Trail and Commercial Pack Stock Management In the Ansel Adams and John Muir Wildernesses

Record of Decision

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, age, disability, and where applicable, sex, marital status, familial status, parental status, religion, sexual orientation, genetic information, political beliefs, reprisal, or because all or part of an individual's income is derived from any public assistance program. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at (202) 720-2600 (voice and TDD). To file a complaint of discrimination, write to USDA, Director, Office of Civil Rights, 1400 Independence Avenue, S.W., Washington, D.C. 20250-9410, or call (800) 795-3272 (voice) or (202) 720-6382 (TDD). USDA is an equal opportunity provider and employer.

Introduction

This document presents our decision for the Trail and Commercial Pack Stock Management in the Ansel Adams and John Muir Wildernesses project. This decision results in a non-significant amendment to the Land and Resource Management Plans for the Inyo and Sierra National Forests in California.

The analysis area includes the Ansel Adams and John Muir Wildernesses, covering 810,581 acres of California's Sierra Nevada range. The eastern portion of the analysis area ranges from west of Lone Pine, California to State Highway 120 in the north. The western portion of the analysis area extends from the southern boundary of Yosemite National Park to west of Sequoia Kings Canyon National Park. The planning area lies within Madera, Fresno, Inyo, and Mono Counties.

The John Muir Wilderness was established in 1964 by the Wilderness Act and enlarged 81,000 acres by the 1984 California Wilderness Act. The John Muir Wilderness extends from Mammoth Lakes, California in the north, forks around the Sequoia Kings Canyon Wilderness, and extends some 100 miles to the south with its southern most boundaries just west of Lone Pine, California. The John Muir Wilderness is one of the most heavily visited wildernesses in the National Wilderness Preservation System. There are 580,323 acres within the Wilderness, with 228,366 acres on the Inyo National Forest and 351,957 acres on the Sierra National Forest. Approximately 26,000 acres in the northern portion of the Fish Creek watershed are Sierra National Forest lands administered by the Inyo National Forest.

With the completion of the Ansel Adams, John Muir and Dinkey Lakes Wilderness Plan in 2001, new direction for the management of these wildernesses was incorporated into the Land and Resource Management Plans for the Inyo and Sierra National Forests. The Wilderness Plan was the culmination of nearly ten years of public involvement and focus on wilderness management planning on the two Forests.

In April 2000, a lawsuit filed against the Inyo and Sierra National Forests alleged violations of the National Forest Management Act, National Environmental Policy Act (NEPA), and the Wilderness Act. The judge found in favor of the plaintiffs on the NEPA claim, determining that in authorizing the special use permits for the pack stations prior to 2001, the Forest Service failed to adequately document environmental impacts as required by the NEPA.

A Court Order was issued that required the Forest Service to complete a two step process for issuing commercial pack stock special use permits. First, a cumulative impact analysis of pack stock operations in the Ansel Adams and John Muir Wildernesses must be completed no later than December 2005. The Court ordered that the analysis consider limits on numbers of stock animals, limits on group size, trail suitability and designation of campsites for use by commercial pack stations. Secondly, by December 2006, the Forest Service is to complete a site-specific analysis for each permittee. The court allowed all nineteen pack station operations to continue to be authorized, with specified conditions and restrictions imposed by the court.

An interdisciplinary team conducted an extensive, broad condition assessment in approximately 75% of the areas used by pack stock operators. In areas where field assessments were not

conducted due to costs or time constraints, existing Forest Service records were used. These areas were typically areas of low use or low concerns. We feel we have collected adequate information on the conditions in the locations where commercial pack stock operate to make this decision, and that this level of information reduces the uncertainties and risks of decision making.

