource in this area, not allocating additional commercial use.

Response: The DEIS does not propose an additional pack station to provide services in the Florence area. The 2001 Wilderness Plan identifies the four pack stations that are in the area and allocates service days. In the case of Muir Trail Ranch the service days are shown entirely in Day Rides, which is in error, 135 of the 319 service days shown should have been categorized as Overnight Use. The correction does not represent any change in use, but merely reflects a clerical error in the 2001 Wilderness Plan. The correct allocation of service days is shown in Alternative 1 in the DEIS.

The DEIS discloses that overlap may occur in the Florence/Bear area and may increase, but this is not identified as an issue. The Preferred Alternative (and Alternative 2) in the FEIS proposes use that is controlled by very specific destination quotas, along with daily and seasonal stock numbers. Overlap of different pack stations is not in itself an issue since the destination quotas limit each operation to a specific number of trips to a particular location or zone. The numbers of trips were allocated appropriate to the destination, “Generally locations that were suitable and sustainable were identified for potential growth while areas where impacts were high or current use was of a concern were identified for reductions” (DEIS pg. IV-482).

In 2004 Lost Valley Pack Station had no use.

Public Concern #167: *The Forest Service must analyze the non-conforming use of the access road to Muir Trail Ranch and Lost Valley Pack Station.*

Vehicular use of an access road to Muir Trail Ranch and Lost Valley Pack Station has not been previously disclosed and is creating significant impacts. In a FOIA request submitted in 1998 to the Sierra National Forest, we specifically requested all documents related to non conforming uses in wilderness, including vehicle access to private in-holdings. No documents specific to this request were supplied, so we were left with the impression that this was a nonissue. The 2001 Wilderness Plan FEIS did not identify the several mile long four-wheel drive road and motorized access as an issue or non-conforming use, nor do the Special Use Permit and Operating plans for Muir Trail Ranch and Lost Valley Pack Stations. This begs two questions: (1) what authorizing instrument was used to establish and justify this non conforming use; and, (2) was an analysis and public process performed under NEPA?

We first learned of this situation in the DEIS (at p. IV 481 & 482):

“Both Muir Trail Ranch and Lost Valley have private in holding within the interior of the wilderness boundaries. A four wheel drive access trail to private in holdings will continue as a non conforming use. The presence of the road has both experiential and environmental effects. Multiple trailing has occurred due to confusion, desire for direct access to east bound destinations and historical grazing by the pack stock associated with the permittees in the area. This causes some confusion and a high density of trails in a small corridor. Both the presence of the road and the confusion and resource impacts of multiple trailing can diminish the wilderness experience for users. Both the private in holdings and their associated four wheel drive access trail impact wilderness character.”

This statement identifies negative impacts to the physical resource, the experience of visitors, and the wilderness character, but then indicates that this non conforming use will continue and measures to mitigate the situation are not up for discussion. The Forest Service cannot permit additional/new services from either the Muir Trail Ranch or Lost Valley Pack Station. Law and policy require that non-conforming uses such as vehicular access to inholdings should have been analyzed prior to commencement of such activity. An analysis of this non-conforming use must meet the standards in the Wilderness Act. Until this analysis is completed, or documents provided that indicate this analysis has been adequately accomplished, this non-conforming use should cease. (response # 196)

Response: Muir Trail Ranch has a Special Use Permit that was issued to them on July 13, 1956 for the purpose of “Using and maintaining an existing public jeep road between the boat landing at the southeast end of Florence Lake and the Muir Trail Guest Ranch. The road is to be used for hauling freight and guests between these two points and to a lesser extent for the same purposes by other landowners in the Blayney Meadow Area.” A previous Special Use Permit for this road was issued to Nate R. Combs on Jan. 2, 1948.

The area surrounding the Muir Trail Ranch became wilderness as part of the California Wilderness Act of 1984. The jeep road to Muir Trail Ranch is mentioned in a Committee report (Report No. 98-40) on pages 21 and 22. In this report it is stated “As a final matter, the Committee notes that the boundaries of the wilderness additions were drawn with the understanding that traditional motorized access will be allowed in the private inholdings within the wilderness by special use permit. The particular lands in question are owned by Karl Smith of Ahwahnee, Fred Ross of San Jose, and David and Miriam MacKenzie of Menlo Park. Current access to those inholdings is by primitive road from Florence Lake to the inholding itself. The committee intends that the designation as wilderness will not preclude the Forest Service from continuing to issue appropriate special use permits for access to and from those properties.”

The Wilderness Act (Section 5. (a)) provides for “...such rights as may be necessary to assure access to such State-owned or privately owned land...” Initiation of an analysis of the access to the private lands is outside the scope of the FEIS. This access is under long standing Special Use Permit that pre-dates wilderness designation. The right of access is based on private land ownership and long term private businesses that occur on private land and not on the off-site pack stock portions of the landowners businesses. The FEIS analyses the use of pack stock on National Forest System lands that occur off the private land.

Rock Creek Pack Station/Mt. Whitney Pack Trains

All comments are from response #275

General

Public Concern #168: *The Forest Service has already decided to eliminate Mt. Whitney Pack Trains. In the Executive Summary they have removed Mt. Whitney Pack Trains. When you read through the entire 1000 page document you will see that the Forest Service decides to eliminate this most historical pack station. That is because the Forest Service has decided to have spot and dunnage trips. Mt. Whitney is typical of the style of packing the Wilderness Act intended to save.*

And realistically, the Congress was more aware of Mt. Whitney Pack Trains because it was the main packer to the Sierra Club. How ironic that the Forest Service in 2005 proposes four times the use for llama operators as the historic Mt. Whitney Pack Trains. (response # 275)

Response: The Forest Service is not eliminating Mt. Whitney Pack Trains. In the DEIS, Alternatives 1 through 4 analyze the services provided by Mt. Whitney Pack Trains (Alternative 1, page II-7, proposed current Wilderness Plan service day allocations). Alternative 2, as proposed in the June 2004 Proposed Action distributed for scoping, pages 74 and 83, allows a service day allocation and seasonal and daily stock quotas. (The DEIS service day information for Alternative 2 was left out inadvertently.) Alternative 3, page II-41, proposes a service day allocation and existing daily trailhead quotas. Alternative 4, page II-56 proposes a reduced service day allocation from current Plan allocation. All alternatives were described and analyzed in Chapter 4. There are no base facilities authorized or used in conjunction with the Mt. Whitney Pack Trains operations. The selected alternative analyzes Mt. Whitney Pack Trains as an authorized outfitter/guide providing pack stock services. Pack stock operators under outfitter/guide special use permits will be counted in existing daily trailhead quotas. The Forest is not eliminating full service trips offered by commercial pack stock operators. The selected alternative has revised the extent of llama operations.

Trails, Comments on Chapter 3

Public Concern #169: *There are a number of trail-related discrepancies in the Draft EIS that affect Rock Creek Pack Station.*

Comment: *III-80- Disagree with assessment of trail at Second Crossing.*

Comment: *III-92: The Mono Pass Trail was put in without adequate water bars. The standards of construction were not followed with complicity of the Forest engineers. It is not the heavy use that destroyed them but lack of maintenance and proper water bars.*

Comment: *III-93 Trails in 3.2.1.3 Hilton Trail System*

The plan says that the trails on the Hilton Ridge are simply shortcuts. Not true. This was the original trail to Davis Lake and has been continually used since 1919. The trail to Lake #3 has not been maintained or poorly maintained since according to Keith Waterfall, the Deputy Forest Supervisor said not to maintain it until the Trail Plan was finished so that there would be a place for the llamas to go.

The Pine Grove to Hilton Lakes trail is used by stock. It is a vital link between the Lower Corral and the Hilton area.

The trail that the writer says is a shortcut is shown on the main Inyo National Forest as a system trail. It is improper for this document to imply that a system trail is shortcut. And, to remove a system trail since the 1920's with wrong and deceitful information is improper.

Why doesn't the Forest Service say that they don't maintain the trails, clear logs and this is the reason there are bypass trails. And, many of the trails are from stock out grazing. Inadequate analysis of the whole trail system in Fourth Recess AU.

As part of this DEIS, the Forest Service should include their trail maintenance plans for the various regions the last 20 years. This information combined with a history of the new trails and reconstructed will help the public in their analysis.

Comment: III-94 *Fails to say that the Third Recess Trail has not been maintained or water bars kept in place. Wilderness managers and some elitists in FS want this to be a stock free area and purposely didn't put any time or money into trail. When and how much money was spent on this trail over last thirty years?*

The shortcut trail you describe is a main trail that was primarily used by the Westside packers to get to Pioneer Basin. And, it has always been in use as a trail. It is not a shortcut but a regular trail.

Comment: III-95 *We use the Second Recess trail crossing all the time. "impassable?" It shows how little the Forest Service knows about what is going on in the wilderness. We have repeatedly asked for fixing the crossing to make it easier. However, the wilderness management team purposely has refused to let the trail get more difficult.*

This is another perfect example of how those elitists in the Inyo and Sierra National Forest achieve their personal aims to eliminate stock when management direction stated to maintain the trail.

Comment: III-138. *Shepherd Pass. Shepherd Pass can be maintained if there is management direction to move rocks near the top. Inyo Management doesn't want stock up the trail and purposely spends all the money close to the road so it is easy to get home.*

If there was proper staff and direction, a few good men could clean the rock and maintain the Shepherd Pass Trail. A Sierra Club volunteer group maintained the trail for a few years ago and it was a wonderful trail.

Comment: *We strongly object to the Forest Service removing the system trail that the DEIS calls 2904C. This has been a system trail and is not a cutoff. The Forest Service fails to analyze the effects of removing a trail that disperses use and allows for a significant amount of stock to travel to Davis Lake without affecting other users at Lake #2.*

The trail to Lake #2 from Rock Creek is very poorly constructed and the steps are difficult for livestock, children and disabled people. This DEIS implies throughout the document that this is a cutoff trail. The Forest Service needs to be honest to the public.

Please refer to our previous correspondence regarding this trail from Rock Creek to Davis Lake. This trail should be maintained at a class 3 or 4. The Forest Service proposes closing this trail because it allows the District Ranger and Wilderness Manager to exert control over the commercial packer. This is primarily a personal vendetta instead of decision based on resource concerns and the general public.

The Pine Grove to Hilton trail should be at least maintained for a 2 or 3 and it is a good trail from the Lower Corral to Hilton.

It is good to maintain the trail to Lake #3 and Lake #4. The trail to the 5th-9th lake should have maintenance to keep the water from further eroding the trail. Commercial stock should be allowed as it has been since the early 1900's.

The trail system in Pioneer Basin is not correctly drawn. Need to allow for user created trail that cuts across the dry section from Lake #2A over to the trail coming from Mud Lake to Lake #4. This is environmentally the best route and allows you to travel to the tarns.

We have provided comments in writing and orally regarding the trail system in Hilton Lakes, Tamarack Basin and Little Lakes Valley. We would like those comments and submitted maps to be considered as part of this record.

Local Forest managers propose a highly bureaucratic set of rules and regulations that increase jobs and responsibility for Forest Service mid-level officials and their ever increasing staff. Where is the money and commitment by Congress to fund the staff to monitor and manage the ambitious programs in Alternatives 2-5?

Trails are closed such as the trail from Long Lake up towards Morgan Lake where the Sierra Club trip of 1963 camped. An ideal campsite and the area is beautiful and in excellent shape. However, the Forest Service restricts use to this camp. Access is good and the resource is protected.

Comment: *Disagreement with specific trail assessments and decisions:
Second Crossing Use Trail*

Hilton Trails – Maintain UTs to 5th, 6th, 7th, 8th, 9th Lakes.

Pine Grove to Hilton – Critical access from lower corral.

Hilton Ridge Trail and Hilton Cutoff – put back on system.

Mudd Lake to Mono Creek Camps Use Trail – add to system.

Third Recess and Second Recess – just need better maintenance.

Shepherd Pass Trail – Just need better maintenance.

Pioneer Basin – Incorrect locations and decisions.

Response: Trails were assessed using a team of specialists looking at many different aspects on each trail, including current trail condition, risk factors, maintenance considerations, resource impacts, consistency with other destination direction, and records of past recent commercial activity. An objective assessment process was followed on trails visited by the IDT. It is understandable that there may be different opinions about these trails, and these comments were individually considered for the selected inventory in the FEIS. Where appropriate, the comments above were incorporated into the Final EIS and Alternative 2 – Modified.

Public Concern #170: *We do not feel that this document adequately discusses removing system trails such as the Hilton trail. In page 33- it says, “trails removed from the inventory generally did not exist on the ground and there appeared no reason to provide transportation management to this destination.” However, this DEIS does not follow this procedure when eliminating trails in the Rock Creek/Hilton drainage.*

Response: Another factor considered in removing trails from the system is whether there is duplicate access provided. While the primary Hilton Lake trail may have some isolated characteristics that are not comfortable to equestrians, this trail is generally stable and can sustain repeated stock use.

Public Concern #171: *III-95- We disagree with your comments that the Goodale Pass Trail is stable. It is deteriorating rapidly and is treacherous for stock. It is probably more dangerous to stock than the Second Recess Crossing. The Forest Service calls the Goodale Pass Trail good*

and Second Recess Crossing impassable. A perfect example of the inconsistencies of writers of the plan not having a clue about stock use and trails.

Response: Goodale Pass trail is generally stable and in good condition in the Graveyard AU (south of the Pass). However, on pg III-81 in the DEIS, the description of the Goodale Pass Trail in the Silver Divide AU, (north of the Pass), states: "...it is in degraded condition" and compares it with a nearby use trail as "equally awkward, with jumpoffs and erosion."

Campsites

Public Concern #172: *Designated campsites are a terrible consequence to the public and not consistent with the Wilderness Act. And the closure of camping from Third Recess to Second Recess is even worse than having a few camps. The Forest Service proposes a few designated campsites for Rock Creek Pack Station and fails to tell the public what that impact will have when they go to take a pack trip.*

Response: The purpose and need in the DEIS (Chapter 1, I-5) clearly states the agency's intention to follow the legal constraints of the Wilderness Act. There is no language in the Wilderness Act that prohibits the designation of campsites. Reference DEIS Chapter I-3, Purpose and Need for Action, Item 1, states: "There is a need for establishing additional management controls for commercial pack stock operations in order to achieve and maintain desired resources and experiential conditions identified in the 2001 Wilderness Plan and ROD." The Record of Decision for the 2001 Plan gave the Forest the ability to establish designated sites (page 4) in order to protect wilderness values. We believe that designated campsites are consistent with relevant laws, regulations and agency policy. Refer to DEIS, III-96. The Mono Pass Trail has been identified as an area of special American Indian concern and is currently considered and evaluated as a potential Traditional Cultural Property. Use of campsites known to be located directly on cultural sites is known to have direct impacts.

McGee Creek Pack Station

All comments are from response # 355

General

Public Concern #173: *We prefer alt 2 with seasonal stock quota and seasonal day ride service days being replaced by total number of stock allowed by the Permit.*

What we would prefer to see: Limit number of livestock on the McGee Creek Pack Station permit to 65. Determine highly visible spot/dunnage and stock holding camps as: Horse Heaven, Sheep Camp, Point Camp and Hilton Camp in Upper Fish Creek; Genevieve Cloverleaf and Edith (no stock holding unless authorized by line officer on special occasion); Davis lake outlet camp; Round Lake and Grass Lake in McGee Canyon. Then, repair all access, reinforce any stream banks or crossings necessary. This work should be done cooperatively by the end of summer 2006. Until then limit number of stock to Clover-leaf/season to 50, with a definite sunset by the time Special Use permits are issued. Maintain trails to other lakes and campsites as determined by trail alternative's 1 & 2. (Alternative 1 plus 2 trips/year to Meadow Lake). Make a designated tie up area at Round Lake and Beaver Meadow. Allow caching of feed in bear proof boxes out of sight of the public, especially in overnight spot trip areas. Allow spot and dunnage trips access as done historically to low use areas on a limited basis. (1-2 trips/year - counted as 1 party/1 trip)(areas such as Meadow Lake, Lee & Cecil Lakes, Constance Lake.

Allow spot and dunnage trips to all other areas as provided by limited number of livestock on permit. Limit day rides by number of livestock on the permit, allow mitigation needs for higher use areas, (day ride tie up or turnaround areas, etc). Further concerns, mitigations, emergency measures or problem areas can be addressed by the annual Operating Plan written by the Permittee, the District Ranger and the Permit Administrator.

Response: All of these comments were considered in the Final EIS and when Alternative 2 – Modified was created. Some of the suggestions above are beyond the scope of this project. Once completed, the SUP EIS document will give the District Ranger and the Permit Administrator the authority to determine mitigations measures for problems and emergency situation under the annual operating plan.

Day Rides

Public Concern #174: *Day rides - McGee Creek numbers (in the best possible scenario! Alt. 3 - the alt. that allows for growth) increases our numbers by nine! There should be no number on Day rides, until and unless the FS analyzes day use by all users. The court did not ask for day use to be limited in anyway. There is no significant rationale for this small amount. Day use should reflect demographics. Increased visitation to the Mammoth Lakes area; shorter vacations filled with more activities. Horseback riding is one of those activities. Overnight wilderness use is decreasing steadily - the demand is for short, daily experiences. When businesses are being overly penalized in one area, we should not be burdened with additional penalty in not allowing ANY growth in day use. Alt 2 has a reduction of 40 clients, this is not ok. Again, there should be no numbers, but if day riders are to be counted essentially with service days there should be a minimum of 900.*

Response: Specific limitations on day rides are not included in Alternative 2 – Modified. Rather, a stock in the wilderness at one time cap is implemented. This will provide additional flexibility for operators wishing to provide day rides.

Day use outside the wilderness will be considered under the SUP EIS. Opportunities for expanding short, daily experiences will definitely be addressed under the SUP EIS with an emphasis on developing opportunities for growth in non-wilderness areas.

Quota

Public Concern #175: *There is disagreement as to the quota and threshold numbers allocated to McGee Creek Pack Station in the Draft EIS.*

Comment: *McGee Creek - too many quotas and thresholds. Allocation limitations need to be dictated by the number of stock allowed on the permit for overnight use and for day use.*

As shown the seasonal client threshold discriminates against the spot and dunnage trip groups. The Seasonal stock threshold does not allow the public to enjoy wilderness as they see fit. Congress dictated that these Wilderness areas should be ‘untrammeled’ - not controlled by human device. This multiple layering of quota’s, thresholds, etc certainly restricts and controls the ability of the American public to enjoy their Wilderness areas. We disagree with these methods. We continue to advocate for the one appropriate method of ‘limitation’ - the number of stock allowed by the permit. This allows the business owner to balance cost with demand. In turn this provides maximum quality service due to a healthy business operation.

Comment: McGee Creek Pack Station advocates for a maximum number of livestock allowed by the permit. A total of 70 head of livestock to be used to supply public demand.

Comment: Alt 2: Seasonal Stock quota of 700 too low. Allows only 14 days of operation at maximum. It also allows for a possible maximum of 300 spot/dunnage trip visitors. When packers stock is included, this is a very low number, highly restricted from past years, with no reason.

Comment: Alt 2: Destination quotas based on low years of court injunction - this appears discriminatory. It appears as if there is no understanding of our business operations - a spot trip should never be counted as "2" trips. A spot trip is one round trip service. To count a round trip dunnage as 2 trips is also irregular and discriminates against the lower 'impact' type of trip. Due to campfire closures in upper McGee, the number for Grass Lake is too low. Same with Horse Heaven - campfire closures increase the need for use of areas open to campfires. Numbers for Cloverleaf, Genevieve and Hilton are also too low. We appreciate the ability to take 1 trip a year to Meadow Lake. Rock Creek has 44 trips to Hilton Lakes, most of which are All-Expense with stock, while ours are mostly spot trips. Our low number should be raised.

Comment: The "seasonal threshold for McGee Creek is lower than the current allocated Service Days. Further, it is half of pre-2001 Wilderness Plan use. It would likely allow for service of fewer than 200 people per year. The Stock threshold discriminates against the spot trip party forcing us to provide only dunnage services! This is a forced loss of revenue!

Comment: The Laurel Quota and Seasonal Stock Threshold ignores the admitted errors in the 2001 wilderness plan where data of commercial use was ignored or forgotten. This DEIS continues the same error. This trail is heavily used to access the Convict basin and is the only way to access the basin. By lowering the quota to half of the legal party size it becomes impossible to accommodate larger families. This is a huge basin, the many camps are ideal for groups of 10-15. Use by the hiking public is limited, there is no rationale for the overly restrictive numbers. The seasonal stock threshold of 80 is impossibly low. This would mean only 2 spot trips of approx. 7-8 could enter the basin in 1 entire season. This is RIDICULOUS! No where is there a rationale for this low number. NUMBERS SHOULD BE RAISED TO DAILY Quota of 15, "Seasonal stock threshold of 500. Regarding quota, even Cloverleaf Lake allows a group of 15 - yet the reserveable quota does not allow a group of 15 to enter the Wilderness.

Comment: Trail Crest - page II-44. It is beyond our understanding why the Forest Service considers a trip commercial when hikers hike out in 1 day over trail crest with the packer carrying their gear back to the starting trailhead. Why would the Forest want to block and deny the very use they should be encouraging in order to reduce overnight stays on the Mt. Whitney trail? 40% of the quota should remain available as stated, the statement "but are currently unguided and unsupported to exit Trail Crest." should be dropped. "Exit Trail Crest" also establishes the improper use of an exit quota.

Comment: Destination Quota's - Limiting Cloverleaf to essentially 2 spot trips is not supported and there appears to be no rationale for why this would improve the current condition of the trail. (See party size comments). Limiting the entire Convict basin to 18 trips or 9 spot trips is not supported. Limiting Tully Lake to only 2 spot trips is not supported.

Response: Comments noted and considered in the FEIS. The six alternatives propose quotas, thresholds, maximum number of stock in wilderness at one time and stock limits at pack stations. Allocation of service days were developed by using the highest year of a three-year average. These service days included and counted the spot and dunnage trip as two days which reflects the current operation—not a decrease.

Trail Crest Exit Quota was established prior to the 2001 Wilderness Plan and was supported and retained at that time; this trail provides additional access to the Mt Whitney Trail which is the most heavily used and regulated trail in these two wildernesses. Commercial guiding is not needed or authorized on the Mt Whitney Trail except for special circumstances. Pack stock use is prohibited. No additional management direction is necessary for Trail Crest.

Alternative 2 – Modified provides for unguided trips by commercial pack operators.

Primary Operating Areas

Public Concern #176: *Primary operating areas are assigned yet Pine Creek given trips in Hilton. This is not a warranted decision. There is not historic use of the Hilton Lakes basin by Pine Creek Pack Station, nor is it a primary operating area.*

Response: Primary operating areas will be assigned under the SUP EIS document.

Party Size

Public Concern #177: *Party Size - Tully Lake is reduced by party size as well (8) in this alternative - With limited numbers of trips (2) why reduce the party size as well. Limiting the Tully Lake campsite to groups of only 8 is not supported by any reasonable rationale. The legal group size should be allowed. Using Recreation categories to rationalize this limit is a violation of the Wilderness Act.*

Response: Tully Lake area was assessed using a team of specialist looking at campsite density and carry capacity of the area. It was determine that the Tully Lake area could accommodate a party of eight or less without increasing the degradation of the wilderness character along with a total number of two trips a year.

Trails

Public Concern #178: *There are a number of trail-related discrepancies which affect the operations of McGee Creek Pack Station.*

Comment: *I-117 Trail 2802 - Trail displayed as Level 2 and as NRFS. Trail should not be reduced from level 3 to level 2. Not appropriate for access to area. This is the main canyon trail. Lower part (which is no longer accessible to stock) should be distinguished as separate from rest of trail.*

Comment: *I-118, Trail 2802A - Dorothy Lake Spur. This is a major trail to access only camps at Dorothy - Should not be Level 1.*

Comment: *I-119, Trail 2804 - Laurel Lake to Edith, (use trail continues to Cloverleaf). This trail was built by the Forest Service trail crew and is currently the only access for stock to the Convict basin. Trail is major route to the canyon due to closure of Convict Canyon trail (by default - lack of repair), should be a Level 3 not 2. Trail from Edith to Cloverleaf Creek Crossing is the same as the system trail, it is not a user trail. Currently user trail is better trail than*

system trail. System trail needs to be repaired and maintained. No maintenance has been done for over 20 yrs. on that trail.

Comment: I-120, Trail 2902C - Baldwin Canyon. Should be a level 3 Trail. THIS IS A MINE ROAD! Should not be downgraded due to Forest Service lack of maintenance. The only needs are water removal. Very simple fixes. Currently there are wooden and steel culverts on the road which are plugged up.

Comment: I-121, Trail 2902 C - Baldwin Canyon - Should not be downgraded from a Level 3 to 2. Again, this is a mine road! Simple maintenance would resolve minor issues of water running down the road from summer thunderstorm activity! Should not be reduced due to forest inefficiency or lack of resolve on the part of past trail/wilderness manager. HIGHLY CONTESTED - in Trail Suitability Table - this is TOTALLY CLOSED TO Pack Station in ALT. 3!!! This is discriminatory - how does the Forest distinguish use by commercial stock vs. private stock. This is heavily used by private stock owners from Mammoth!!!! Alt. 2 should be adopted. Further this road has the potential to be a Heritage Resources designation.

Comment: I-122, Trail 2902D - Steelhead lake. Should not be reduced to level 2. Major access to 2 lakes of McGee Canyon. Very popular areas, with high use. Beginning terminus confusing?

Comment: I-124, Trail 2902F - Baldwin Cutoff. It is appropriate as shown in Alt. 3 - should be Level 2 trail class, as long as trail always allows use by Pack Station. Beg. & End. Terminus description is incorrect: Beg. Term is 1.2 mi above junction of McGee Pass Trail and Baldwin Canyon Road. Ending terminus is at McGee Pass Trail above Steelhead junction.

Comment: I-125, Trail 2902G - Big McGee Lake - Level 2 is appropriate as shown in Alt's 1 - 4, as long as open to Pack Station stock.

Comment: I-126, Trail 2907*- Hopkins Pass. This trail should not be listed as 0. It was present at the time of wilderness designation. Should be maintained on the inventory, even if at Level 1.

Comment: I-127, Trail 2902, McGee Pass - appropriate as shown in Alt. 3: Level 3.

Comment: I-128 - I131 are appropriate.

Comment: I-132, Trail 2000.3, PCT - this should trail should remain as a Level 4 trail in Alt. 3, (as in Alt 1 & 2).

Comment: I-136, Trail 2902H - Tully Lake - need to have historical access to Tully lake via whichever trail is deemed safe and appropriate

Comment: UT87 - Cloverleaf North of Creek. This trail is approved in Alt. 1 & 2 until the system trail is repaired. It should also be approved in Alt. 3 under the same conditions.

Comment: UT93 - Baldwin Cutoff. Use is approved until Canyon/McGee Pass trail is fixed. (Designation of trail is incorrect). Once Canyon Trail is repaired, Baldwin cutoff needs to still be approved for use for ACCESS to campsite. This access can be stipulated from one trail or the other, but at least from one, most likely the Baldwin Canyon Mine Road trail.

Comment: UT94 - Round Lake campsite - which "new route to relocated campsite"? What needs to be done as identified by Inyo Line Officers is re-enforce the stream bank.

Comment: *UT95 - CCC Camp site access - is approved in Alt. 2 but Prohibited in Alt. 3. This trail should be approved in alt. 3 as there is assigned use in the Alt. 3 to the campsite. This was a packer camp long before it was used by the CCC.*

Comment: *CANT FIND HILTON LAKES DRAINAGE IN System Trail Table 2.3.1 (Recieved by email from Marty Hornick 6/6/05). Hilton Trails 2942 should remain Trail Class 4. The rest of the Hilton trails look appropriate.*

Comment: *As for improving access to the CCC camp above Big McGee, that is a good idea. However in Alt. 3 access is denied until "Heritage Clearance". This is unreasonable. This was a packer camp long before it was a CCC camp. Further, Packing is a "Heritage Resource" and campsites are a major component of the activity.*

Response: See response to other trail specific comments for Public Concern #169.

Public Concern #179: *System and Use Trails to Lee Lake and Cecil Lake from McGee Pass Trail should be maintained and open to stock.*

Comment: *I-133, Trail 2810, Lee Creek - Check McGee Creek Pack Station files - trail was wheeled by Diana Pietrasanta in 2002. The system trail (1988 inventory) is Level 2, 1.5 miles. This takes the trail to Cecil Lake. The 2001 Appendix C, shortened the trail to .8 mi (although inappropriate action). Even so, .8 mi takes the trail just past Lee Lake. This table lists the trail to "Sheep Camp" as .4. This is incorrect. Sheep Camp is .1 from the McGee Pass trail Junction. This is an error. The trail should remain at Level 2 to Lee Lake.*

Comment: *I-134, Trail 2810 - this is part of the same trail above. Should be maintained at the same level to NE Lee Lake. This entire trail is of historical significance and has potential to be listed as a Heritage Resources designation.*

In Trail Suitability Table - Lee Creek trail above Sheep Camp is closed to Commercial Pack Stock in all alternatives. DISCRIMINATORY! It is open to private stock. Yet the 'trail' to Hortense - admittedly a non-system trail is available for use. The trail does not even exist - yet a system trail to Lee Lake is closed. FIX THE TRAIL, don't close it. Further, in Chapter 4, page IV341, the Agency admits no use will not improve the resource concerns. In addition, the concerns will continue to multiply unless restorative work is done. The restorative work would include the same requirements to re-store and repair the trail. In addition, due to what appears to be pre-planned, pre-determined outcome of the CEA-EIS - the Forest missed an opportunity to repair these concerns during Fish Creek Watershed project where a trail crew did work for 2 summers in the area in 2002 and 2003.

Comment: *UT109 - Cecil Lake - trail should be allowed for grazing, historical access. Campsites*

Response: Trail and resource concerns in the trail corridor to Lee Lake are some of the most severe in the planning area. While it is true (as with other trails in the planning area) that the resource impacts will not naturally recover without active physical management, removing recurring stock use from this area will likely slow the rate of further degradation. When physical repairs are made, their chance of success will be increased without recurring equestrian traffic.

Camping

Public Concern #180: *On page II-35 - why is it written: "Designate 2 stock camps at Horse Heaven - 1 site only"?*

Response: This editorial error has been corrected in the Final EIS.

Public Concern #181: *Designated Camps: after much thought, we disagree with this practice. It will provide opportunity for the anti-stock, anti-commercial advocates to pinpoint our use, and will not allow the flexibility required to serve the public.*

Response: Designated camps are an important part of the Destination Management Strategy which allows the agency to pinpoint resource concerns and remedy any resource-related problems related to commercial pack stock. See also responses to Public Concerns #106 and #172.

Public Concern #182: *Limiting groups camping at Cloverleaf Lake to only 8 head of livestock is effectively no more than a spot trip of 3. This is discriminatory. The only consideration here is the trail, the public should not be denied a normal experience due to the Forest Service's lack of quality trail maintenance. This regulation should be temporary at most, with a 'sunset' date of 2 years allowing time for the trail work to repair the short section of trail. This work needs to be done as currently there is no reasonable system trail access to a lake which is shown on the inventory as having a system trail. This is misappropriation of funds - if the Forest submits a certain number of miles of system trail for funding purposes, the lack of maintenance on those trails should not be used as means to discriminate against the recreating public.*

Response: Due to the geographical nature of the Convict drainage and the carry capacity of the Cloverleaf area, eight head of a stock at one time was determined to be the appropriate stock size for the conditions.

Rainbow Pack Outfitters

Public Concern #183: *In forest decisions that were both arbitrary and capricious, the number of head we were authorized to have in the barn went from 80 head to 40 head, upon the purchase of our outfit in 2000. Also, the service day numbers for our outfit went from 800 down to 400 service days per season. The grazing allotment that had historically belonged to Rainbow Pack Outfit was put on hold, citing resource concerns and the need for further analysis, which is yet to be done six years later. These are the kinds of slow and inefficient management technique that hurt our historical businesses. Lakes that had been historically used by Rainbow Pack Outfit and were named by the packers that discovered them have been closed off to use. Access to lakes like Marie Louise, Margaret Lakes, Tyee Lakes, Ruwau, Chocolate Lakes, and Ledge Lake, has been taken away from us. The proposed trail closures that take the access away to these lakes means a 33% decrease in the destinations in our basin where we can take the public. Without documented resource concerns, it is wrong to take away historic use by the trail management proposals, that are discussed in the DEIS (response # 279)*

Response: Decisions made at the time of pack station purchase are outside the scope of this analysis. The permit holder has been notified since purchase of the pack station in 2000 that use of pastures would be analyzed during pack station term permit reissuance; and, the use of these pastures is being analyzed the subsequent EIS and therefore outside the scope of this analysis. In terms of the areas closed to commercial pack stock (e.g., Marie Louise Lake), there are documented resource concerns within the planning record.

Sequoia Kings Pack Trains

All comments from response #311

Public Concern #184: *There is an error on page ES-10 – the operation is referred to as Sequoia Kings Pack Trips.*

Response: Comment noted; correction made in the FEIS.

Public Concern #185: *The DEIS proposes to reduce the ability of the operation to serve 800 people to 212.*

Response: Respondent is referring to use allocations prior to the 2001 Wilderness Plan. The Wilderness Plan set allocations based on packer provided use reports, as policy directs. This current allocation is described in Alternative 1. The DEIS provided a range of alternatives to address levels of use. Alternatives 2 and 3 as proposed do allow for additional use. Use levels in the selected alternative reflect discussions and input from Sequoia Kings National Park.

Wilderness

Public Concern #186: *The public needs to accept that there will be some areas in designated wilderness that are simply going to be more heavily impacted and thus perhaps need to be more heavily regulated – than other areas dues to their popularity, ease of access etc... Examples of such areas include Thousand Island Lake and Little Lakes Valley. Use should not be shut off to commercial pack stock in these areas, but measures can and should be taken to assure that such areas aren't further degraded by wilderness users. (response # 216)*

Response: Alternatives 1, 2, 3 and 4 all continue use to the areas mentioned and standards and guidelines proposed in each alternative represent measures to assure no further degradation and remedy of unacceptable impacts.

Public Concern #187: *Commercial use should follow strict use restrictions as it is a non-conforming use of wilderness and could be accommodate in non-wilderness areas. (response # 170)*

Response: Commercial outfitter and guide services are not non-conforming uses, they are allowed by the Act to the “extent necessary” for meeting the purposes of the Act. The stated Purpose and Need of this environmental analysis is to assess the need for commercial service and manage this need so as to preserve the wilderness character.

Public Concern #188: *There is a discrepancy between the figure on page III-14 that suggests the number of people visiting the wildernesses is increasing at a rate of approximately 500 people per year and the data from the last four years that shows the number of visitors have stabilized or may be decreasing. (response # 248)*

Response: The Table on page III-14 is for the Sierra National Forest only. The table does show that on the Sierra NF overall trend from 1996 to the present is upward, but that over just the last four years the trend is downward. The FEIS presents a revised chart for the Sierra NF that incorporates a longer timeframe that shows an overall downward trend from 1991.

Public Concern #189: *Stock supported wilderness travel does not contribute to high quality wilderness experience. In fact, livestock seriously interfere with human use and enjoyment of the wilderness, the objective of seeking primitive and unconfined experience and opportunities for solitude certainly is not furthered by the presence of livestock. Solitude is foregone by parties that travel with stock. (response # 392)*

Response: Some visitors hold this opinion. Other visitors are achieving their wilderness experience on recreational stock, which is a form of transportation that is consistent with wilderness purposes. Conflicts in values, experiences and perceptions are a significant factor and are considered in the effects to wilderness character portion of this analysis (see the Environmental Consequences for Wilderness in Chapter 4).

Public Concern #190: *The DEIS improperly relies on claims by the commercial outfits that they spread the minimum-impact message. The DEIS implies that wilderness character would suffer if commercial pack stock enterprises were reduced, because the commercial packers effectively educate wilderness visitors about proper wilderness behavior, and that the positive impacts of the packers message is greater than their impacts. There is no basis in fact for this claim, and it is, frankly, ridiculous.*

The Forest Service should refrain from repeating anecdotal statements by commercial packers that they provide wilderness ethics education, unless they can provide evidence to support this claim. The available evidence indicates that the commercial packers do not provide effective low-impact education to their clients or others. (response # 196)

Response: The analysis has been reviewed and statements that are believed to be anecdotal and not properly referenced have been removed.

Wilderness, Social Considerations

Public Concern #191: *The DEIS does not include a discussion of the effects of commercial pack stock-related manure and urine on other user groups.*

Comment: *There is no discussion in the DEIS of the impact of large quantities of manure on the hiking experience. (response #241)*

Comment: *Impacts from pack animals, including urine and feces on the trail has made recreating in the wilderness unpleasant for other users. (response # 178)*

Response: This experiential component has been considered and addressed in the Wilderness section of Chapters 3 and 4 of the Final EIS.

Wilderness, Comments on Chapter 3

All comments are from response # 198

Public Concern #192: *On page 111-76 there is a correction. Historically, McGee Creek Pack Station did the necessary packing for the Federal Fish and Wildlife Service who were studying fish in upper Convict Lakes Basin for a number of years. The canyon trail along Convict Creek was used. In 1953 and 54, that trail was in good shape. McGee also took some private pack trips to the lakes that Convict could not handle. Convict was mostly conducting day trips then. The Summers Mammoth Pack Outfit used the Laurel Pass trail beginning in the early part of the century or before. The Summers ran cattle up into the Laurel Meadows and owned some mining claims up there. When the Roesers bought Mammoth Lakes Pack Outfit, we used the Laurel Pass Trail to the upper basin beginning in the early 1960's.*

Response: This information has been added to Chapter 3, "Wilderness –Fish Creek-Convict-McGee"

Public Concern #193: *More corrections on page 111-78. The DEIS mixes up two of the lakes, Papoose and Squaw, in the Lakes of the Lone Indian basin. This is understandable since some old commercial map first made the error and then other maps followed suit. Papoose Lake is the lake on the John Muir Trail. Squaw Lake is the lake to the east and adjacent to Lake of the Lone Indian. That is the correct designation from the Forest Service trail crew who were working on the Silver Pass Trail in the summer of 1949. The switching of the 2 lakes occurs throughout the document.*

Response: We will note the historical names for these lakes; however, since every map and guide for at least 35 years has shown it the same as named in the DEIS we feel it would be confusing and outside our jurisdiction to change these place names back to their 1949 names.

Public Concern #194: *There is incorrect information contained in the Wilderness section of Chapter 3. (All comments are from response #275)*

Comment: *The assessment of the affected environment makes no attempt to assess whether the impacts that the FS calls “high, noticeable & bad” are from people or stock. The camping impacts are generally the effects of people and not stock. And, there is little to no determination of non-commercial to commercial use.*

Response: It is not possible to determine if impacts were caused by private stock, commercial stock and in some case from hikers instead of stock. There are some impacts that are clearly related to stock (i.e., roots exposed at tree wells in areas void of vegetation and apparently used for high lines, at or adjacent to campsites). The analysis clearly states that the purpose was not to determine cause of impact, but to record the conditions where pack stock have identified their operation and determine what, if any, management actions are needed to continue this use. Where pack stations identified their campsites, trails grazing, we assessed the condition and proposed actions for managing into the future.

Comment: *Page III-76: The Forest Service makes the comment that D&F conducts few full service trips over Goodale. In the last ten years there has been significant use. And, most of the trips went to Grassy Lake and the stock remained for the duration of the trip.*

Response: Refer to Appendix B, Table 1 in the Draft EIS to see that recent use by D & F Pack Station has not been significant in the area accessed over Goodale Pass. Refer to the destination quota table in DEIS, page II-20. The quota for D&F reflects their use over the last 4 years. Use data does not reflect this statement. Use by D&F has been light.

Comment: *Page III-76: The writer says Rock Creek’s use was limited by resource concerns. The major concern was over competition for customers.*

Response: The limitation on use by Rock Creek Pack Station was indeed based on resource impacts resulting from all expense traveling trips. The concern was not over competition for customers, but an overuse by all outfits of the area. Authorized officers at the time specified an amount of use by Rock Creek in response to primary operator concerns.

Comment: *Page III-76: Grazing numbers of stock for 2001- 2003 wrong. Missing data.*

Response: We have reviewed and updated our files regarding grazing data.

Comment: *Page III-77 The Forest Service says impacts are high relative to use levels occurring. What impacts and compared to what? Perhaps the Forest Service is lacking use data*

and the impacts are low compared to the use. Also, other private stock users and hikers are using campsites that cause impact.

Response: See pages 6-7 and 12 for a discussion of the methodology for categorizing use levels and impacts.

Comment: *Page III-78: The Forest Service does not indicate that the camps in Cascade Valley show heavy impact. The heaviest used campsites of the 1980's barely show any use. It proves that large numbers of people, with large numbers of stock can result in campsites that are fine.*

They make note of a highly disturbed Third Crossing campsite. This has been a relatively small used campsite compared to others in the region.

In summary, the description of the campsites of the 2nd Crossing to Island Crossing is totally lacking in being comprehensive.

This analysis of the affected environment does not disclose the number of campsites, who used them historically and why they don't show recent use. Lacking is the historical record of use. Unfortunately, the writers of the plan look at one year or perhaps a few years of use.

It is interesting that in Court documents, the plaintiffs use wilderness ranger's comments indicating the harm to the wilderness when up to 75 animals per night were grazing in Cascade Valley per night up to 3 nights a week. Contrast that to the occasional trip of 20 that frequents the area the last few years.

This Cumulative Effects analysis of this area is poorly written and does not allow that average reader a good understanding of the historical and current use patterns. Neither does it adequately present an analysis of what things look like on the ground.

Response: Comment noted and appropriate changes are made in the Final EIS.

Comment: *III-89: False Statements: "Conflicts with Rock Creek"? We never have had a conflict with High Sierra Pack Station in Mono Creek over grazing, use, packers, etc.*

Response: In a personal communication, the "conflict" was identified by High Sierra Pack Station as an explanation why they do not do as many trips into Pioneer Basin. Another way to present it is that some operators have chosen not to be in conflict with other packers by not going to certain areas. This situation was what was meant by "conflict."

Comment: *Grazing data for 2001 missing.*

Response: Updated grazing data has been included in the FEIS.

Comment: *III-89: False Statements: FS implies extensive use trails is because of travel between stock camps. The trails have been in use since the 1930's. Not use trails.*

III-89, 2nd to last paragraph: The Forest Service is wrong. These are not use trails but trails in continuous use since the 1920's for travel between campsites and locations at Davis and Lake #2.

The trail from Mudd Lake to Third Recess is a trail and not a use trail.

Response: "Use trail" describes a trail that is not on the System. See definition of use trail in the Glossary. Trails to campsites, although they have been used, some for many years, are still considered use trails.

Comment: III-89: False Statements: Solitude is high in July in Hilton Lakes

Response: Solitude is subjective. The concept was used to provide a consistent means to describe a quality of Wilderness that is used to define Wilderness in the Wilderness Act. Certainly, a person may go to Hilton in July and see no one. But because Hilton is used regularly and frequently by commercial pack stations in July, as it offers good early season access, the opportunities for solitude are lower.

Comment: pp. 89-90: The Forest Service gives one paragraph about day use of 100-150 hikers per day. And, doesn't comment that this is bad, wrecks the social experience, causes high number of use trails, causes water pollution, etc. Totally inadequate EIS when you don't divulge the environmental effects of use.

This EIS should put the commercial pack stock use in perspective with others use in the wilderness. The plan states there is a lack of solitude in Hilton Lakes and then follows with the statement of high day use in Little Lakes Valley. The DEIS doesn't state that there is no solitude in Little Lakes Valley in spite of little commercial use. Shouldn't a good environmental document use numbers to compare and contrast use patterns?

And, for example the wilderness alongside of the Mt. Whitney Trail should be used as an example of what the wilderness looks like without horses and mules. It shows that people are as much or more of a resource problem than commercial livestock.

Response: The FEIS does include considerable more attention to day use and where relevant is brought into the cumulative effects discussion for the area. Because Mt. Whitney is not an area used by commercial stock, it is not a focus of the analysis.

Comment: III-90 Untrue statements! Use trails aren't proliferating. The Forest Service is using maps that don't reflect the actual layout of the land, don't know the numbers of the lack and have little knowledge of the trails and use patterns.

Last year I provided maps and information to the Forests about the problems and sent return receipt letters to the Sierra National Forest--two times and they refused to correct their mistakes or acknowledge constructive help on identifying proper camps, names and locations of lakes and trails.

Response: The Forest Service utilized USGS maps which are the standards for resource management. The map provided by the respondent was a 1950s fishing map. We did not consider this map to be the definitive map of place names and locations for these two wildernesses and stand by the use of USGS 7.5 minute quads as the official map. Naming of camps in the DEIS tried to follow what we knew to be commonly used names by packers, however because of confusion, we have created a new naming convention for campsites to eliminate the confusion of perhaps different names that different packers give the same site.

Comment: III-90 Use trails in Pioneer are getting more faint and less notable.

Response: The appearance of trails being fainter rather than heavier very well may be true by some people's perceptions. The issue the Forest Service is attempting to deal with is the resource concerns associated with the trail, which even though fainter, may still be considered a concern that must be managed. The data does show that Pioneer Basin has a high density of trails (mostly "use trails") many of which have severe resource concerns. It is true that many trails that were identified by the packers were not visible. These were not considered in the condition described

as a high density of use trails, since they appeared to be cross-country routes not trails. Possibly these could have at one time been more visible and the condition has improved, but nonetheless less the use trails that do exist have notable concerns that this analysis addresses.

Comment: *III-90: Use in Hopkins Lake is not concentrated at Lake for commercial use. We have had one or less trips per year to lake. Absolute lie of describing campsite that we use. This is a backpacker and perhaps an occasional private stock user has used. Absolute lie and the impacts are not from Rock Creek Pack Station's stock camps.*

Response: Rock Creek Pack Station identified seven campsites in the vicinity of Hopkins Lake during the time we requested information on all pack station operations for the purposes of this study (Forest Service files). In addition there are numerous entries on Rock Creek Pack Station's tally sheets for "Lower Hopkins" and "Hopkins Lake."

Comment: *III-91: Second Recess. We use it all the time. Stock travel is not difficult other than the creek crossing. Forest Service wilderness managers purposely don't fix so that it is treacherous to cross.*

Response: Reported recent use records show no overnight use to Second Recess for spot, dunnage or grazing. The field reports indicated that the trail has not been maintained and are terribly difficult for stock passage and showed no use. If a packer had used it in the past five years they most likely would have cleared the trail. By Forest Service accounts, it is not the crossing of Mono Creek but the lack of maintenance on the trail that makes it difficult for stock.

Comment: *III 91: Third Paragraph. We use Second Recess and take stock up the canyon. The fact that the Forest Service can't see evidence of stock use could mean several things:*

- a. They didn't get up Second Recess (stream flow was high when id team was looking at Mono Creek)...*
- b. The id team got lost and didn't use the trail that I have personally used since 1957 when I was three years old.*
- c. The Forest Service fails to acknowledge that when you put picket lines in good locations and move them that you can't find the use.*

Response: See response above related to Second Recess. A Forest Service pack string did go up Second Recess and was able to follow the trail and make the crossing.

Comment: *III-100: It says that "the field evaluation was aborted because of high creek flows in Mono Creek inhibiting the crew's ability to cross into Second Recess. This EIS should divulge all the sections that are impacted by the field evaluation impacted by high rain.*

Response: The interdisciplinary team had initially planned to travel up into Second Recess and camp. It was determined to be not safe for foot travel to cross the stream due to high water. Instead, the pack string and pack stock specialist from the team traveled there, took photos and looked for some of the key pieces of information as best as they were able. It should be pointed out that there are many sources of information other than the field visit by the interdisciplinary team. It was not possible (due to time and budget) nor was it the goal for the ID team to go absolutely everywhere identified by pack stock operators. Nor was it possible to do anything more than an extensive assessment. Additional source of information came from Sierra National Forest Staff who have years of observations as well. The Forest Service feels there is adequate information to make this decision.

Comment: *III-134 Rock Creek and Mt. Whitney Pack Trails graze Sawmill Meadow. We use the Cottonwood and South Fork grazing areas on trips.*

Response: The statement in the DEIS was that Pine Creek Pack Station was the only reported grazing use in Sawmill Meadow. Our records show this to be a true statement.

Comment: *III-135. The Forest Service fails to mention that they burned the corrals and refuse to replace them or allow us to have overnight stock holding facilities. This has reduced commercial use. And, the Forest Service purposely doesn't allow or maintain the road to Taboose.*

Response: The Forest Service did not intentionally burn the corrals, the corrals burned during a wildfire in the area.

Comment: *III-135. There is no Baxter Trail Use by commercial stock because Garry Oye refused the two requests that we made by families to use the area. As one client was told by a senior Forest Service staff member... "we never intended or ever intend to allow commercial stock use on Baxter Trail".*

Response: Comment noted.

Comment: *Kearsarge Pass: The Forest Service fails to adequately explain why there is commercial stock use. It is for the most part because of restraint of trade provisions by the Forest Service and the Packers Association.*

There is heavy demand for use at Kearsarge Pass. If Mt. Whitney Pack Trains was allowed to use Kearsarge Pass or chose to do so....there would be a lot more trips that originated at Kearsarge and exited at Taboose, Sawmill and Shepherd Passes. There is incredible public demand for stock supported trips.

Response: Commercial stock use was considered and evaluated for all areas needed by the public in the 2001 Wilderness Plan and again in the FEIS. Many areas, particularly trail-less areas and very difficult and remote trails were restricted for commercial operators because of the potential for resource damage. Not all areas that commercial pack stock clients need access to were approved for commercial use.

Comment: *The exit quota situation at Trail Crest needs to be addressed in this document. There is an incredible demand that the Forest Service is denying to pack stock operators.*

Response: Refer to public comment # 175 response.

Comment: *There is a totally inadequate description of why, where and when there is commercial stock use into Sequoia National Park.*

Response: A discussion of use into Sequoia and Kings Canyon National Park was in the Draft EIS (Chapter 3, Section 3.2.1.1 John Muir Southeast). In addition, as the proposed actions affect use or impact into the Park, it is discussed in the cumulative effects section, specifically at the geographic scale, in John Muir Southeast and Florence/Bear, where this use from the forest into the park occurs.

Wilderness, Comments on Chapter 4

Public Concern #195: *There is incorrect information contained in the Wilderness section of Chapter 4. (All comments are from response #275)*

Comment: Page IV-14: Wilderness Scale: Party Size: I am not sure you can say there has been a trend toward more dunnage trips. Where is the data? Where is the statistical data?

The whole paragraph doesn't make sense and I believe does a poor job of looking at party size.

There are often smaller numbers of people in a commercial dunnage trip. That is because the cost is getting so expensive that the person requiring the service gets his or her dunnage packed in and then the rest of the group gets a general reservation permit.

Maximum party size is reached by Rock Creek many times. The comment is made that maximum party size is rarely reached. Reducing group size and changing grazing regulations has done more to cause an increase in stock per person than the assessment of the analysis made in IV-16

Response: The party size discussion has been subject of disagreement from both sides of the argument. The analysis was modified to try and include suggested elements brought out through all comments on the issue. There is very little direct research on party size and no research is going to determine a “proper” party size. The Record of Decision indicates the decision makers feel the level of analysis was adequate for the decision to be made.

Comment: Page IV-16: Wrong to talk about unintended consequences saying that the number of stock used has increased. The Forest Service should be saying that there is an incentive to get more money per service day. There is not an incentive to use more stock because stock costs a lot of money to maintain.

“Recently with the court ordered reduction in service days, the number of stock used has increased.” Absolute Lie. In the data you present there is a reduction in stock from over 8000 in 2000 and 2001 to 7004 in 2004.

You state that there was an incentive to service less people for a shorter period of time. Where does it show this in figure 4.2.2 and 4.1.3?

The Forest Service does not adequately know how to analyze the data. In many cases, there is more stock used since the party size has been reduced to twelve people. That means that instead of having one group of 12 guests, 3 crew and 10 head of stock...you will have a group of 8 guests plus three crew and then another trip of four guests plus two crew and a total of about 17 head of stock.

Response: Relative to the allocation and the actual use of service days, the data does indicate that more stock was used to service fewer people. This is what Figures 4.2.1 and 4.2.3 indicate in the DEIS. If one looks at the use of service days in 2001 compared to the number of stock and compare to that proportion in 2003 or 2004, you see the point—there was 44% less service days used and yet only 16% less stock. The analysis does not try to interpret the relationship between party size and stock, merely service days and stock. The Forest Service does not allow a party to be split into two as described above to avoid the party size limitations. If this happened or is found to occur, it is considered a violation of the intent if not the letter of the regulation.

Comment: No statistics are used in IV-17 and even if you believe there is a trend (I don't)...the difference in numbers isn't going to affect the environment. If you look at their three year analysis we are saying that we would use 142 head of stock to service 100 people in one year and 147 head of stock to service 100 people on another year. However, before the new regulations took place in 2000 we would have use 145 head of stock per 100 people.

And, the data provided the participants in the Programmatic notes set out in July 2004 use different numbers of people, service days and stock than in the plan. The Inyo Packer Use for 2001 was 6141 people/8541 stock and 2002 E of people 4735 and 6404 #stock, 2003 the # of people 5290 and # of stock 7575. If you use these number you will get .71, .73 and .63 ratio of people per stock. This is a different set of numbers included in the DEIS. (these numbers would be used on page III-5 and for III-6.

Response: The analysis in Chapter 3 and 4 has specifically accounted for the use of stock for two-way spot and dunnage. A calculation was not done in the figures used in the “programmatic agreement notes.” The calculations were done to more accurately assess the use of stock, as ordered by the court. Previous reporting of stock has only calculated the number of stock once even though the stock was used twice, to service in and to return on a later date and bring the party out. This analysis was done from 2001-2004 for the FEIS. And 2001 is the baseline of use prior to all the changes from the Wilderness Plan and the court order. It provides a useful comparison. As stated in other responses, data prior to 2001 is incomplete, rendering a comparison impossible. In your contact with the Inyo National Forest, it was not clear what report you were referring to. Often resolving the differences cannot be done off the top of someone’s head, but requires adequate information and consideration.

Comment: *The EIS should be addressing important information:*

1. *Did the stock stay overnight?*
2. *What percentage of stock was tied to a picket line or allowed to roam free?*
3. *Was the stock used both ways? For example, if a mule takes a load of gear for one group and brings out another person’s dunnage is the stock counted twice even though it didn’t make two trips down the trail?*
4. *How much stock was used to haul feed vs. haul people’s gear?*
5. *Is the stock that is used to haul feed counted the same way as the stock used to haul people’s gear?*

If the Forest Service presented the data differently, one could possibly make informed conclusions about the effects of the 2001 Wilderness Plan and Court Directed relief.

Response: Much of this suggested information is not feasible or practical to collect for all the operators and as noted in many responses, accurate data from pack stations has been difficult to attain. It would likely provide little additional information that is needed to make decisions regarding the resource impacts we are attempting to respond to.

Comment: *The Forest Service fails to divulge the effects of its elevational grazing closures to stock. In 2004 the Inyo called the year a normal year...probably one of the driest in many decades. It forced packers to relocate trips and pack feed. This increases the stock count on the trail for feed.*

The DEIS isn’t looking at the impact per stock number. The Forest Service is looking at a few operators and improperly assuming that each packer wants to rent more livestock. Economically, it makes sense to charge more per animal than less. The data doesn’t support the conclusions.

Response: Delaying grazing until forage and soil conditions reach “range readiness” is a Forest LRMP Standard. Appendix G of the JM/AA Wilderness Plan re-states this direction, and

identifies that range readiness will be determined for pack stock use following the guidance in the Forest Service Range Management handbook (2209.21). The Record of Decision for the AA, JM and DL Wildernesses FEIS identified the issuance of Forest Orders as the tool for implementing range readiness standards, and the Wilderness Plan for the AA, JM and DL Wilderness Areas states that these Forest Orders may be revised annually, if necessary, to established grazing start dates. The CEA/EIS does not propose a change in this direction, and therefore the effects of delaying grazing until range readiness standards are met are not evaluated as part of this document.

Predictions of range readiness dates are made annually prior to the start of the pack stock grazing season, based on percent of normal snowpack. This prediction is used as a basis for the establishment of grazing start dates incorporated into the Forest Orders implementing grazing closures. The elevational closures are intended to reduce the impact of packing feed on packstock users by allowing grazing in lower elevations while waiting for range readiness in the higher elevations of the Wilderness areas. The desire to utilize packstock in areas prior to meeting range readiness conditions may necessitate the packing in of feed, and this increase of stock on trails is an effect that is described in Chapter 4.

Comment: *In IV-18 there is the statement that there is no incentive to use less stock. I strongly disagree that there is an incentive to use more stock.*

Response: The statement was that the court order (reduced service days) “seemed to be an incentive to use more stock.” This is supported by the tally sheet data. Some packers have indicated that this is in fact the response to the reduced service days. There have been implemented a minimum stock number for services by some outfits as example. Perhaps not all outfits responded this way, but there is supporting evidence that this does appear to be the case.

Comment: *The EIS is flawed in that it assumes that with daily and seasonal stock quotas there will be an increase in the number of clients. And, then furthermore it states that it is the number of stock and not the number of clients that affect the resource. This document does not assess what the impact on the resource will be by encouraging more clients.*

Response: The EIS does not so much assume there will be an increase in clients but attempts to provide the incentive—in Alternative 3—to serve more people without using more stock. The focus of the courts issues were on stock impacts, and research does indicate that stock has more impacts (albeit different) than hikers. There are impacts with people and more people, and the FEIS attempts to provide more discussion of these impacts.

Comment: *On page IV-19 the Forest Service gets into operating areas. Instead of assessing the cumulative effects on the resource of having various outfitters and members of the public utilize overlapping areas...the Forest Service proposes to eliminate overlapping commercial stock use. This is wrong. Instead of doing a proper environmental analysis the Forest Service makes the decision to eliminate overlapping use. And, the Forest Service wrongly assesses the impact of this decision on the resource.*

Furthermore, they lie that packers are doing more traveling trips into areas where they had not historically operated.

Response: There is no reference to this comment and such a statement could not be located in document. Since there is no significant assessment or attempt to assess “historic use” this may be taken out of context.

Comment: *How can the Forest Service say that assigning primary operating areas to those operators at a base facility will result in less impact to the Forest Service? First, the Forest Service needs to look at the environment and assess what are the affects of multiple operators using camps and drainage areas. Secondly, there is NEPA requirement to look at various alternatives and divulge reasonable environmental consequences.*

Response: The analysis does not state there will be less impact to the Forest Service, but it does help the Forest Service manage overlapping uses better. The analysis has determined that in at least one of the areas where there are many operators—Silver Divide—the impacts are more severe. Many of the operators have indicated that it has been a source of the problem.

Comment: *Chapter IV-21 states that the wilderness character will be improved. Unfortunately, it doesn't state that it removes the ability of the public to move through the wilderness with freedom. The Wilderness Act was established to allow the public to use their wilderness and not deal with all the regulations and restrictions suggested in Alternative #2.*

Response: In the same section (IV-20) the statement is made “Packers’ freedom of movement and camping will be substantially limited by the alternative.” The analysis does recognize this element of wilderness character that is being affected by more direct controls. The FEIS will clarify that not only packers, but clients of packers are limited, as that was intended but not well stated in the DEIS.

Comment: *Chapter IV-page 26 has a discussion of party size. Again, the Forest Service misses the opportunity to look at the impact of party size on the wilderness resource. The Wilderness Act specifically wanted historical use of livestock to support traveling trips such as the Sierra Club Hiking and Riding trips in the Sierra.*

If 25 people want to travel the length of the Muir Trail there will be less impact if we send one group of 25 with 20 head of stock than three groups of ten people with 45 head of stock.

Every time the Forest Service cuts party size, it requires more stock and packers to service less people. The stock per client and service day ratio climbs. If we want to have less stock per person or service day we need to increase the party size.

Smaller party size creates more traveling trips down the John Muir Trail. We used to be able to take 20 people with five crew on trips from Rock Creek to Mammoth. Now it would take three trips to get the same number of guests down the trail. As a result, there is a lot more use by fewer people.

Response: The commenter clearly believes that larger group size will have fewer impacts. This opinion will be noted in the analysis, and further discussion on the disagreement on this issue from various respondents will be provided.

Comment: *56a. Failure to evaluate the effects of trail head quotas and group size on the environment.*

Response: Substantial analysis of the effects of trailhead quotas and group size is provided in the “Wilderness” section for each alternative. Although it may not reflect every individuals opinion on these matters, there is not a failure to evaluate it.

Comment: *Page IV-244. It is good that you mention that Alternative 2 reduces Rock Creek Pack Stations ability to use this Ansel Adams Area. This will eliminate most of the opportunity for the general public to take a packer assisted pack trip the length of the John Muir Trail; this*

should be clearly stated. Why should you allow non-historical day use to increase and eliminate historical use of commercial pack stock that travel along the John Muir Trail?

Response: Many opportunities still exist for the public to take a packer assisted trip the length of the John Muir Trail. Some of this use is also regulated by Yosemite National Park, a terminus for the John Muir trail. Alternatives provide different levels of use that are determined to be appropriate and necessary in meeting the purposes of Wilderness Act and preserving wilderness character.

Comment: *I am not clear what is meant by the last paragraph of Chapter IV-247 regarding not controlling use into the Park. This is the only example I find in this EIS where the Forest Service has altered its plan following last year's document about pack stock use. Does this mean that Rock Creek Pack Station will have no control to enter Yosemite? Or, is this a specific courtesy granted to Frontier Pack Station?*

Response: The discussion on page IV-247 is in regards to the effects analysis for Alternative 3. Alternative 3 only controls use at trailheads, not by the direct methods of the Proposed Action where destination quotas specifically limited the number of trips into the Park. No, this does not mean that Rock Creek's use will be eliminated, in fact the next sentence states "It is likely that unless Yosemite National Park was to control the use over the boundary, there would be a possibility that more use could be along this corridor" (IV-248).

Comment: *Chapter IV-337. Fourth paragraph says that crowding will only be high in Cascade Valley and Iva Belle. Where is the crowding in Cascade Valley? Look at the use levels for the last 25 years. You can't find the campsites hardly in Cascade.*

Responses: There were two campsites in Cascade Valley identified in this discussion, one at Third Crossing and one at Second Crossing. Although conditions may have improved in the last fifty years, these sites continue to see impacts and are as the statement says "noticeable."

Comment: *You say trailhead quotas are not limiting use. False. You have no destination quotas in the existing management plan. There was never any intent to reduce use in Cascade Valley. Why would you reduce use in Cascade Valley when the use levels continues to decrease?*

Response: The statement is the trailhead quotas are currently not limiting use. Commercial pack stock use could, under current management continue to grow." This is merely stating the effects of current trailhead quotas, where commercial pack stations are not to any significant degree being limited by the daily quotas and the use continues at a similar level as it did prior to the Wilderness Plan.

Comment: *Chapter IV-337. Document is flawed in that there is a grazing plan and the only problem is that the Forest Service didn't enforce the plan. And, the Forest Service has allowed growth by numerous people. This is a poor analysis of Alternative 1. The Forest Service is currently obligated to work with packers on an operating plan. Under Alternative 1, the Forest Service is supposed to manage the wilderness correctly. Any adverse affect to commercial grazing, campsite use, etc may be managed with the operating plan. There is no need to put Alternative #2 in place to achieve management objectives.*

Response: It is true that the Forest Service uses the operating plan to address site-specific management issues not typically included in LRMPs. And, it is true that grazing management direction was developed in the 2001 Wilderness Plan. However, it was not until site-specific

data was collected in 2002-05, that range suitability and other site-specific grazing determinations could be decided. The 2005 FEIS incorporates the new data and analysis, and includes and evaluates minor adjustments to the grazing management direction in the different alternatives.

Comment: *A statement on IV 337 “There are few limits on grazing currently and management of grazing will likely respond reactively to impacts”. This is the situation that has occurred in Cascade Valley, even recently, as Second Crossing was closed after impacts had been identified. Current direction has not fully been implemented and it will be noted that within this Alternative there could be responsive management.*

Response: see response to comment above

Comment: *Chapter IV-338 You state that you will cut Rock Creek’s use by 46%. Where will these people go in the wilderness? If you are going to propose an alternative that reduces this much use you should identify what the effect is going to be in the wilderness. This EIS fails to give a reasonable alternative.*

Response: If the use is cut, the people will not be in the Wilderness. There will be fewer commercial clients and the effects of such are described.

Comment: *You state that you are going to increase Upper Fish Creek by ten trips and 9 trips to Cascade Valley and show a sizeable increase in spot and dunnage trips. Your analysis suggests that this will reduce impact. Yet, on page IV-339 you say that there will be 100 less stock using the unit by removing Rock Creek Pack Station’s Use. However, you replace Rock Creek’s use with 20-30 other trips without stock and service day units and say that there is less chance for stock use? What is going on? The implication is that you can increase 20 trips by McGee and Mammoth and reduce a couple of Rock Creek Trips and there will be less impact?*

Response: The reduction in full service stock supported trips will have a beneficial effect on grazing and campsites in the area. Spot and dunnage trips do not utilize these resources to the degree that full service trips do.

Comment: *Chapter 4 page 342. First paragraph is misleading. Historical use patterns have changed. However, the change is that there is little use from Red’s Meadow compared to considerable use year ago. And, there weren’t pack trips from June Lake. The increase in use is from June Lake.*

Rock Creek Pack Station has been trucking livestock to Red’s Meadow, Mammoth Pass and occasional other trail heads since the 1940’s. Rock Creek Pack Station has used Mammoth Pass as a trailhead since the 1970’s and continues to service some of the same clients.

The Forest Service has permitted significant increases of Hilton Lakes by the packer at McGee Creek.

The Forest Service fails to mention that the problem is that the packer at Mammoth and Red’s Meadow doesn’t want competition. They want to eliminate traveling trips over Mono Pass. Then, they don’t want anyone to truck to another trailhead. The real issue is one of restraint of trade and has very little to do with resource impact.

Response: This is not consistent with use data and other comments from packers using the area and demonstrates the various opinions and perceptions that exist on use levels and effects. The analysis attempts to not assign blame to individual operators. Over twenty years ago the Forest

Service limited Rock Creeks use from Rock Creek to Mammoth and Yosemite trips. This apparently is not a new issue. Over time the limitation either lacked enforcement or was forgotten. The actions of Alternative 2 very much mirror the actions that were in operating plans in the 1980s.

Comment: *There is so much less use than twenty years ago that this whole discussion of cumulative impacts is almost ridiculous. Our crews seldom see other livestock and there are few outfitted pack trips that we encounter in the Fish Creek and Jackson/Grassy Lake area.*

Response: See response above on perceptions of impacts. The court has required the Forest Service to do a cumulative impact analysis because of evidence of resource impacts. It is the Forest Service's responsibility to establish the record on the type and level of severity of resource impacts from commercial pack stock in these wildernesses. As difficult or ridiculous as the descriptions may seem to those with more tolerant views of impacts, it is nonetheless a requirement.

Comment: *This DEIS is so deceitful in creating a perception of overuse and conflict of overlapping commercial use in the wilderness. Unfortunately, there is a lack of thoughtful analysis and field work that backs up the conclusions suggested in the DEIS.*

Response: We disagree that a 500-page effects analysis that considers effects at a very localized levels for five alternatives could be considered lacking in thoughtfulness. It may not match the opinions of others.

Comment: *Why doesn't the EIS give a physical description of the camp and explain how many feet are taken by tents, picket line, paths, etc. Why not mention the actual number of camps in a particular area and the percentage used of camps. And, why not mention the duration of the use? An environmental analysis should focus on concrete physical analysis and quantitative data. It is lacking in much of the document.*

Response: This is a programmatic document that provides direction of site-specific management of campsites. There seemed little need to discuss the level of detail suggested in the comment above in a programmatic document. As it stands the level of detail is far more than is required of an environmental analysis at the programmatic level. Perhaps a false expectation had been created with some of the details. An environmental analysis needs to focus on the relevant issues and information for the decision to be made. We hope that the Final EIS provides adequate direction for annual operating plans to fulfill the goals and objectives laid forth.

Comment: *Grazing at Jackson Meadow and Grassy Lake Area: There needs to be a wide variety of campsites and grazing options that allow people to stay for more than one night. Most people go to a central area so that they can fish and explore this area's lakes.*

Response: Given the resource impacts in this area, it is a proposal in one of the alternatives to limit camping to a one-night stay. This is a fairly common tool to use in wildernesses in locations where conditions warrant a reduction in use, but not a total closure.

Comment: *Chapter IV-383: Whether or not you have designated stock camps there will be similar uses. Perhaps the Forest Service should maintain the trails. No appreciable maintenance since 1968 of almost all of the trail from Rock Creek to Hilton. Could that be the reason for deterioration of trail resources?*

Response: Substantial repair efforts were performed on much of the Hilton trails in 1980 and in the early 1990s. Basic maintenance is performed annually or as often as funding allows. It is likely that more maintenance will be required on trails in the Hilton Lakes area that continue to receive heavy commercial stock use. Some responsibility for assisting with trail maintenance lies with the commercial operators who primarily use the trail systems.

Comment: *Why allow multiple operators in Hilton and not in Cascade Valley or other regions of the wilderness?*

Response: Multiple operators are allowed in both Hilton and Cascade Valley. However, only one primary operator—for spot and dunnage trips—is allowed in Cascade Valley. In Alternatives 2 and 3, three primary operators are identified for Hilton primarily because there are multiple way of entering into Hilton, from the Rock Creek side and from the Hilton Creek side, and that three operators had been using these access points for a number of years, and two of the operators had very little use.

Comment: *IV-385. Lie that Pioneer Basin has seen a proliferation of use trails. Less use and many of the trails used in the past are not possible to see.*

Response: The statement has been modified in the Final EIS to reflect that there are a high number of use trails with resource concerns. It was noted as a cumulative effect of past use and present general public and commercial pack stock use. Observations from the public, Forest Service and other packers indicate that there has been a proliferation, which again points to a difference in perceptions.

Comment: *Chapter IV-391 The discussion of trails into Fourth Recess and Pioneer Basin is ludicrous. There are multiple trails into Fourth Recess to get to various camps...primarily for spot and dunnage trips.*

Response: The discussion on page IV-391 of the DEIS predicts the effects of fewer stock camps. It has been modified in the Final EIS to add that trails will persist to spot and dunnage sites, as this use will not be controlled.

Comment: *The comments about Pioneer Basin are incorrect. There are not excessive amount of trails in Pioneer Basin. The trails are all going someplace and allow someone to ride around the Basin in one day. By closing trails you will have people spending several days trying to get to various lakes. Therefore, by closing trails you will be causing a lot more impact.*

Response: It is highly unlikely that by closing some of the impacted trails to commercial stock use it would take the public several days to get to the lakes. For example, the distance from Mudd Lake (where commercial pack stock can travel to) to the upper most lake is approximately 2 miles. Perhaps there will be some people who will be excluded from some of the many lakes in the basin if they are unable to walk the distance, but it is not likely that most people will be excluded, nor would it require several days of walking.

Comment: *Chapter IV-480-485—Where is Orchid Lake's use described. Rock Creek pack station wants to go to Orchid. Need to mention the permanent camps and trails built in the 1950's and 1960's.*

Response: Orchid Lake's use is described in Chapter III in the Florence- Edison Geographic Unit. There currently is not a visible trail to Orchid. There is not recorded use in the past five years. Orchid Lake is mentioned in Arn Snyder's 1962 report where he proposed permanent type

camp at various locations, including Orchid, but there is no record that this was done at Orchid, nor is there any evidence of any heavy use from the past.

Comment: *Chapter IV-530 Limiting stock number to Taboose and Sawmill essentially prevent use by Mt. Whitney and Rock Creek Pack Station. The restrictions in Alternative 3 are awful and essentially close the use to stock.*

There currently aren't resource problems from the trails and there is no reason to put more restrictions.

Response: Page IV-53 of the DEIS describes Alternative 3 for Taboose and Sawmill. Both trails access Sequoia-Kings Canyon National Park and these numbers respond to both current use levels and the park's stated desire not to increase use on these trails into the Park. This analysis must consider use that is affecting adjacent lands administered by other agencies. We have worked closely with the park to insure that our actions are consistent with their management objectives.

Comment: *Chapter IV-531. You state that Cottonwood will be one operator. Mt. Whitney has been using the Basin since 1921 and this statement is wrong.*

Response: In Alternative 3 (IV-p.531 discussion) there will be one operator in Cottonwood Basin. It is not relevant to the discussion that there was historic use to the basin by a second operator. There are no current records for use by other operators, so no effect to a second operator was described.

Trails, General

Public Concern #196: *The writers of this document refuse to research the files and extensive public historical collections of pictures, maps and journals that explain where, why and how these trails were built.*

Response: The scope of this project is to determine the management of commercial uses and trails of the planning area. Where, why and how trails were built while interesting, is not necessarily a relevant factor that needs to be considered in any detail. Where this information is relevant, it has been noted. The EIS is not intended to be an account of the history of all management and uses in these Wildernesses. References are noted and cited when applicable.

Public Concern #197: *Trails improved to stock standards have a greater effect on wilderness character, and are more costly to maintain than trails with little or no packstock use. (response # 301)*

Response: As disclosed in the DEIS, the somewhat higher profile of high-use stock trails may be seen as having a greater imprint of human influence on wilderness. Pack stock—both private and commercial—are acceptable uses of wilderness lands and trails, so most trails are maintained for such use. Private equestrians are allowed on all trails in the AA/JM wilderness, though some lesser-used trails are of a very limited scale, and have a relatively small profile.

Public Concern #198: *An alternative should have been analyzed that restricts commercial pack stock to certain trails, and to campsites within a limited distance (1/2 mile) from those trails. (response # 301)*

Response: Alternatives 2, 3 and 4 in the DEIS and the selected alternative in the FEIS restrict commercial operators to certain system and use trails which are determined suitable for commercial stock. They are also limited to traveling off-trail to less than ¼ mile to access camp sites.

Public Concern #199: *No alternative considered charging fees to maintain or repair trails. (response # 301)*

Response: This suggestion is outside the scope of this project.

Public Concern #200: *The Forest Service should limit pack stock to trails that were designed for that use.*

Comment: *Trails that have not been adequately located, designed, constructed, and maintained to fully withstand the heavy impacts of stock use should be closed to all commercial stock animals. As a starting point, all "Class 1" trails identified in Alternative 4 should be closed to commercial stock. (response #form letter C, form letter D, form letter E, form letter B, 65)*

Comment: *Trails such as Mono Pass, Taboose Pass, and Sawmill Pass should be completely closed to stock animals. It is clear that neither the Forest Service nor our country can afford to repair the destruction of constant pack animal use in the high country nor should we have to. (response # 178)*

Comment: *Commercial pack stock should not be allowed on trails in poor condition or subject to excessive degradation by the use of pack stock on them. (response #36, form letter B)*

Response: The 2001 Wilderness Plan allows private stock on all wilderness trails except Mt Whitney and Meysan Lakes, but does allow for certain trails to be closed to commercial pack stock. In the selected alternative, commercial stock is restricted from approximately 90 miles of trail in the AA/JM Wilderness, which were determined to have the greatest potential concern with recurring pack stock use. Another 9 miles of trail are temporarily closed until concerns can be mitigated. Other trails, which can only stably handle limited numbers of stock are allowed for commercial use, but use is restricted to sustainable levels through quotas and destination limitations. Use trails (non-system) have only been approved when it appears that anticipated uses will not lead to unacceptable resource effects.

Public Concern #201: *Trails that are frequently used by pack groups should be actively maintained throughout the peak months to minimize or eliminate the horrible and unpleasant dust problems for users. (response # 318)*

Response: While dusty trails are unpleasant, attempting to eliminate dust from stock and/or hiker trails is neither a practical action, nor within the scope of this analysis.