Summary of the Decision

It is our decision to select **Alternative 2 – Modified** as presented in the *Trail and Commercial Pack Stock Management in the Ansel Adams and John Muir Wildernesses Final Environmental Impact Statement*. We believe Alternative 2 – Modified meets our purpose and need, meets our public service commitment to provide for use and enjoyment of these lands as wilderness, and that the keystone of the alternative—destination management—responds to environmental concerns and allows us to remediate the environmental concerns and preserve wilderness character most effectively. The Final EIS discloses that at the wilderness-wide scale, the effects of commercial pack stock use in the Ansel Adams and John Muir Wildernesses are negligible. There are, however, site-specific “hot spots” in these wilderness areas that need to be managed to ameliorate the effects of this use. **During our analysis, it became clear that the key to protecting the wilderness character of these areas is to control the timing, frequency, intensity and location of commercial pack stock use. The overall levels of use were not as critical as how, where, and when these uses occur. The destination management approach of Alternative 2 – Modified is a site-specific strategy that allows us to pinpoint resource concerns and take direct actions to remedy impacts.**

We have made our decision after careful review of the public comments on the Draft Environmental Impact Statement prepared for this project pursuant to the National Environmental Policy Act (NEPA). The 2001 Wilderness Plan for the Ansel Adams, John Muir and Dinkey Lakes Wilderness and Record of Decision is modified by this direction. This is a non-significant amendment to the Land and Resource Management Plans for the Inyo and Sierra National Forests.

An open, inclusive approach was used to make this decision. Although we make this decision based upon the best information currently available to us, it is not without some uncertainty or risk. We fully expect that by placing an emphasis on adaptively managing these commercial uses to achieve prescribed conditions, we can actively manage these uses and continue to improve conditions over time.

Key Features of the Decision

Listed below are the key features of the management direction for these wildernesses as described in Alternative 2 – Modified, the selected alternative.

Trail Plan

Alternative 2 – Modified adjusts trail maintenance levels to reflect recreation categories, desired conditions and allowable levels of use.

The Extent Necessary

This decision, based on a thorough analysis of the selected alternative, identifies the need for the type, location and amount of commercial pack stock services. Furthermore, we have determined—as required by the statutory requirements of the Wilderness Act—that this level of use is needed by the public and represents a level of use that does not degrade the wilderness character of the area. We demonstrate in the analysis and this decision that the number of permits, area of operations and levels of use are limited to the “extent necessary” that will preserve wilderness character.

Destination Management

All destinations that will be used by commercial pack stock operators will have a prescribed use and desired condition to achieve. The desired condition is driven by the three recreation categories outlined in the 2001 Wilderness Plan and by an assessment of the capacity of the destination for the prescribed type and amount of use. Approximately 190 destinations will be managed for commercial use.

Destination management is achieved through a strategy that describes desired condition by destination. Desired condition includes recreation category setting, access, grazing, use levels, campsites and any corrective actions (remedy) that must be taken. The emphasis of destination management is to articulate the conditions we are managing for over time. Many tools are used to achieve the desired conditions depending on the site specific needs including designated campsites, party size limitations, limits on numbers of stock, trail restrictions, and grazing strategies.

Day Rides

Day rides will be managed within the desired conditions established for destinations. The intensity of day ride activities varies considerably across the planning area. Where day ride activities occur with identified cumulative effects from other activities (Mammoth Lakes Basin and Reds Meadow to Rainbow Falls) a finite number of rides is identified. In all other areas, the location, type and number of stock to be used for this activity are identified and will be managed to insure that desired conditions are met.

Trail Suitability

This direction identifies trails that are not suitable for commercial stock, based on an assessment of resource conditions, the desired conditions of a destination and projected levels of use. While

some suitability determinations are temporary based on the future trail work needed to improve the condition of the trail, most determinations are not subject to change in the foreseeable future.

Designated Campsites

This direction identifies overnight stock holding camps for commercial operators. All overnight stock holding and all expense or traveling trips in the wilderness must take place at a designated campsite determined suitable and approved by the Forest Service. Approximately 180 designated campsites are identified in Alternative 2 – Modified.

Party Size

Party size wilderness-wide is 15 persons and 25 stock. In addition, based on an assessment of the capacity of the destination, Alternative 2 – Modified identifies 15 site-specific locations where the commercial pack stock party size is lower to assure wilderness resources are protected.

Stock Numbers

Each operator will have a limit on the number of stock in the wilderness at one time. This number includes stock used for day rides. In addition, 13 locations have site-specific limitations on the number of stock to destinations. The analysis identified that these limitations are necessary to maintain the desired condition for the destination area.

Campfires

Minor adjustments to the elevational closure are made with this decision. Where adequate fuel wood has been identified there will be a change in the boundary of the closure to reflect the areas as open to campfires for all visitors. In one case, where fuel wood is sparse, the boundary is modified to reflect the area as closed to campfires.