Public Concern #202: *Designate a network of hiker-only trails in the AA/JM Wilderness. (response # 345)*

Response: The 2001 Wilderness Plan specifically "...permits recreational pack stock and hiker use on all trails except Mt Whitney and Meysan Lake, which are closed to pack stock." (Record of Decision, pg. 4)

Trails, Off-Trail Travel

Public Concern #203: *The Forest Service should not allow off-trail travel by commercial pack stock.*

Comment: *For travel off of designated trails (i.e., off-trail or across-country travel), we recommend the following group size limits as indicated by the latest research for the protection of wilderness resources and values: maximum eight persons per group, with no stock animals allowed off-trail, except for grazing at approved forage areas. The suggested limit of eight persons/group for off-trail travel would provide important protection for resources and visitors experience in little-used areas (see Cole 1989a, 1990, 1997), and would be consistent with limits in effect at the adjacent Yosemite National Park and Hoover Wilderness. In addition, given the high likelihood for significant impacts whenever stock animals leave designated and maintained trails, your final plan should also specify that off-trail travel by stock animals shall be allowed only on specific routes identified after careful site-specific NEPA analysis with full public involvement. (response # 196)*

Comment: *Scientists have long recommended that stock animals should stay on trails that have been designed, constructed and maintained to withstand the impacts of stock use. Commercial stock should be required to remain on designated trails, with no exceptions. No off-trail travel by commercial stock should be allowed. In Alternative 4, commercial pack stock use must stay on existing trails. Off trail travel must not be allowed, and any commercial pack stock travel must be restricted to designated maintained trails and identified grazing areas only. Allowing off-trail use will result in negative impacts of pack stock into areas where trails do not reach. (response #form letter B and D, 33, 35, 36, 153, 372)*

Response: In the selected alternative, commercial operators are limited to certain system trails and approved use trails. A small number of the “use trails” were relatively undeveloped and undefined “cross-country” routes. Generally these were approved for very limited numbers and during a specific season of use (i.e. “Hunting use only”), with the intent of maintaining the undefined character of these routes.

Trails, Settlement Agreement

Public Concern #204: *The Forest Service should comply with the terms of the Settlement Agreement between the Backcountry Horsemen and the Forest Service. (response # 276, 278)*

Response: The April 2004 Settlement Agreement with the Backcountry Horsemen of California (BCHC) contained five key items. The first three ensured that the inventory in Appendix C of the Wilderness Plan would not be used to change the management of trails in the AA/JM Wildernesses, and that the forests would maintain trails to their “current assigned levels” to the best of their ability.

Item four states “Defendants will complete a Trail Transportation Plan pursuant to a public process, with the objective of completing it by December, 2006.” Item 5 states: “In preparing the NEPA analysis for the Trail Transportation Plan, defendants will use the 1987-88 trail inventory as the “No-Action” alternative for the Inyo National Forest.” The “no action” inventory for the Sierra NF was not addressed in the settlement, and no pre-2001 inventory for the Sierra was available.

No part of the agreement related to any other guidance in the 2001 Wilderness Plan, including the use of three Recreation Categories, which provide “desired conditions” for various areas in these wildernesses and which affect future development and maintenance of trails accessing these areas.

Public Concern #205: *The DEIS does not meet the intent of the Court Order requiring that the agency look at “trail suitability for various types of use.” (response # 276, 278)*

Response: Within the context of the Court Order, “trail suitability” is interpreted as relating to the suitability of commercial stock on Forest trails in the AA/JM Wilderness.

Trails, Trail Management Plan

Public Concern #206: *Rather than reduce trail quality and trail miles, why don’t you use volunteers and other community groups that would love to help maintain trails? (response # 180)*

Response: The Inyo and Sierra National Forests frequently utilize the volunteer efforts of many groups and individuals to maintain trails. These efforts have helped the forests to maintain trails and reduce resource impacts. In cases where Trail Class designations have been reduced in the Trail Plan, it is generally to meet the intent of the desired condition of a destination, and the anticipated use types and levels on a particular trail. The trail class defines the level of development and maintenance, whether the work will be accomplished by volunteers, permittees, or Forest staff.

Public Concern #207: *The Forest Service should not engage in destructive practices such as blasting to accommodate stock use of trails. (response # 221)*

Response: While certain maintenance activities, such as blasting may be seen as “destructive”, the goal of trail maintenance is to ensure that there is one stable route, passable to anticipated trail users—both pack stock and hikers. Blasting is one of the tools which is occasionally used to provide this system. Failure to employ such techniques could make a trail impassable to both stock and hikers and has potential to cause resource impacts from trail users bypassing obstacles.

Public Concern #208: *The Forests should allow commercial pack stock to use all trails and areas historically used by stock, and these trails should be maintained accordingly. Commercial stock should not be restricted from trails that private stock are allowed to use, since all stock have the same impacts, and commercial operators can handle safety issues on the trails. (response # 198)*

Response: The 2001 Wilderness Plan specifically “Permits recreational pack stock and hiker use on all trails except Mt Whitney and Meysan Lake, which are closed to pack stock” (Record of Decision, pg. 4). The plan also provides for designating certain trails as “Not Recommended for Stock,” which would directly prohibit commercial operators from using such trails. This designation in the FEIS is now “Not Suitable for Commercial Stock” (NSCS), to clarify the intent. The Pack Stock Management analysis is focused on commercial pack stock operators, and is not intended to make actions directly affecting private stock or other Wilderness users.

The NSCS designations are primarily focused on resource impacts and/or destination limitations, and are not intended to deal with safety issues. Commercial operators are capable of making judgments regarding the safety of their clients, stock, and wranglers related to relative risks on a

trail, but where there are trail or resource instability concerns, it may be necessary to remove recurring stock use. Since private stock makes up such a small fraction of stock use, and an even smaller level of total trail use; and since most of the private equestrian use is on higher level trails, the comparative impacts are relatively low.

Public Concern #209: *On page IV-46, the Forest Service seems to not want to invest in maintenance resources and by keeping commercial stock off the trail; they believe they might not need to maintain the trails. "Hikers can go anywhere". On page IV-109 "Trails with severe water and soil resource impacts may be repaired within 10 – 30 years". This does not sound like a high priority issue! (response # 198)*

Response: It is the intent of the Forests to maintain trails in a manner that keeps them stable under the anticipated uses. Recurring use by commercial stock—especially on less-developed trails—is a factor which can increase the instability of a trail without high levels of maintenance. In areas with high risk factors and/or other limiting factors, reducing pack stock may increase trail stability. Funding for both the Sierra and Inyo NF is inadequate to equally maintain all trail infrastructure and resource stability on every trail with every use type and level. Prioritizing these limited financial resources allows the Forest Service to focus on trails receiving the highest levels of commercial and private use.

Public Concern #210: *The trail inventory [for the Sierra NF] referenced in the DEIS is incorrect, incomplete, and improperly referenced. A more accurate trails inventory than the 2001 Wilderness Plan was made available during the Backcountry Horsemen lawsuit. (response # 273)*

Response: An inventory was in place for the Inyo NF at the time of the last FLRMP (1988), but no comparable inventory was found for the Sierra NF, and was not directly referenced in the Settlement Agreement with the BCHA. As stated in this comment above and in the Purpose and Need for the DEIS, all known inventories—including the 2001 Wilderness Plan inventory (Appendix C)—had a variety of errors, omissions, improper inclusions, and other inaccuracies. This is part of the need for completing the analysis.

Public Concern #211: *The decision related to commercial pack stock may have a profound effect on the future of private stock in these two wildernesses. Private stock use, according to the Forest Service records reported in the DEIS, comprises a very small percentage of total use (3%). It may become increasingly difficult to justify expenditures related to managing the trail system for such a small amount of use. (response # 273)*

Response: While private equestrians account for a small number of total users, trails will continue to be maintained in a manner which accommodates their use, within budget constraints. The vast majority of private equestrian use occurs on higher level (Class 2 and 3) trails, in part due to the long-term awkward conditions historically found on most lower-level (Class 1) trails.

Public Concern #212: *The DEIS violates NEPA by failing to adequately consider the effects of reducing trail standards on historic users. The DEIS choose not to address the issue that trails in Recreation Category 1 areas will become impassable to stock because the issue was decided in the 2001 ROD. Although the proposed alternative does not specifically close trails in Recreation Category 1 to stock use, design attributes for Trail Class are not sufficient to accommodate passage with pack and saddle stock. (response # 276, 278).*

Response: When Recreation Categories (RC) were determined in the 2001 Wilderness Plan, the existing uses and development of facilities (including trails) were considered. In general, these areas have low-development trails, because historical and existing uses are relatively low. There are generally very few trails in RC1 areas, and these are often assigned lower Trail Classes (TC1 and TC2) since the trails can remain open and stable with low use and with minimal development and management. It should be noted that approximately 40-50% of all trails accessing RC1 areas are TC2 or TC3. All Trail Classes have maintenance standards which are intended to allow passage of pack or saddle animals, though TC1 trails are much more difficult to travel than higher-development trails.

Public Concern #213: *The DEIS concludes that establishing trails not recommended for stock and prohibiting commercial packstock on some trails may reduce conflicts between users. The document uses conflict management as part of the justification for selecting Alternative 2, yet fails to consider a full range of alternatives for accomplishing that objective. We suspect that the real motivation of these restriction is to accommodate a relatively small minority of ‘wilder-extremists’ (both inside and outside the agency) who object to seeing stock in the wilderness and object to knowing that commercial packers are providing services for profit. (response # 276, 278)*

Response: Reducing conflicts was described as an effect or byproduct of the designations, not as a purpose or need for the analysis. In the FEIS selected alternative, trails are no longer described as “Not Recommended for Stock.” Similar advisories may be provided in public information to help trail users with expectations of conditions. Trails closed to commercial stock are based on resource concerns, as well as potential effects on various factors, including wilderness character at the destinations. The criteria are described in the summary section of each alternative in Chapter 2.

Public Concern #214: *The DEIS violates NEPA by failing to analyze the effects of allowing stock use on trails that are not managed to accommodate that use. For example, insufficient clearing widths and heights on TC 1 will likely result in stock users leaving the trail to go around logs and other obstructions. (response # 276, 278)*

Response: Most Trail Class 1 trails receive very low equestrian use, and the trails should remain generally stable under such limited use. The potential effects of stock use on underdeveloped trails were disclosed in the DEIS Chapter 4. Standards for Trail Class 1 trails are clarified in Chapter 2 to ensure that obstacles will be removed to accommodate packs and saddles when such use is present, so that stock can stay on the trail.

Public Concern #215: *The Forest Service should not implement the proposed “National Trail Management Classes.”*

Comment: *The Purpose and Need Section makes assumptions, or inaccurately interprets legislation, that are inconsistent with the intent of law or policy. Specifically, the use of proposed trail service levels and maintenance standards in the DEIS does not conform with direction in the Forest Service Directives system. The National system of trail classes or service levels and the classification system they are a part of has not been subject to NEPA analysis nor has it been approved by the Chief of the Forest Service. Current direction in the Forest Service directives system calls for a three classification system of “easy, more difficult, and most difficult” and provides design guides for these three classes that are substantially different than those for the service levels in the DEIS. (response # 276, 278)*

Comment: *In accordance to the Wilderness Plan, in all of the proposed alternatives within the DEIS, inventories of trails within the wilderness areas will be subjected to a "National Trail Management Classes," which does not exist at the present time (DEIS at II-2). How can there be so much discussion about "trail classes" and levels of management when the National Trail Management Classes, and the attendant "service levels" ascribed to each class, have not been determined? Since its does not yet exist, there is, presently, no way to determine whether the National Trail Management Class formulated in the hills and woodlands of the eastern United States will have relevance to the Sierra. (response # 357, 348)*

Comment: *The National Trail Use Standards listed in this document are not yet approved nationally. These standards are being applied in this document improperly and used as if they were approved. (response # 273, 278)*

Comment: *Although an improvement from the 2001 Wilderness Plan, there is concern over some of the trail design standards. Specifically, the TC-1 tread width is insufficient to accommodate anything but very light stock without resource impact. Surface obstacles are also a problem. For TC-2 standards, there is still a concern with the standard for surface obstacles. (response #273)*

Response: While the national direction regarding Trail Classes is not currently in the Forest Service Trails Handbook (FSH 2309.18), it has been interpreted as an expansion and clarification of management and design in existing similar classifications (described as "Difficulty Levels" in the 1991 Handbook). The five-level National Trail Class system was based on a long-standing five-level system used prior to 1991, and has been in development and use since 2001, as a way to more accurately classify trails for costing and consistent management.

The Inyo and Sierra Forests described intended management for each of the AA/JM Wilderness trails in the DEIS, using the Draft National Trail Management Classes as a baseline. These were then modified slightly, to clarify specific direction for these two wilderness areas. Design guidance for trails within the AA/JM was also based on the Draft Design Parameters, which take into account the Trail Class and use type in managing trails.

While there are slight differences between the "Difficulty Level" system and the Trail Class system, the definitions in the new system—especially as clarified in the AA/JM document—make clear the intent to accommodate varying levels and abilities of pack and saddle use on trails in the AA/JM Wildernesses. Standards in FSH 2309.18 for trails designated "Most Difficult Pack and Saddle Trails" specifically state that "pack animals are normally not accommodated on most difficult trails." Since the JM/AA 2001 Wilderness Plan allows private stock on all trails, TC1 standards are designed to at least minimally accommodate all users.

Public Concern #216: *The following statement of the "Purpose and Need for Action" is inconsistent with the intent of the Wilderness Act: "Use of inaccurate inventories and trail management objectives that were not be in compliance with the 2001 Wilderness Plan has led to ineffective management of the trail system, which in turn adversely affects both users and resources.. Past trail system inventories for these areas are incomplete, have a variety of inaccuracies, and in many cases are inconsistent with the management of the areas that they access." Unless it can be clearly documented that management actions since designation have resulted in development of the trail system to a higher level than that which existed when Congress determined the two areas as suitable as wilderness, or unless there is specific statutory wording directing that the trail standards be downgraded to a lesser standard than existed when*

Congress deemed them suitable, it must be acknowledged that “past trail system inventories” are consistent with Congress’ intent regarding the management of the areas they access. (response # 276, 278)

Response: By carefully assessing both the existing and anticipated needs of the trail system, an accurate inventory can be developed. As described in the purpose and need in the DEIS, some “trails” on the inventory clearly had never been a distinguishable trail, and others clearly had always been incongruent with their stated management levels. Management direction for these wildernesses that is more recent and builds upon the Wilderness Act (such as the Inyo and Sierra Forest Plans and the 2001 Wilderness Plan) provides more specific guidance regarding trail management in these Wildernesses. The selected alternative in the FEIS has an inventory which considers this specific management direction.

Public Concern #217: *The DEIS inadequately assesses the cost of managing a trail system to accommodate allowed use and correct the effects of deferred or otherwise inadequate maintenance. The Forests are using inadequate maintenance budgets as justification to exclude, limit, or otherwise discourage allowed and historical uses and to create a favorable setting for a special class of users. (response # 276, 278)*

Response: The FEIS has a more complete analysis of costs associated with managing the trail system. The Forests recognize that under current budgets, not all trails can be maintained to the designated standard.

Public Concern #218: *A comparison of any map published before 1964 with a Forest Service map available now reveals that there are less trails represented on Forest Service maps now than there were on maps published prior to 1964. The reason for this is open to speculation, but the fact that a trail is not represented on a current Forest Service map does not mean that it does not exist. Thus, the “trail inventories” submitted by the Forest Service probably exclude many trails which will no longer “exist” if the terms of the DEIS are adhered to. To wit, at page IV-33, the DEIS states, “Trails removed from the inventory generally [emphasis added] did not exist on the ground . . . In some cases, these trails appeared on published maps.”*

The DEIS contains references to the savings in cost of diminishing trail maintenance through the “reclassification” of trails to a lower trail class level. (IV-35) The exclusion of these “non-existent” trails (1) eliminates the cost of maintaining them, and (2) closes them to pack stock (II-3). To save a few dollars (and by not allowing volunteer trail maintenance efforts), trails will be lost or closed to pack stock. (response # 348, 357)

Response: See Response to Public Concern # 216

Public Concern #219: *The DEIS fails to evaluate the current as well as historical environmental impact of all uses in the areas in establishing a Trail Management Plan, notwithstanding that the DEIS recognizes that uses other than stock use have a significant impact. (ES-8) (response # 401)*

Response: The current analysis is primarily focused on commercial pack stock operations. The trail plan attempts to respond to anticipated use types and levels, whether hiker, private equestrian, or commercial equestrian. As stated in the introduction for the trails section in Chapter 4, all trail users have a variety of effects on a trail system and resources in the immediate corridor. The effects of hiker use on a trail are different than equestrian use, and are described in that section.

Public Concern #220: *California Equestrian and Trails and Lands Coalition objects to the proposal in the DEIS to adjust trail maintenance levels to reflect recreation categories and desired conditions in the 2001 Wilderness Plan. Alternatives 2-5 will restrict the use of much of the trail system by historic pack and saddle stock, limit pack and saddle stock to heavily impacted portions of the wilderness and deny pack and saddle stock users the opportunity for solitude and a primitive or unconfined recreation intended by the Wilderness Act. (response # 278)*

Response: See Response to Public Concern #212 and #214.

Public Concern #221: *Have pack stations lost the use of trails by combining the Trail Plan with the Commercial Pack Stock Management EIS? (response # 311)*

Response: No. The analysis of the two planning efforts is being conducted jointly, in part because many of the considerations are the same. However, the actions for each planning effort are being undertaken separately, so that the Commercial Pack Stock Management actions are limited to commercial users, and the Trail Plan affects all trail users.

Public Concern #222: *When providing education about trails not recommended for private stock, limit signage within wilderness to the minimum.*

Comment: *We also would suggest that that warning signs on trails Not Recommended for Stock (NRFS) be done only in a general sense at the trailheads or perhaps listed in some sort of handout that could be given to stock users. Risk is inherent in Wilderness, and most of the wilderness areas surrounding the Ansel Adams and John Muir have policies against warning signs within wilderness areas. Signing within the wilderness may imply this sort of hazard is safe if not signed, and set precedence for those using other parts of the Sierra. Closing a trail to prevent resource degradation does not necessarily violate our policies in the park, although signing is kept to a minimum. (response # 426)*

Comment: *The level of signing for trails designated as "Not recommended for Stock." In general, wilderness should be as free from human installations as possible. Since these trails are primarily limited to commercial operators, it is reasonable to expect these operators to know where they can and cannot go. To place signs to assure no use seems unnecessary and counter to wilderness management practices. (response # 425)*

Response: Trails "Not Recommended for Stock" will not be designated in the FEIS, and will be designated as a future administrative consideration. This comment will be considered when evaluating the best and most appropriate methods to communicate this advisory to the public.

National Trail Management Class

Public Concern #223: *The DEIS promises, at ES-5, "The Wilderness Plan direction is to adjust trail maintenance levels to match the three recreation categories (cite). This does not prohibit stock in recreation category 1 areas. Trails may be more primitive and rough, but this does not exclude stock use." And yet the DEIS contains a lot of discussion of just how pack stock WILL BE EXCLUDED from "Class 1" trails! (At pages I-2; II-48; IV-45; I-8; II-3, just to name a few examples.) In fact, the DEIS recommends, at page D-40, "Trail Management Direction: Do not upgrade any trails from maintenance level 1 and 2 solely for the purpose of facilitating stock use." But this statement is contradicted by other citations within the DEIS which show that, in fact, "Where the trail is of poor quality or blocked, thereby forcing detours, additional impacts may occur," (IV-66, Table 4.1.19) and also, "In many cases, designating a higher trail class to*

meet an immediate or expected demand will have beneficial effects on the physical environment. If a use trail or low-development system trail with minimum management is not so difficult to travel that use is limited, and it is currently receiving heavy use, it is likely that the trail is already causing some physical resource impacts that could be corrected by more intensive management. In these cases, designating a higher class and bringing the trail to standard would likely have a beneficial effect by stabilizing damaged sections of trail, improving drainage and reducing effects on various resources without significantly changing use patterns" (at IV-35). It would appear that trails used by pack stock actually benefit the ecology of those trails, and that would be consistent with the fact that the majority of the trails in existence today were created by stock users before 1964. (response # 348)

Response: See Response to Public Concern # 212 and #214.

Public Concern #224: *An economic analysis of trail maintenance funding, including historical, current and anticipated funding, as well as maintenance backlogs by various alternatives must be provided for the public to understand the consequences of the alternatives. (response # 196)*

Response: An economic analysis of trail maintenance and funding is in the FEIS document. As described in the FEIS, very few trails are likely to receive “upgrades” from their current development level, though various adjustments have been made—both up and down—in response to a variety of factors. It is also understood that under the current funding regime, it is unlikely that every trail will be fully maintained to the desired standard to meet area management goals.

Public Concern #225: *System trails listed in the DEIS are in conflict with what is found on the ground. In a document in the DEIS project file, the Interdisciplinary Team Leader for the project stated in August 2002:*

“System trails listed in the plan were in conflict with what was on the map as a system trail. Many of the system trails were listed as a higher class than what we observed on the ground. Some of the system trails were not listed in the FEIS, but in a subsequent SNF inventory. “

The plan must include an accurate, objective inventory of system trails as they actually exist. (response # 196)

Response: As pointed out in the above quote, made during the planning process, as well as disclosed in the DEIS Purpose and Need, all known inventories of the trail system had inaccuracies, omissions, and other errors as compared to what was found on the ground. This is one of the key purposes of the trail plan. In the FEIS, a summary of the comparison between observed trail development and various alternatives is displayed.

Public Concern #226: It is not clear whether the trail management plan is intended to be a programmatic or site-specific document. This is very problematic because it’s not clear when the Inyo and Sierra NFs will evaluate the environmental consequences of upgrading the trail designations. What will be the impacts of upgrading a specific trail to the standards identified? What will be the cumulative consequences of upgrading all of the trails in the planning area to the new standards? Forest Service staff has said in the past that the site-specific impacts will be evaluated in project-specific documents. But when it’s time for project-specific analysis, they say that the decision on trail class has already been made they’re just upgrading the trail to the identified level, and the trail class/level designation is not up for discussion. The Forest Service cannot have it both ways: the Forest Service must either evaluate the impacts of upgrading trail

designations at the programmatic or site-specific level. And the Forest Service cannot properly adopt inflated trail classes/designations that would allow substantial upgrades, putting off the issue until project-specific analyses, and then argue during project-specific analyses that such analysis is unnecessary (or that trail class is not up for re-consideration) because the decision has already been made at the programmatic level. (response # 196)

Response: This document designates the Trail Classes which will be used in future trail management. Project specific NEPA will be undertaken to analyze site specific physical effects of the repair work, which will use the Trail Class design guidance as the basis for the proposed design of the project. That analysis will not change the trail classes designated in this effort.

Public Concern #227: *The National Trail Management Class system is still in Draft form, and there is no national directive that it must be used. Additionally, the design guides for the Trail Classes have direction that is inconsistent with wilderness management, and should be modified for wilderness trails.*

Comment: *The Trail Management Classes (TMCs) have never undergone any formal rulemaking, and they are not included in the Forest Service Manual or Forest Service Handbook. Thus, they do not constitute law, regulation, or policy. The proposed action claims that they are national direction, yet there is no binding national directive that requires their use. The DEIS does not adequately describe what actions will be taken on what trails to bring them up to the identified TMCs. Thus, decision-makers and the public are not able to understand the extent of the proposal, or the environmental consequences. (response # 196)*

Comment: *The plan must acknowledge that elements contained in the TMCs are inappropriate in wilderness. Trail Class 2 allows for destination signs. Trail Class 3 mandates that destination signs will be Atypically present, that signs will be provided for user reassurance, that trail bridges will be constructed as needed for appropriate access, and that maintenance activities will be conducted for user convenience. Trail Class 4 provides that substantial trail bridges are appropriate at water crossings, that trailside amenities may be present, that a wide variety of signs is likely present, and that trail maintenance activities will be implemented to provide user comfort and ease. None of these things are generally appropriate in designated wilderness. The Inyo and Sierra NFs must not simply incorporate the national Trail Management Classes as written into their trail management plan for these wildernesses, but must both modify them to make them appropriate for designated wilderness, and analyze and disclose the environmental consequences of doing so. (response # 196)*

Response: See Response to Public Concern # 219 regarding the intended use of Trail Classes for the AA/JM Wildernesses. Design Guides for the trail classes were clarified in the Draft EIS to show how trails in the AA/JM Wildernesses would be managed. These have been further refined in the FEIS.

Public Concern #228: *More trails should be closed to commercial stock. (Attached list of approx 60 trails). Stock should not be allowed to travel cross-country unless site specific analysis shows that this can occur without affecting erosion rates or wilderness character. (response # 196)*

Response: Trails which have been determined by the IDT to be most unstable under continued commercial use are closed to commercial pack stock (NSCS). Other trails accessing areas where destination concerns about commercial use were also considered, and in some cases, use is either

prohibited or limited to levels which should be appropriate at these destinations. See Response T5 for similar comment.

Public Concern #229: *Use Trails Adaptive Management Strategy is inadequate. The so-called adaptive management strategy for user trails is subjective, non-scientific, and so full of loopholes that it would be incapable of ensuring protection of the wilderness character. (For example, visible tread is allowed to increase by 20% on trails rated 0 before use could be reduced; this number is absolutely arbitrary and does not take into account sensitive resources or provide objective triggers for action.) More simply, scientists have long recommended that commercial pack stock should not be allowed on any non-system user trail(s), except where site-specific environmental analyses demonstrates that a specific route can be open to stock use without increasing erosion rates or otherwise adversely affecting the wilderness character. No user trail should be open to commercial stock travel unless it is: (1) evaluated and cleared by resource specialists, and (2) designated as open to commercial stock in a public NEPA process. At minimum, this highly questionable adaptive management strategy should undergo scientific peer review (by qualified external scientists) before it is utilized by managers. (response # 196)*

Response: Use trails approved for use by commercial packstock have been analyzed to determine the likelihood of current and future unacceptable impacts to resources, including wilderness character. Some have had intensive field survey, while others were analyzed based on available information. Since conditions may change over time, monitoring and future management activities will be implemented in response to unacceptable changes. Measuring the percent of visible trail on otherwise undefined routes is just one measurement that is monitored, in addition to point feature impacts. Generally, point feature physical effects on lightly used routes are not as severe as those on heavily used, defined routes, however. Depending upon the type of effect, a variety of actions may be implemented to mitigate effects. Over time, these actions may lead to fewer trails being approved over time, or may allow for other changes in use.

Trails, Specific Comments on Trails/Trail Inventory

Public Concern #230: *Lamarck Col Trail should be closed to commercial stock. Such use is unnecessary, and the trail is being impacted by the stock use. The very small amount of stock supported hiker use is contributing to the notable resource effects in the National Park west of the col.*

Comment: *While hiking over Lamarck Col I encountered a group a people hiking without backpacks. They had hired the commercial packer to carry their packs to the base of the Col (very near the top). They said to me: "It's only \$120 each and we'll be fresh when we get to the top." These were all strong, able-bodied men who could have easily carried their own packs, and in fact were planning to carry their packs over Lamarck Col on a rugged backpack trip into Kings Canyon NP and beyond. How is this commercial use necessary? I repeat: How does the Forest Service rationalize this commercial use as necessary?*

It is of course not necessary. Such one-way dunnage trips are the ultimate in elitism. If you have enough money, you can have a mule carry your pack to the top of the first pass, to get a head start on everyone else, to get quickly past the dust and crowds that the Forest Service has allowed to degrade the trailhead areas, and never mind the erosion it causes, because the Forest Service and the packer don't care. It's all about convenience, luxury, comfort---and money.

So in my earlier letters, I asked for some information. And what did I find?

The Forest Service approved commercial use of this route for one-way dunnage trips, despite known and documented resource concerns (i.e., “impacts to riparian and meadow areas,” “known mountain yellow-legged frog populations,” “multiple trails and erosion concerns”). Without any elaboration or further study of the issues, the Forest Service simply approved commercial stock use to continue.

Despite the fact that the route has never been adequately designed, constructed, or maintained to withstand stock travel, despite the fact that the route is actively eroding and the erosion is being significantly exacerbated by stock travel, despite documented impacts to riparian and meadow areas, the Forest Service allows unnecessary commercial stock use to continue. (response # 346)

Comment: *Some specific aspects that we [Sequoia and Kings Canyon National Park] do not support are: The classification of Trail 3004C, Lamarck Col, as Trail Class 2. We previously communicated our concern that stock support will contribute to the amount of use over the Col and into a fragile and untrailed area of Kings Canyon National Park. This area has received notable resource impacts, including multiple braided use trails and user-built cairns, and a demand for emergency medical services to people who become injured due to their ability not meeting the technical nature of the route. Though the level of use facilitated by stock may seem small, we believe that each incremental effect adds up to an undesirable cumulative impact. We again encourage you to designate Trail 3004C as “Trail Class 1*, Not Suitable for Commercial Stock.” (response # 425)*

Response: In Alternative 2 - Modified, the Lamarck Col Trail is designated as “Not Suitable for Commercial Stock,” with a Trail Class of 2. The trail class 2 designation will allow for adequate structural mitigation to handle the moderate to high number of hikers on the trail. The trail used by pack stock has always ended before the top of the col, at a tarn, and this will remain the ending termini. Use trails continue over the pass into the park, which will be consistent with the unmanaged travel on the west side of the pass.

Public Concern #231: *Trails are closed such as the trail from Long Lake up towards Morgan Lake where the Sierra Club trip of 1963 camped. An ideal campsite and the area is beautiful and in excellent shape. However, the Forest Service restricts use to this camp. Access is good and the resource is protected. (response # 275)*

Response: The Little Lakes Valley Trail, which goes from Long Lake over Morgan Pass (and on to Morgan Lake) is open to all users—including commercial pack stock—under every alternative. All other system trails in this area are open to all trail users and commercial stock, with the exception of the Gem Lakes Trail, which was designated as Not Suitable for Commercial Stock in Alternative 4 only. Access to camps on the bench above Long Lake (toward Treasure Lakes) is also provided.

Public Concern #232: *Trail closures due to lack of maintenance or need for structures should have a ‘sunset’ date. We should all be working to find a solution to problems and then fix them, rather than close use. (response # 355)*

Response: In cases where trails could be readily repaired and few risk factors were present – aside from the need for physical mitigation – these trails were only temporarily closed to commercial stock. After repairs, some level of use would be allowed. In cases where stabilizing a trail would demand an inordinate amount of repair, or would require repairs that would be inconsistent with area desired conditions, or where risk factors are present that would make

repairs unlikely to succeed with continued stock use, trails were designated as closed to commercial stock use.

Trails, Comments on Chapter 2

Public Concern #233: *II - 31: System Trails - what “educational efforts” will be implemented? The public should be able to review this before trail closures take effect that would punish only those visitors who use Pack Station services. (response # 355)*

Response: The “educational efforts” mentioned in this section refer to signing and other notification of private equestrians to ensure awareness of which trails are designated “Not Recommended for [private] Stock”, and what type of conditions should be expected on these trails.

Public Concern #234: *We are frustrated with the Trails Plan because the Forest states that impacts to trails are caused by pack stock, yet recognize that in most cases these impacts can be mitigated and stopped by routine maintenance and appropriate structures. The Forest also recognizes that high backpack use causes the same type of impacts. Further, these impacted conditions (in the scope of 1.1 million acres) are extremely minimal and likely will not improve even if pack stock is re-moved. Since hiking/backpacking/day hiking has increased dramatically over the last 40 years, while at the same time stockpacking use has declined drastically, it is reasonable to assume the impacts of concern can be attributed to hiking use. Yet no disclosure is made of what these impacts are attributable to, pack stock is the only use being restricted, thereby denying access to certain lakes, trails and campsites used by families and groups for generations. (response # 355)*

Response: It is recognized that many impacts occur to trails and other areas within wilderness that are not attributable to commercial pack stock. While certain impacts can be traced to certain activities, the intent is to evaluate the current situation, and address or reduce impacts where possible. Actions within this document are focused on the permitted activities of commercial operators. While these actions will not solve every impact of every wilderness user, or even every impact of commercial stock, it is expected that these actions will have beneficial effects toward meeting desired conditions of these wilderness areas.

Public Concern #235: *2.3.1 Trail Management Plan - Construction of new trails needs to be left as an option. Should be only allowed on a case by case basis. (response # 355)*

Response: The 2001 Wilderness Plan provided direction that the current trail system adequately served the needs of access within the wilderness areas, and that no new trails would be needed. Realignment trails or placing an existing use trail on the trail system are actions specifically allowed within the Wilderness Plan, when such actions will have a beneficial effect on the wilderness resource.

Public Concern #236: *2.3.1, Trail Management Plan - Trails should never be removed from the “trail system” once access to an area has been established. If it is to be allowed, it should be a last option and only case by case. (response # 355)*

Response: In general, this is the approach that the Forests are taking when trails are removed from the system. As stated in Chapter 4, some “trails” removed from the system have never been an actual defined trail; others have different purposes and levels of use currently than when the trail was originally constructed. For example, mining roads or trails that are not used for

mining any longer combined with a lack of recreational demand has eliminated the need for a maintained trail. In some cases, trails were removed from the inventory if they duplicated a stable system trail to the same destination. Trails which require management to remain stable and available to anticipated uses were not removed from the system.

Public Concern #237: *2.3.1 - Trail Management Plan - Bullet pt. 11 is contradictory - Trails should be available to provide access for the public. (response # 355)*

Response: The referenced comment is from the 2001 Wilderness Plan, and is intended to clarify that the existing character of a trail will not be changed solely to improve the accessibility of an area – rather, that improvements will be based on an overriding benefit to the wilderness resource.

Trails, Comments on Chapter 4

Public Concern #238: *Trails: page IV-41.. Why doesn't the Forest Service fix the Mono Creek Trail? Why would you fund the McGee Pass Trail for reconstruction and not fix the Mono Creek Trail.*

The Forest Service fails to have a system in place to fix trails based on need and the public interest. In many cases, the wilderness management team refuses to maintain trail or propose new funding to threaten and penalize commercial packers who refuse to do the bidding of the local wilderness managers. And, perhaps there is money allocated to fix certain trails as quid pro quo for not challenging the Forest Service. COMPLETE LIES!!!

Often times trail maintenance is done so that it is convenient for the Forest Service people to be back home by closing. And, for many years an elitist attitude has prevented maintenance of any project that doesn't fit the personal philosophy of the wilderness managers. More LIES!!!

The Forest Service has refused to fix or maintain the Mono Creek Trail and the trails to Second and Third Recess. And, they refuse to fix the Shepherd Pass Trail. Another good example is the failure of the Forest Service to fix the trail to the Third Lake in Hilton.

The Trail plan lacks a previous history of trail maintenance and a plan for the future. (response #275)

Response: Each Forest submits proposals for special funding to repair trails based on that Forest's priorities and driving issues. McGee Canyon and Mono Creek trails are on different forests, so their funding structures are different.

The Inyo National Forest has invested funds in the Shepherd Pass trail during the past 20 years, including a substantial reconstruction effort in 1989. Each year since (including 2005), obstacles are removed, and basic recurring maintenance performed. This trail, like certain other eastside trails is only occasionally used by stock, and is lightly used by hikers, compared to most other trails in the AA/JM Wilderness. Expending large portions of the limited forest trail budget on such a trail would make very poor economic sense. The upper headwall has unique problems, which make long-term repairs impractical or impossible. As funding or volunteer resources are available, this trail will be maintained to the standards laid out in the FEIS.

Heritage Resources

Public Concern #239: *The document fails to acknowledge Packing as a “Heritage Resource” as required by law.*

Comment: *The National Environmental Protection Act (NEPA), as well as the California Environmental Protection Act (CEQA) provides protection to historic resources as it does for the natural environment. Pack operations as an historic activity which have remained in place through the present, as well as the historic trails and pack stations from which they operate, must be considered as valuable historic resources. Impacts to this activity, the trails, and the stations, must be considered under this review to comply with NEPA and CEQA, and mitigation measures must also outlined should your decision alter packing activities as they are currently in place. (response #form letter F, 104)*

Comment: *By law, pack stations and the packing industry are recognized as Heritage Resources. These resources are not limited to prehistory Indian usage sites. Nowhere in the document did we note that the Forest Service acknowledged the cultural and historical resources of pack stations and the professional packing industry. The only historical concern is primarily obsidian chipping grounds. Transportation with livestock is as old as the history of man and to imply that it is out of character in wilderness is absurd. Packing has been going on in the Sierra Nevada Mountains for over 150 years. This was long before there was a Forest Service or a Park Service, or environmental groups who have been born since the advent of technology and have no clue over what the real natural world actually is. The land is constantly changing naturally without the help of environmentalists who think it was in a mythical pristine condition 1,000 or so years ago and we must return to that imagined perfect condition. (response # 198)*

Comment: *It is clear that the USFS does not value the horse and mule packing industry as a cultural or historical resource. In looking at the Appendix C Literature Cited, a heavy tribal bibliography is cited, but only one book that addresses horse and mule packing and pack stations is included. By the very omission of good historical essays on the history of horses and mule packing in the Sierra, the forests have proven their continued indifference of packing as a cultural and historical resource that is valuable to our modern day society. (response # 279)*

Comment: *The DEIS does not address the use, history, or impacts of any reductions or loss of services of commercial packing that would result in each of the alternatives. The Heritage sections are remiss in not meeting the direction in the Programmatic Agreement. The PA clearly directs the agency to identify impacts, as it states “equestrian ... and stock packing are cultural resources that contribute to the significance of historic properties, and accordingly must be considered in addressing impacts on such properties.” (response # 279)*

Response: CEQA is not applicable to this project. NEPA does not have a term “heritage resources.” As stated in the DEIS “Heritage resources include archaeological sites, historic buildings, cultural landscapes, objects, and environmental features that inform us about human activities.” There is no legal definition of this term. A pack station over 50 years old is a heritage resource and as such needs to be evaluated to determine whether it is an historic property as defined in the implementing regulations for Section 106 of the National Historic Preservation Act (36 CFR 00.16.1[1]):

Historic property means any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the National Register of Historic Places maintained by

the Secretary of the Interior. This term includes artifacts, records, and remains that are related to and located within such properties. The term includes properties of traditional religious and cultural importance to an Indian tribe or Native Hawaiian organization and that meet the National Register criteria.

Section 106 requires that federal agencies take into consideration the effects of an undertaking on historical resources, not historical activities or industries per se. Compliance with 36 CFR 800 meets the NEPA requirement that the agency consider

“The degree to which the action may adversely affect districts, sites, highways, structures, or objects listed in or eligible for listing in the National Register of Historic Places (40 CFR 1508.27(b)(8)). See Chapter 4.1.1.4 for a discussion of identification and monitoring efforts.