In all areas where campfires are not allowed all visitors will be allowed to have charcoal fires with a fire-pan and required to pack out the ash. A monitoring component is included in this direction to assure that this action does not lead to unacceptable impacts associated with charcoal campfires. The use can be revoked site specifically if compliance is not achieved.

On a case-by-case basis, specific areas meeting strict criteria may be identified where commercial pack stock operators may have wood campfires provided they pack in wood from outside the wilderness or an approved source, use a fire-pan for the fire, and pack out the ash.

Grazing Management Strategy

Identified grazing areas were assessed and a determination of suitability was made.

Estimates of suitable forage availability were made within grazing zones and are measured and prescribed site-specifically in terms of stock nights. Critical areas too wet for grazing or

containing Yosemite toads or fens are protected and not available for grazing. A rest rotation strategy is used in areas where hydrologic conditions were identified with a downward trend.

All drift fences associated with commercial pack stock use were assessed in terms of the needs they served for resource protection and visitor safety. Where these two elements were not met, drift fences will be removed.

Heritage Values

This decision conforms to the *Controlling Impacts on Historic Properties; Management of Ansel Adams, John Muir, and Dinkey Lakes Wildernesses, Inyo and Sierra National Forests Programmatic Agreement*. This agreement was designed to manage and protect the historic resources of these wilderness areas.

Recreation Category Changes

Adjustments to the recreation category boundaries were made at 36 locations to better reflect the conditions we intend to be managing for with the 2001 Plan direction. These areas were most likely mapped incorrectly due to lack of accurate information.

Rationale for the Decision

How the Decision Meets the Purpose and Need

1. There is a need for additional guidance for managing commercial pack stock operations in the Ansel Adams and John Muir Wildernesses in order to achieve and maintain desired resource and experiential conditions identified in the 2001 Wilderness Plan and Record of Decision.

The 2001 Wilderness Plan implemented new management direction for these two wilderness areas relying strongly on the “recreation category” concept to define desired conditions. This concept recognizes that within the context of preserving wilderness there are different settings, objectives and goals across the 800,000 acres. There are popular destinations that are managed—and should be managed—differently from the vast majority of the very pristine, rarely visited areas. This is a common practice in wilderness management and fully supported by agency policy (FSH 2309.21.1).

It has been our goal in this process to make sure that the management of commercial pack stock use is consistent with the 2001 strategy. Alternative 2 – Modified contains a number of control mechanisms with the key component of this strategy being destination management; that is, managing the use to ensure that the conditions at the destinations are consistent with the assigned recreation category.

We have concluded that destination management as displayed by Alternative 2 – Modified is the best method to manage site-specific impacts and use of commercial pack stock. A number of land management agencies commented on the Draft EIS and generally consider this approach to

be the most effective strategy for managing commercial pack stock use. In addition, all the resource specialists in their analysis of the alternatives in Chapter 4 have indicated that the direct and responsive nature of destination quotas is the superior method of managing impacts and protecting resources.

It is not simply the level of use that determines the protection of wilderness; rather, the timing, frequency, intensity, and location of use are most relevant. Research on wilderness recreation repeatedly emphasizes this, as is documented in Chapter 3 of the Final EIS. Our specialists' analysis affirms this and shows that when the frequency and intensity of use is controlled to a destination the relationship between use and impact can be better managed and evaluated.

This destination management approach enables us to pinpoint resource concerns and take direct actions to remedy impacts. This approach effectively incorporates and combines other commercial stock management tools including designating camps for holding stock, limiting commercial stock from using unsuitable trails and applying use trail and party size restrictions at certain destinations.

At the center of this approach is the destination quota, this controls the frequency, intensity and location of use to each destination. This measure ensures that each destination is protected and consistent with the desired condition. Each destination for spot and dunnage services has a capacity that has been determined based on resource information, the recreation category desired condition, and professional judgment by an interdisciplinary team of specialists and decision makers. The stock at one time limitation controls the timing of the use, and insures that trail encounters with pack stock do not exceed an acceptable level. Collectively, the actions in Alternative 2 – Modified control the timing (stock at one time), frequency (number of trips), intensity (party size, stock number limitations) and location of use (destination management).