All heritage resources within the inventoried areas were recorded and considered. In determining which were impacted by the pack station operations, the forests used monitoring data collected at over 300 historic properties in the wildernesses to derive “resources of interest”, i.e., those potential historic properties that may be adversely affected by the proposed action. The list of resources of interest does include some heritage resources associated with packing such as trash dumps and drift fences.

There are no actions planned that will adversely effect the historic values of trails. Future trails work will include consideration of historic values under Section 106 (Chapter 2: Direction Common to All). The pack stations themselves are being evaluated under SUP EIS and appropriate Historic Property Management Plans developed for each that will include mitigation where needed.

An expanded history of packing is included in the Final EIS.

Public Concern #240: *The proposals will have an adverse effect on historic pack station properties protected under the National Historic Preservation Act. (response # form letter A)*

Response: There are no planned activities that will adversely affect pack station properties.

As stated above, Section 106 of the National Historic Preservation Act requires federal agencies to take into consideration the effects of actions on historic properties. It does not require preservation of historic properties.

Response: The FEIS will address the use, history and impacts of the alternatives on commercial packing.

Public Concern #241: *Closing historic trails, destroying historic sites, denying historic usage of trails to any one group, is in clear violation of the Historic Sites Act of 1935. (response #103)*

Response: No destruction of historic sites is planned. Studies have shown that trails follow various alignments within corridors over time depending upon a variety of human and environmental variables. Historic trail corridors are not being closed.

Public Concern #242: *It should be explained why tephra deposits are singled out from other geologic materials as a heritage resource (section 3.1.1.4). Also, while shod hooves may trample flaked stone tools, what is the probability of that occurring per mile of trail and does that exceed the probability of a hiker or backpacker picking one up and putting it in their pocket. (response # 248)*

Response: Tephra deposits are singled out because of their chronometric importance and the paleoenvironmental information they contain.

Both shod and unshod hooves have been demonstrated to trample flakes and other artifacts such as pottery. The probability of a flake being trampled on a given stretch of trail would be dependent upon flake density, trail condition, the length of the stride of the horse, mule, or llama involve, the weight of the load the animal is carrying, and possibly other variables. All of which is moot as it is stated in Chapter 4, Table 4.1.19 Effects on Resources of Interest, that “Continued [trail] use in and of itself does not appear to be an adverse effect.”

Soils and Hydrology

Water Quality

Public Concern #243: *The NEPA document should contain appropriate measures to ensure compliance with water quality standards and control measures of the Regional Board’s Water Quality Control Plan (Basin Plan). The NEPA should consider potential impacts from both short and long-term effects resulting from pack animal and human usage of trails and wilderness areas. Impacts such as stream crossings that have habitat destruction due to stomping or water quality issues due to animal or human fecal material. The continued use of the same campsites could potentially cause long-term erosional impacts. Water quality could be degraded from surface runoff as a result of increased erosion from pack animal and human activities. Best management practices for mitigation of potential impacts need to be included in the NEPA document for both temporary and permanent impacts to streams and wilderness areas due to pack animal and associated human activities in the John Muir and Ansel Adams Wildernesses. (response #5)*

Response: The FEIS includes a revised and lengthened discussion of the water quality standards in the Water Quality Control Plans in Chapter 3 Hydrology Section (under the heading “Water Quality”). The potential impacts to water quality from commercial pack stock and the associated human use throughout Chapter 4 Hydrology Section (under the headings “Water Quality – Animal Waste” and under each wilderness-scale effects analysis, “Grazing water quality effects,” “trails,” and “Cumulative Impacts”).

In Chapter 4 Hydrology Section, the effects of commercial pack stock campsites are discussed under each Alternative at the wilderness-scale and at the Geographic Unit scale. The current level of compliance with BMPs related to campsites is in Chapter 3 Hydrology Section under the heading, “Campsites.”

Methods proposed under each alternative to manage the effects of commercial pack stock use on water and soil quality are included in the DEIS and FEIS throughout Chapter 2, especially in Sections 2.2 and 2.3.

The effects to wetlands is discussed in Chapter 4 Hydrology Section, under each alternative at the wildness and geographic unit scales, under the headings “Meadows/wetlands,” “Meadow hydrologic function,” “meadow stream functional condition,” and “meadow soil effects.”

Public Concern #244: *The Forest Service should not allow stock animals to roam freely where they can deposit manure into drinkable surface waters. The Forest Service should prevent such*

water contamination by requiring stock animals to be tied or fenced away from surface waters (response # form letter G)

Response: The FEIS includes a revised and lengthened discussion of the possible effects of pack stock manure on water quality in Chapters 3 and 4, Hydrology Section (under the headings “Water Quality” and “Water Quality – Animal Waste, respectively).

The FEIS contains a more thorough discussion of potential pathogen transmission from pack stock to surface water and humans than was in the DEIS (in Chapters 3 and 4, Hydrology Section). The Forest Service reviewed more articles pertaining to pathogens in pack stock manure and in Sierra Nevada wilderness water. In our review, we could not find any data that showed a connection between pack stock use and degraded water quality or pathogen transmission to humans. We could also find no data that suggest significant levels of human pathogens or other pollutants are in surface water within the John Muir and Ansel Adams Wildernesses. While it is acknowledged that pack stock deposit manure in water when crossing streams, watering, or grazing, there is no evidence that beneficial uses of water (such as drinking, swimming, fish spawning habitat) in the AA/JM Wildernesses are being substantially affected by this manure.

Due to the lack of evidence that enough manure is entering surface water to degrade current water quality or affect beneficial uses except very locally at the site of manure deposition, management actions were not taken to address this issue.

Public Concern #245: *Pathogens. The analysis of pathogens in the DEIS (IV-98) is less than one page long, and is totally inadequate. Scoping comments from interested parties clearly alerted USFS to the issue of pathogens in packstock manure. The USFS allows commercial packstock (i.e., horses and mules) to freely roam and deposit manure into surface waters that are consumed by wilderness visitors. There are NO fences to keep packstock from depositing manure directly into streams and lakes from which wilderness visitors drink.*

The DEIS properly cites a recent study by Derlet and Carlson, but fails to acknowledge that these scientists found pathogens in 18.5 percent of packstock manure samples. This means that approximately 18.5 percent of packstock manure that is deposited directly into surface waters is polluting surface waters with human pathogens (in addition to nutrients and other pollutants). In short, packstock are polluting streams and lakes in the Muir-Adams Wildernesses with human pathogens.

This is in spite of the fact that management practices (i.e., portable electric fencing, packed in feed, pickets, diapers, etc.) are now readily available to keep packstock manure out of surface waters. The DEIS must evaluate all available options for preventing this on-going pollution.

The DEIS fails to mention any State water quality standards for pathogens, nor does it mention Antidegradation requirements. Neither the Forest Service, nor the Central Valley Regional Water Quality Control Board, nor the Lahontan Regional Water Quality Control Board have made the findings required by State Water Resources Control Board’s Resolution 68-16 to allow degradation of water quality by packstock manure and urine that is deposited directly into surface waters.

The DEIS concludes that: pack stock manure is not known to have contaminated water with human pathogens. This is a ridiculous statement. We know that packstock manure contains human pathogens. The study by Derlet and Carlson (cited in the DEIS) documents this fact. And

we know that packstock roam freely to graze when they are not working, and regularly deposit manure directly into surface waters. This is enough evidence to know that water is being contaminated with, and polluted by, human pathogens.

The analysis of pathogens in the DEIS is also flawed because it implies that the only pathogens in packstock manure are bacteria. In fact, Derlet and Carlson also found that packstock manure contains giardia, which is a protozoal parasite more resistant to disinfection than bacteria.

The DEIS's analysis regarding pathogens is woefully inadequate. We know that packstock manure contains pathogens (not only harmful bacteria, but also giardia). We know that packstock manure is deposited directly into surface waters, because packstock are allowed to roam freely and have many times been observed defecating directly into surface waters (in addition to contaminated runoff from manure deposited in near-stream areas). And we know that such impacts are avoidable, because modern management practices could be applied to prevent the contamination, even in remote wilderness settings. (response # 196)

Response: The FEIS contains a more thorough discussion of potential pathogen transmission from pack stock to surface water and humans than was in the DEIS (in Chapters 3 and 4, Hydrology Section). The Forest Service reviewed more articles pertaining to pathogens in pack stock manure and in Sierra Nevada wilderness water. In our review, we could not find any data that showed a connection between pack stock use and degraded water quality or pathogen transmission to humans. We could also find no data that suggest significant levels of human pathogens are in surface water within the John Muir and Ansel Adams Wildernesses.

There is evidence that areas heavily used by backpackers and pack stock, or areas grazed by sheep or cattle, have increased levels of pathogens and fecal coliform in the water (Suk et al. 1987, Suk et al. 1986, Derlet et al. 2004, Derlet and Carlson 2003). The Suk studies found that giardia existed in low concentrations in sites used heavily by backpackers and packstock, but in some other areas heavily used by pack stock and backpackers, no giardia were found. There is plenty of circumstantial evidence that drinking water in the wildernesses has made hikers sick, but this evidence is difficult to substantiate. The connection with pack stock manure is unknown.

The few limited studies completed on human pathogens in pack stock manure in the Sierra Nevada (Johnson et al. 1997, Derlet and Carlson 2002, Atwill et al. 2000) found that there are pathogens in a minority of manure from packstock used in Sierra Nevada wilderness areas. Johnson et al. (1997) and Atwill et al. (2000) found that less than 5% of pack stock manure sampled contained giardia, and found no cryptosporidium. Derlet and Carlson (2002) found pathogenic bacteria in 15 of 81 samples, and giardia in one sample taken on trails in Yosemite, Sequoia and Kings Canyon National Parks.

While these studies suggest that there is a risk of pack stock manure carrying human pathogens and depositing these pathogens in water when crossing streams, watering, or grazing, there is no evidence that water quality in the AA/JM Wildernesses is being substantially affected by this manure.

Page IV-98 of the DEIS (section 4.1.2.1) states, "Derlet and Carlson (2002) found that 15 of 81 samples of fresh pack stock manure on trails in Yosemite and Sequoia/Kings Canyon National Parks contained pathogens capable of causing human disease." This corresponds to 18.5%. In the FEIS, we included the percentage, for greater clarity.

Public Concern #246: *Nutrients. The DEIS acknowledges (at p. IV-98) that packstock manure and urine could lead to increased nutrient levels in lakes. Alteration of nutrient levels can lead to alteration of aquatic ecosystems and create a more fertile environment for bacterial preservation and reproduction. Such human-caused alterations of nutrient levels are potentially significant, and are not allowable, because no antidegradation findings have been made to allow nutrient increases in the high quality waters normally found in the John Muir and Ansel Adams Wildernesses. The USFS needs to evaluate and implement modern, feasible, reasonable, and readily-available management practices to keep packstock manure and urine out of surface waters and wetlands (i.e., portable electric fences, diapers, etc.). And the USFS must address federal and State Antidegradation requirements before it allows any further human-caused increases in nutrient levels due to recreational practices. (response # 196)*

Response: There is very little research available discussing nutrient levels in Sierra Nevada waters. We could not find any that relate nutrient levels to commercial pack stock or other recreational use, although as stated above, the DEIS does acknowledge that there is a potential for such increases.

The FEIS includes a more thorough discussion of nutrient levels in the Sierra Nevada than was included in the DEIS in Section 3.1.2.2. The discussion is as follows:

There have been few studies about nutrients in Sierra Nevada Lakes, and no studies were found that discussed terrestrial nutrient inputs. A few studies suggest that algae and phosphorous levels have increased in Sierra Nevada Lakes over a wide area in the past two decades (Sickman et al. 2003, Schindler et al. 2001), but these studies cite introduced fish and atmospheric deposition as causes. Sickman et al (2003) suggested that the widespread nature of eutrophication suggests that nutrients entering lakes are airborne. Nutrient contributions from recreational activities are unknown, but could occur from human waste, soap used for washing, sunscreen washed off in lakes, or packstock or cattle manure.

The FEIS also includes discussion of the antidegradation requirement included in the Water Quality Control Plans, and the effects of each alternative on water quality pursuant to the antidegradation requirements. The discussion in Chapters 3, Hydrology Section under the heading, "Water Quality" is as follows:

Quantitative water quality data was not collected as part of this project, partially because beneficial uses, such as swimming, municipal drinking water, and fish spawning habitat, were not observed to be affected by water quality. Downstream water quality at the areas of municipal use is assumed to be an indication of wilderness water quality, because the water originates in the wilderness. Municipal water quality is not completely indicative of wilderness water quality. Some wilderness values and beneficial uses within the wilderness, such as wildlife habitat, may be more sensitive to water quality than municipal uses downstream. Further, any pollutants become diluted downstream. Because it is assumed that the water quality currently meets or exceeds water quality standards from the Lahontan Water Quality Control Plan (standards can be found in *Water Quality Standards* document in the project record), the water is subject to the "nondegradation objective" (LRWQCB 1994). This object requires, "continued maintenance of existing high quality waters" that exceed quantitative standards, with no degradation. There is no indication that water quality has been degraded by recreational uses, according to the small amount of quantitative data available.

There are not enough quantitative data to determine whether that assumption is correct.

While the FEIS acknowledges that manure enters water and can affect local water quality, it is assumed that there is not enough manure deposited in the water to affect beneficial uses or degrade water quality away from directly adjacent to the site of manure deposition relative to past conditions.

Public Concern #247: *It has long been known that stock holding areas pose the potential to cause significant nonpoint source water pollution. The Forest Service's own Best Management Practices Evaluation Program has shown that backcountry stock holding areas have among the lowest implementation and effectiveness scores of any nonpoint source pollution category. The DEIS states that the Forest Service and/or permittees will prevent nonpoint source water pollution from stock camps by installing BMPs within five years of permit issuance. The Forest Service cannot legally put these problems off for up to five years. It must move more diligently to prevent water pollution from stock holding areas. (response # 196)*

Response: Under the selected alternative, Alternative 2 – Modified in the FEIS, implementation of designated stock holding campsites that meet BMPs will occur within two years, not five years as written in the DEIS.

Public Concern #248: *The description of the affected environment clearly states that many areas contain meadows, streams, and trails with degraded conditions and hydrological functions which may adversely affect water quality and sensitive critical areas. Although the action alternatives include elements to protect critical areas and reduce adverse impacts, the alternatives do not significantly improve the degraded conditions of these areas. We recognize the contribution of historic high-levels of grazing, mining, and other wilderness uses to current environmental degradation. However, EPA remains concerned with the minimal water quality and ecological improvements provided by the proposed action alternatives.*

EPA recommends additional management actions be integrated into the preferred alternative to ensure full compliance with water quality standards and more rapid restoration of degraded meadows, streams, and trails. We urge the Forest Service to consider stock night quotas that are aligned with meadow hydrological conditions, closure of meadows with stream segments assessed as functional at-risk with a downward trend, and exclusion of stock from standing water and saturated areas occupied by the Yosemite toad during the breeding and rearing season.

A detailed description and commitment to monitoring measures and enforcement is not provided in the DEIS. The lack of this information is of significant concern. Projected improvements to degraded resources are based upon compliance with new, more stringent use standards. We understand that more detailed enforcement and monitoring measures and commitments may be provided in subsequent NEPA analyses for individual Pack Stock Special Use Permits (p. I-2 and telephone conversation with Mary Beth Hennessy, June 23, 2005). If this is the case, we recommend the Forest Service describe the general framework for enforcement and monitoring in the Final Environmental Impact Statement (FEIS) for the Use Authorization action and commit to NEPA analyses for the individual Pack Stock Special Use Permits. These individual Special Use Permit NEPA analyses should include a detailed description and evaluation of monitoring and enforcement measures that will be applied to each permit.

Response: This EIS is a programmatic document addressing commercial pack stock use in the Ansel Adams and John Muir Wildernesses. It does not propose management actions for all uses of the wilderness including other recreational use, mining, or non-commercial pack stock grazing. Site specific actions to more rapidly improve conditions of trails, meadows and campsites than possible by altering management of commercial pack stock use will be addressed in future processes, as necessary.

We considered and analyzed the effects of closure of meadows with stream segments assessed as functional at-risk with a downward trend, and all meadows with severe hydrologic function alteration in Alternative 4. We included exclusion of grazing stock from saturated areas occupied by the Yosemite Toad as a management actions under Alternatives 2-5. As stated in the Wildlife section of Table 2.2 in the DEIS, Yosemite Toad breeding habitat areas would be considered critical areas, where a 5% use standard would apply. The 5% use standard is basically a tool to exclude grazing, while allowing for accidental entry with negligible effects at the limit of measurement.

Alternative 5 considers and analyzes the effects of having no commercial pack stock use in the Wilderness. It therefore analyzes the effects of the maximum protection possible with management changes only commercial pack stock.

The FEIS includes a monitoring plan that will describe monitoring procedures and the specific monitoring findings that will trigger management changes. In the future Special Use Permit EIS, enforcement procedures will be described.

Water Quality

Public Concern #249: *The Sierra streams provide drinking water to millions of people. It seems strange that the problem of water pollution from wilderness recreation has received so little attention. Water pollution is so prevalent that even travelers in remote, high-altitude parts of the wilderness have to treat the water. Yet there have been few studies to identify the pollution sources.*

Cattle grazing is known to be associated with the spread of the giardia organism, and it seems likely that pack stock also transmits this pathogen , especially since it appears in high altitude areas that are not subject to cattle grazing. Removal of pack stock should improve water quality in the wilderness although, of course, other pollution sources would remain.

It is recognized that pack stock manure can be a source of increased nutrient levels in lakes. The amount of nutrient increase traceable to this source is not known, but it seems clear that this poses a potential threat to amphibians and aquatic wildlife. (response # 392)

Response: See response to Public Concerns #245 and #246

Public Concern # 250: *As the designated water quality management agency under the Clean Water Act Section 208 Management Agency Agreement, the Forest Service is required to implement Best Management Practices (BMPs) and other measures to achieve full compliance with all applicable State water quality standards. Implementation of BMP measures alone do not necessarily ensure full compliance with State water quality standards. For instance, the 2002 Clean Water Act Section 303(d) list identified over 50 streams impaired by excessive sediment, nutrients or pathogens associated with roads, silvicultural activities and/or grazing throughout the Sierra Nevada. Additional management actions beyond BMPs may be required to achieve full compliance with all applicable water quality standards. The Final Environmental Impact*

Statement (FEIS) should describe water quality standards and BMPs for the project area, including standards for pathogens and Clean Water Act antidegradation requirements. Evaluate the Forest Service's ability to ensure full compliance with water quality standards through the use of BMPs and identify additional measures that may be necessary to achieve compliance.

Response: In response to this comment, the FEIS includes a more thorough discussion of water quality standards and BMPs for the project area (Chapters 3, Hydrology Section), Water Quality subsections. It includes a list of the applicable BMP measures and describes the nondegradation requirement in the state Water Quality Control Plans (Section 3.1.2.2). Throughout the sections of the DEIS on water quality, meadows/wetlands, campsites, and trails, the DEIS describes the known and suspected effects of commercial pack stock use on water quality. The analysis includes estimates about whether actions will degrade water quality or not.

In Alternatives 2-5, measures beyond BMPs are described that are intended to reduce water quality degradation. These measures include more strict grazing management, trailhead and destination quotas, campsite designation, closure of sensitive grazing areas, trails and destinations, exclusion of commercial pack stock from many areas that currently receive little use, and others.

Public Concern #251: *Survey results of meadow hydrologic function alteration, properly functioning stream conditions, soil compaction, sod fragmentation, campsite and stock holding area conditions, grazing effects, and trail conditions clearly demonstrate the potential for continued water quality and ecosystem impairment under all alternatives (Chapter 3 and Chapter 4). For example, 8% of trails analyzed are causing severe alteration of soil or hydrologic processes (p. III-25). Under Alternative 2, the Proposed Action, five meadows determined suitable for grazing would continue to have a high potential for increased sod fragmentation (p. IV-115). Continuing current practices where commercial pack stock use appears to be contributing to adverse water quality effects is of concern, especially given the adverse effects of past grazing and mining practices.*

Recommendation: EPA recommends that destination quotas, grazing allocations, daily and seasonal stock quotas, and other levels of use controls be aligned with management direction to improve resource conditions. Where commercial pack stock use is clearly contributing to continued impairment of water quality and ecological function, we recommend implementation of more stringent use limits, temporary closures, grazing rotation systems, and other management practices to reduce and eliminate these impacts. We recommend all meadows with severe hydrologic function alteration, nonfunctioning streams, or streams with functional at-risk downward trends be designated not suitable for grazing and closed to grazing.

Response: See response to Public Concern # 248

Public Concern #252: *The DEIS states that some meadows might continue to have a minor reduction in hydraulic function under Alternative 2 if the recommended number of grazing nights are fully utilized (p. IV-111). However, the DEIS states that it is unlikely that proposed stock nights would all be used in all meadows. Meadows with streams that are functional at-risk with downward trend would continue to have a high number of grazing nights similar to, or more than, recent use (p. IV-113). We recommend the number of maximum grazing nights be allocated based on reduction of hydrologic function alteration and functional at-risk criteria, whether or not these grazing nights are used in their entirety in all meadows. Use limits should not be determined on the assumption that an area will not be grazed at the allocated high stock night*

numbers (e.g., p. IV-262). We recommend the grazing night allocations respond more aggressively to recorded sod compaction, functional at-risk and other identified water quality and ecosystem impairments. The number of maximum stock nights should be aligned with the carrying capacity of the resource or, if use is low, with current practice. For example, the proposed stock nights for Johnston Meadow is 193 stock nights. Even though current reported use is 20 stock nights, the stream is incised, and the meadow has moderate vegetation alteration and is expected to trend away from its potential under Alternative 2 (pps. IV-262 to 263). Because of these degraded conditions, the maximum number of stock nights at Johnston Meadow should be 20 nights or less.

Response: see response to Public Concern #248

Public Concern #253: *Most of the analyzed campsites within 50 feet of water, regardless of the site type, are contributing sediment and/or manure to surface water (p. III-34) with significant local adverse effects (pps. III- 27 to 34). Furthermore, of 9 stockholding sites and 11 spot/dunnage sites located less than 50 feet from water, over 90% are contributing substances to water and are water quality concerns (pps. III-33, III-34). These adverse water quality effects are of significant concern given the high use of surface waters by other wilderness users.*

Recommendations: The Forest Service should work closely with pack operators to address water quality impacts caused by stockholding sites and campsites less than 50 feet from water. Of specific concern is Fish Camp in Mono Creek which is located within 10 feet of the water with observable water quality degradation (p. III-34). Other sites causing water quality concerns should be addressed (e.g., Waterfall Camp in French Canyon, p. III-34; specific problems identified at the stockholding campsite near the junction of Shadow Creek and Nydiver Creek, p. III-60). We recommend closure or relocation of campsite and stockholding areas with significant and observable adverse effects to water quality.

Response: Under Alternatives 2-4 and Alternative 2 – Modified, stock holding campsites would be designated. As stated on page II-33 of the DEIS, all designated sites would be “contained in a manner that is consistent with Best Management Practices.” Fish Camp would not be open under any action alternative, because it is within 10 feet of water and therefore cannot meet BMPs. The Preferred Alternative in the FEIS (Alternative 6) also requires designated stock holding campsites that must meet BMPs.

Public Concern #254: *Although the DEIS describes concerns with water quality inputs from campsites, eroded/incised trails, stockholding, and grazing areas, it states the assumption that water quality in general is very good with impacts locally moderate to severe (p. III-27). The DEIS does not describe water quality monitoring or quantitative data to support this assumption. The FEIS should describe current water quality monitoring, if any. EPA recommends implementing a monitoring program in areas with known moderate to severe water quality degradation and high use. If funding and staffing resources are limited, the Forest Service should consider a limited, one-time water quality sampling project to validate water quality assumptions and determine if human health risks are present in drinking water sources (e.g. e-coli, guardia, other bacterial pollutants).*

The Forest Service should commit to the development of subsequent NEPA analyses for specific Pack Stock Special Use Permits. These NEPA documents should include water quality and management effectiveness monitoring plans.

Response: See response to Public Concerns #245 and #246.

Public Concern # 255: *The DEIS does not appear to describe or address packstock watering practices which could contribute to water quality impacts. The FEIS should describe packstock watering practices and the potential for environmental impacts to water quality, threatened and endangered species, fish and wildlife, and sensitive aquatic habitat. If potential impacts are likely, describe alternate stock management practices and mitigation measures to reduce these impacts.*

Response: In response to this comment, the FEIS includes discussion of the water quality effects of watering practices, under the headings “Grazing Water Quality Effects” in Chapter 4, Hydrology Section, at the wilderness scale.

The FEIS contains a more thorough discussion of potential water quality effects from pack stock than was in the DEIS (in Sections 3.1.2.2 and 4.1.2.1). The Forest Service reviewed more articles pertaining to pathogens in pack stock manure and in Sierra Nevada wilderness water. In our review, we could not find any data that showed a connection between pack stock use and degraded water quality or pathogen transmission to humans. We could also find no data that suggest significant levels of human pathogens are in surface water within the John Muir and Ansel Adams Wildernesses. While it is acknowledged that pack stock deposit manure in water when crossing streams, watering, or grazing, there is no evidence that beneficial uses of water (such as drinking, swimming, fish spawning habitat) in the AA/JM Wildernesses are being substantially affected by this manure. Therefore, mitigation measures were not deemed necessary.

Wetlands/Meadows

Public Concern #256: *Many of the high elevation, mountain meadows may meet the definition of jurisdictional wetlands under the Clean Water Act. We are particularly concerned that significant impacts to seasonal wetlands may occur due to uncontrolled trampling by packstock in the early season when soils are saturated during, and immediately following, snowmelt. No specific grazing start dates are described in the DEIS. The Forest Service should identify the location, extent, and functions and values of jurisdictional wetlands within the project areas and potential impacts to these wetlands from the proposed project. The FEIS should establish adjustable grazing start dates that prevent adverse impacts to the hydrology and biology of wetlands and meadows. These start dates should be based upon range readiness and monitoring results.*

Response: In the FEIS, Chapter 3, Hydrology Section, it includes more clear language that the Forest Service considers all wet and moist meadows as wetlands. The potential effects to those meadows/wetlands under all alternatives are described in Chapter 4, Hydrology Section. See also response to Public Concern #288.

Public Concern #257: *Wetlands. Most high-elevation meadows are wetlands, and the USFS does not control packstock sufficiently to protect these wetlands from degradation caused by packstock trampling. The most significant damage occurs in the early summer season, following snowmelt, when heavy stock animals trample saturated soils. The USFS's start dates for grazing were chosen more to continue current practices than to protect wetlands. The start dates do not consider in any way the site-specific soil or hydrologic conditions of the high-elevation wetlands in these wildernesses.*

Response: see response to Public Concern #288

Public Concern #258: *The DEIS says that 94 meadows in these wildernesses were grazed by packstock from 2001 to 2003. Yet it would allow 138 meadows to be grazed under Alternative 2 (June 2004 Proposed Action), 133 meadows to be grazed under Alternative 3 (currently favored action), and 113 meadows to be grazed under Alternative 4. Thus, impacts to wetlands will likely increase under all of the action alternatives (except Alternative 5, which would ban all packstock, and is not likely to be seriously considered), but the DEIS fails to admit this simple fact. Instead, the DEIS relies on unrealistic assumptions to conclude that wetlands will be adequately protected. (response # 196)*

Response: The FEIS includes, in the Meadows/wetlands Chapter 4, Hydrology Section, the total number of meadows requested for grazing by commercial pack stock operators. This was considered the realistic number of meadows that was likely grazed at least once in the long-term. Only 94 meadows had reported grazing between 2001 and 2003, but more were grazed in past years (some, such as those in Pioneer Basin and McGee Creek, were closed for resource protection within the past 10-20 years) and therefore have effects that may be at least partially attributable to commercial pack stock. As stated in the Meadows/wetlands Chapter 4, Hydrology Section, "227 of those [meadows] grazed regularly in recent years and most likely to be grazed were analyzed in the field." Therefore, about 1/2 of all meadows requested for grazing and reasonably likely to be used in the future were approved for grazing.

Standards for meadows in wilderness are that meadows and their streams should be in proper functioning condition and the meadows should be in satisfactory rangeland condition (Sierra Nevada Forest Plan Amendment, 2004). Although more meadows are able to be grazed, it is assumed that limits such as stock night allocations, 5% trampling allowed in critical areas such as fens and wetlands, and limits on traveling trips described in Alternatives 2 and 4 would allow meadows to meet resource standards.

The following is included in the FEIS, Chapter 4, Hydrology Section

Under Alternative 2, effects in meadows should be slightly improved from current conditions. Only 94 meadows were actually grazed between 2001 and 2003, and this alternative would allow 138 meadows to be grazed by commercial pack stock. However, meadows found to be unsuitable for grazing or have currently unacceptable impacts would be closed to use, and only meadows found to be suitable for grazing would be open for grazing.

Although 138 meadows would be open to grazing, it would be unlikely for commercial pack stock operators to have grazing in each of those meadows every year. Over the long term, it is likely that they would graze all or most of those meadows, some annually and some only every few years. The commercial pack stock operators requested to use 385 meadows, and are allowed to use about 1,500. However, they only used 94 between 2001 and 2003, and it is assumed that they would continue about the total number of stock nights used in the past, or less, under Alternative 2. They might use less because the number of overnight traveling trips would be reduced and therefore there would be less need for grazing.

Elimination of grazing on some meadows found to be unsuitable for grazing would allow for some local soil and hydrologic condition recovery. Of the 94 meadows that were grazed from 2001-2003, 20 would be closed or rested and 15

would have substantially reduced grazing (at least 20 stock nights less) under Alternative 2. Therefore about 1/3 of the meadows/wetlands that were grazed from 2001-2003 that are unsuitable for grazing would be closed or have reduced impacts from fewer stock nights. About 70 meadows with no reported grazing from 2001-2003 would be opened to grazing. It is assumed that because those meadows were found to be suitable for grazing, and because they were given a grazing allocation to meet utilization standards, the negative effects, although they may occur, will be minimal and within standards.

Under all alternatives, including Alternative 5, which would have no pack stock use, only slight improvement in overall meadow/wetland functional condition is expected (as shown in Table 4.1.31 in the DEIS). Under all alternatives, about 200 meadows are expected to remain in their current hydrologic functioning condition, with almost 40 expected to have improved condition under Alternative 5 and roughly 25 expected to improve under Alternatives 2-4.

Soils

Public Concern #259: *It is clear that pack stock can break up meadow sod and create unsightly areas where water will accumulate. However, in the eastern Sierra, I have not read of any studies that document plant species changes or changes in species composition or density.*

Without data to support measurable changes in stream channel morphology or turbidity increases, I respectfully suggest that the pack stock “problem” is one of perception and is best addressed by the methods used by social scientists. Vague and all encompassing jargon such as “resource concerns” is no substitute for clear and concise description of individual problems.

Commercial pack stock operations are a valid and long standing historic use that should continue to be available to those who desire or require alternative transportation and a different wilderness experience. (response #358)

Response: The interdisciplinary team used the best available literature as a part of this analysis. (see Literature Cited, Appendix C). The research considered and cited includes the most recent research specific to packstock use in similar, and adjacent, ecological settings. This research does assess plant species changes or changes in species composition or density associated with pack stock use in the Sierra Nevada mountains (see Literature Cited, Appendix C, especially the 2004 *Journal of Range Management* article by D. N. Cole, J. W. Van Wagendonk, M. P. McClaran, P. E. Moore, and N. K. McDougald: *Response of mountain meadows to grazing by recreational stock*).

Throughout Chapters 3 and 4, Hydrology Section, there are site-specific descriptions of stream morphology condition, meadow hydrologic function, soil compaction, and possible sediment increases in channels and lakes. The assumed causes are discussed, and the uncertainty in causes are also discussed. The term, “resource concerns” is often used in the Wilderness or Trails section of the DEIS to summarize the effects to many resources. However, within each specialty, such as “physical sciences” and “vegetation,” more specific terms, such as “stream functional condition,” “meadow hydrologic function,” and “increased fine sediment in streams” are used to describe observed effects.

Beginning on pages III-143 in the DEIS, there are a series of tables (Table 3.2) that describe specific effects to each meadow analyzed. These effects include, “hydrologic function change,” “PFC” (stream functional condition), “vegetation composition change,” “% that never reaches range readiness,” and “spring impacts.”

There are no qualitative data available regarding stream morphology or turbidity related in the AA/JM wildernesses. The observations uses were often one-time observations, using visual methods described in the Study Plan (available in the project record). While these observations are not measurable, many used established protocols, such as the Proper Functioning Condition (PFC) protocol, or the Best Management Practice protocol for stock campsites in the wilderness. These established protocols, and other methods described in the Study Plan, can be repeated by future specialists to determine whether the condition has changed over time. The PFC protocol estimates the ability of a stream to withstand high flows, based on the channel form and vegetation on the banks, and addresses stream morphology.

Public Concern #260: *Erosion and Sedimentation. The DEIS acknowledges that 30% of meadows visited by USFS specialists have moderate to severe sod fragmentation which is leading to soil erosion and sedimentation of surface waters (DEIS p. IV-126). Yet the USFS proposes to continue grazing in many of these meadows without controls to avoid exacerbation of the on-going erosion and sedimentation. The DEIS has at least three major flaws in its analysis of the potential for erosion and sedimentation: (1) It fails to evaluate management practices that could reduce trampling of sensitive streambanks, lakeshores, and wetlands by packstock (i.e., portable electric fences to keep stock animals out of sensitive areas, more meadow closures and better grazing start dates to avoid trampling of wet areas, etc.). (2) It relies on wholly unrealistic methods to keep packstock animals out of sensitive and closed areas. (3) It allows up to five years or more for BMPs to be installed at stock holding sites, with no plan for monitoring implementation or effectiveness of the BMPs. (response # 196)*

Response: The DEIS evaluates three alternatives (Alternatives 2, 3 and 4) where grazing is allowed, but is controlled by allocation of grazing stock nights, implementing a 5% trampling standard for critical areas, and closing meadows that are especially susceptible to erosion. Under the effects analysis in Chapter IV, section 4.2.2.1, the DEIS discusses the predicted effects of grazing strategies under each alternative. It assumes that simply closing sensitive meadows and allocating stock nights would reduce sedimentation overall, because there would be less grazing on those meadows susceptible to erosion.

The DEIS does not prescribe specific practices to meet the required standards: the Forest Service responsible official would work with the commercial pack stock operators to meet the standards using described and available tools in the selected alternative. If operating direction is not met, the responsible official would take appropriate actions to ensure compliance, which could include reducing or eliminating grazing.

Monitoring and Enforcement

Public Concern #261: *The DEIS states that there is a high degree of uncertainty in some locations regarding the feasibility of keeping grazing pack stock out of critical areas in accordance with the proposed 5% inadvertent trampling standard (p. IV-111). For instance, Alternative 2 would continue to allow grazing in Upper Spooky Meadow at levels similar to current grazing, even though trampling to the spring with fen characteristics would be difficult to keep at less than 5% without changes to stock management (p. IV-291). Monitoring, compliance, and enforcement of proposed management measures are key in ensuring that projected improvements are achieved. The Forest Service needs to demonstrate that proposed management measures are feasible and enforceable and that management direction will be fully implemented. The FEIS should describe present and future management, monitoring, and*

enforcement measures to ensure that proposed use limitations in meadows, campsites, critical areas, and trails are adequately implemented. Describe and evaluate grazing and stock management practices that can be used to keep pack stock out of critical areas and in compliance with use restrictions (e.g., portable electric fences, drift fences, pack lines). Include a list of mitigation measures that will be implemented if impacts are in excess of the allowable inadvertent level of use. We recommend monitoring to validate the assumption that packers can control grazing stock to prevent their use of critical and unsuitable areas from exceeding inadvertent use levels. The FEIS should include a commitment to implement an adaptive management program which can respond to changing conditions. We recommend working closely with pack operators to maximize implementation of proposed use limitations to prevent excess grazing impacts.

The NEPA analysis for individual Pack Stock Special Use Permits should include a specific monitoring and enforcement plan.

Response: The selected alternative, Alternative 2 – Modified identifies the conditions that must be achieved, and provides the responsible official and operator with various tools to do so. Prescribing the specific approach to achieve the condition for every destination given the many variations and differences in operations is not practical or necessary. If the condition cannot be achieved by the operator, the grazing will not occur.

The FEIS includes a monitoring plan that will describe monitoring procedures and the specific monitoring findings that will trigger management changes. In the future Special Use Permit EIS, enforcement procedures will be described.

Public Concern #262: *To protect sensitive areas from trampling and erosion, the DEIS relies on the employees of the commercial outfits to monitor stock movements, and to somehow, magically, to keep packstock from roaming into sensitive areas as they freely drift and graze throughout the night. The DEIS (IV-111) acknowledges that there is a large amount of uncertainty about the feasibility of keeping grazing pack stock out of critical areas when they are grazing at large. Yet despite the expressed doubts, the USFS proposes the business-as-usual approach (i.e., identifying critical areas but adopting no realistic measures to protect them). (response # 196)*

Response: The selected alternative, Alternative 2 – Modified identifies the conditions that must be achieved, and provides the responsible official and operator with various tools to do so. Prescribing the specific approach to achieve the condition for every destination given the many variations and differences in operation and operators is not practical or necessary. If the condition cannot be achieved by the operator, the grazing will not occur.