Other alternatives utilize less precise control mechanisms on commercial pack stock operations, such as trailhead quotas and service days (Alternatives 1, 3, and 4). For these less precise mechanisms, the analysis indicates that resource protection is achieved only through probability; that is, if a certain number of people travel from a trailhead the probability is that they will disperse and not cause overcrowding and associated resource impacts. Although the likelihood is that commercial pack stock use will have fewer impacts on the resources by an overall reduction in use—such as Alternative 4—it is not at all certain, since the frequency of use can change and the intensity of use to a destination is not controlled. Destination management directs the controls at specific locations which, in the end provide far better protection and management of resources than relying on the probability of trailhead quotas.

Our destination management approach also addresses remediation that the courts considered necessary for past damage caused by or contributed to by commercial pack stock activities. In most cases, we determined it was not appropriate to conduct “pick and shovel” work to remediate damage to meadows that may not have been caused by commercial stock, or may be just natural vulnerabilities or historical grazing impacts that can over time heal if the disturbance is removed or reduced. However, in situations such as serious resource impacts caused by trails or campsites, where commercial stock use has been heavy, we either reduced use and/or prescribed no use until the trail or campsite is stabilized or brought up to standard.

At a destination or site-specific level, we are prescribing the relocation of campsites where needed, party size limitations, seasonal limitations on stock, and rest of grazing areas throughout

the wilderness. Each situation and each destination was assessed to consider how effective the management options would be to remedy known concerns or past effects.

This management strategy not only identifies and corrects known resource concerns but provides the framework to continue to improve or insure that acceptable conditions are maintained over time. This, along with the very site-specific controls on commercial uses, constitutes what we consider appropriate remediation for past damage to wilderness character qualities.

2. There is a need for a trail plan that accurately identifies a system of trails for all users, and appropriate trail management objectives for each system trail, consistent with the desired condition of areas within the two wildernesses as identified in the 2001 Wilderness Plan and Record of Decision.

The trail plan component of this project was originally scoped as a separate environmental analysis. After receiving public comments and reviewing the two projects, we recognized the potential for the trail plan and commercial pack stock management project to be considered connected actions. In addition, there were obvious cumulative effects associated with the two efforts that should be analyzed together. The DEIS combined the trail plan and commercial pack stock management projects and offered four variations (including the No Action) on the proposed trail plan. The trail plan adopted in Alternative 2 – Modified responds to comments received on the Draft EIS.

Alternative 2 – Modified meets this need by providing a system of trails that is consistent with our objectives of wilderness management and is fully aligned with the strategy of destination management. The trail plan in Alternative 2 – Modified also accomplishes the goal in the 2001 Wilderness Plan that direct the forests to “provide a transportation system that ensures suitable access for the types and numbers of trail users, protection of resources, and is consistent with management objectives for the areas accessed.”

Alternative 2 – Modified provides a trail system that aligns the level of development of the trails with the assigned recreation categories. Adjustments were made so that there are fewer anomalies between high development trails in a recreation category 1 and low development trails in a recreation category 3. This trail system is more consistent than any of the other alternatives with the levels of development that currently exist, and although the levels may seem high to some, and low to others, they usually reflect the class that is presently on the ground.

Besides connected actions and cumulative effects, the primary issue we assessed in response to the trail plan was the issue of trail development. There were many DEIS respondents who expressed the desire to have more highly developed trails and fewer trails at the “primitive” level. There was a concern that these trails (Trail Class 1) would not be available or managed for riding and pack stock. Although our trail class standards clearly convey this is not the case, there was still a concern that over time, these trails will deteriorate and not be cleared or maintained even at the primitive level. Our ability to maintain all trails to standard will continue to be a challenge, but it is not a reason to establish an inventory that either increases the trail class level, or reduces the trail class level for reasons other than what the resource and management of allowable uses requires. We set our inventory and trail classification consistent with what was reasonable and needed for the expected levels and types of uses.

We know there is a constituency of visitors that prefer lesser developed trails, not to be confused with un-maintained trails. We feel that our inventory reflects and responds to the settings of the

landscape, with no preconceived goals for miles in each trail class. The inventory responds to the needs of users and the resource, which was our objective.