Soils/Hydrology, Comments on Chapter 3

Public Concern #263: *Clarification on page 111-82. This paragraph comes to totally incorrect conclusions because of the lack of some occurring facts. The Hurricane Olivia storm occurred in September of 1982. Severe flooding occurred throughout the Sierra. Jackson Meadow, Tully's Hole and Cascade Valley were lakes for many days. Fish Creek incised during that storm. It was not man caused and neither meadow impacts nor trail impacts had anything to do with it. It was days of heavy rains – a natural event. Streams and rivers throughout the Sierra were incised by the floodwaters. In Cascade Valley, prior to the flood, there were logjams and debris that slowed the flow of Fish Creek. These were washed out in a few days. In*

wet years Cascade Valley and Fish Creek have flooded but never like the “storm of 1982”. The flood event of New Years Day 1997 also seemed to have done some flood damage in Cascade Valley. There is a clarification on page 111-79 that relates to the Hurricane Olivia event in Convict Canyon. This was the storm event that originally washed out the trail in Sept. of 1982. Before this event, the trail was quite good for many years. (response # 198)

Response: The information you provided about the date of the storm and its cause were included in the FEIS in Chapter 3, Hydrology Section. Further, we added further discussion about the uncertainty regarding the cause of incision. The discussion now reads as follows:

In the Cascade Valley AU, Fish Creek is incised throughout Cascade Valley in the segments that are not bedrock. According to historical accounts (Michael Morse, Forest Service, personal communication, 2004), the stream incised in 1982 during a very heavy hurricane-induced rainstorm. It is unknown whether meadow or trail impacts adjacent to the stream or upstream made any contribution to Fish Creek incision, or whether it was a natural process due to high flows and previous drought conditions that reduced vegetative cover. Its current incised state makes it less able to withstand high flows without further incision and widening. The creek continues to widen, and it is possible, although not verifiable, that meadow conditions contribute to lack of recovery. Meadow conditions could contribute to lack of recovery because the compacted surfaces with reduced vegetative cover reduce infiltration rates. Rainfall and snowmelt therefore runs off on the meadow surface at a higher velocity and at greater volumes than under natural conditions. The high flows enter streams and are transported downstream at higher velocities and higher discharge more capable of eroding stream banks. This process has contributed to incision of streams in Grassy and Jackson Meadows, but it is unknown whether it has contributed to incision of Fish Creek in Cascade Valley downstream.

The storm in September 1982 that resulted in Fish Creek downcutting created the second largest flow in recorded history (since 1922) in the San Joaquin River, just downstream of its confluence with Fish Creek (at the Miller’s Crossing stream gauge). In December 1955, a larger flow was recorded, which did not incise Fish Creek. It is impossible to determine the combination of conditions required for incision, and whether human causes contributed. However, it is possible that there was some human contribution. Gully erosion may be triggered by any, “changes in the watershed or climate which result in more flow, less sediment, reduced vegetation cover, a downstream base-level change, and increased valley floor slope, or a change in subsurface process,” (Hagberg 1995). Both climate and grazing impacts can result in more flow and reduced vegetation cover, and therefore could contribute to stream incision.” Many researchers have correlated gully erosion and stream incision with grazing impacts (Hagberg 1995, Woods 1975, Warren et al. 1986), although there remains uncertainty about the exact conditions and mechanisms that lead to gully erosion.

The following comments are from response #275:

Public Concern #264: *III-82—The implication that meadow conditions are causing the incision and widening of Fish Creek are ludicrous. The banks are primarily lined by sand and silt. Incredible flash flooding and runoff creates erosion forces.*

There is no mention of weather and the drought followed by the occasional heavy snow year and flooding. The runoff in Cascade Valley is from up stream. The collapsing of the riverbanks is not from the condition of the meadow.

Anything is possible and the hydrology assessment fails as an adequate analysis of hydrologic function in Cascade Valley. At least on III-83 the commentator talks about natural occurring flood events. (response # 275)

Response: see response to Public Concern # 263

Public Concern #265: *III-84: What are the campsites that do not meet BMP's?. Aren't they backpacker camps? (response # 275)*

Response: The FEIS clarified the type of sites where BMP evaluations were completed in Chapter 3, Hydrology, under the Campsites subheading. The clarification states,

Commercial packers identified approximately 1,617 campsites that they have used in the past or would like to use in the future, and of those, 163 sites were evaluated for water quality effects using the BMPEP protocol and other observations. The sites evaluated were all identified by commercial pack stock operators as sites they use or would like to use. However, some of the sites evaluated did not have any evidence of pack stock use.

Public Concern #266: *III-98 The plan suggests that water degradation is due to the campsites of commercial use. For example it states on III-98 that many sites along Mono Creek are located less than 100 ft from the creek and can contribute sediment to the creek during rainfall or snowmelt. It doesn't state that almost all or 100% of the use in these campsites is due to non-commercial wilderness users.*

Response: The statement in the DEIS was not clear about the type of sites and the number intended by "many." The wording was therefore changed from, "Many campsites along Mono Creek are located less than 100 feet from the creek and can contribute sediment to the creek during rainfall or snowmelt" to "Of the four pack stock holding or spot/dunnage sites along Mono Creek analyzed for compliance with BMPs, all are located less than 100 feet from the creek and can contribute sediment to the creek during rainfall or snowmelt. An unknown number of sites that are predominantly used by backpackers are also located within 100 feet of Mono Creek. Although many of these sites exist, they tend to be smaller and individually contribute less sediment into Mono Creek."

Public Concern #267: *Campsites: Hiker caused BMPEP protocols. There is always a potential for local and lake-wide water quality issues. This document fails to note that the major threat to water quality issues is people and not stock.*

Picket lines are hundreds of feet to over a thousand feet from the lakes. The comment I heard in the last meeting regarding hydrology in the Basin was that the manure from picket lines would leach into the underground water and contaminate the lakes. Is this the concern noted? What doesn't the Forest Service look at actual water quality samples in Hilton Creek and use them?

There are evidence of picket lines close the water in occasional places. This is due to non-commercial stock users.

Where is the campsite along Hilton Creek that causing sediment? We don't use any camp on Hilton Creek. There is an old camp where backpackers occasionally use and was used in the 1960's. If this is the camp referred to...it should be so stated. It shows that there can be lasting effects to disturbed areas. What it shows is that non-commercial users often cause much more severe effects than commercial users.

In the second to last paragraph on page III-98 they refer to the Fourth Recess AU. They state that 40% of the campsites are contributing sediment to water. They fail to mention that many or most are camps that commercial users don't use. There is no attempt by the Forest Service to separate out use throughout the plan.

Yet, how does the Forest Service refer to the Bench Camp at Hopkins Meadow? Are they confused with a camp at Third Recess? It shows the lack of understanding of the Forest Service of what is actually going on in the backcountry.

The Forest Service refused to allow the commercial packer from Rock Creek to participate in meeting the id team in Mono Creek. And, we have provided information to our permit administrators over many years to prevent this type of miscommunication.

The writers of the section on campsites does not mention or show where we camp at Hopkins Basin, Hopkins and Mono area, Second Recess and the Fourth Recess Lake area. They do make a reasonable attempt at Pioneer Basin.

If this is an environmental assessment of campsites and pack stock use; why then doesn't the Forest Service separate out dunnage, spot and fully outfitted trips?

The DEIS overstates how many stock camps are less than 100 ft. from water and contribute to sediment. In an environmental document that is supposedly site specific...we should know the number and location of the sites.

In many cases, the campsites that have the most use show the least amount of impacts and potential for having water shed during runoff. Reading this analysis does not allow the public or decision makers to make reasonable assumptions about where and how much livestock is appropriate.

Response: This document focuses on commercial pack stock effects, and therefore only discusses impacts of humans not using pack stock in general terms and in the cumulative effects analysis. The following statements have been added to the FEIS to better address the impact of humans and other non-pack stock related uses.

Section 4.1.2.1: Analysis common to all alternatives/ Water Quality-Human waste subsection:

Humans, beavers, deer, dogs, and other animals can also carry human pathogens and deposit them in soil, on the soil surface, or in water (Derlet et al 2004, Derlet and Carlson 2002, Atwill 1995). While the few studies completed suggest that there may be a risk of pack stock transmitting human pathogens into surface water, the severity and extent of actual transmission is unknown. From the low prevalence of pathogens found in pack stock manure and in most Sierra Nevada water sampled, the risk appears to be low.

Section 4.1.2.1: Alternative 1, Cumulative Effects:

The effects of Alternative 1 on cumulative Wilderness water quality outside of grazed areas is unknown. Effectors to water quality within the wilderness include human waste, pack stock waste, human products such as soap and shampoo, domestic animal waste, wild animal waste, atmospheric deposition, cattle waste, and in some locations, possibly mine tailings. While there is evidence of increased coliform and bacteria below heavily used pack stock areas, there is also increased coliform in areas with little to no pack stock use, and no coliform found in areas with high levels of pack stock use. No studies have directly correlated heavy pack stock use with water contamination, although IDT

observations of pack stock defecating directly in water suggests that pack stock manure does enter water, and could have negative effects to water quality. What is known is that one or a combination of the above listed effectors has increased nutrient levels across the Sierra Nevada, and that there are levels of human pathogens and other bacteria in some lakes capable of affecting human health. Pack stock and the clients supported by commercial pack stock likely add some fraction of the contaminants to surface water throughout the AA/JM Wildernesses, but the degree of their contribution is unknown.

The concern about campsites in the Hilton Creek area is that camps are located too close to surface water. In the Wilderness Plan, campsites are required to be 100 feet from surface water, unless topography precludes this distance, and in no case should the sites be less than 50 feet from surface water. As stated on page III-33, "Table 5 in Appendix B displays the summaries of BMPEP protocol campsite results by analysis unit." In that table, it shows that of the 10 commercial pack station identified sites in the Hilton Lakes Analysis Unit, six are within 100 feet of water and six are contributing sediment to water.

In the Hilton Creek area, two commercial pack station operators identified a combined 61 campsites for requested use. Six of these sites were along Hilton Creek adjacent to Davis Lakes. It was assumed that the sites requested by commercial pack stations were used at some point by the commercial pack stations, and therefore the effects were assumed to be from groups using commercial pack stock. It is not stated whether the picket lines are less than 100 feet from the lake in the Hilton Lakes area, but the BMP protocol measures the distance to water from the edge of the campsite, not from the picket line.

As stated on page III-32 of the DEIS, all sites where BMP compliance was evaluated for pack stock related campsites only, and the sites evaluated were chosen out of the campsites identified by the commercial pack station operators. Campsites were recorded either as stock holding or spot/dunnage sites, and on page III-33, figure 3.1.10 shows how the two types of sites were separated for analysis of water quality effects.

The DEIS includes the number of sites that were found to be within 100 feet of water. On pages III-33 of the DEIS, it refers to analysis-unit specific BMP results in Table 5, Appendix B. In that table, it shows that out of the 163 sites analyzed for BMP implementation, 91 are within 100 feet from water. It also shows that 63 are contributing sediment to water. The location of the sites is described in more detail in hydrology portion of the Geographic Unit sections of Chapter 3, where site specific information is included.

The Forest Service does not have data for the amount of use at each campsite, so it was not possible to determine whether the campsite use levels affect the soil and hydrologic impacts. Through use information from the commercial pack stock operators and observations in the field, the IDT was able to determine whether a site was a stock holding site or a spot/dunnage site. Figure 3.1.10 shows that there was a greater percentage of stock holding camps with water quality impacts than spot/dunnage sites, especially with the sites 50-100 feet from water. The IDT assumed that stock holding camps were more likely to cause impacts to water quality because they are generally larger in size and therefore cause more surface runoff than smaller sites (p. III-34). breaks down soil structure.

To clarify the location of campsites where BMP analyses were completed, the Forest Service included a table in the FEIS project record with campsite locations and BMP results, referred to in Chapter 3, Hydrology Section, Campsites subheading. A map showing BMP locations is also

included in the project record, referred to in Chapter 3 in the FEIS. For clarification about campsite locations, in the FEIS the camp at the junction of Hopkins Creek and Mono Creek is not referred to as Bench Camp, but as the Camp at the junction of Hopkins and Mono Creeks.

Public Concern #268: *On page III-99 the Forest Service doesn't adequately describe the campsites in the Graveyard AU. Did the id team go up the Goodale Pass Trail? There are multiple large hiker camps alongside of the creek and on the trail.*

Where is the Bench Camp they refer to? Their assessment is wrong in the second to last paragraph. The camps they refer to is called the Bench Camp...never have been.

The picket lines are placed at the direction of the Forest Service. Easy to rectify by moving. What is substantial amounts of sediment?

Many sites along Mono Creek are located less than 100 feet from creek. But, they are from hikers. Not stock.

Response: The IDT did hike the Goodale Pass trail, and observed low campsite densities, as described on page III-99. The IDT was focused on effects of pack stock use, and therefore did not specifically visit campsites unless they were requested by commercial pack stock.

Bench Camp, as stated on page III-98, is at the confluence of Hopkins and Mono Creek. In the FEIS, it is referred to as "the camp at the confluence of Hopkins and Mono Creek." The name "Bench Camp" is not used.

The picket lines, as you suggest, would be moved over 100 feet from water (or far enough to meet BMPs) under all action Alternatives, as required in the Wilderness Plan.

"Substantial" amounts of sediment is not a quantifiable description. Here, it suggests that sediment was being observed entering water in visible quantities, outside the range of normal sedimentation.

The Mono Creek campsite discussion was changed in the FEIS to the following:

Of the packstock related campsites evaluated for BMP compliance in the Fourth Recess AU, 40% are contributing sediment to water. One of these sites, at the confluence of Hopkins and Mono Creeks, is one of the campsites of highest concern in the project area. The stockholding site is within 10 feet of a stream, with substantial amounts of sediment were observed entering the stream from the site. Of the four pack stock holding or spot/dunnage sites along Mono Creek analyzed for compliance with BMPs, all are located less than 100 feet from the creek and can contribute sediment to the creek during rainfall or snowmelt. An unknown number of sites that are predominantly used by backpackers are also located within 100 feet of Mono Creek. Although many of these sites exist, they tend to be smaller and individually contribute less sediment into Mono Creek.

Public Concern #269: *III-99-Absolute lie that there are many stock campsites within 100 ft of water.*

Response: The language in the FEIS was clarified. The DEIS read:

While a number of camps are located less than 100 feet from water, and social trails associated with the camps are contributing sediment to the lakes, campsites are generally not causing water quality problems or excessive soil productivity degradation." [regarding Pioneer Basin campsites].

The FEIS reads,

While a number of camps are located less than 100 feet from water, some are hiker related and some are pack stock related. Three commercial pack stock-related spot/dunnage sites were evaluated, and two were found to be less than 100 feet from water. These sites appear to be contributing minor volumes of sediment into surface water, but campsites are generally not causing water quality problems or excessive soil productivity degradation.

Soils/Hydrology, Comments on Chapter 4

Public Concern #270: *Chapter 4.1.2. The comment about pack stock manure contained pathogens capable of causing human disease implies that pack stock manure is causing problems. Their study is misleading and their paper is not the best way to address the public health concerns of livestock in the wilderness.*

The general public and decision makers can make better management decisions with appropriate public health data.

It is unsettling that the Forest Service didn't research the subject better and include citations that actually suggest the relative risk of people getting sick from manure from horses and mules.

This EIS should address water quality issues. The real danger is from the amount of people, where they camp and where they defecate. Commercial outfitters typically use pit toilets and bury the manure where appropriate. Probably the worst offender affecting water quality is day users of the wilderness. Why doesn't the Forest Service reduce day users and encourage better education to eliminate water pollution.

Response: See response to Public Concerns #245 and #246.

Public Concern #271: *Chapter IV-102: Third Recess Meadows always had commercial pack grazing. They state little grazing from 2001 to 2003 and in 2004 to 150 nights. The records of Rock Creek Pack Station bear little resemblance to what is being reported to the EIS. Someone lost the cards?*

Before going to the final EIS we first should look at what data the Forest Service is using and attempt to get a proper number and where the stock is grazing.

Response: The DEIS (and the FEIS) disclose the best information available on past grazing in the wilderness areas. Grazing numbers will be verified for the Final EIS.

Public Concern #272: *Chapter IV-117 The last paragraph doesn't make sense. Use is less now than ever. Look at use over the last 25 years. There has been considerable management of the area and in this section they mention adverse cumulative effects from campsite use. Elsewhere in the document on the affected environment on Fish Creek there are opposite claims.*

All alternative 2 does is give McGee Creek and Mammoth Lakes the right to control all of Fish Creek and eliminate Rock Creek and Red's Meadow Pack Stations from using the area.

This document does a very poor job of looking at cumulative effects from multiple pack stations. Where is the data? Where is the analysis through time that show what the impact is of multiple operators? Alternative 2 doesn't improve the environment. There is substantial regulations and the major effect of Alternative 2 is that because you can't graze, or stay in camps on the John Muir Trail there will be a lack of opportunity of people to travel the John Muir Trail and end up at Fish Creek. It has nothing to do with more regulations of campsites, etc.

Response: The last paragraph on page IV-117 reads,

Overall, the risk of adverse cumulative effects would be minor, except in the Upper Fish Creek, Silver Divide, Cascade Valley and Purple Bench Analysis Units in the Fish/Convict/ McGee GU. In these areas, it appears that recent commercial pack stock use has contributed to moderate intensity adverse cumulative effects from campsite use, commercial pack stock use of trails, and moderate to heavy grazing in meadows. These effects are also likely connected to historical cattle sheep and packstock grazing, non-commercial pack stock users, and hikers, the commercial pack stock also appear to have contributed. The more stringent management proposed under Alternative 2 in this area has the potential to reduce adverse cumulative effects to soil and water resources.

In the FEIS, a statement has been added to the end of the paragraph.

...although some would likely remain over the short term. In the long term, the commercial pack stock related impacts would likely be reduced due to a reduction in grazing in meadows with current moderate to severe hydrologic function alteration and functional at-risk streams.

This statement attempted to clarify the intent of the paragraph, that commercial pack stock effects occur currently, as a result current use combined with past uses, and that while some of these effects will continue in the short-term, in the long term there should be improvements. Throughout the physical environment section, Chapter 4, there is consistency in treatment of Fish Creek, as the area with the most widespread soil and hydrology impacts that can be at least partially attributable to recent commercial pack stock use.

This document does not differentiate between effects of different pack station operations, but combines all pack station when looking at current conditions and predicting effects under Alternatives. Therefore, it does look at cumulative effects of different operators.

Alternative 2 will limit grazing in the Fish Creek watershed, and will therefore affect commercial pack stock operations. The analysis of effects to operations can be found on pages IV – 74 to 77.

Public Concern #273: *IV-403. Hilton Analysis has lots of overnight commercial pack stock. Hundreds of animal nights per year.*

Response: The statement that “there is little no overnight commercial pack stock use” intended to show that there was little holding of stock overnight within the Hilton Lakes Basin. The forest was using stock grazing numbers, with a high reported of 42 stock nights, and no grazing in the other years. However, the forest does not have data about overnight holding of pack stock without grazing. This sentence is omitted in the FEIS, and only stock nights of grazing are discussed.

Public Concern #274: *IV-409—Under Alternative 3 you state there are no limits on traveling trips. I don't think this is correct?*

We disagree that Mono Creek Corridor will have grazing closed. And, we disagree with the analysis that there is excessive sediment of dirt going into surface water.

Response: The sentence on page IV-409 of the DEIS that stated, “Under Alternative 3, there are no limits on traveling trips” was clarified in the FEIS. It was changed to, “Under Alternative 3, there are no specific limits on the number of traveling trips that could occur. The number of traveling trips is only limited by the number of stock at each pack station and trailhead quotas.”

Throughout the Mono Creek Corridor, up to 323 stock nights could be used annually, as reported in Table 2.4, p. II-146. The area would not be closed to grazing, although some specific meadows, such as the meadow at the junction of Hopkins and Mono Creeks, would be closed to grazing or have limited use allowed. The grazing in the corridor itself would be reduced from a high around 520. There would also be over 500 stock nights allowed in canyons tributary to Mono Creek, including Second Recess and the Hopkins Creek Corridor.

Sediment was observed entering the water from campsites during a rainstorm in summer 2003, along Mono Creek. According to Best Management Practices, sediment or other substances should not enter water from campsites or other uses. Therefore, the sediment observed entering the water is excessive.

Wildlife

Public Concern #275: *Pack stock groups are drawing bears. Since you opened up the Davis Lake areas (above Thousand Island Lake) to pack stock groups the bears are now inhabitants. I have backpacked to Davis Lakes for over 30 years and never encountered a bear until two years. (response # 220)*

Response: The wilderness manager for the Rush Creek area has not received any bear problem complaints at Davis Lake. The commercial pack stock camp has been present since 1994. Davis Lake area is suitable bear habitat and therefore it is logical bears would use that area and may have in fact become more abundant, however we have no data to show that is the case. Improper food storage typically shifts bear movements in wilderness and non-wilderness alike where bears could be perceived as being drawn to an area. The Forest Service requires the use of proper food storage methods of all wilderness users in Rush Creek to prevent bears from being “drawn” into the area.

Public Concern #276: *The Forest Service should consult with U.S. Fish and Wildlife Service on any threatened or endangered species in the Wilderness areas. We have previously provided information on effects to listed and proposed for listing species. (response # 196)*

Response: The U. S. Fish and Wildlife Service has requested that we only consult on the final EIS preferred alternative. This consultation is completed.

Public Concern #277: *Aquatic Biodiversity Management Plan objectives set by the Department for areas in the Big Pine, Mt. Tom, Bishop, and Middle Fork of the San Joaquin watersheds are in conflict or may be in conflict with pack stock holding, dunnage, and camping areas proposed in some of the alternatives. Most pack stock destinations are at or near waters that are managed for recreational angling rather than fishless. In addition, restoration areas may require conservative management to protect sensitive species and their habitats, for example from trampling or lower water quality. Due to general descriptions of existing or proposed stock holding areas, camps, and dunnage locations in the DEIS, the Department suggests meeting with the USFS to determine potential conflicts or impacts with the Department’s proposed and existing restoration and resource areas. (response # 238)*

Response: The Forest Service met with the Department to discuss this issue on July 20, 2005.

Public Concern #278: *The alternatives (except for Alternative 5) do not provide for the future viability of wildlife in the wildernesses. They do not even protect the habitat of endangered*

species as required by the Endangered Species Act. In Alternatives 1, 2, 3, and 4, outcomes for wildlife viability cannot be predicted. Alternative 5 offers full protection for all meadows and thus eliminates potential adverse effects for ground nesting birds that frequent meadows such as the willow flycatcher. Under Alternatives 1-4, it is possible for stock to intrude into suitable unoccupied willow flycatcher meadow habitat and even into occupied habitat.

Meadow dependent species, especially amphibians are most obviously threatened by the continuation of pack stock grazing. None of the alternatives except for Alternative 5 materially increases the level of protection accorded endangered amphibians such as the Yosemite Toad and Mountain yellow-legged frog. (response # 392)

Response: The DEIS concluded that based on the analysis there would be no adverse effects of any alternative on any Federally listed threatened, endangered or proposed species or their habitat. The DEIS analysis also concluded as well that stock use of meadows under Alternatives 1 through 4 would not adversely affect the viability of riparian or meadow edge MIS bird guilds or the yellow warbler across the wilderness analysis area, or the willow flycatcher that nests in shrubs. The DEIS noted no willow flycatchers are known to utilize the wilderness meadows for nesting at this time. The critical area 5% maximum trampling standard for key habitats in meadows in Alternatives 2 through 4 is designed to protect Forest Service sensitive amphibian habitat for the Yosemite toad and mountain yellow-legged frog. The Yosemite toad and the mountain yellow-legged frog are federal candidates for listing but have not been listed as either threatened or endangered.

Public Concern #279: *Removing pack stock from the wilderness would guarantee nearly completely undisturbed habitat for the Yosemite toad. In contrast, the other alternatives consider only a single survival factor – protection of Yosemite toad breeding sites.*

The DEIS discusses at length the consequences of pack stock grazing areas overlapping with Yosemite toad breeding sites. There are other threats to the toad in connection with pack stock meadow grazing. Among these are loss of breeding and rearing sites due to impaired hydrologic function; silting of pools caused by erosion in meadows and along trails; trampling of vegetation and disturbance of insect prey habitat; and isolation of toad populations to a single meadow or meadow complex because of topography changes. Some of these pack stock grazing consequences are mentioned in the DEIS, but the alternatives do not provide mitigation measures.

Substantial pack stock signs have been observed at breeding sites that were not identified for pack stock grazing. This raises the question as to how much unrecorded overlap is occurring.

Alternative 1 clearly threatens Yosemite toad viability.

Provisions in Alternatives 2 and 3 (including the 5% disturbance limitation) is an improvement over the essentially unregulated conditions of Alternative 1, but it does not offer real protection for the toad.

Since in general the effects of pack stock meadow use are not really understood, no meadow should be considered suitable for pack stock grazing from a wildlife conservation standpoint. (response # 392)

Response: The 2004 Yosemite toad monitoring study as well as numerous interdisciplinary field trips across the AA/LM Wildernesses from 2001 through 2004 only documented 1 meadow

not identified as a grazing area (DEIS, Chapter 4 page 159) where substantive pack stock trampling impacts were noted at a Yosemite toad breeding pool.

The analysis compares the various alternatives and discloses the unknowns and the uncertainty related to the continuation of commercial pack stock grazing and use of meadows inhabited by Yosemite toads. It also notes that livestock grazing has been occurring in such meadows in the wilderness and as well as livestock allotments outside of wilderness and on a number of other Forests, and Yosemite toads continue to occupy those habitats (Chapter 4, page 157). Given the uncertain aspect of grazing effects on the toad and its habitat, the fact that toads have persisted for many years in grazed areas, as well as the implementation of a Regional study to assess the effects of grazing it is reasonable to allow the continuation of grazing with management measures. This is the logic behind the determination in the Biological Evaluation that individual toads may be affected however the viability of the species would be maintained.

Public Concern #280: *EPA is concerned with the potential impacts to associated aquatic-dependent wildlife such as the Yosemite toad. Potential impacts to Yosemite toad are of specific concern because the U.S. Fish and Wildlife Service has concluded that the Yosemite toad may warrant protection under the Endangered Species Act. More than 90% of Yosemite toad habitat occurs within Forest Service wilderness areas and National Park Service lands, especially around Yosemite National Park. Fifty-eight (58) meadow areas identified as suitable for commercial pack stock grazing under Alternative 2 would overlap Yosemite toad breeding areas and could result in trampling and chiseling of Yosemite toad breeding pool habitats (p. IV-167). We recommend the Forest Service exclude stock from standing water and saturated soils in wet meadows and associated streams and springs occupied by the Yosemite toad during their breeding and rearing season. The FEIS should include management measures and a commitment to minimize potential impacts to Yosemite toads and their critical habitat. (response # 427)*

Response: The recommendation is noted. The 5% critical area standard in Alternatives 2 through 4 that includes Yosemite toad breeding areas addresses this concern.

Public Concern #281: *III-100: The DEIS should disclose that there are a lot of people who steal and collect Goshawks. (response # 275)*

Response: The DEIS Chapter 4, page 179 acknowledges the falconry take of goshawk in the cumulative effects section.

Public Concern #282: *Wildlife Chapter IV-141. #3. Cattle and Horse graze significantly different. Don't presume to extrapolate from cattle for horses. They graze differently, they graze different plants and they travel totally different. There are many studies on grazing of horses and their interrelationship with grazing. I would suggest you could extrapolate from horse studies to commercial horse studies. The difference between horses and commercial horses is not that much different.*

There is quite a bit in the literature about wild horse and the relationships with wildlife. I would be glad to share my literature with the Forest Service. (response # 275)

Response: We believe the extrapolation of livestock grazing studies is appropriate to assess the impacts of commercial pack stock grazing impacts on wildlife habitat. The extrapolation is appropriate since the analysis focuses on the cropping of herbaceous and woody vegetation at various utilization levels as well as trampling and chiseling impacts irrespective of the type of

animal. The Forest Service would appreciate any information you could share concerning horse grazing studies specific to effects on wildlife habitat.

Public Concern #283: *Chapter IV-142. Again, they assume Baxter Pass will be closed. The Forest Service said in 2001 that Baxter Pass would be available on a case by case basis. Now, here is closed.*

This is a perfect example of how the Inyo National Forest publicly states one management objective and then implants another. (response # 275)

Response: Alternative 1 considered maintaining the trail as suitable for commercial stock on a case by case basis. Your comment will be fully considered in the development of the Final EIS adopted alternative.

Public Concern #284: *Page IV-177—In the analysis of Goshawks there is no discussion about people collecting the young birds. (response # 275)*

Response: The DEIS Chapter 4, page 179 acknowledges the falconry take of goshawk in the cumulative effects section.

Vegetation

Sensitive Plant/Weeds

Public Concern #285: *All (commercial) pack animal users should be required to utilize certified-weed-free feed if traveling in/through areas where utilization of natural vegetation might have negative impacts on the natural ecosystems. (response # 301)*

Response: See Chapter 3, Weeds. SNFPA (2004) directs that use of weed free hay and straw be encouraged and that a program for use will be phased in as certified weed free products become available. An MOU among California agencies is currently in place to develop a weed free forage program, but the very limited availability of certified weed free hay and straw does not support requiring it in particular areas of the state as yet.

Grazing Resources

Public Concern #286: *Grazing zones and their rotation create problems related to the management of stock. Stock are creatures of habit and have a memory of grazing areas. There would be difficulty in rotating these animals from familiar grazing areas. This is not to say that rotation away from specific areas may not be warranted due to specific conditions. However, we believe that grazing should be consistent with traditional patterns unless contra-indicated by specific meadow conditions. We believe that the grazing provisions of February 2005 MOU should be adopted.*

We believe that meadow management should be based upon long term monitoring with identified baselines and standards for measurement of meadow health. If it is determined that a meadow is in decline, the cause of that decline should be identified before a management decision is made to exclude commercial pack stock as a “solution.” It is not appropriate to penalize pack operators unless it is definitively determined that their activities are the cause of resource decline. (response # 325)

Response: Grazing Zones are based on areas where the packers indicated that pack stock have actually grazed, so they should reflect the traditional patterns (see Common Management Direction to Alternatives 2-4, Commercial Packstock Grazing in Chapter II). Within the grazing zones “key areas” have been identified. Key areas are areas of traditional grazing by packstock and or areas of importance for monitoring. This monitoring will provide the information needed for adaptive management and flexibility to move use in response to compliance with applicable standards and to help progress toward desired long-term trends. Rotational grazing is only proposed in the DEIS in a few limited places (see the discussion of Rush Creek, and Hilgard/Rosemary in Chapter II and Chapter III).

The February 2005 MOU only addresses opportunities to validate site-specific grazing start dates and contains no other grazing provisions (see 2005 MOU). Grazing implementation is as directed by the decision in the referenced Wilderness Plan Record of Decision (Inyo and Sierra National Forests, April 2001). This decision is to: establish grazing utilization standards; adopt range readiness standards; establish commercial packstock forage use through special use permits; limit stream bank trampling and chiseling to less than 20%; include conditions in permits requiring operators to be involved in monitoring and to cease using meadows when grazing standards are reached; and for a full closure of meadows to all packstock grazing for the following season when over utilization of vegetation has occurred (see the Wilderness Plan ROD, page pp 4-5 and 16, the Packstock Management Guide, Appendix G, and Appendix A, relevant Laws, Policies, and Regulations). This analysis collects and interprets the information needed to implement the identified Wilderness Plan management direction.

Historical impacts and related meadow problems are discussed in Chapter III (see Grazing Operations, Meadows, and Hydrologic Function sections in Chapter III, and especially the Grazing Resources sections of the Ansel Adams West and Mono Creek/Rock Creek geographic areas. Additional descriptions of historical impacts and current conditions is found in the 2001 Wilderness Plan (Inyo and Sierra National Forests, 2001) and the Sierra Nevada Forest Plan Amendment (USFS, Pacific Southwest Region, 2004) and is referenced rather than duplicated in this EIS).

Today’s management emphasis is on assessing current conditions and desired conditions and then identifying needed changes in those factors, including stock use, contributing to current conditions being inconsistent with desired conditions. Possible management practices, and or alternative actions, are then identified to accomplish the needed changes. In some cases packstock use was not singled out as the sole factor resulting in unstable or degraded conditions. However once a site is damaged or becomes unstable continued grazing related impacts of the degraded or unstable system could delay or prevent recovery (see the discussions of Meadows, Soils, and Hydrological Function in the Physical Environment sections of Chapter IV and the discussion of Assumptions About Effects in the Grazing Resources section of Chapter IV).

The Wilderness Plan Monitoring Framework calls for long-term monitoring of ecological state and transition at key benchmarks (Wilderness Plan pages 37-39, and Appendix G, Pack Stock Management Guide). There is Management Direction in the Wilderness Plan to prohibit or mitigate ground disturbing activities that adversely affect hydrologic processes,” “develop measures to protect bogs and fens,” “modify or suspend grazing based on existing conditions.” There is no management direction to attempt to isolate one cause as the only or the primary cause before implementing a possible management practice (see the Commercial Packstock

Grazing section of Chapter II, as well as the associated referenced pages in the Wilderness Plan, pages 23-26, and the Wilderness Plan Stock Management Appendix, Appendix G).

Public Concern #287: *Grazing issues can be mitigated among packers who are already concerned with enhancing backcountry resources. (response # form letter A)*

Response: Grazing issues can indeed be mitigated among packers who are already concerned with enhancing backcountry resources. The process for this to occur is site-specific implementation of applicable Management Direction as directed by Forest Service Line Officers and facilitated by Forest Service permit administrators through the Special Use Permit process (see the paragraph on Adaptive Management in the Commercial Packstock Grazing section of Chapter II).

Public Concern #288: *Given that hydrological function is “impaired in many areas” and “These conditions are of significant concern, and indicate that use is occurring each year before soils ...are dry enough...” (DEIS, III-48), current grazing start dates are inadequate. The Forest Service needs to adopt grazing start dates that prevent such impacts. (response #form letter G)*

Response: Changes in the grazing start date management direction are outside the scope of this analysis. Grazing start dates are implemented as directed by the Wilderness Plan Record of Decision based on implementing the existing direction in the 2001 Wilderness Plan, as described in Appendix G, Pack Stock Management Guide (Inyo and Sierra National Forests, 2001). Basing the grazing start-dates on elevation and interpretation of snow conditions, as described in the Pack Stock Management Guide, is the most efficient given current time and funding constraints. This process and schedule was developed in response to the packers need to have grazing start date information in late winter to early spring for the purposes of trip planning and booking. The Pack Stock Management Guide states “...timely posting of grazing start dates, well in advance of the grazing season, will allow commercial operators and visitors to make trip itineraries with some level of certainty on where and when forage will be available in the wilderness...” (Wilderness Plan, Appendix G, page 6). The start dates are posted, that is notification is provided in letter to the packers and made available to the public, according to a schedule in the Pack management Guide.

The challenge facing Forest Staff is to provide the grazing start date information “well in advance of the grazing season” in response to the needs of the packers and to also comply with management direction in the Wilderness Plan and the Sierra Nevada Forest Plan Amendment protect the riparian resources and special aquatic features. Part of the compromise that must be accepted is if the packers need an early date for their trip planning that date must also be conservative to prevent impacts and in some instances the date will fail to adequately protect the resource unless the packers also accept responsibility for monitoring and complying with range readiness criteria as the summer progresses.

Additional site-specific determinations may be made if time and funding allow for the necessary field inspections (see the Commercial Packstock Grazing section of Chapter II, the Wilderness Plan pages 23-26, the Pack Stock Management Guide, Appendix G, and the 2005 MOU). The Wilderness Plan Record of Decision states that the Forests will require commercial packers to monitor grazing conditions, including range readiness (ROD, pages 5 and 16) which is intended to help ensure timely and accurate information on range conditions.

Public Concern #289: *The proposed grazing management scheme will not work. How can you say that an area is “closed” to grazing if an immediately adjacent area is “open” to grazing? Stock animals do not read the rules, and will drift freely from the open areas into the closed areas. The Forest Service does not have sufficient staff to monitor or enforce such an obviously impractical scheme. The result would be significant trampling and grazing impacts in the supposedly closed areas. (response # form letter G)*

Response: Meadows with critical areas will be identified for the packers in the operating plan. The packer will work with the permit administrator and range personnel to determine an effective way to avoid the critical areas (see the Commercial Packstock Grazing section of Chapter II, the referenced Wilderness Plan pages 23-26, the referenced Wilderness Plan Stock Management Appendix, Appendix G). It will then be the responsibility of the individual packer to ensure that the wranglers conducting individual pack trips implement the planned management at specific sites.

As is described in the section on Common Management Direction to Alternatives 2-4 (see Commercial Packstock Grazing in Chapter II) the on-site wranglers will be expected to manage the stock to avoid stock entry into these critical areas. However zero tolerance is neither possible nor necessary in a natural setting, therefore a slight amount of inadvertent entry and impacts (the 5% levels) will be tolerated (see Commercial Packstock Grazing sections by Alternative in Chapter II). This should give the District Ranges, permit administrators and permittees the flexibility needed to respond to site-specific conditions and implement grazing management to protect critical areas. Methods for avoiding critical areas may include but are not limited to: temporary fencing; using a bell-mare; having animals under direct wrangler control while grazing; packing feed; or others that packers may request and District Rangers may approve.

Critical areas where negative impacts have been observed will also be given a high priority for development of site specific management plans and monitoring (See Alternative 6/Appendix).

If avoiding critical areas was considered highly unlikely because of the intermingled nature of the meadow/wetland mosaic, the meadow was not considered suitable for grazing (see the Commercial Packstock Grazing section of Chapter II, and the referenced Wilderness Plan Stock Management Guide, Appendix G, page G-11, Table 2-4 Grazing Recommendations by Alternative, and the Study Plan).

An important tool to help keep grazing use and related impacts within standards is to set a conservative stocking rate for the grazing zone and then to adjust that stocking rate up or down based on monitoring and analysis of compliance with applicable standards as well as on resource condition and trend. The initial estimates of available forage, given in stock nights, are intended as guidelines for permit administrators and packers. Stock nights are based on the area (acres) of a key area meadow where grazing can occur, considering suitability, range readiness and resource conditions as described in the.

The identification of key areas and the process for estimating the stock nights of available forage are based on standard range protocols as described in the Regional Rangeland Analysis and Planning Guide (see the Commercial Packstock Grazing section of Chapter II, as well as the associated referenced pages in the Wilderness Plan, pages 23-26, the referenced Regional Rangeland Analysis and Planning Guide, the Wilderness Plan Stock Management Appendix, Appendix G, and the Study Plan). Implementation of the Wilderness Plan Record of Decision (see the ROD, top of page 5 and bottom of page 16) to require the permittees to be

involved in the monitoring of grazing conditions is intended to help with compliance in a era of staffing shortages.