In meeting these above needs, the following purposes must be met:

(1) Provide for needed commercial pack stock services.

The Needs Assessment (Appendix D) clearly establishes the need for commercial packing services in the Ansel Adams and John Muir Wildernesses and identifies a range for this need. The Needs Assessment indicates demographic trends point to the likelihood that in the future, more people will need these services and our assessment must consider such future needs and not be entirely focused on the past or present situation. While Alternative 2 – Modified does not meet the full level of public need as displayed in the Needs Assessment, it does allow for a reasonable level of service that is within the low end of the need range. We believe Alternative 2 – Modified contains the combination of control mechanisms that will preserve the wilderness character of the area and still allow for the prescribed use range of needed commercial packing services.

Alternative 2 – Modified allows for reasonable use of these wildernesses by persons needing commercial pack stock services. We feel it is important to allow all segments of the American public the use and enjoyment of these wilderness areas as wilderness. The Needs Assessment identifies that a segment of visitors to these wildernesses need commercial pack stock services for their access and proper wilderness uses. Without pack stock commercial services, these visitors' opportunities for using these areas would be severely limited or perhaps eliminated. It is important that future generations be allowed to experience and enjoy these wilderness resources and appreciate the value they have in our society and culture. If we exclude all but the fit and healthy, we are not fulfilling the Wilderness Act goal to secure for the American people of present and future generations the benefits of an enduring resource of wilderness devoted to "the public purposes of recreational, scenic, scientific, educational, conservation, and historical use."

It is important on a number of levels to provide access to these wilderness areas to a diverse population as in many cases it is access and enjoyment of these areas that builds support and constituency for the wilderness concept. As David Brower in his 1948 Sierra Club Bulletin article "Are Mules Necessary" so appropriately concluded:

So it would seem that the big traveling trips through the wilderness such as initiated by the Sierra Club in that first Annual Outing, should be continued, by whatever organizations may be qualified to conduct them. The argument that John Muir presented remains valid. If we want mountain wilderness—the spacious scenic wilderness that means something—we must make it known to the men who, knowing it will protect it. Those who like best the most Spartan of wilderness trips—cross-country backpacking—must make haste slowly in any attempts to impose such trips upon others, or there may be too few men in the wilderness to protect it.

Today, the overall condition of these wildernesses is significantly improved from the stock impacts described in 1948 by changes in regulations and management; however, the need for and the benefits of commercial packing services remain and to some degree continue to fulfill the needs envisioned by John Muir and David Brower of introducing and educating citizens to wilderness and its purposes.

(2) Comply with the Wilderness Act by preserving wilderness character.

Throughout the environmental analysis process, the protection of wilderness character has been identified as an essential prerequisite in selecting a commercial service alternative. Four components of wilderness character were evaluated and compared: untrammelled¹, undeveloped, opportunities for solitude or primitive and unconfined recreation, and natural conditions. These concepts are used in the legislative definition of wilderness in the 1964 Wilderness Act. Our analysis rigorously explored the elements of wilderness character in relation to the various levels and types of commercial pack stock use proposed in the alternatives. A summary of the selected alternative's compliance with wilderness character preservation can be found below in the Wilderness Act part of the *Findings Required by Other Laws* section.

Two of the four components, untrammelled and undeveloped, have minimal application to commercial pack stock use and management actions in this plan. The trammeling of wilderness would take place with large-scale manipulations of ecological processes, such as dams, fire suppression, animal, or plant restorations. With all alternatives, the level of commercial pack stock use is not causing any manipulation of ecological systems at a scale near that of dams and fire suppression, i.e. not allowing natural processes to occur. Relative to permanent improvements, human habitation, and structures, commercial pack stock represents very limited and insignificant development. Primitive drift fences—wire strung between short native wood posts for a short distance—is the extent of the development in these alternatives. Though this level of development may affect some visitors, the overall conditions of these wildernesses continues to provide a striking contrast to modern civilization, perhaps even more so now than in 1964.