Public Concern #290: *At IV-140, the DEIS states, “The Science Review acknowledges that the available literature is replete with statements about the probable effects of grazing, many of them observational or anecdotal, but rarely is there controlled studies from which to accurately assess different levels of grazing. Most studies refer to heavy grazing without actual forage use quantification by cattle or sheep, and do not examine moderate grazing intensities that are proposed in this EIS.” Again, pack stock users have modified their methods to protect grazing areas, which are important to their livelihood, and again there is less stock grazing now than in years past. Additionally, horses and mules graze differently than cattle and sheep since they do not pull out the grasses by the roots and they favor the tops of the grasses. Further, the meadow monitoring methods used by the Forest Service are quasi-scientific and as such are subjective and can, and indeed are (as admitted to me by a Forest Service employee) slanted to fit the anti-pack stock bias of the person doing the monitoring.*

Volunteer groups, as well as Commercial groups, help monitor the fences in the meadows. If you would put more people in the field this topic would not be such a secret in your assessment of stock use and meadows. (response # 357)

Response: The statement quoted is from Diaz, (1999) as quoted in the Wildlife section of Chapter IV. This analysis uses the best available literature, including some as discussed, acknowledges that discussion by Diaz, and also uses and cites other more recent available scientific literature. Including this quote indicates that the interdisciplinary team used the best available literature, including, discussing, and considering any available critiques of the literature, as a part of this analysis. (see Literature Cited, Appendix C).

In addition to the research discussed by Diaz, research considered and cited includes the most recent research specific to packstock use in similar, and adjacent, ecological settings. An example of this is the 2004 Journal of Range Management article by D. N. Cole, J. W. Van Wagendonk, M. P. McClaran, P. E. Moore, and N. K. McDougald. *Response of mountain meadows to grazing by recreational stock* (see Literature Cited, Appendix C).

The interdisciplinary team is aware of and incorporated instances where packstock users have modified practices, (such as is discussed relative to Alger Lakes, Hilgard, and Rosemarie Meadows in the Grazing Resources sections of Chapter III). The EIS also discusses historical changes in grazing. This comment gives no specific additional examples of how or where pack stock users have modified their methods so it is not possible to respond to the comment other than to refer the reader to the existing discussions in Chapter III of the EIS. The historical trends in livestock use are discussed in the EIS and were considered by the interdisciplinary team during the analysis (see the Wilderness Scale, Grazing Operations, Historical Visitor Use discussions in Chapter III, and the referenced documents including Forest Plans, the 2001 Wilderness Plan, and the Sierra Nevada Forest Plan Amendment of 2004).

The use of grazing related research irrespective of the type of animal is appropriate; especially so since in this analysis the concern under discussion is often the ancillary impacts to grazing such as trampling of critical areas. While cattle and horses may employ different grazing techniques, one animal may lift the head to remove vegetation after biting while the other twists the head for example, the impacts of removal of vegetation and the associated ancillary impacts, such as trampling and fragmenting the sod by animals of similar weights, may still be considered and

discussed. If the author of this comment has any literature related to the differences in grazing methods between equestrian and bovine grazers in addition to that already cited in the Literature Cited Appendix it would be helpful to make that literature available.

The monitoring methods are based on interdisciplinary team implementation of the direction in the Wilderness Plan, the Pack Stock Management Guide, Appendix G, and methods described in the Regional Rangeland Analysis and Planning Guide (see the Study Plan).

The Wilderness Plan direction "...require(s) the permittees to be involved in the monitoring of grazing conditions" (Wilderness Plan FEIS ROD, page 5, 16) and is to "Conduct monitoring of these packstock management guides by wilderness managers" (Wilderness Plan, page 24

Public Concern #291: *All of the alternatives reduce grazing without adequate study. There are new standards imposed that essentially eliminate the use that the Wilderness Act was in part created to allow by saving public lands. By eliminating grazing the Service eliminates traveling trips. None of the alternatives explain this is the effect.*

Grazing should be permitted at historic levels. Packing cubes is not a good alternative. There are site specific measures to solve problems in those areas where grazing is not suitable.

Much of the grazing studies done for this EIS were done without sufficient amount of time or manpower assigned to correctly assess the environment. And, the conclusions reflect that inadequacy. A perfect example is the amount of grazing assigned to Quail Meadows. Or, the amount of grazing assigned to the Tamarack area near Dorothy and Kenneth Lake. The best example is of allowing about 20 animal unit nights at Hopkins Meadow Complex in Mono Creek.

The only grazing alternative that allows packing to continue is the Alternative 1. Alternatives 2-4 too often reduce grazing to numbers too low to allow use. Rather than assign animal nights, there should be a system at looking long term trends and utilization standards.

Unfortunately, using animal nights per meadow is not going to work. It is far better to allow for grazing numbers for a larger geographic region.

The Forest Service plans to close Graveyard Meadow....one of the best places in the Sierra to graze. Why? Certainly doesn't explain why.

In the Appendix B Tables regarding Bear Creek...most of the grazing are alongside of Meadows and grass alongside of the trail that aren't even included a part of the grazing. And, the whole side of the mountain to Orchid Lake.

The entire grazing allocation system is flawed because it just covers certain large patches of meadow. A good percentage of grazing is done outside of these areas. Unfortunately, the Forest Service GIS system is able to incorporate this data.

There are lots of grazing areas that aren't being included. This amount of available forage should be considered in assigning grazing AUM's. (response # 275)

Response: This analysis implements the direction in the Wilderness Plan to use the Grazing Response Index methods and forage utilization standards in conjunction with rangeland suitability criteria, range readiness, and recreation strategy objectives to identify the grazing levels and management needed to maintain or reach desired conditions (Wilderness Plan, 2001, page 4, Pack Stock Management Guide, Appendix G, all but especially see pages 3, 6, and 11).

Grazing is allowed throughout the project area. Grazing is reduced or prohibited locally on those specific sites where it is not appropriate due to degraded conditions, the intrinsic inability of the site to reach range readiness, or where the complexity of the arrangement of critical and non-critical areas precludes grazing without a high probability of damage to the critical areas (see the Commercial Packstock Grazing section of Chapter II, Table 2.4, the Wilderness Plan, pages 23-26, the Regional Rangeland Analysis and Planning Guide, the Wilderness Plan Stock Management Appendix, Appendix G, and the Study Plan). How different pack stations will respond and the effects on traveling trips and are discussed in the Operations sections of the consequences chapter (see Chapter IV, Socioeconomics and Operations, Effects to Operations).

Grazing by commercial pack stock is eliminated in Alternative 5. Grazing is not eliminated in Alternatives 1-4 and Alternative 2 – Modified, but is proposed for those sites where it is appropriate and at initial levels estimated to allow for protection and sustainability of other resources at varying levels for different alternatives. The proposed initial stock nights available across the project area vary by alternative based on the alternative-specific management emphasis as described in the alternative descriptions in Chapter II. For analysis purposes grazing use for Alternative 1 is assumed to be similar to the highest recently reported (between 2001 and 2003) which is 5,755 stock nights. The initial estimates for the other Alternatives are: 10,793 stock nights for Alternative 2; 15,023 stock nights for Alternative 3; and 8,778 stock nights for Alternative 4, (see Table 2.4 for site-specific estimates).

According to this analysis levels of use comparable to the recent levels of use will be accommodated at Quail Meadow. Alternatives 2, 3, and 4 propose an initial 48 stock nights available in the Quail Meadow Grazing Zone (Table 2.4). The actual reported use at Quail Meadow was 0 stock nights in 2001, 48 stock nights in 2002, and 31 stock nights in 2003.

The time and manpower devoted to this project may be considered insufficient by some, however this analysis is being accomplished with the time and manpower available and is significantly more than comparable evaluations in other wilderness areas (see the Commercial Packstock Grazing section of Chapter II, Table 2.4, the Wilderness Plan, pages 23-26, the Regional Rangeland Analysis and Planning Guide, the Wilderness Plan Stock Management Appendix, Appendix G, and the Study Plan).

It was necessary to do an extensive and rapid paced assessment to comply with the necessary deadlines and to allow for re-issuance of the Special Use Permits in a timely manner. The Purpose and Need includes: “Proposals for individual pack stock special use permits...through a subsequent NEPA analysis to be completed by 2006” (see Chapter I, Purpose and Need). Planned follow-up studies and adaptive management will be able to adjust the authorized activities based on the results of monitoring (see the Monitoring and Adaptive Management description in Chapter II, section 2.2).

Historical causes of meadow problems and the existing resource conditions, and the identified management needed to move toward desired conditions, including at Graveyard Meadow, Dorothy Lake area, and Hopkins Lake area are discussed in Chapter III (see Grazing Operations, Meadows, and Hydrologic Function sections in Chapter III, and the specific Graveyard discussion in the Mono Creek/Rock Creek, Grazing Resources, section of Chapter III).

The Grazing Zones have been identified to account for larger areas of potential grazing opportunities than were included in the key areas. Grazing Zones and Key Areas are based on areas where the packers indicated that pack stock have actually grazed, so they should reflect the

traditional grazing patterns (see the section on Common Management Direction to Alternatives 2-4, Commercial Packstock Grazing in Chapter II). Smaller “key areas” have been identified within these grazing zones for monitoring. This monitoring will help provide flexibility to move use in response to compliance with applicable standards (see the sections on Adaptive Management in Chapter II). The use of key areas to represent large areas or grazing zones is an established management practice (see Chapter II section 2.2 and the Regional Rangeland Analysis and Planning Guide).

Public Concern #292: *The grazing strategies in Alternatives 1-4 raise questions as to whether the limits to be imposed are stated in terms of measurable quantities and the conditions are described with sufficient precision. The capacity (in stock nights) of grazing zones is based on the calculation of suitable area, vegetative productivity, and reported use in the past three years. It is not clear to what extent ecological characteristics and processes in the meadows are taken into consideration at arriving at the capacity estimates.*

Compliance with the grazing rules requires only that a trend toward desired conditions be shown. The concept of desired condition is itself rather vague and varies depending on the recreation category assigned to the zone. Further, there is no standard method specified (at least not in the DEIS) for detecting trends. In addition, implementation of these strategies requires monitoring and control and herding of stock to keep within guidelines. There is no assurance that the required monitoring and herding will occur.

Grazing suitability of meadows is especially troublesome. If this is a meaningful concept, it ought to be defined in terms of objective criteria that are generally accepted. But suitability clearly is not objectively defined here, since the same meadow is classified as suitable in one alternative and is unsuitable in another. (response # 392)

Response: The quantities and conditions used are standard and in common use (see the Sierra Nevada Forest Plan Amendment, the Wilderness Plan, the Pack Stock Management Guide, and the Regional Rangeland Analysis and Planning Guide, as referenced in the EIS and included in the Literature Cited Appendix).

The areas where grazing is prohibited and the total proposed initial stock nights available across the project area do vary. The variation is based on the alternative-specific management emphasis as described in the Alternative descriptions in Chapter IV.

For example: Under Alternative 3 part of the alternative description is to:

“Allow grazing at the utilization, range readiness, inadvertent use/impact critical area 5% standard, and other standards as for Alternative 2 with initial identified stock nights available as for Alternative 2 for areas that are assessed as Fully Functional or Functional at Risk with an upward trend.

- No use will be authorized on key areas determined to be Functional at Risk with a downward trend.”

Under Alternative 4 the emphasis of the alternative becomes progressively more stringent. Suitability for grazing in Alternative 4 is defined as:

“Allow grazing at the utilization, range readiness, inadvertent use/impact critical area 5% standard, and other standards as for Alternative 2 with initial identified stock nights available as

for Alternative 2 for areas that are assessed as Fully Functional or Functional at Risk with an upward trend, with the following exceptions:

- A 30% maximum utilization factor will be set on key species in key areas determined to be Functional at Risk with no apparent trend.
- No use will be authorized on key areas determined to be Functional at Risk with a downward trend.
- No use will be authorized on key areas categorized as having severe alteration of hydrological function.”

It is true that successful management is generally defined as a trend toward desired condition. The social aspect of the desired condition relative to the experiential nature of the wilderness resource varies by recreation category and is the desired condition described in the Recreation Goals and Objectives (Wilderness Plan, Chapter 2, page 16). However the desired condition for the grazing resource is defined in the Recreation Stock Forage Goals and Objectives (Wilderness Plan, Chapter 2, page 58) and does not vary by Recreation Category.

The extensive and rapid data collection methods used in this analysis are based on interdisciplinary team implementation of the direction in the Wilderness Plan, the Pack Stock Management Guide, Appendix G, and standardized Regional methods described in the Regional Rangeland Analysis and Planning Guide (see the Wilderness Plan Pack Stock Management Guide direction on Suitability Determinations and the Study Plan).

The EIS also references the Wilderness Plan, Pack Stock Management Guide, and the Regional Rangeland Analysis and Planning Guide. These documents provide management direction regarding monitoring and details of the monitoring protocols (see Chapter II, 2.2 Common Direction to all Alternatives). The Wilderness Plan Monitoring Framework calls for Long-term monitoring of ecological state and transition at key benchmarks (Wilderness Plan pages 37-39).

The Wilderness Plan direction “...require(s) the permittees to be involved in the monitoring of grazing conditions” (Wilderness Plan FEIS ROD, page 5) and to “Conduct monitoring of these packstock management guides by wilderness managers” (Wilderness Plan, page 24). The Forest Service is also willing to consider any offers of assistance. The Forest Service will continue to place employees in response to annual budgets.

Additional areas were included as not suitable for grazing after the initial proposed action as a result of the ongoing analysis process. Suitability is based on factors determined locally by an interdisciplinary team and these factors may, and should, respond to the locally determined management emphasis factors, including ecological and process factors such as those that resulted in the progressively more stringent alternatives as described above (see also the Wilderness Plan, the Pack Stock Management Guide, the Regional Rangeland Analysis and Planning Guide, and the Study Plan).

The analysis responds to ecological characteristic and processes as it assesses the consequences of implementing progressively more stringent and prohibitive grazing on those sites where it is not appropriate due to degraded conditions, the inability of the site to reach range readiness, or where the complexity of the arrangement of critical and non-critical areas precludes grazing without a high probability of damage to the critical areas (see the Commercial Packstock Grazing section of Chapter II, Table 2.4, the Wilderness Plan, pages 23-26, the Regional Rangeland

Analysis and Planning Guide, the Wilderness Plan Stock Management Appendix, Appendix G, the Study Plan, and the Meadow Rating Criteria and Spreadsheet in the Project Record).

Public Concern #293: *Alternative 2 does not protect meadows that contain critical habitat. Designating them as critical does not prevent some degree of trampling and other disturbance. Further, no standard means is prescribed for measuring the extent of damage or limiting damage to 5%, nor is there clear evidence that the 5% figure, if adhered to, will be adequate to prevent further decline in meadow stream function or vegetative conditions. (response # 392)*

Response: Alternative 2 includes the same standards for impacts in critical areas as Alternatives 3, 4 and Alternative 2 – Modified (see Chapter 2 – Common Direction to all Alternatives, Common Management Direction to Alternatives 2-4, Commercial Pack Stock Grazing). Grazing is prohibited in Alternative 2, and in Alternatives 3 and 4 as well, where the complexity of the arrangement of critical and non-critical areas precludes grazing without a high probability of damage to the critical areas (see the Commercial Packstock Grazing section of Chapter II, Table 2.4, the Wilderness Plan, pages 23-26, the Regional Rangeland Analysis and Planning Guide, the Wilderness Plan Stock Management Appendix, Appendix G, the Study Plan, and the Meadow Rating Criteria and Spreadsheet in the Project Record).

Zero tolerance is neither possible nor necessary in a natural setting, therefore a slight amount of inadvertent entry and impacts (the 5% levels) will be tolerated (see Commercial Packstock Grazing sections by Alternative in Chapter II). Monitoring, including of 5% trampling impacts, will follow the standard protocols to be used to monitor the other standards, such as 30% or 40% vegetation utilization and 20% stream bank disturbance (see the Wilderness Pack Stock management guide and the Regional Rangeland Analysis and Planning Guide). For critical areas such as Fens or Yosemite Toad habitat the standards and monitoring protocols are being developed and will be implemented as they are developed (see Monitoring Plan).

Public Concern #294: *The DEIS clearly shows that Alternative 5 is superior to all other alternatives in terms of effects of alternatives on meadow hydrologic function and expected change in stream functional condition. (response # 392)*

Response: This analysis considers more than just the alternative that is superior in terms of effects on meadow hydrologic function and expected change in stream functional condition. The Needs Assessment defines the need for commercial pack stock activities (see the Needs Assessment). The Purpose and Need for Action section of the EIS describes the need to provide further standards and guidelines for commercial pack stock activities (Chapter 1, Purpose and Need). This analysis describes the appropriate mix of actions and the environmental consequences of implementation associated with meeting the identified need.

Public Concern #295: *Grazing privileges for commercial packstock should require time- and site- specific advance permits granted in a manner similar to that employed in granting overnight permits, in order to prevent possibly destructive overuse as well as “near range wars [between various commercial packstations]” as reported in the district court trial record. (response # 301)*

Response: Specific permit and operating plan issues will be addressed in a subsequent environmental process that issues the permits (see Executive Summary, Issues and Concerns Not Addressed in This Document). This analysis identifies the initial stock nights of available forage and the applicable grazing standards to be applied at specific locations. The location and amount

of available forage will fluctuate annually. Decisions regarding the allocation of that available forage will be made by the environmental process for permit issuance and will be adapted annually by the District Rangers in consultation with the Special Use Permit administrators and individual packers through the Annual Operating Plan process (see Section 2.2 Common Direction to all Alternatives, Common Management Direction to Alternatives 2-4, Commercial Pack Stock Grazing).

Public Concern #296: *Grazing start dates need to be determined on a site-specific basis, not elevational. (response # 428)*

Response: The decision to implement grazing start dates was made in the Wilderness Plan in 2001. Interdisciplinary team assessments have indicated that the trampling associated with a grazing activity is resulting in more impacts than the grazing itself. The process for predicting and posting the grazing start date is described in the Pack Stock Management Guide (Wilderness Plan, Appendix G, page 7). One of the primary reasons a process based on elevation guidelines was developed is that the packers described a need to know the grazing start date in late winter and early spring, before the snow even melts from the meadows. The trip dates need to be published in various bulletins and periodicals early enough for potential clients to arrange vacations and book trips in advance. Therefore packers must be able to plan and book trips well before the wilderness sites are accessible in the spring; even before the snow begins to melt in some years. Providing an estimated grazing start date based on an evaluation of snow conditions, anticipated runoff dates, and including considering the effects of elevation is a service the Forest provides to the packers to facilitate the trip planning process.

Site-specific range readiness assessments may be done where time and funding allow. Assessing individual sites and determining a grazing start date for individual sites is possible and would provide a date with a more accurate assessment of conditions. An important consideration is that a site-specific range readiness assessment requires multiple visits to an adequate number of sites to track changes in conditions as the spring weather progresses each year. The range readiness assessment cannot be done faster than the snow melt and runoff process occurs. While individual assessments can be done at a few very locations, overall, given the size and complexity of the project area, it is not possible to provide site-specific assessments to packers in time for them to plan, advertise, and book trips.

Public Concern #297: *The proposed grazing management strategy is unrealistic, full of loopholes, and would result in degradation of the wilderness character. Under all alternatives the proposed grazing management scheme would lump suitable and unsuitable areas together into large grazing zones that were delineated based on requested areas for grazing by the commercial pack outfitters. (DEIS at II-3) The grazing zones would include mosaics of wet and dry areas, including unsuitable and even critical habitat areas.*

All alternatives assume that stock users will avoid stock entry into critical areas and areas identified as unsuitable. This expectation is completely unrealistic. First, stock animals will naturally drift between adjacent or nearby open and closed areas unless their movement is controlled. Second, stock users cannot be expected to control stock movement into closed areas unless it is required.

Forest Service representatives indicated during our 5-21-04 meeting that grazing in closed areas would be a citable offense. However, the proposed action contains no such provision. In fact, the proposed action would allow regular drift of stock animals from open areas into closed areas.

Even critical and unsuitable areas may be regularly grazed: There would also be an inadvertent level of use of up to 5% ground disturbance allowed in these critical and unsuitable areas. This, too, is arbitrary and completely unrealistic. First, the 5% standard for ground disturbance in critical areas is arbitrary, and would likely be inadequate in many areas. For example, stock animals should be prohibited entirely from entering occupied breeding habitat for Yosemite toads, which have been determined by the USFWS to be warranted for listing as threatened or endangered. Second, the Forest Service does not, and cannot be expected to have sufficient funds to monitor the many critical and unsuitable areas in these remote wildernesses.

Rather than drawing the grazing boundaries as requested by commercial permittees, and rather than lumping suitable and non-suitable areas together, the Forest Service should instead identify where grazing is suitable and would not cause significant effects, and limit grazing to those areas only. Site-specific range readiness criteria (i.e., grazing start dates) and stock-night limits should be developed, and stock users should be required (using temporary, portable electric fences, hobbles, or other management techniques) to keep their stock out of closed areas. But, this can only work if grazing in closed areas is a citable offense, and if the Forest Service enforces such a requirement.

The drift fences in these wildernesses exist primarily for the convenience of stock users. Most B if not all B of them should be removed.

Site-specific and/or area-specific grazing start dates must be established. The 2001 Wilderness Plan and ROD called for grazing start dates to be established. The grazing start dates that have been established are based on elevation. This was done for expediency, and the existing start dates are better than none. However, there are many other factors that necessitate that grazing start dates should be site-specific or area-specific as opposed to elevation-based (i.e., aspect, vegetation type, soil depth, soil type, slope, etc.). The Inyo and Sierra NFs should establish site-specific or area-specific refinements to their elevational grazing start dates (as is done in the adjacent Sequoia and Kings Canyon National Parks).

Specific monitoring procedures for grazing must be described and mandated as part of the adaptive management proposal. The so-called adaptive management strategy for grazing does not constitute adaptive management. It is essentially an unscientific loophole that would allow managers to approve administrative changes to the grazing plan based on unspecified monitoring. The monitoring program is not mandatory, and it is undefined and unfunded. There are no objective criteria to guide decisions for making changes to the grazing management scheme, and there is no provision for public involvement or NEPA analysis. Adaptive management is a scientific process, but it appears to be invoked here primarily to allow easy changes to the grazing scheme without public involvement or proper environmental analysis. (response # 196)

Response: Key areas and critical areas will be identified for the packers in the annual operating plans. The packers will work with the permit administrators and District Rangers to determine an effective way to avoid the critical areas (see the Commercial Packstock Grazing section of Chapter II, the referenced Wilderness Plan pages 23-26, the referenced Wilderness Plan Stock Management Appendix, Appendix G). It will then be the responsibility of the packer to ensure that the wranglers conducting individual pack trips implement the planned management at specific sites.

As is described in the section on Common Management Direction to Alternatives 2-4 (see Commercial Packstock Grazing in Chapter II) during each trip the on-site wranglers will be expected to manage the stock to avoid stock entry into these critical areas. Zero tolerance is neither possible nor necessary in a natural setting therefore a slight amount of inadvertent entry and impacts (the 5% levels) will be tolerated (see Commercial Packstock Grazing sections by Alternative in Chapter II). Critical areas where negative impacts have been observed will be given a high priority for development of site-specific management plans and monitoring in subsequent years.

If avoiding critical areas was considered highly unlikely because of the intermingled nature of the meadow/wetland mosaic, the meadow was not considered suitable for grazing (see the Commercial Packstock Grazing section of Chapter II, and the referenced Wilderness Plan Stock Management Guide, Appendix G, page G-11, Table 2-4 Grazing Recommendations by Alternative, and the Study Plan). As suggested, methods for avoiding critical areas may include but are not limited to: temporary fencing; using a bell-mare; having animals under direct wrangler control while grazing; packing feed; or others that packers may request and District Rangers may approve.

An important tool that was used to help keep grazing use and related impacts within standards is to set a conservative stocking rate for the grazing zone and then to adjust that stocking rate up or down based on monitoring and analysis of resource condition and trend. The initial estimates of available forage, given in stock nights, are intended as conservative guidelines for permit administrators and packers. Stock nights are based on the area (acres) of a key area meadow where grazing can occur, considering suitability, range readiness and resource conditions as described in the Pack Stock Management Guide (Wilderness Plan, Appendix G).

The identification of key areas and the process for estimating the stock nights of available forage are based on standard range protocols as described in the Regional Rangeland Analysis and Planning Guide (see the Commercial Packstock Grazing section of Chapter II, as well as the associated referenced pages in the Wilderness Plan, pages 23-26, the referenced Regional Rangeland Analysis and Planning Guide, the Wilderness Plan Stock Management Appendix, Appendix G, and the Study Plan). Implementation of the Wilderness Plan Record of Decision direction (see the ROD, top of page 5) to require the permittees to be involved in the monitoring of grazing conditions will help with the staffing shortages.

The existing drift fences are not retained to accomplish grazing resource objectives, as a drift fence tends to keep stock in a general geographic vicinity without protecting the localized site-specific critical areas. However, the fences have been identified as necessary for operational stock management including for the safety of both the clients and of hikers along the trails (see Operations sections).

Public Concern #298: *Under camping limitations only one night grazing per trip in Cascade Valley and Silver Divide analysis units is allowed. How do you handle a two-way overnight spot trip? The packer and stock remain with the party overnight when they are packed in and the packer goes in the day before the parties' out date to pick them up. That adds up to 2 nights of grazing. Does this put an end to 2-day spot pack trips. Most parties don't appreciate getting out at midnight not to mention the potential dangers of packing out in the dark. (response # 198)*

Response: The two-way overnight spot trip scenario described in the comment may be accomplished by packing feed when returning, with mostly empty pack panniers, to pick up the

party. The stock are fed rather than grazing that night and the panniers will then be empty and may be loaded for the trip back to the trailhead. It is important to recognize and take advantage of opportunities to only allow stock to graze when it is truly necessary.

Public Concern #299: *We strongly disagree with Grazing Zone concept of management. The alternatives do not tell the public that they are ending the practice of taking pack trips in the Sierra. The Forest Service is selecting a methodology that is easy for the government but denies the public access to the wilderness. Little effort is made to craft a grazing management strategy that allows people to travel up and down the Muir Trail. This is why the Wilderness Act was passed. People wanted somewhere that they could travel for a week to several weeks and not have to see cars and civilization. (response # 275)*

Response: Grazing Zones and Key Areas are based on areas where the packers indicated that pack stock have actually grazed, so they should reflect “traditional patterns” (see the section on Common Management Direction to Alternatives 2-4, Commercial Packstock Grazing in Chapter II). Smaller “key areas” have been identified within these grazing zones or areas of traditional grazing by packstock areas of importance for monitoring or resources have been identified, which helps provide adaptive management flexibility to move use in response to monitoring of compliance with applicable standards. Pack trip are not eliminated, but grazing is authorized in locations and at levels that is sustainable. It is important to recognize and take advantage of opportunities to only allow stock to graze when it is truly necessary, and in locations where it is sustainable.

The packers will work with the permit administrators and District Rangers to determine an effective way to allow stock to graze within the grazing zones and avoid the critical areas (see the Commercial Packstock Grazing section of Chapter II, the referenced Wilderness Plan pages 23-26, the referenced Wilderness Plan Stock Management Appendix, Appendix G). It will then be the responsibility of the packer to ensure that the wranglers conducting individual pack trips implement the planned management at specific sites. The packers are encouraged to work with the District Rangers and Permit Administrators to identify stock management techniques that will work for their individual operation. As has been suggested, methods for avoiding critical areas may include but are not limited to: temporary fencing; using a bell-mare; having animals under direct wrangler control while grazing; packing feed; or other methods that packers may request and District Rangers may approve.

Public Concern #300: *The Forest Service has to look at a method of allowing grazing in wet areas of meadows and grasslands. This is not production grazing; rather, it is grazing to support recreational use of the wilderness. Standards should be different. At times, the wilderness use will be heavier in some areas to allow people to travel through the Sierra. Congress anticipated this use and did not want to close off the wilderness to people and livestock.*

Now, when the Forest Service proposes so many restrictive standards....the agency is really closing the wilderness to grazing. This is wrong and the various alternatives don't truthfully point this decision out to the public. (response # 275)

Response: The direction to protect wetlands and special aquatic features is from the Sierra Nevada Forest Plan Amendment (USFS, 2004) and the Wilderness Plan (USFS, 2001), decisions. Pack trips are not eliminated (see Alternative descriptions in Chapter 2). Grazing use is authorized in locations and at levels that is sustainable (see Alternative descriptions in Chapter

2). Uses as commercial pack stock grazing may be authorized as necessary in the direct support of clients and to the extent that it is ensured that human influence does not impede the free play of natural forces or interfere with natural successions in the ecosystems (see FSM 2320). As has been suggested, methods for avoiding critical areas may include but are not limited to: temporary fencing; using a bell-mare; having animals under direct wrangler control while grazing; packing feed; or other methods that packers may request and District Rangers may approve.

The introduction to the Socioeconomic and Operations section of Chapter 4 states: “This section combines the operations and economics sections and discusses the effect of the five alternatives on the regional economy and the operations of the pack stations” (see Chapter 4, section 4.1.1.5). The Socioeconomic and Operations section of the analysis also states “The team concluded that the following operational indicators would effectively measure the differences between alternatives and their effects to commercial pack stock operations” and then goes on to discuss the identified indicators and conclusions (see Chapter 4, Effects to Operations). The conclusions include that for high-complexity operations the change will be from a high percentage of grazing to a substantial increase in packed feed and an increase in site-specific stock management which will also require additional employees (see Chapter 4, Effects to Operations).

Vegetation, Comments on Chapter 3

All comments are from response #275

Public Concern #301: *III-101 There is substantial overnight stock use in Hilton. Probably more than any area of the Inyo National Forest.*

Conclusions of Dorothy Lake fail to address the improvements since cattle and sheep left. The writer mentions the Dorothy Lake Meadow grass is dying in half the meadow. Why? In the entire document, if there was evidence of stock grazing....commercial pack stock would be used to explain the damage. Here, no stock grazing.

On the other hand, when there is no grazing by stock...the writer doesn't make a conjecture. The document should mention that there is incredibly vast amounts of good forage in the Tamarack area. And, that the vigor is excellent in spite of heavy past grazing.

Response: The overnight stock use figures used in the grazing resources sections of this analysis were as reported for 2001, 2002, and 2003.

The description of conditions at Dorothy Lake Meadow, as well as at other locations, is a summary of existing conditions as documented on-site by the interdisciplinary team. The historical impacts of stock grazing are acknowledged in the Meadows section of Chapter 3 as well as in the Grazing Resource section. Historical stock impacts, as discussed in these sections are at least as common at Dorothy Lake as elsewhere in the project area.

The Grazing Resource section of the Mono Creek Rock Creek Geographic Area documents a loss of perennial grass and sod in the meadow at the outlet of Dorothy Lake and also documents that elsewhere there is little change from high-seral vegetation except at localized stream crossings. The cause of the loss of perennial grasses is unknown. However, the interdisciplinary team located historical camps, trails, and diversion ditches that were likely from the earlier sheep and pack stock days at the Dorothy Lake outlet meadows (see Chapter III, RockCreek/Mono Creek Geographic Area, section 3.2.1.1, Commercial Pack Station Operations,

section 3.2.1.2 Wilderness, Tamarack). As is documented in the analysis once a site is degraded the effects linger and recovery can take decades (see Chapter III, section 3.1.2.2, Meadows).

Public Concern #302: *III-102. Continued lie and mistaken assumption about use at Lower Hopkins Lake. What is meant by current? 1 year, 5 year, 20 year and 50 year? The id team members lack the ability to determine the effects of use from last year or twenty years ago throughout most of the plan. Hopkins Lake is probably the best example.*

Current use since 2002 has been at Hopkins Creek at the 10,000 ft level. We have had less than a handful of spot and dunnage trips at Hopkins Lake.

Response: Current in this context means concurrent with the time period of this project. There was reported overnight use by commercial operators in Hopkins Basin and Hopkins Meadow during the reporting years used for reported levels of grazing in this analysis, 2001, 2002, and 2003 (Chapter III, Grazing Operations, section 3.1.1). The Commercial Pack Station Operations section of Chapter III (section 3.1.1.1, History and Background) cites data from 1999 to 2003.

Public Concern #303: *III-103. The Forest says there is no negative impacts at Kip Camp and no recent reported use. This was one of the most heavily used stock and hiker camps along the John Muir Trail. This document should use this as an example of how much better the Wilderness is than in the 1970's.*

Response: No stock use was reported by the commercial operators between 2001 and 2003 at Kip Camp. (see section 3.1.1.1, History and Background). There were no negative current stock related impacts noted at Kip Camp. The presence of standing dead lodgepole pine in saturated soils and debris deposits in the creek at Kip Camp do indicate there may have been a recent historical change in hydrologic conditions.

Public Concern #304: *In the DEIS, the Forest Service missed the opportunity to show that in spite of heavy livestock and human use, the wilderness area looks good. There are numerous campsites and areas that should be used to describe the affected environment. Compare and contrast what they were like in the late 70's when the first John Muir Wilderness Management Plan was implemented.*

Response: There is a discussion of historical impacts in Chapter III, Hydrology, Meadows (Chapter 3). The analysis states that recent surveys indicate that the vegetative composition of meadow is generally in satisfactory condition as defined by the Wilderness Plan, with some meadows and some locations within meadows still exhibiting an observable change away from desirable, late-seral vegetation (see Chapter 3, Vegetation, Vegetative Composition).

Today's management emphasis is on assessing current conditions and desired conditions and identifying needed changes in those factors, including stock use, contributing to current conditions being inconsistent with desired conditions (see Chapter 2 and the discussions of Meadows, Soils, and Hydrological Function in the Physical Environment sections of Chapter IV and the discussion of Assumptions About Effects in the Grazing Resources section of Chapter IV).

Public Concern #305: *III-143 The 2001 grazing use data from Rock Creek is not included in the document. The postcards must have been lost by the Forest.*

The proper data should be included in any final document.

Response: The overnight stock use figures used in the grazing resources sections of this analysis were as reported for 2001, 2002, and 2003 (see Chapter 3, Grazing operations).

Vegetation, Comments on Chapter 4

Public Concern #306: *IV-419 - The conclusions of Tamarack aren't very good and the whole analysis needs to be redone. Should be more grazing.*

IV-426 - should permit grazing in Alternative 3 at Tamarak.

Response: Uses such as commercial pack stock grazing may be authorized as necessary in the direct support of clients and to the extent that it is ensured that human influence does not impede the free play of natural forces or interfere with natural successions in the ecosystems (see FSM 2320). Tamarack is close enough to the pack station that it is not truly necessary to graze stock. Stock can easily return to the packstation, or if stock are held overnight for a day ride the next day the stock not needed for the day ride can easily return to the packstation for feed. It is important to recognize and take advantage of opportunities to allow stock to graze when it is truly necessary, and in locations where it is sustainable (see Table 2.4, Grazing Recommendations by Alternative, and the Needs Assessment).

Public Concern #307: *IV-427 - The writers miss much of the grazing options and grasslands in the entire Mono Creek area.*

Response: Grazing Zones and Key Areas are based on areas where the packers indicated that pack stock have actually grazed, so they should reflect traditional patterns and use levels (see the section on Common Management Direction to Alternatives 2-4, Commercial Packstock Grazing in Chapter II). The areas identified by the packers were used in conjunction with aerial photographs to plan interdisciplinary team assessments. Smaller "key areas" have been identified within these grazing zones or areas of traditional grazing by packstock areas of importance for monitoring or resources have been identified. The key areas and grazing zones helps provide adaptive management flexibility to move use throughout a grazing zone in response to monitoring of compliance with applicable standards. The majority of the Mono Creek area is identified as a grazing zone and is available to be grazed. We have accounted for the majority of the ecologically sustainable grazing options in Mono Creek that are necessary to support the needed operations (see Table 2.4, Grazing Recommendations by Alternative, and the Needs Assessment, and Maps).

Social and Economics

Economics

Public Concern #308: *The economic analysis should be redone to better reflect the economic contributions of commercial pack stations to the local economy (response #275).*

Response: NEPA sets out broad direction and objectives for the treatment of economic issues in an environmental analysis. For example, the CEQ NEPA Implementing Regulations at 40 CFR 1508.8 includes economic and social effects as the effects that should be considered in an environmental analysis. There is no specific direction; however, that mandates what needs to be considered in an economic NEPA analysis. The scale and focus of the economic analysis is tailored to meet the needs of the project and is decided upon by the Responsible Official. For

this project, the appropriate economic analysis is one which includes an examination of the effects of the alternatives on both the regional economy and the operations of the pack stations.

The economics analysis in the EIS utilizes an accepted economic model, the Impact Analysis for Planning (IMPLAN) model. The IMPLAN model that was used in the analysis includes the expected spending of visitors who utilize commercial pack station services. This includes spending on services and goods in the communities around commercial pack stations. The output of the model is labor income and number of jobs that are created by both the spending of visitors directly for the pack stock services and the incidental spending that occurs during the visit. In the Final EIS, the analysis will be clarified to better explain the model and how it provides an evaluation of the economic activity generated by commercial pack stations.

Public Concern #309: *The DEIS does a poor job of fully disclosing the effects of additional regulations on the packing industry. (response #275)*

Response: The Draft DEIS discloses that there are a number of uncertainties associated with the alternatives and their impact to the pack stations operations. The operations effects analysis discusses the expected effects of the alternatives on the future operations of commercial pack stations. There are a number of uncertainties, however, including some factors that the Forest Service has no control over. To some extent, the services offered by pack stations will be dependent upon on the economy, the public's demand for various services, and the ability of pack stations to attract customers. As to the number of pack stations operating in the future, it is expected that the current number of pack stations will continue to operate into the future. Outside of the NEPA process, there will be a Financial Availability Determination (FAD) made for each pack station. In addition, a separate planning effort will issue the permits for the pack stations. The FAD and the SUP EIS will determine how many pack stations will operate

Public Concern #310: *The Forest Service should ensure the viability of pack stations (response #253).*

Response: The purpose of the economic effects analysis in the EIS is to disclose the expected effects that the various alternatives on the regional economy as well as the operations of the pack stations. Components of the alternatives that may adversely affect the viability of these operations are identified and disclosed in the environmental document. The Forest Service cannot ensure the viability of commercial pack stations. There are a number of factors that may impact the viability of pack stations, many of which the Forest Service has no control over.

Public Concern #311: *The Forest Service should not subsidize the operation of commercial pack stations but should allow the market to decide whether these operations survive. (response # 301)*

Response: The market has historically played a role in the viability of commercial pack stations and will continue to influence the viability of these operations for years to come. Some businesses have continued to operate while others have closed or combined with other operations. The market has clearly indicated that there is a demand for these commercial services to operate in the wilderness. It is the job of the Forest Service to determine the appropriate level of commercial service in the wilderness while still protecting the wilderness values of these areas.