The other two components, opportunities for solitude or primitive and unconfined type of recreation and natural conditions, are most relevant in this analysis. It appears from our analysis that the most affected component of wilderness character resulting from commercial pack stock activities is the unconfined recreational experience. This is true in each of the alternatives. To a lesser extent, the natural component is affected, but only at a site-specific local level, and not at the wilderness scale and not to a degree that has any significance in the overall natural conditions of these areas. Since commercial pack stock use is so tightly controlled and managed, our strategy for preserving one component of wilderness character—natural conditions—is arguably detrimental for some public's opportunities for solitude or unconfined recreation. However, we conclude that protecting the natural components of wilderness character are more fundamental to preserving wilderness *as wilderness* than insuring that every person has the experience they want—when and where they want it. To protect wilderness “as wilderness” requires that we manage for the long-term conditions of wilderness, not necessarily the short-term experiential values that are fleeting and intangible and often reflect opinions and beliefs, not concrete measurable conditions.

The five alternatives had varying effects on the wilderness character qualities of solitude or unconfined recreation and natural conditions. Of the six alternatives, Alternative 3 provides the best opportunities for unconfined recreation; however, there are less predictable impacts to natural conditions and opportunities for solitude. Generally, there is more of a risk of ecological impacts becoming more pronounced with management controls (trailhead quotas) that are less

¹ “untrammelled is one of the most misunderstood words in the Wilderness Act. An untrammelled area is where human influence does not impede the free play of natural forces or interfere with natural processes in the ecosystem”

directly tied to the actual impacts. Alternative 2 and 2 – Modified contain a number of features such as party size and grazing limitations that will result in an improvement of natural conditions in these wilderness areas (compared to current management or Alternative 1).

Alternative 4 limits commercial pack stock operations to the lowest amount and fewest locations, other than Alternative 5, which analyzes no commercial use. However, the overall level of use that is identified (in service days) has less of an effect on the extent of operations than the trail limitations, designated campsite requirements and party size restrictions; which collectively substantially reduce the extent of operations. Opportunities for solitude will increase in all areas where pack stock is not allowed, but the areas where use is proposed to be eliminated are traditionally where these commercial services has been low and infrequent. The unconfined and primitive recreation qualities are greatly diminished in Alternative 4 as a result of the more severe limitations. Naturalness will improve over time in areas where commercial pack stock operations are prohibited, but not immediately, as other uses will continue.

Reductions in overall use levels, without direct controls over frequency and intensity of use at specific destinations does not necessarily result in vast resource improvements. In fact, Alternative 2 – Modified with internal quotas and specific destination management actions will result in a greater resource improvement than Alternative 4, even though there is a higher level of use allowed in Alternative 2 – Modified compared to Alternative 4. The key to protecting the wilderness resource is controlling the timing, frequency, intensity and locations of commercial pack stock use. Compared to the other alternatives, Alternative 2 – Modified provides more direct and responsive remedies to past environmental harm and will insure that the wilderness is maintained **as wilderness** over time.

The safest approach to full protection and preservation of wilderness character is to prohibit all use. However, when Congress directed the preservation of wilderness character, we do not interpret their intent to direct the elimination of all use and enjoyment of these wilderness areas. In fact, recreation is one of the six uses specifically mentioned in the Act that wilderness areas are devoted to. To close all meadows to grazing, for example, for the purpose of preserving unimpaired conditions goes beyond what we consider to be a reasonable and practical approach to providing use and enjoyment and preserving wilderness character.

Our task has been to understand the effects of these actions and uses on the various components and values of wilderness. Our analysis demonstrates the care and attention given to this task. We believe that balancing these multiple values as we have in the management direction articulated in Alternative 2 - Modified, does not value one element at the detriment of another, but rather values each element to achieve as many of the goals of the Wilderness Act as possible.

(3) Comply with the January 10, 2002 court order from the United States District Court for the Northern District of California granting injunctive relief in High Sierra Hikers Association v. Powell (No.C-00-01239) by:

a) Identifying appropriate group size limits for commercial stock operations.

Alternative 2 – Modified re-affirms a wilderness wide party size limit of 15 persons and 25 stock. Although pack stock have greater resource and experiential effects than other uses in the wilderness, research shows that party size may have the least effect on physical impacts than other managerial controls (McClaran and Cole, 1993).

All of these behaviors [party size limits, requiring feed to be packed in for stock, encouraging riders to stay on trails, restricting loose herding of stock on trails, restricting the practice of tying stock to trees, encouraging the use of hitchlines, restricting the practice of picketing stock, encouraging the practice of hobbling stock] have been suggested as potential means of reducing packstock impacts (Cole 1989c). If visitors would comply with these regulations or guidelines, impacts associated with packstock use could be reduced substantially without reducing the amount of use. **Of these behaviors, limits on party size may have the least effect on physical impacts** [*emphasis added*]. Party size limits are likely to be the most effective where physical impacts are likely to occur quickly (Cole and others 1987). Because most impacts occur with initial use in such areas, subsequent use isn't as important. Party size limits may be more important to avoid conflict with backpacking groups. Such groups particularly dislike encountering large parties with stock (Stankey, 1979).

Our analysis relied on existing party size research, and a review of the occurrences of large commercial stock parties in these wildernesses. We concluded that party size is most relevant to address social concerns but generally not physical impacts. Only 30% of all commercial trips have a party size greater than 10 persons and 15 stock and less than 2% have a party size greater than 12 persons and 20 stock. This is not a significant amount of use. With relatively few occurrences of large commercial pack stock parties in these wildernesses it does not seem either necessary or effective to arbitrarily reduce the party size to respond to social concerns expressed by a small percentage of visitors.

When ranked against other perceived problems in these wildernesses party size is amongst the lowest ranked problem. In the John Muir Wilderness it ranked as 13th in the list of problem identified by hikers (Watson et al., 1993). Watson et al. (1993) summarizes his findings with:

Stated as simply as possible, hikers who dislike meeting horses in wilderness believe the horse should not be in wilderness; they believe they are an inappropriate use of the resources. These hikers also are not as likely to accord high status to horse users, have stronger relationships with the wilderness, and place more value on the opportunities for solitude than those who do not dislike horses.

Translating this knowledge into management strategies requires acknowledging first of all that hikers who dislike horses are in the minority.

Reducing party size would not likely reduce the overall stock numbers (which is a greater concern) and may, in fact, lead to a greater number of small parties and stock. Research indicates that many people would prefer to see one large party rather than multiple small parties. Without a reduction in overall stock numbers, the party size limit in and of itself is irrelevant to reducing impacts. Alternative 2 – Modified controls overall stock numbers in wilderness at one time, which we conclude will most effectively reduce the environmental effects of stock when combined with other actions of this decision.

We also considered the effects of party size on and off trails. This direction re-affirms the 2001 Wilderness Plan direction that commercial operators must stay on designated trails. There are approved use trails, and very limited approvals for cross country travel as discussed below under (c), but these are limited occurrences. When a trail or use trail was determined to need further limits on either party size or annual stock limits, these are implemented site specifically.

We acknowledge there are specific locations that benefit from a reduced party size. Alternative 2 – Modified identifies 14 locations that have known environmental issues or constraints and we imposed site-specific reductions to the 15/25 party size limit to address the issues. The destination management approach provides for continual monitoring and the ability to control

numbers of stock per year to destinations, or at one time, or by party as needed and site specifically.

We considered alternative approaches to party size in this analysis. Alternative 4 restricts the party size to 12/20; but more importantly, this alternative allows the trailhead quota to further limit party size as borrowing quota from the next day is prohibited. This would have significant effects on party size and would greatly reduce the ability of an operator to utilize the wilderness-wide party size, either very often or in very many locations. We considered this approach recognizing that the plaintiffs have a very strong interest in reducing the party size. In fact, we received comments on the DEIS that stated that Alternative 4 approach, “did not go far enough.” However, we concluded that further restricting the party size, on top of all the other restrictions and limitations contained in Alternative 2 – Modified, is neither necessary nor desirable. Although there are some limited beneficial effects for the resources from a reduced party size limit, there would also be significant limitations imposed upon public access to these wilderness areas including the impact on extended family gatherings, youth groups and others that benefit from a more generous allowance on party size. We do not feel the issues of party size are significant enough to warrant such a severe policy. We feel that we can manage this site specifically and through our existing policies.

Our party size decision takes into consideration the larger wilderness landscape picture. Ansel Adams/John Muir Wilderness visitors travel into and from Yosemite National Park, Sequoia Kings Canyon National Park, and the Emigrant Wilderness. Our neighboring forests and parks have worked together to develop the 15/25 party size maximum. Only Sequoia Kings Canyon National Park has a different party size of 15/20, which is an anomaly in the Central Sierra. Alternative 2 – Modified maintains consistency with neighboring forests and parks in terms of party size and manages for exceptions as needed to respond to environmental constraints.

b) Establishing camping limitations (designated campsites) on commercial pack stock operations.