Public Concern #312: *The Forest Service should acknowledge that most pack stations are in poor financial shape and will be in worst shape in the future. (response # 275)*

Response: The current financial condition of commercial pack stations are not fully known and, to some extent, outside the scope of this EIS. The EIS does discuss the expected effects of the alternatives on the future operations of commercial pack stations. A more complete financial accounting of these operations will be done when the permits are issued next year.

Public Concern #313: *The Forest Service should not use gross revenue as a method for assessing economic viability. Rather, net revenue figures, along with the profits generated by each operation should be included in the EIS. (response # 275)*

Response: The economic analysis in the EIS clearly states the limitations associated with gross revenue figures from commercial pack stations and warns against making any conclusions based on these figures. It is not appropriate to include profit figures in the EIS. There is a permit process that will take place next year that will assess the viability of each pack station before a permit is issued.

Public Concern #314: *The Forest Service should better estimate the costs increases of commercial pack stock trips as a result of new regulations.*

Response: The DEIS provides the agency's best estimation of how the alternatives will affect the future cost of commercial pack trips. No attempt was made to quantify the change in price for various pack trips.

Public Concern #315: *The Forest Service should ensure that commercial packing trips remain affordable to the public. (response #75)*

Response: The economics and operations analysis discloses that additional regulations may affect the commercial pack stations and their ability to provide services to the public. As the analysis discusses, one possibility is that the prices of trips may continue to rise. At some point, a large percentage of the population may be priced out of these trips.

There is a disagreement as to the overall effect that new regulations will have on commercial pack stations. The EIS provides the agency's best analysis as to how the various layers of regulations will interact and affect future operations of these businesses. There is a high level of uncertainty, however, and the analysis readily discloses this. Many factors, some of which are outside the control of the Forest Service, affect the profitability and viability of these operations.

Public Concern #316: *Additional regulations on pack stations will severely limit their ability to provide service to the public and will adversely affect local economies. (response # 275)*

Response: See response to Public Concern # 315

Social

Public Concern #317: *The Forest Service should provide a better analysis of the proposed regulations on different ethnic groups and races (response # 275)*

Response: The DEIS discusses the effects that may occur to low-income users of commercial pack stock services. As is disclosed in the document, any regulations that increase the price of these trips will likely have greater effects to low-income users of the service.

There is limited data that provides a baseline as to the historical use of commercial services by low-income and minority groups. If, however, overall visitation to the Inyo National Forest is any indication of the racial/ethnic composition of commercial pack stock clients, it is likely that the overwhelming majority of users are white. According to the 2003 Inyo National Visitor Use

Monitoring Results study, 91% of Inyo National Forest visitors are white, while 4.2% identified a Spanish, Hispanic, or Latino ethnicity. Respondents identifying themselves as Black or African American made up .2% of those surveyed. Given the low percentages of non-white visitors to the forest, it is unlikely that any of the alternatives will result in any disparate effects to racial or ethnic groups.

Public Concern #318: *Social disagreements and equity issues are not resource concerns and not the reason for this EIS (response # 275).*

Response: In addition to the physical environment, an EIS should analyze and disclose the effects of a federal action on the social environment. A portion of the social environment analysis can include public attitudes and opinions of the proposed action. The disclosure of public opinion is one of many factors that a decision maker weighs when making a decision. The analysis simply points out to the decision maker that the issue of commercial pack stock in the wilderness is fairly polarizing for the public with very vocal opponents of this wilderness use balanced with vocal proponents of continued commercial pack stock operations in the wilderness.

Health and Human Safety

Public Concern #319: *The NEPA document has not adequately analyzed the impact of commercial pack operators on the human health and safety. (response # 166)*

Response: The EIS does consider certain aspects of human health and safety, for example, water quality. The comment does not specify what other human health and safety factors should be analyzed. The relevant factors related to human health and safety are analyzed in the EIS.

Appendix D Needs Assessment

Appendix D Needs Assessment

Needs Assessment for Commercial Pack Stock Services in the Ansel Adams, John Muir and Dinkey Lakes Wildernesses

Summary

This Needs Assessment evaluates and analyzes the need for commercial pack stock services in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. It supplements the Needs Assessment contained in Appendix D of the 2001 *Wilderness Management Direction for Ansel Adams, John Muir, and Dinkey Lakes Wildernesses Final EIS*. The preparation of this Needs Assessment is guided by both interpretation of the legal requirements of the Wilderness Act and direction in Forest Manual 2320.

Commercial pack stock use has a long history in these wilderness areas; however, recent trends point to a decrease in both the number of pack stations and the number of clients serviced. To assess the need and appropriateness of commercial pack stock services in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses, a survey was conducted in July and August 2005. The survey targeted 2004 overnight commercial pack stock clients. Based on the analysis of this survey, the services currently provided by these operations are proper and consistent with the intent of the Wilderness Act. The Needs Assessment concludes that there is a need for at least the current level of commercial pack stock use in these wildernesses. The Needs Assessment further concludes that the public need for these services is actually higher than what is provided today. Commercial pack operations in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses are already heavily regulated by the Forest Service as the need for public access to the wilderness areas is limited by the need to preserve the wilderness character of the areas. Some of these regulations have, to some extent, limited the commercial packer's ability to meet the public's full need for these services. Also, based on demographic trends, there will be increased need in the future for commercial pack stock services in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses.

Document Structure

The Needs Assessment is divided into two sections. The first section provides the legal basis and direction for preparing a Needs Assessment. Next, a brief history of pack stations in these wilderness areas is provided along with a review of the services that they provide. Current commercial pack stock trends are examined including the types of services offered and groups serviced by these operations. To finish this section, there is a discussion of commercial pack stock use in the wilderness within the context of other uses, along with the regulations and mechanisms that have been placed on pack stock operations to protect the wilderness character of these wildernesses. The second section contains an analysis of the need for commercial pack stock services in these wilderness areas. Current levels of use will be discussed and evaluated by

two tests: first, whether the activities associated with the commercial pack stock use are proper in the Wilderness and second, whether there is a need for the service.

Also discussed will be the extent necessary; that is, whether the level of service is the extent necessary to realize the purposes of the Wilderness Act. A survey of past commercial pack stock clients conducted during the summer of 2005 will provide much of the basis for this analysis of current level of use. The next subsection of the second section will focus on whether the public's need for commercial pack stock services is being fully met today. Lastly, demographic trends and their implications for the future need of commercial pack services will be discussed.

Section 1 – Background and History/Trends for Commercial Packing

I. Legal Requirements for a Needs Assessment

As this Needs Assessment is being applied to wilderness areas, requirements of the Wilderness Act, signed into law in 1964, need to be considered. The Wilderness Act states that “commercial services may be performed to the extent necessary for activities which are proper for realizing the recreational or other wilderness purposes of the Act.” The “recreational or other wilderness purposes of the Act” is clarified earlier in the Act in Section 4(b) which specifies that “except as otherwise provided in this Act, wilderness areas shall be devoted to the public purposes of recreational, scenic, scientific, educational, conservation, and historical use.”

The primary Forest Service Manual direction for the preparation of a Needs Assessment can be found in Manual 2320 which states that “[a]s identified in forest land and resource management plans, provide for commercial outfitting and guiding services that address the concerns of the public health and safety and foster small business.” The 1988 Inyo National Forest Land and Resource Management Plan identifies the general need for commercial services in the wilderness. Further, the 2001 Wilderness Plan identified the need in Appendix D, Needs Assessment, for commercial pack stock services in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. The level of service needed is not identified in the 2001 Needs Assessment; however, the document did conclude that there was a need for pack stock services in these wilderness areas. It is the intent of this Needs Assessment to further analyze and identify the extent to which commercial pack stock services are needed in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses.

There is a basic tension between the Wilderness Act objective of preserving the wilderness character of an area and the devotion of the area to public purposes such as recreation. This is particularly true with respect to commercial pack stock use in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. As the Needs Assessment will show, there is a definite and clear need for commercial pack stock services in the wilderness areas and these services are appropriate and proper for realizing the recreation and other wilderness purposes of the area. This use, however, has to be limited by the need to protect wilderness character. The purpose of this Needs Assessment is not to resolve this tension between recreation and wilderness character. Rather, it is to acknowledge that this tension exists and that the resolution of the tension is a challenge fraught with difficulty. For these wilderness areas, the decision as to the appropriate

level of commercial packing services will be made in the Record of Decision for the Trail and Commercial Pack Stock Management Final EIS.

II. History of Packing in the Sierra Nevada

Chapter 3 of the *Trail and Commercial Pack Stock Management in the Ansel Adams and John Muir Wildernesses Final EIS* provides an extensive review of the history of commercial packing in these wilderness areas. The history of guiding with pack and saddle stock in the Sierra Nevada, including these wilderness areas, indicates that commercial guides and services—as well as the first rangers and military patrolling the forest reserves—began in the late 1800s. In 1871, Tom Agnew, who built a cabin in what is now called Agnew Meadows, guided visitors with pack stock in the San Joaquin drainage for the Yosemite Park Rangers. Allie Robinson in 1872 packed commercially from Onion Valley. E.H. Edwards Mercantile in Lone Pine advertised “Outfitting store for camping expeditions to Mt. Whitney and Cottonwood Lakes” in 1874. The Pine City Feed and Livery Stable (later known as the Lake Mary Pack Station) transported people and supplies in 1878 across the Sierra to and from Mammoth City and Fresno Flats. Helen McKnight Doyle, in her book *A Child Went Forth*, describes pack trips into the Mammoth and June Lakes area for fishing vacations. The Pioneer Stables, located in Bishop Creek, advertised in the *Inyo Register* in 1887. (Eastern Sierra Packers Association, 2000)

The founding of the Sierra Club by John Muir in 1892 focused widespread public interest on visiting the Sierra Nevada and preserving Yosemite Valley, the giant sequoia groves, and other natural landmarks. In order to develop a constituency for the Sierra Club’s preservation efforts William Colby started a tradition of conducting trips into the Sierra Nevada in 1901. For the next 50 years the large Sierra Club High Trips kept packers busy and led the way for thousands of wilderness adventurers. They were elaborate affairs, lasting 2 to 4 and sometimes up to 8 weeks involving an average of 150 people, around 50 packers and long pack trains of up to 250 mules carrying 100 pound stoves and full-time cook crews (Farquhar, 1965; Dilsaver and Tweed, 1990; Jackson, 2004). These types of outings helped to promote the wilderness concept and contributed to building the necessary support for passage of the 1964 Wilderness Act (Eastern Sierra Packers Association, 2000).

The unrestricted use of forest reserves by packing operations ended in 1906 with the creation of the Forest Service. (The Inyo and Sierra National Forests were created in 1907.) Regulations were instituted to control the degradation of public lands. They included the number of animals used in each forest, the allowed period of time for grazing, a requirement for grazing permits, a grazing fee, and the approval for structures such as out-buildings, tent sites, drift fences, and corrals. Other concerns such as fire suppression, camp sanitation, trail maintenance, and adherence to Fish and Game laws were addressed. By 1920, both the Park Service and Forest Service required a concessionaire’s permit for packing operations (Jackson, 2004).

Packing became a profitable business in the 1920s, with 36 large pack outfits operating in the southern Sierra Nevada and, of those, 15 (42%) were on the east side (Jackson, 2004). Many of the currently operating pack stations can trace their history back to the 1920s and 1930s (Eastern Sierra Packers Association, 2000). The earliest pack station on the Inyo National Forest that is still functioning is Rock Creek Pack Station, established in about 1919 or 1922 (Marye Roeser, former co-owner of Mammoth Lakes Pack Outfit, Personal communication, 2004 and 2005).

Most of the early recreation use in the back country, almost all of which was supported by pack trains, was fishing and hunting. After the hoof and mouth epidemic in 1924 reduced visitor use for several years, pack outfits increased in the southern Sierra Nevada to 71 in 1935 with 22 (31%) in the eastern Sierra Nevada (Livermore, 1935).

The Great Depression and World War II brought problems to commercial packers in the Sierra Nevada. Gasoline rationing restricted travel to pack stations and lack of personnel due to the military draft brought near disaster to the pack outfitters. Even the profitable Sierra Club High Trips were suspended until the end of the war (Jackson, 2004). The Inyo National Forest, which administered all Forest Service land in the eastern Sierra Nevada, listed nine pack operations in 1942. This was 14 less from the war's beginning in 1941.

The number of pack stations again increased to about 60 on both sides of the crest between Sonora and Walker Passes in 1947 after World War II. As a result of an improved economy, longer vacations, better access to the mountains by automobiles, and light weight materials, recreational packing boomed (Livermore, 1947). Two-thirds of those outfits and stock were based on the east side. The growing numbers of operations created intense competition and customers demanded better service. With this increased competition came an increase in more stringent business practices such as liability insurance, performance bonds, financial reports, schedules of personnel and stock, and logs to track the numbers of animals grazed, number of customers, service days, destinations, and day trip rentals. Along with bookkeeping was added pack station maintenance and increasing costs of doing business such as feed, salaries, stock, equipment, supplies, maintenance, and insurance. Pack outfits either lost money or barely met expenses (Jackson, 2004).

Beginning before the war and continuing into the 1950s, packing operations began to feel other changes that made the business less profitable (Jackson, 2004). Government contracts became scarcer and the automobile and airplanes began to replace mules as a means of transportation. Much of the back country was closed to hunting when Kings Canyon National Park was established in 1940 (Livermore, 1947). Boats were restricted to non-motorized ones and permits were required to pack them in. Loose herding of stock was prohibited on non-hazardous trails by 1950. Overused camps and meadows for grazing were placed off-limits and even permitted meadows could no longer support the demands of pack trains. In 1946 the number of animals permitted on any single trip into the national parks was limited to 75.

Commercial pack stations hit their peak in the ten years or so following World War II. Since the 1950s, the number of pack stations has decreased considerably. Likewise, the number of stock and clients serviced has also decreased.

Not accounting for fluctuations, the decline in the intensity of pack operations in the southern Sierra Nevada (from Yosemite National Park south) can be partly measured by the estimated number of stock owned, which decreased from 2764 head in 1935 to 1420 in 1986—a 51% decrease. There was also a consolidation of pack stations between 1935 and 1964 although the total number of pack stations in 1964 implies a secondary peak of 66 in a downward trend, of which only 17 (25%) were on the east side, the lowest percentage since 1920 (Jackson, 2004; Livermore 1935; Sierra Club 1952; High Sierra Packers Association, 2000).

This downward trend continued into the 1990s. The number of pack outfits decreased to less than 50 in 1990. Major pack stations from the Kern Plateau to Silver Lake numbered 71 at a historical maximum and only 13 by 2004, an 82% reduction. In order to maintain a viable

business a few of the more prosperous pack stations in the northern study area, Frontier, Red's Meadow, and Rock Creek Pack Stations have been supplementing their income by offering saddle day trips to tourist-organized horse drives in the Long Valley and Mono Basin areas. This is in addition to the earlier variety of trips offered outside the fully outfitted traveling trips such as spot trips, trail rides, base camps, and dunnage packs and caches.

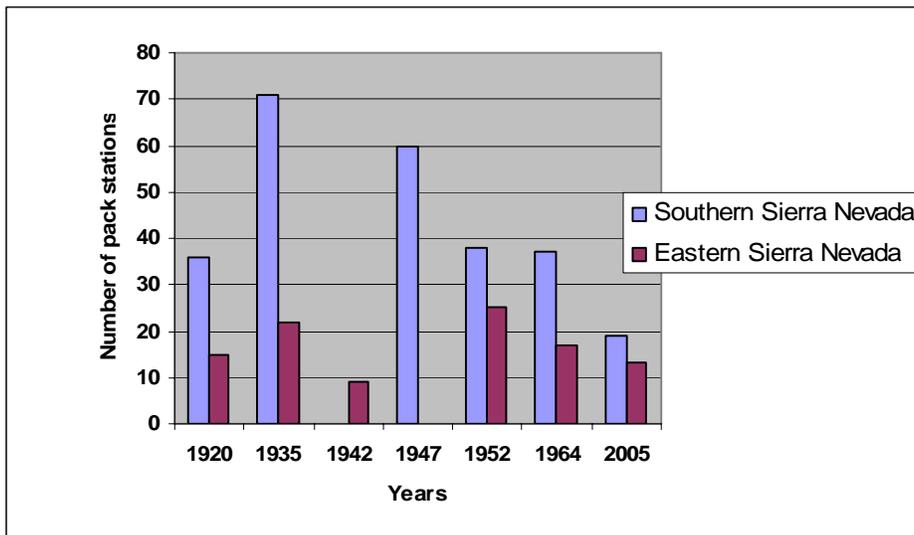

III. Current Packing Trends and Activities

Commercial packing operations in the Sierra Nevada peaked in the years following World War II. Since the 1950s, there had been a trend towards fewer pack stations, commercial stock in the wilderness areas, and clients utilizing the services. There are a number of reasons behind this downward trend including the development of roads closer to wilderness boundaries and the proliferation of personal automobiles. The discussion below focuses on the downward trend of the number of pack station, commercial pack stock, and clients serviced.

Pack Stations Numbers

After peaking in the years before and after World War II, the number of commercial pack stations servicing the Sierra Nevada has declined considerably. Figure 1 shows the decrease over the last fifty years. Numbers were generated from several sources and, in some cases, are for somewhat different geographic areas. The overall trend, however, is clear: there are far fewer pack stations servicing the Sierra Nevada today compared to fifty years ago. *The Tourist Packing Business of the High Sierra Region*, a study by Norman B. (Ike) Livermore, Jr. conducted in 1935, reported 71 pack stations serving the High Sierra area from Kernville to Yosemite, with over 2700 head of stock. (Livermore, 1935) Today, the number of pack stations serving the same Sierra region is less than 30. Several operations were consolidated and some were eliminated as roads penetrated farther up the east and west slopes of the Sierra Nevada, thereby reducing the need to originate trips from the valley floor. In the 1920s and 1930s trips would take anywhere from 10 to 30 days. In today's world, few visitors are willing to commit the same amount of time on a wilderness vacation.

Figure 1. Comparison of the number of commercial pack stations servicing the southern and eastern Sierra 1920-2005

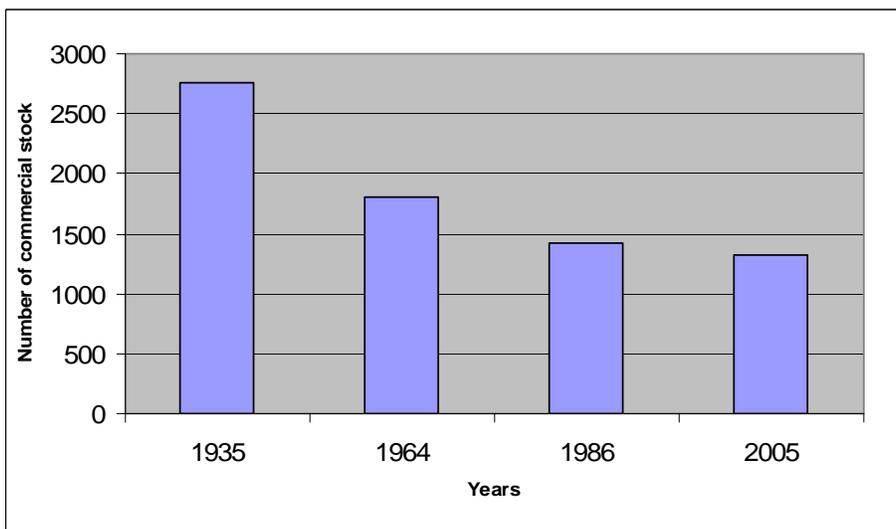

Note: The eastern Sierra includes pack stations from Silver Lake to the Kern Plateau. The southern Sierra Nevada includes pack stations south of Yosemite. (sources: Jackson, 2004; Livermore, 1935; Sierra Club, 1952; Inyo National Forest, n.d.)

Commercial Stock Numbers

Paralleling the decrease in the number of commercial pack stations has been a decrease in the number of commercial pack stock in the Sierra Nevada. Using historical sources, it is not fully known how the numbers of pack stock have fluctuated in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. These historical sources, however, can be used to compare commercial stock use in a wider area. Figure 2 shows the drop in the number of commercial pack and riding stock used in their operations in the Sierra Nevada region over the last 70 years.

Figure 2. Commercial pack stock in the Sierra Nevada 1935-2000.

Sources: Jackson, 2004; Livermore, 1935; Sierra Club, 1952; Inyo National Forest n.d.

The reduction in stock numbers from 1935 to 2004 is 1446; or a total reduction of 52%. The reduction in stock numbers from the 1964 Wilderness Act to 2004 is 489; or a total reduction of 27% for roughly the same general area.

Pack Stock Client Trends

According to use data presented in the John Muir Wilderness Plan (1979), from 1972 to 1976, the total use in the wilderness averaged 84,873 people. At the time, commercial pack clients made up 5% of the use in the wilderness and so during the 1970s there were an average of 4,244 pack stock clients in the John Muir Wilderness. For the years 2001-2004, the average number of pack station clients for both the Ansel Adams and John Muir Wildernesses was 4,783. The John Muir Wilderness portion in 2001-2004 averaged only 3,319 clients. This represents an average of 925 fewer clients or a 22 percent reduction between the 1970s and 2000. This contention is further supported by the 1979 John Muir Wilderness Plan (page 6): “Nineteen commercial packers serve the John Muir Wilderness. Most of these operate out of facilities located near the trailhead they use. Commercial pack stock use has not increased appreciably over the past two decades.” And, the 1979 Minarets Wilderness Plan (page 5) states, “Commercial pack and saddle stock use has remained static or has even declined slightly during the past decade.”

IV. Limiting commercial and non-commercial uses in the wilderness to protect wilderness character

The need for commercial stock service in these wildernesses has been established in a number of management documents including the 1988 Inyo National Forest Land and Resource Management Plan and the 2001 Ansel Adams, John Muir, and Dinkey Lakes Wildernesses Final Environmental Impact Statement. The limiting factor defining the extent necessary for areas served are the wilderness standards set to preserve the wilderness character. For more than 30 years, the Forest Service has determined that higher levels of pack stock use could unacceptably impact the wilderness character of wilderness areas and as a result has imposed use and activity limitations and restrictions on them. For example, the 1979 Minaret Wilderness Management Plan (USDA Forest Service, 1979) states, “Pack station stock numbers will not be allowed to increase, unless special studies show an increase to be compatible with the wilderness resource.”

Over the years, controls on commercial pack stock have become more stringent and site-specific. Prior to 2001, commercial pack stock operations did not operate under quotas. Appendix L of the 2001 Wilderness Plan (Quota Rationale) was used for setting first-time commercial quotas, and did include an analysis of appropriate commercial (and non-commercial) quotas based upon the identified resource concerns and limiting factors. Further, the 2001 Wilderness Plan Record of Decision stated that “Alternative 1 Modified establishes quotas at levels of use that we believe are compatible with maintenance of wilderness character. Quotas were examined by comparing recent actual commercial and non-commercial daily use levels by entry point with their impact on the physical, and to a lesser extent, social/experiential resources (such as potential for crowding due to topography and use patterns). Quotas were evaluated and sometimes adjusted for non-commercial and established at appropriate levels for commercial operators consistently across the wilderness. In areas where it was determined that by reducing the daily overnight use levels there would be a positive effect or correct an identifiable resource concern, appropriate adjustments were made to quotas” (Appendix L, 2001 Wilderness Plan).

Additional standards set in the 2001 Wilderness Plan that directly and indirectly define the limits for allowing areas to be used by commercial pack stock and their clients include trail and user-created trail standards, campsite and campfire restrictions, grazing standards, best management practices for water quality, and standards to avoid impacts to critical wildlife areas. These standards define and limit the areas accessible and available to commercial pack stock use and service. For example, the 2001 Wilderness Plan directs that “All commercial pack stock must stay on designated trails, except where authorized in advance by the Forest Service for alternative routes or to access campsites and grazing areas.” This defines and limits the extent of areas and locations that commercial pack stock services are permitted. Clients of commercial packers are generally limited to only areas with approved trails. The 2001 Wilderness Plan also directs that no new trails will be constructed. This further defines that trail expansion or opening of new areas will not happen. Areas open to commercial pack stock clients are further limited by the availability of suitable grazing areas, campsites, campfires, and approved use-trails.

The 2005 wilderness planning efforts continue this trend by adding new restrictions including designated campsites, destination quotas, grazing and trail suitability, and stock limits. These new regulations will further define where, when, and how commercial pack stock can travel in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. Collectively, these limitations restrict commercial pack stock services to about 9% of these wildernesses.

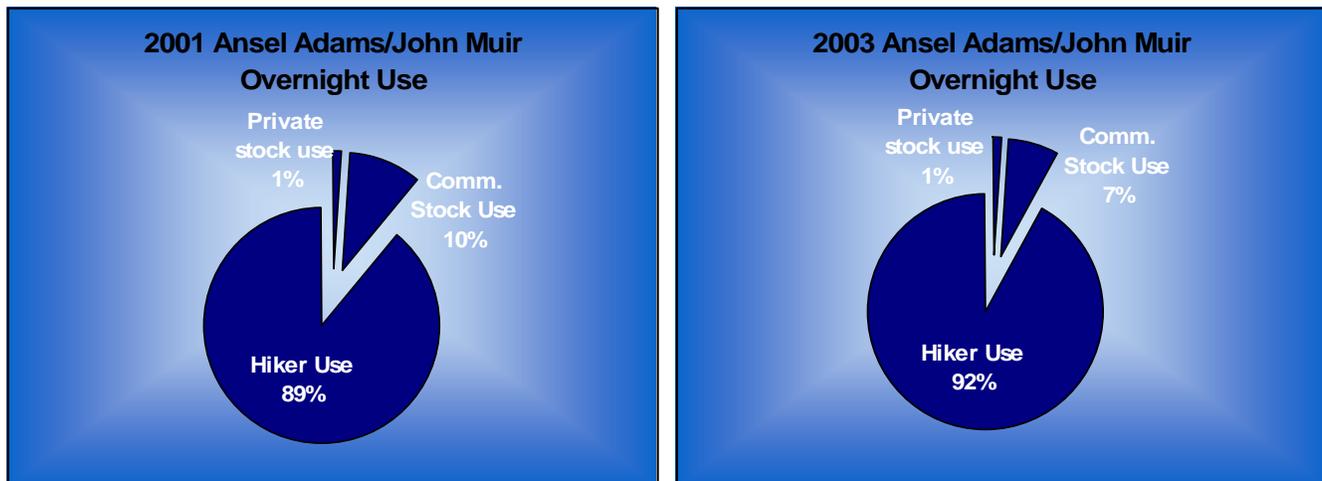

Allocation of capacity between wilderness user groups

Along with wilderness capacities and putting in management standards, another issue to resolve is how to allocate use of the wilderness between the various user groups, including commercial pack stock, backpackers, and outfitters/guides. This balancing between different visitor groups is a fundamental issue in the wilderness without an easy answer. In the 1970s, when the Forest Service first required wilderness permits, established trailhead quotas to manage use, restricted party size, restricted camping and campfires, and took other actions judged necessary to protect the wilderness character, it was the managers’ objective to “freeze” the level of commercial pack stock activities. This level of use for commercial pack stock services resulted in a relatively finite number (measured in stock numbers and service days) that effectively prevented them from growing or meeting the needs of visitors. With the necessary wilderness protection controls and restrictions in place, managers determined it was adequate to use only a permit and daily trailhead quota for the vast majority of the users (mostly backpackers) and maintain a constant level of commercial pack stock regulated by service days and pack stock numbers.

There has been an annual capacity allocation of roughly 6-8% to visitors needing commercial pack stock services, 5% to visitors needing other commercial services, and more than 87% to non-commercial visitors. Allocating only 6-8% of the use capacity of these wildernesses to people needing commercial pack stock services is probably not enough in light of future trends (see discussion below of demographic trends).

Commercial pack stock use in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses currently make up a relatively small percentage of use (see Figure 3).

Figure 3. Comparison of overnight use in the Ansel Adams and John Muir Wildernesses 2000-2003

Note: The percentage of overall commercial use changes annually as a result of total overall use changes as well or as much as commercial use changes. This shows the fluctuation between 2001 and 2003. Changes in these years resulted from the court ordered reduction in commercial pack stock services.

Since more than one user group is competing for the available capacity during popular times of the year to visit these wilderness areas, limits and allocations must be set for all user groups. For commercial packers, the most sensitive factor that managers have consistently concluded must be limited and regulated is the use of the pack stock. It is this reason that pack stock services and numbers have been held static at benchmark levels and the service area restricted to only 9% of the total area where it is judged sustainable and compatible with preserving the wilderness character.

V. Commercial Packing Services and Trips

In 2004, commercial packers serviced approximately 4,000 overnight clients in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. Similar to past years, commercial packers provided a number of different trips and services for both the public and private sector. The following is an overview of the trips and services provided by commercial pack stock operations.

Types of Groups Serviced

This section describes the types of groups that commonly utilize commercial pack stock to access and experience the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. Section 2 will introduce and discuss the topic of need categories.

Family and Multi-generation Groups: Many individuals and families have traditionally engaged in summer wilderness “pack trips” in these wildernesses areas. Grandparents (and great-grandparents) who have spent many summers in the Sierra want to share and experience the wilderness with their children, grandchildren, and great-grandchildren—all together. More and more “Baby Boomers” who were backpackers in the 1970s now need the services of packers in order to access these areas with their families and children. For these family groups, the Sierra experience is very important to them for their wilderness recreation and enjoyment, and to

pass along to their children and families their wilderness values. Because many of these families have young children or members unable to walk or carry their own equipment, the packer services are needed for their transportation to wilderness. For others, the riding and pack trip itself is the experience desired; many people who want to experience a stock supported trip do not have access to animals or knowledge to use them. No attempt to quantify these types of trips will be made here; however, visits to pack stations during the summer of 2005 revealed a number of multi-generational trips. Many of these groups included fairly young children who were entering the wilderness—with the help of commercial pack stock—with their parents and their grandparents. Anecdotal conversations with these types of groups revealed a common theme—older wilderness users were eager to experience the wilderness with a younger generation.

Organized Groups: Groups sponsored by Boy and Girl Scouts, churches, YMCAs, schools, universities, companies, conservation groups, clubs, organizations, camps, inner-city youth programs, and others commonly require packer services to provide their camps and logistics for their wilderness trips. Many of these groups have been taking pack-supported trips for decades, some even pre-dating the Wilderness Act. Without packer services, many of these groups would not be able to serve their group needs, as often not everyone is capable and fit enough to walk and carry their own gear.

Special Function Groups: These trips are generally organized for a specific purpose related to wilderness use; they often focus on an educational aspect of wilderness such as photography, art, writing, spiritual enrichment, research, medicine, nature study, etc. Agency sponsored trips are also supported by pack and riding stock, and include trail crews, search and rescues, fish stocking, survey crews, mapping specialists, military personnel, and Congressional representatives among others. Special function groups often have materials and equipment too bulky and heavy to carry with backpacks and include members who are not capable of walking or carrying their own equipment. Visits to pack stations during the summer of 2005 provided an opportunity to talk to these types of groups. Again, there is no attempt here to quantify the number of groups that fall under the “special function” grouping. Pack station visits conducted during the summer of 2005 did reveal, however, that a number of groups utilize commercial pack stock to transport their gear. A number of fishing related parties were encountered as well as a landscape painter who was utilizing commercial packers to transport easels and painting equipment. Native American groups also utilize commercial pack stock support to help with their annual traditional walks. Bishop Pack Outfitters, for example, has for a number of years provided pack stock support for some Native American walks free of charge. In addition, during the Draft EIS public comment period, a comment was received from the State of California Snow Survey group reiterating the importance of commercial pack stock support for their activities.

General Outings: There are hundreds of visitors each year who travel individually or gather with a small group of friends, family, or work associates and take a commercial pack-supported trip to simply enjoy and experience the wilderness. They may engage in several types of activities while in the wilderness such as day hikes from a base camp, fishing, photography, etc. Many of these visitors desire to experience wilderness riding and using pack stock, but do not have access to private stock or the knowledge to properly use and handle pack stock in a wilderness setting. Again, anecdotal conversations with commercial pack stations clients during the summer of 2005 revealed a number of groups that consisted of friends and family who

desired to experience the wilderness but did not have the knowledge or physical ability to backpack into the area over night.

Types of Commercial Pack Stock Supported Services

There are a number of services currently provided by commercial pack operators. The following provides an overview of these types of services.

Spot Trips: Visitors ride and their gear is packed to a pre-selected area. The stock and packer do not generally stay in wilderness but return for the visitors on a predetermined date to take them out. Some spot trips are one-way spot trips in which the client rides in the first day to help with elevation acclimation and then hikes out at the end of their trip.

Dunnage Trips: Visitors' backpacks, food and camp equipment are packed into a specific location, and they hike to meet it. Spot and dunnage trips comprise approximately 80% or more of the overnight services provided by packers.

All Expense/Traveling Trips: These are customized trips that will meet the visitors' specific needs for dates, locations, and members of the party. The pack and riding stock, packer and a cook are also provided on these trips. There are several variations of the all expense trip including hiking with pack stock, continuous hire of stock and packer, and trail rides. **Hiking with Pack Stock** offer visitors the option to have all of their equipment, food and supplies provided, or they can supply their own. Generally the visitors will hike, and have their camp and equipment packed. There may be some visitors who choose or have to ride because of physical limitations. **Continuous Hire of Stock and Packer** are for those who wish to have the packer and stock remain with them throughout the duration of their trip. The camp-gear and provisions are provided by the visitors. **Trail Rides** travel to pre-advertised locations within the wilderness and provide the "classic" Sierra pack trip wilderness experience. They can either be fully outfitted by the pack station, or there can be a combination of equipment supplied by the visitors. The outfitter supplies the packing and riding stock, a packer and a cook, and the staff will stay with the party for the entire trip. These are pre-advertised, with set dates and locations.

Day Rides: Commercially guided riding trips are available for those visitors who want to enjoy the wilderness scenery, take photos, go fishing, or visit a special area for just a few hours. Rides vary in length from one hour to all day.

Section 2 –Need for Commercial Packing Services in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses

This section analyzes the current level of commercial pack stock use in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. The analysis will consist of two tests: first, whether the activities supported by commercial pack stock are consistent with the intent of the Wilderness Act and second, whether there is a need for the wilderness user to utilize commercial pack stock to experience the wilderness. A survey was conducted during the summer of 2005 to quantify the appropriateness and level of need for commercial pack stock services. The survey is described in more detail below.

The strategy for determining the need for commercial pack stock will be to look at current use levels and determine whether the current level of service reflects the actual need for commercial pack stock service in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. This need will be examined by analyzing the current level of commercial pack *clients*. The need for commercial stock services can be best analyzed using this approach. Another strategy may be to address whether the current number of permitted pack *stations* are necessary for realizing the intent of the Wilderness Act. This strategy is inferior and largely irrelevant to determining the need for commercial pack stock service in the wilderness as it does not address the level of actual public use in terms of client numbers. The current number and location of pack stations in the project area has evolved to its current state over a number of years. Pack stations are generally located in areas that are in drainages in close proximity to recreation areas. Most of these operators have been operating in their current locations for a number of years and have a high level of knowledge of the area. Most importantly, the number of operators does not matter to the overall need to protect the wilderness—the number of trips and level of use is what is important to analyze. Eliminating operators will have no effects on the impacts of commercial packing unless the use level is also lowered. Reducing the number of operators, however, may have serious implications for the public's ability to use the service as some areas may become underserved unless new operators are willing to truck their stock to distant trailheads. The question of the level of need is best addressed, then, by examining the public use of the services.

The 2005 Commercial Pack Client Survey results will be used to determine whether the activities associated with commercial pack stock are appropriate and consistent with the intent of the Wilderness Act. The survey results will also be used to analyze the level of need for commercial pack stock services. Part IX will look at demographic trends that may influence the future need for commercial pack stock service in these wildernesses.

The next section will describe the two tests. The results of the survey are discussed below in the Public Purposes of the Wilderness Act and Need for Commercial Packing Services sections.

Part VI Description of Two Test Evaluation of Current Levels of Commercial Pack Stock Use

Test One: Public Purposes of the Wilderness Act

The first test for the current level of commercial pack services is whether the service supports activities consistent with the public purposes of the Wilderness Act. The Wilderness Act allows for commercial services in the wilderness that support “activities which are proper for realizing the recreational or other wilderness purposes of the Act.” The language “recreational or other wilderness purposes of the Act” is clarified earlier in the Act in Section 4(b) which specifies that “wilderness areas shall be devoted to the public purposes of recreational, scenic, scientific, educational, conservation, and historical use.”

The following is an overview of the ways in which commercial packers contribute to the public purposes of the recreational, scenic, scientific, educational, conservation, and historical uses of the Wilderness Act.

Recreational: The types of trips and services that are recreational in nature are for relaxation, fishing, hiking, horseback riding, photography, enjoyment of the wilderness areas, and to basically get away from the urban environment. The historic and classic “Sierra Pack Trip” fits into this type of use. Many family or group members are not physically capable of walking and/or carrying their gear because of their age, physical conditions or other limitations. Some groups lack the specialized knowledge or experience to travel and camp safely or properly in wilderness. For many individuals and groups, packers offer the needed services and support to allow wilderness visitors to use and enjoy these areas for proper recreation purposes. Annually, packers serve approximately 4,000 overnight visitors and approximately 3,500 day riders. This may represent less than 8% of the total visitors to these wildernesses, but without packer services, many of these visitors would not have any opportunity or ability to recreate in these areas.

Scenic: These wildernesses are some of the most scenic areas in the world. Overnight and day use visitors to these wildernesses frequently mention that viewing the scenery is one of the primary purposes for their visit. All of the individuals, groups, organizations, and agencies that commonly use and rely upon pack stock services for their recreational benefits also realize scenic benefits from their wilderness visits. Pack station operators make it possible for many people who otherwise could not hike to see and appreciate the scenery of these areas.

Scientific: Extensive research and study has been conducted in these three wilderness areas. Generally, equipment and supplies needed to support the research is bulky and heavy, and is needed in very remote locations. Commercial pack stock services are generally the most suitable and appropriate form of transport in these wildernesses. The alternative modes of transport, such as helicopters, are less appropriate. Some examples of research efforts supported by commercial pack stock are: Earthquake Research by University of Nevada – Reno, U.S. Geological Survey (USGS), University of Utah, U.C. Berkeley, the University of Hawaii, and China; Volcanic Research by USGS; Mineral Deposits by USGS and Bureau of Mines; Water Resources by California Department of Water Resources for snow and water surveys; Yellow-legged Frog Research by UC Santa Barbara, California Department of Fish and Game; Bighorn Sheep Research by California Department of Fish and Game; Spotted Owl Surveys by Forest Service and Pacific Southwest Research Station; and Fish Stocking Research by California Department

of Fish and Game. The Eastern Sierra region, including the Sierra Nevada range, is one of the most heavily used areas for research and study because of the vast wildernesses, parks, and other public lands that make it ideal for studying the undeveloped and natural world. Packers play a significant role in facilitating the transport for many of these research projects. And, without their services the impact on the wilderness solitude would certainly be more significant as researchers and agencies would be forced to rely more frequently on mechanical transport.

Educational: These wildernesses are natural learning centers. Universities, organizations, agencies, and individuals use these areas for educating students, members, and personnel. Pack stations often are needed to transport base camps, personnel, and equipment to wilderness locations. Pack stations have provided support to organizations, agencies, and companies developing documentaries about wilderness. Natural History, Geology and Astronomy courses are frequently offered through universities and conservation organizations in cooperation with and supported by Eastern Sierra Packers. Some groups with programs assisted by the packers include: U.C. Riverside, U.C. San Diego, Saddleback Community College, Santa Rosa Community College, and U.C. Davis. Other youth programs that have a long history with using packers for trips include: Youth Enrichment (LA PD), YMCA (20 or more locations), Churches (20 or more locations), Bear Valley Native American program, and Girl Scouts and Boy Scouts. Groups promoting personal growth such as Pacific Crest Outward Bound are also supported by packers. Packers also sponsor and support horse packing and horsemanship courses, professional packing schools, and minimum impact stock courses for persons using stock in the wilderness.

Conservation: Historically, commercial packers have contributed to the conservation component of the public purposes of the Wilderness Act by facilitating public access into the wilderness areas of the Sierra Nevada and by providing support for conservation related

President Roosevelt and John Muir Horseback, 1903
(Source: Yosemite Museum National Park Service)

activities in these wilderness areas.

The early days of the Sierra Club outings in the Sierra Nevada, for example, were primarily supported by commercial pack stock. Today, commercial packers continue to build constituency for the wilderness concept by providing access to these wildernesses for individual and groups who might otherwise not have the ability to experience and enjoy the areas.

In terms of conservation projects, Forest Service, California Department of Fish and Game, California Water Resources Department, and other agencies use the packing services of

these pack stations for supporting resource and conservation work in wilderness. Removal of litter and facilities, trail maintenance, watershed restoration, airplane wreckage removal, maintenance of fish barriers, and similar support are provided by commercial pack stock. Studies and inventories by agency specialists sometimes use packers. Packers are also called upon to provide the support for “partnership and policy trips” including federal agencies,

congressional representatives and staff, judges, county and state leaders to discuss and review conservation efforts and work. In fact, Sierra packers have served dignitaries such as Secretary of State Robert McNamara, Governor Ronald Reagan, Supreme Court Justice William O. Douglas, Theodore Roosevelt IV, and the California Fish and Game Commission.

Historical: A “Sierra Pack Trip” is considered by some to be the ultimate experience reflective of our rich western and wilderness heritage. While commercial pack stock services have a practical and necessary function of transporting people who need help to access and use these areas, to others, their services are part of the wilderness experience itself and provide the only practical opportunity for many visitors to experience the wilderness pack stock tradition of these wildernesses. Without their packing services, many people who desire this recreational and historical experience would not be afforded it, as few people have the necessary pack stock, skills, knowledge, or experience to use pack stock in a wilderness setting by themselves. Not only is the history of these wildernesses deeply rooted in the use by commercial pack stations, many of the prominent landmarks are also either named by or after packers. Packers pass along their historical knowledge to their clients and enrich their experiences and understandings of these areas and about wilderness itself.

Test 2: Need for Commercial Packing Services

This section discusses the second test for current levels of commercial pack stock; whether there is a need for the use. Six categories of need have been identified. This test and these categories provide the basis for addressing the Wilderness Act standard that, “Commercial services may be performed within the wilderness areas designated by this Act to the extent necessary for activities which are proper for realizing the recreational or other wilderness purposes of the areas.”

Categories of Need

1. Persons with physical limitations that make them unable to walk and/or carry their own equipment.

- Disabled persons
- Persons physically and medically limited (back/knee injury)
- Persons with diseases and health conditions that limit strenuous exertion (heart, hypertension, etc)
- Elderly and very young persons with limited mobility or endurance
- Persons lacking adequate physical conditioning to achieve desired experience or activity

2. Persons with equipment too bulky or heavy to carry.

- Photography equipment
- Water floatation devices such as rafts or canoes
- Supplies and equipment for extended stays or travel
- Search and Rescue equipment
- Equipment and materials necessary for approved uses and activities such as dam maintenance, mining, watershed and fish projects, etc.
- Equipment and materials necessary for Universities, contractors, and cooperators with approved studies
- Equipment and materials necessary for groups with extended trips into the backcountry

3. Hunters needing pack stock to haul game.

- Deer hunting in wilderness zones under State law

4. Persons desiring a wilderness “pack trip” or “day ride” experience.

- Persons desiring a pack trip but who lack knowledge or skills to handle or use stock in wilderness setting
- Persons desiring a pack trip but who lack wilderness knowledge to safely and properly travel and camp in a wilderness setting, and require professional assistance to guide and advise them
- Persons desiring a pack trip but who do not own stock, or otherwise have access to suitable pack stock
- Persons desiring a pack trip who own private stock suitable for wilderness use but who practically cannot use their own stock
- Persons who are seeking the traditional “Sierra Pack Trip”

5. Persons able to walk but affiliated with persons falling into need categories 1-4, and therefore included as member of commercial group.**6. Native American traditional walks or gatherings requiring pack stock to transport camps and persons not able to walk.****Categories where commercial pack stock support is not necessary include:**

- Persons able to walk and hike and carry their own equipment and their wilderness experience is not dependent upon using pack stock or riding horses.
- Persons wanting horseback rides – but their experience is not wilderness dependent. For these individuals and groups, the horseback ride itself is the desired activity and a wilderness setting is not needed for this experience.
- Persons owning private stock suitable for wilderness travel who also possess the skills and knowledge to properly use them in wilderness.
- People utilizing commercial pack stock to transport equipment that is not legal in wilderness (e.g., chain saws, bikes).

Decisions related to categories determined “not needed or necessary” were based upon either: (1) lack of demonstrated need, (2) activities not dependent upon a wilderness setting, or (3) needs that clearly conflict with wilderness protection standards.

Rationale for Categories of Need

Many categories of need are fairly straightforward and evident, such as persons who require pack stock to transport them and their equipment and supplies because they are physically not capable of hiking and/or carrying camping equipment. As described in the trends section below, this is a large and growing segment of the American population. While this category may be the most obvious and compelling group of persons needing commercial pack stock, they are not the only group needing services for their wilderness access or recreation experience. As previously mentioned, many other individuals, families, groups, agencies, universities, organizations, contractors and tribes also require pack stock assistance to transport people with special needs, to carry bulky and heavy equipment and supplies, and to realize their desired wilderness

experience. Without commercial pack stock support, many of these appropriate wilderness activities would not be possible for those individuals and groups listed.

Persons who may be able to walk and carry their own equipment, but elect to experience wilderness with riding and pack stock—the historical “Sierra Pack Trip”—are also in need of commercial pack stock services in these wilderness areas. Most private citizens wanting this kind of wilderness experience do not have the animals, specialized skills to handle pack stock, or equipment to achieve their desired wilderness experience, and therefore need the services of commercial packers. The history and practices of every wilderness area is different, and Congress clearly recognized that besides wilderness recreation, another important purpose of wilderness was the study and experience of its history. For most of the Sierra Nevada wilderness areas, using pack stock is a historical practice and part of the wilderness experience for many past and present Americans. The use of pack stock, and the packing profession, is deeply rooted in the history of these wildernesses. The “Sierra Pack Trip” is an appropriate and historical form of primitive recreation for these wildernesses; and, the only way that individuals can have this experience is with commercial services, unless they have their own stock.

Some potential consequences to the wilderness environment and administration of these areas in the event the agency determined that “The Sierra Pack Trip” category of need was not appropriate or needed, is significant. People would still have the need and right to use “private” pack stock to realize a desired “pack trip” or “day ride.” They could buy, rent, or borrow animals for their access and use. While some private stockowners (such as Backcountry Horsemen) have the knowledge, skill, and ability (as well as commitment) to practice proper stock ethics in a wilderness setting, most urban and even some rural visitors needing commercial pack stock support for their “pack trip” or “ride” experience do not. (The stock impacts and damages to the wilderness character from many more visitors using private stock rather than using commercial packer’s service would most likely be significant and unacceptable.)

The Wilderness Act does not specifically define or limit who can or cannot use wilderness areas. It states that wilderness areas “shall be administered for the use and enjoyment of the American people in such manner as will leave them unimpaired for future use and enjoyment as wilderness...” The Act also specifies that wilderness, “has outstanding opportunities for solitude or a primitive and unconfined type of recreation” and “shall be devoted to the public purposes of recreational, scenic, scientific, educational, conservation, and historical use.” Forest Service wilderness policy (FSM 2320) states, “Consistent with management as wilderness, permit outfitter/guide operations where they are necessary to help segments of the public use and enjoy wilderness areas for recreational or other wilderness purposes.” In light of the Wilderness Act and Forest Service guidance, all need categories identified and stated above (except those identified as not needed) are determined in this analysis to be appropriate categories to receive commercial pack stock services in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. These service and activity needs are consistent with the outfitting and guiding services provided to the public in these areas before and after the 1964 Wilderness Act, and are consistent and compatible with the intended mode of primitive travel (foot and horseback) appropriate and envisioned under the Act.

Part VII. 2005 Commercial Pack Client Survey

During the summer of 2005, a survey of commercial pack clients was conducted. The intent of the survey was to determine whether commercial pack stock clients were engaged in activities proper for the wilderness and to quantify the level of need for commercial pack stock service.

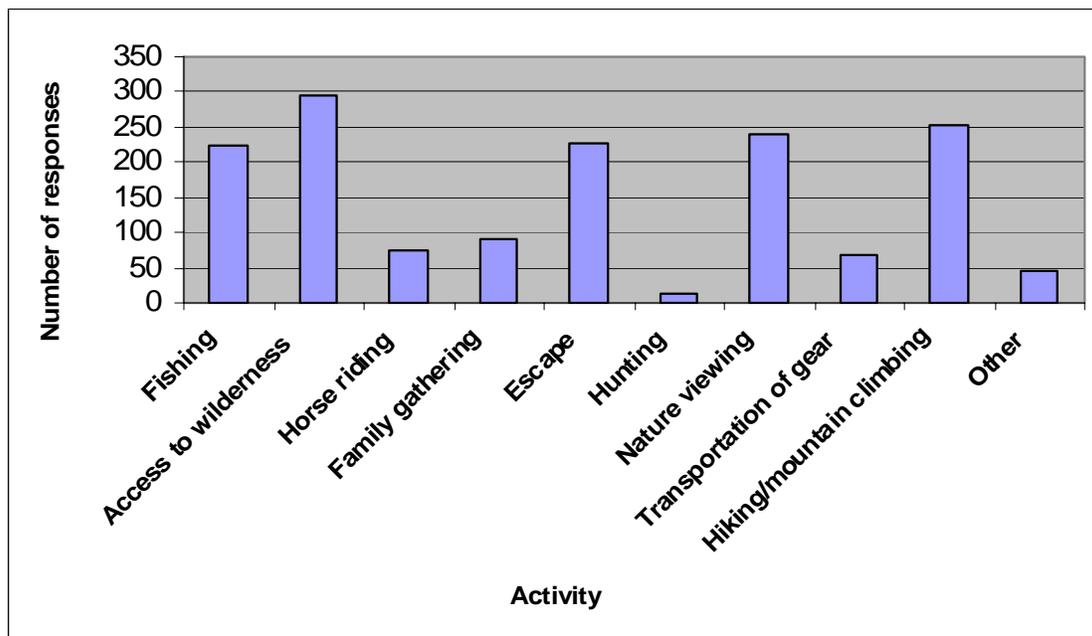

The survey instrument was developed and field tested at several pack stations in July 2005 (see Attachment 1 for a copy of the survey instrument). In early August 2005, the survey was mailed to 537 pack stock clients from 2004. The names and addresses of the clients were gathered from the Inyo and Sierra National Forests' Wilderness Permit Databases. The clients contacted were the individuals who identified themselves as the group leader and provided their names and addresses when receiving their wilderness permit. In 2004, 4,015 overnight clients were serviced by commercial pack stock. The average group size was three individuals, so approximately 1,338 commercial packing groups used the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. A total of 346 surveys were filled out and returned to the forests. In all, data was available from 346 out of the 1,338 commercial groups that utilized commercial pack stock in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses (approximately 40% of the groups). This sample size provides a more than 95% confidence level; that is, we can be more than 95% sure that the results from the 346 respondents accurately reflects the results that would have been obtained by hearing from all 1,338 groups that utilized commercial pack stock services in 2004.

Results of the Survey

Survey Results for Test One: Public Purposes of the Wilderness Act

Test one analyzes whether commercial pack stock services are supporting activities that are proper in the wilderness and fulfill the public purposes of the Wilderness Act. The 2005 Commercial Pack Client Survey was used to identify the activities that people engage in when using commercial pack services to access the wilderness. Of the 346 survey responses, the overwhelming majority included activities that are consistent with fulfilling the public purposes of the Wilderness Act (Figure 4 shows the responses from the survey). The most popular activities identified as being a purpose of the wilderness trip were fishing, hiking/mountaineering, and nature viewing.

Figure 4. Survey results: activities on pack supported trips

Another question asked in the survey: “Could you have met the purposes of your trip by taking a horse trip outside the boundaries of wilderness areas?” reveal the extent to which these activities (for the survey respondents) are wilderness-based. Out of the 339 surveys that responded to this question, 276 or 81% reported that they could not have met the purpose of their trip on a trip outside wilderness.

The survey shows that members of the public are using the services of commercial pack stock operators to enjoy activities that are proper in the Wilderness. Further, survey respondents report that the purpose(s) of their wilderness trip can not be met by taking a trip outside wilderness. The next issue to examine is to analyze how many commercial stock clients fit into one of the categories of need which will be introduced in the next section.

Survey Results for Test 2: Need for Commercial Packing Services

The section will focus on the need for commercial services by looking at whether commercial pack stock clients surveyed in 2005 fall into one or more of six categories of need for these services. Results from the 2005 Commercial Pack Client Survey were used to quantify the need categories described above. A question from the survey (“Why did you choose to use pack and/or riding stock for your wilderness trip?”) was used to determine the need category (if any) the group fit into. This survey focused on groups, not individuals. It is both impractical and impossible to determine whether each individual of a group utilizing commercial pack stock matches an identified need category. The survey was mailed to group leaders and answers from the above question determined whether the group needed commercial pack stock to accomplish the purpose of their wilderness trip. The results from the survey are shown below in Figure 5.

Figure 5. Survey results: level of need

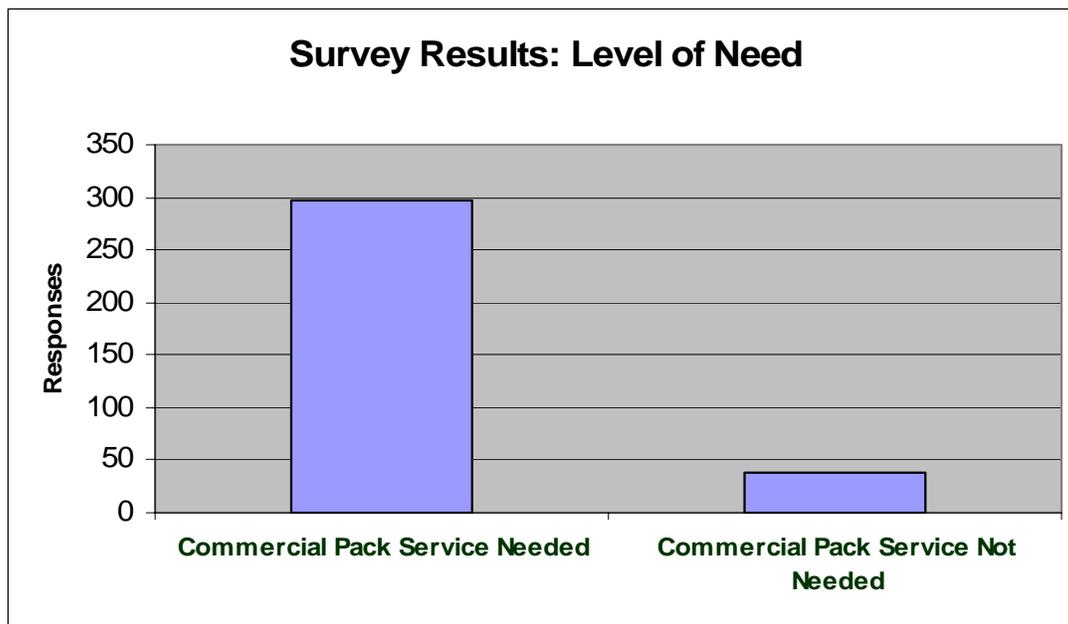

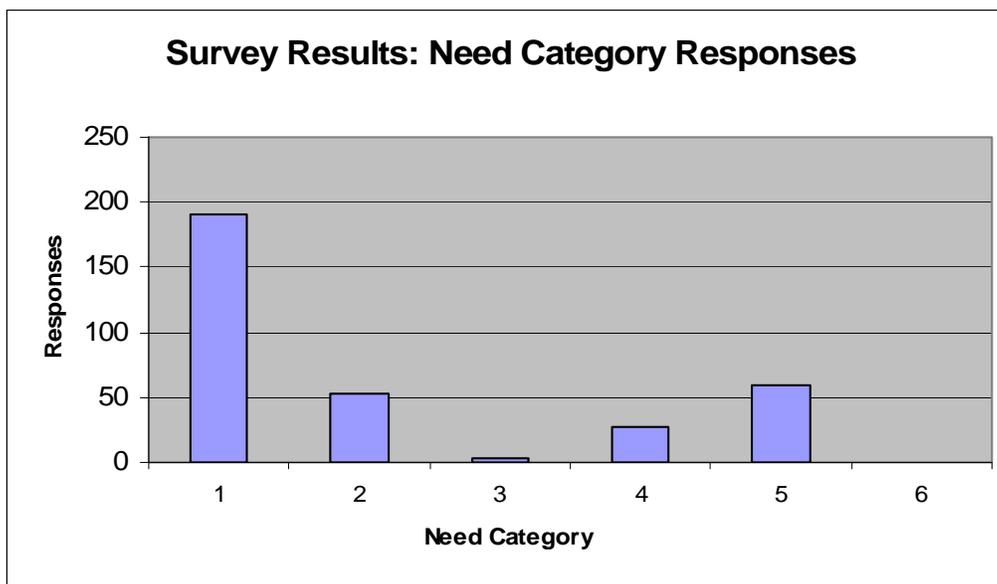

Figure 5 shows that the overwhelming majority of survey respondents needed commercial pack services to accomplish the purposes of their wilderness trip. A total of 336 surveys provided sufficient information to determine whether commercial pack stock service was needed. It was determined that 298 or 88% of the groups needed commercial services. Figure 6 shows the breakdown of groups into the five need categories.

Although the majority of responses indicated a need for commercial services, some survey responses were clearly from groups and/or individuals that did not need the service to access the wilderness. Responses in the “not needed” category were from individuals who indicated that they were physically capable of carrying their own pack, but used commercial pack service for convenience or to save time. One response, for example, said that commercial pack services were used because the wilderness user “was lazy and could afford it.” This is an example of a client who was not placed in one of the six Need Categories. These types of responses, however, were the minority; most of the responses indicated a definite need for commercial pack support for their trip.

Figure 6. Survey results by need categories

*Category 1 includes persons with physical limitations

Category 2 includes persons with equipment too bulky or heavy to carry

Category 3 includes persons hunting deer

Category 4 includes persons desiring a wilderness pack trip experience

Category 5 includes individuals able to pack their own gear but traveling with someone in Categories 1-4

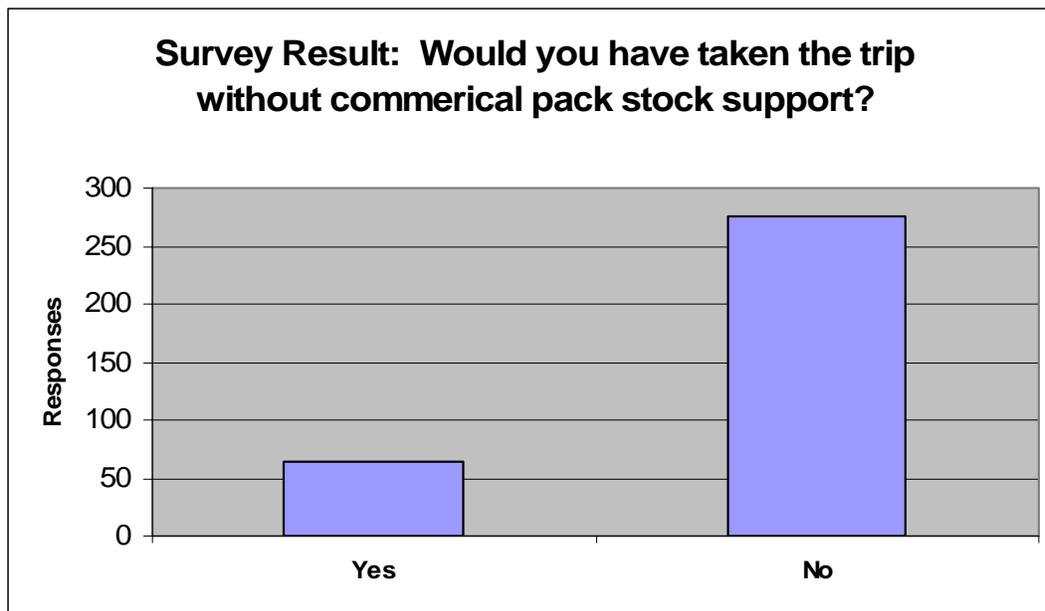

Category 6 includes Native American traditional walks or gatherings

**The numbers in Figure 6 total more than 298 as some groups fell into more than one category.

Category 1, the Need Category related to physical need, was the most common reason cited for securing the services of a commercial packer. Many of these respondents reported that they were elderly or had some physical limitation that made it all but impossible for them to carry a backpack and access the wilderness on an overnight trip. A number of these people also indicated that while they were backpackers at one time, commercial pack stock now provided an essential service for them. Without stock, many of these people would not be able to access the wilderness. Another common response came from group leaders who indicated that they were bringing their entire family, including children, along on the wilderness trip. Many of these respondents said that commercial pack stock support were crucial if children were to be included in the wilderness trip.

The results from another question from the survey (“Without commercial services, would you have taken the trip?”) reinforce the need for commercial services for some of these groups. Figure 7 shows the results of this question.

Figure 7. Survey Result: Would you have taken the trip without commercial pack stock support?

Interpreting the responses to this question were a bit difficult as some individuals answered for themselves while others answered for the groups as a whole. For example, some respondents stated that they would still have taken the trip without commercial pack stock; however, other members of the group would not have been able to. Nevertheless, the results of this question reinforce the overall result of the survey: the overwhelming majority of groups that currently utilize commercial pack stock support need this service for their wilderness trips.

Wilderness Day Rides

Wilderness day rides were not included in the 2005 Commercial Pack Client Survey. Instead, pack stations were visited during the summer of 2005 and anecdotal information was gathered on this activity. During the course of this analysis, several aspects of wilderness day rides became clear. First, the vast majority of wilderness day rides only enter a small portion of the wilderness. The Rainbow Falls Day Ride in the Mammoth Lakes area, for example, only enters wilderness for a few hundred feet and is mostly in Devil's Postpile National Monument. It is, however, considered a wilderness day ride. This ride is quite popular and accounts for more than 30% of all wilderness day rides on the Inyo National Forest. Examining use data shows that this is fairly typical of wilderness day rides: most of these rides do not penetrate particularly deep into wilderness. Most, if not all, of the day rides enter wilderness for only a mile or two or less. The reasons for this are many, but perhaps most significantly, individuals looking for a day ride will not be able to or are not interested in being on a horse for more than a couple hours. Typically, day riders are the least experienced of commercial pack clients and they typically are not interested in more than a two-hour ride. Most of the so-called wilderness day rides are in the front country with a relatively small percentage of the ride entering the wilderness. For many front country trails, the wilderness boundaries are miles from the trailhead and day rides only enter the wilderness for a relatively short distance.

Another aspect of wilderness day rides is the clientele and their need for the service. Anecdotal observations at pack stations reveal that a sizable percentage of day ride groups are made up of

families with younger children. Day rides provide these groups with a new experience and are important in exposing younger generations to the forested environment. The mode of transport (i.e., horses) appears to be an important consideration for day rides. Likewise, there is a need for a scenic destination for the trip. The proximity of the pack station to wilderness boundaries makes it nearly impossible for the rides to avoid wilderness altogether. Although not tracked in a formal survey, it appears as though many of the day riders would fit into Need Category #4 (persons wishing to have a wilderness-based horse back ride).

Currently, there are approximately 4,000 day rides that enter the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. As stated earlier, the majority of these rides only briefly enter the wilderness. Given the limited entry of these rides into wilderness, there are few, if any, environmental effects associated with these rides. In fact, day rides constitute one of the least impacting methods of experiencing wilderness for wilderness visitors.

The demographic trends described below (particularly trends indicating an aging, more urban population) point towards an increased need for day rides in the future. Therefore, there is a need to continue to provide a range of day rides that will accommodate an expected increase in the need for this service.

Survey Conclusions

The results of the 2005 Commercial Pack Client Survey indicate that the vast majority of clients are utilizing commercial stock for activities that are proper and consistent with the intent of the Wilderness Act. The overwhelming majority of the groups that utilize commercial stock are in one of the identified need categories and would not have been able to take the trip without the service. Commercial pack stock provides an essential service to the individuals and groups that utilize it; it is likely that most of these individuals and groups would have limited or no access to the wilderness without commercial pack stock services.

VIII. Current Constraints on Meeting the Full Public Need for Commercial Pack Stock Services

It is important to note that one of the purposes of this Needs Assessment is to provide a sense of what the overall public's need for this service is. A number of other considerations should be factored in when arriving at this overall level of need. It is not reasonable to conclude that by pure chance the Forest Service has arrived at a level of service that is nearly equal to the public's need for commercial services in the Ansel Adams/John Muir Wildernesses. Given the results of the survey and conversations with commercial packers, it is more likely that the public's full need for these services is not being met. The survey showed that the overwhelming majority of current use is proper for wilderness and is needed by the public to access the wilderness areas. In 2004, 4,015 clients were supported by commercial pack stock services in the wilderness. As the survey revealed, nearly 90% of the groups brought into the wilderness fit into one of the identified categories of need. Given the high percentage of current users of commercial pack stock that fit into a need category, it would be logical to assume that there is a certain level of public need for this service that is not being met and indeed based on conversations with pack station operators, it is likely that the full public need for these services is not being met.

Current restrictions on commercial packing in the wilderness have contributed to an inability to meet the full public's need for these services. Commercial pack operators have identified various restrictions that limit the ability of the business to meet the public's need for commercial service, including group size, quotas, limitations on the number of stock per party, and grazing restrictions. Group size particularly was a restriction that commercial packers say limit their ability to meet the public's need. While in the past packers would service larger organized groups such as church groups and Boy Scout groups, the party size limitation has all but eliminated this type of use. Grazing restrictions have also limited the ability of packers' to provide multiple day full-expense trips. According to one packer, these are the trips that are most popular with the public and represent a significant unmet need. Commercial packers indicate that every year restrictions on their operations require that they turn away clients that they cannot serve, but who nonetheless would fit within one of the need categories identified above.

The logistics of operating in a short season also limits the packer's ability to meet the full need of the public for these services. According to Eastern Sierra Packer's Association President, Dave Donnell, "Everyone wants to take a pack trip during the holidays, weekends, and month of August. We turn away people because we don't have the logistical capacity to handle them and the Forest Service limits how many people we can accommodate with quotas, service days, and other regulations."

Furthermore, there is likely a sizable group of individuals who need commercial packing services and fit into a need category but are unable to afford the service. As discussed in the Final EIS, Economics section, the costs of these trips have escalated over the last several years.

Commercial packers indicate that restrictions, particularly restrictions imposed by the Court, have caused an increase in the price of various services. Commercial packers say that the public has started to balk at the prices of these trips and each year people do not book their trip because they are unwilling or unable to pay the price for the service. It is impossible to determine the number of people that are unable to afford the service each year and "needed" the service to access the wilderness. Given that nearly 90% of current use fits into one of the Need Categories, it is logical to assume a sizable percentage of individuals are unwilling or unable to pay for the escalating price of these services. Still another unaccounted group is those that never make contact with the commercial packers because upon receiving a brochure or some other notification of the price of commercial packing services, they realize that they are unable or unwilling to pay the asking price and they do not pursue the trip any further. It is impossible to determine how many people are in this group, but again it is logical to assume it is a sizable percentage.

Another factor to consider when determining the need for commercial packing services is the relatively short season in which these operations have to operate in. The "need" for packing services will vary from year-to-year, depending on seasonal conditions. In a season such as 2005 that had a lingering snow pack well into July, commercial packers will be limited on the number of people that can be serviced. In other years, the season may start early and end late. The best way to account for these seasonal fluctuations in business is to identify a level of need as a range, rather than settle upon a specific number.

IX. Trends Affecting Need for Commercial Pack Stock Services

This section discusses trends and patterns potentially affecting the need for commercial pack stock services now and in the future.

1. According to *Demographic Change & Recreational Activity Trends* (2005) by Gary T. Green, University of Georgia, and Ken Cordell, US Forest Service, Athens, GA, and Becky Stephens, University of Tennessee:

- Population is rapid growing and some groups will literally explode in numbers.
- Incomes, educational levels, and average life expectancy will all increase by 2020.

2. Association of Partners for Public Lands (APPL) compiled in 2004 from websites, reports, and surveys of members and agency partners reported the following trends and patterns information:

- Consumers are seeking out uniquely different experiences when they travel, yet expect certain standards of destinations, tour companies, lodging establishments and transportation. 65% of travelers are city-dwellers living in urban areas with populations of 500,000 or more. Among those visiting a National Park while traveling in the last five years, 75% stayed overnight or within 10 miles of the parks on their most recent trip. (National Geographic Traveler and Travel Industry Association)
- 50% of American adults have taken an adventure vacation in the past 5 years. (E. Sheffield, California State University, Chico)
- Aging baby boomers seek easier ways of recreating but have more money to spend, resulting in desire for greater conveniences like full hook-up campgrounds. (APPL 2004 agency survey)
- Public lands will see more 55+ visitors and more “escapees” from cities, who will want more services. Many of these visitors will be willing to pay for a quality experience. (APPL 2004 agency survey)
- The population of California is projected to have the largest net increase in U.S. population. By 2020 it is projected to increase by 31% compared to 2000, with a 58% increase in Hispanic population, 55% increase in Asian/Pacific Islanders, a 29% increase in Native Americans, a 20% increase in African Americans, and a 4% increase in persons of European decent. By 2030, Hispanics will comprise 43% of the state’s population. (E. Sheffield, California State University, Chico)
- The median age in 2000 was 35; by 2020 it is projected to be 38. (E. Sheffield, California State University, Chico)
- Baby Boomers are now moving into their retirement years, leading to increased leisure time and greater demands on parks. They are the mobile generation of the next 20 years. (Trends in Demographics and information Technology Affecting Visitor Center Use, NPS, 2003)
- The over-50 population is expected to grow by 18.3 million people over the next ten years. (Independent Sector)
- People continue to live longer. By the year 2025, 60 million Americans will be 65 or older. (Aging Americans: Stranded Without Options)
- Increased urbanization of America, and decreasing rural populations. (APPL 2004 agency survey)

- In 1994-95, more than half of the older population (52.5%) reported having one or more disabilities. One-third had at least one severe disability. Most older persons have at least one chronic condition and many have multiple conditions. The most frequently occurring conditions per 100 elderly in 1995 were: arthritis, hypertension, heart disease, hearing impairments, orthopedic impairments, cataracts, sinusitis, and diabetes. (AARP)

Trend Implications Related to “Need For” Wilderness Commercial Pack Stock Services

Given the trends provided above, the following will likely affect the need for commercial pack stock services in these wildernesses: a population that is increasingly urban, less connected or educated about the outdoor world; significantly growing (especially California) and aging; people less physically fit than the past; and, more often temporarily, if not permanently, physically challenged and limited. The American population’s need for outfitter and guide services will be even more important in the next 10-20 years to enable visitors in need to access and experience their public lands. The Forest Service cannot provide these services to the public to meet this need.

X. Quantifying the Need for Commercial Pack Stock Services in the Ansel Adams and John Muir Wildernesses

It is very difficult—if not impossible—to provide an exact number that captures the total need for commercial packing in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. This section instead will provide a range that is needed to meet the future need for these services. This range will include a number of components: the current level of need, the need that is not currently being met because of various restrictions that limit the commercial packers’ ability to provide service, and future demographic trends. Based on these three components, current levels of service are not sufficient to meet the public’s current and future need for commercial packing in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses.

Overnight Clients

Current Level of Need

As the 2005 Commercial Pack Client survey showed, approximately 90% of the current level of commercial use is needed to meet the public’s need for these services. Given the 2004 level of 4,015 commercial clients, it is estimated that **3,613** of these clients truly “needed” the service in the context of this Needs Assessment.

Unmet Need

As described in Part VIII, there are a number of factors that act to limit the commercial packer’s ability to meet the full public need for these services. Some of these factors include restrictions and limitations placed on the commercial packers (e.g., group size, quotas, stock number limitations etc.), while other factors include seasonal limitations on business including weather and snow conditions. Additionally, court-ordered restrictions and other factors have caused the prices of these services to rise considerably over the last five years. Based on conversations with commercial packers, it is estimated that there is a need 25-50% above the current level that is not

being met. Discussions with commercial packers are the only way to really get a sense of how much public need is not being currently met. These discussions are compared with the Forests' knowledge of commercial operations and were subject to professional judgment to provide the most accurate assessment of unmet need.

It is estimated that unmet need represents an additional **1,004-2,008** clients that need commercial packing services.

Demographic Trends

Perhaps the most difficult portion of this need quantification involves quantifying the future need for commercial services given the obvious demographic trends. Given demographic trends, there will be an increased need for these commercial services in the future. Exactly how much of an increased need will result from these demographic trends, however, is difficult to determine. Again using professional judgment, it is estimated that demographic trends will result in a 75-100% increase in need over the current level of service that is provided. This gain translates into a range of need from **1,265 to 2,008**.

Overall Need

Given the three components described above, the level of need for commercial services ranges from **7,329 clients to 9,234 clients**. Again, this range is an estimate using professional judgment of some factors that may essentially be impossible to quantify (e.g., unmet need and demographic trends). The need for these services will increase in the future; exactly how much the need will increase is difficult to say; thus the Needs Assessment provides a range of need.

Day Rides

In 2004, there were approximately 4,000 day rides in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. Again, the term "wilderness day ride" is a bit of a misnomer as the vast majority of these rides only skirt wilderness and do not penetrate very far in the wilderness. Given demographic trends, it is expected that there will be an increase in need for these types of rides. Demographic trends are difficult to quantify, but again it is estimated that these trends will result in a level of need 35-50% above current levels. This results in a range of day ride need of **5,400 to 7,500 clients**.

XI. Extent Necessary for Commercial Services in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses

The results from the 2005 Commercial Pack Client survey indicate that the vast majority of commercial pack stock users are using the service to support activities that are proper for wilderness. Further, the level of need currently provided is likely less than what the public needs to access the wilderness area. Given demographic trends, it is likely that the need for these services will continue to grow in the future. The Needs Assessment has identified a range of need of **7,329 to 9,234 overnight clients**. The day ride need for these wildernesses is estimated to be to **5,400 to 7,500 clients**.

It is the intent of this Needs Assessment to identify the level of commercial services that will meet the public's need for these services. As discussed above, this level is best expressed as a

range. To meet the requirements of the Wilderness Act, the level of need provided must also ensure that wilderness character is maintained in these wilderness areas. The challenge, then, is to settle upon the level that meets the identified range of public need and also protects the wilderness character of the area.

The *Trail and Commercial Pack Stock Management in the Ansel Adams and John Muir Wildernesses Final EIS* provides an analysis and disclosure of the expected environmental effects of six alternatives. These six alternatives provide various levels of commercial packing service along with different mechanisms for controlling that use. The Record of Decision that accompanies the Final EIS will provide the rationale for selecting one of these alternatives. This rationale will include an evaluation of the effect of the selected alternative on the wilderness character of these wildernesses. The ROD will also include a finding of compliance with the Wilderness Act for the selected alternative.

Attachment 1: 2005 Commercial Pack Client Survey

Currently, the Inyo and Sierra National Forests are analyzing the effects of commercial pack station operations in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. A portion of this analysis involves the gathering of information related to the public use of commercial pack stock in the wilderness. Thank you for your assistance.

It would be most helpful if the survey is returned on or before **August 15, 2005**.

1. What wilderness area did you visit on your trip? John Muir Ansel Adams
 Dinkey Lakes Not Sure
 Was this your first visit to a wilderness area? YES NO

2. Please describe the group that went on your pack-supported trip:
 individual
 family
 friends
 organized group
 other (please describe) _____

3. What type of trip did you take?
 day ride
 full service (traveling trip, all expense)
 spot (you ride in with packer and gear to site)
 dunnage (you walk to site, packer takes gear)

4. What was the destination of your trip? _____

5. What was the purpose of your trip (check as many as is applicable)?
 fishing hunting
 access to wilderness setting nature viewing
 horse riding transportation of gear
 family gathering hiking/mountain climbing
 escape from every day routine, relaxation
 other (please identify) _____

6. Why did you choose to use pack and/or riding stock for your wilderness trip?

7. Without commercial services, would you have taken the trip? YES NO
 Please explain

8. Could you have met the purposes of your trip by taking a horse trip outside the boundaries of wilderness areas? YES NO Please Explain