Alternative 2 – Modified designates over 150 campsites and requires their use whenever commercial stock are held overnight in these wilderness areas. Our site-specific destination management approach evaluated and concluded that every destination where commercial pack stock use is approved has adequate sites for spot and dunnage camps or drops. If we were managing under a trailhead quotas scheme, where the frequency or even the locations were not managed, it may require more spot and dunnage designations in order to achieve the same level of protection, as is evident in Alternative 4. The destination management approach allows us to manage for more internal freedom and visitor choice because we are managing the destination and the capability of that destination has been fully considered.

Our analysis concluded that designating campsites is most important when stock is held overnight in the wilderness. The designated site is the main control of where all expense trips camp and plays an important function in managing these types of trips. When not controlled, these sites tend to be larger, more impacted and at higher risk for impacts to heritage resources, water resources and use trails accessing the sites. Designating these sites concentrates the impact and prevents more sites from becoming impacted over time, thereby decreasing the overall extent of impact. It allows us to manage the impacts and hold pack stations accountable for the conditions of the sites. The adaptive destination management strategy includes long-term

monitoring and evaluating of campsite impacts and provides managers with tools to take additional actions to achieve the desired designated camp conditions.

c) Identifying which trails are suitable for use by commercial pack stock.

Existing 2001 Wilderness Plan direction restricts commercial pack stock to existing system trails and approved use trails. Alternative 2 – Modified has a designation of “Not Suitable for Commercial Stock” (NSCS). This designation is used to reflect trails that either have resource concerns or concerns with the appropriateness of the destination for repetitive commercial stock use. The alternative has 89 miles of trails designated as “NSCS.”

Alternative 2 – Modified effectively responds to the issue of trail suitability by approving a limited number of visible use trails that are not maintained as system trails. These are not system trails because they typically serve campsites or areas that are primarily used by the packer, not by the general public; and, they do not duplicate system trails. This greatly minimizes the extent of off-trail travel that occurred in the past. The use trails that are approved typically have minimal resource concerns and are suitable for commercial stock use.

We have very few cases where cross-country travel is allowed. Most of these exceptions are for the occasional hunting trip to access remote areas where hunting takes place. We believe these are legitimate exceptions to manage for. Hunting is a infrequent activity in these wildernesses and occurs in September and October when the peak of the use is past. Conflicts and risks associated with this allowance are minimal. The additional few non-hunting cross-country travel approvals are tied to low levels of use on suitable resilient soil types where trailing does not become an environmental concern (e.g., granite expanses).

Alternative 4 proposes a significant difference in trail suitability determinations. It explored the effects of eliminating commercial stock on 173 miles of trails with a substantial number of areas unavailable for commercial pack stock clients. We did not find that removing commercial pack stock use from many of these areas would have greater environmental benefits as compared to maintaining a low, sustainable use levels. We sought ways to accommodate a sustainable level of use in order to meet the goals of the Wilderness Act, and low use is preferable to no use in order to meet as many of the goals as we can without causing harm to the wilderness resource.

We considered the many trails that were suggested for “NSCS” designation that went into the adjoining National Parks. We discussed the trail continuity issues with the National Park Service to insure that our actions were consistent with current park management and made our trail suitability determinations to reflect their desired conditions.

d) Identifying an appropriate level of stock to be used in conjunction with the commercial operations.

Each alternative looked at different mechanisms for limiting stock numbers. Alternative 2 proposed daily and seasonal stock limits on each operator in combination with destination quotas. We refined this approach in Alternative 2 – Modified to produce more direct effects. We concluded this is a more effective approach than stock thresholds described in Alternative 3. The threshold concept concerned both operators and the public in that it did not include a defined limit. Alternative 4 merely used a tight trailhead quota on people to control stock, albeit indirectly. Although this would greatly reduce use, it was not a direct stock control.

We settled on the **stock at one time limitation** to provide a temporal control and prevent spikes in use and direct the control on the source of the impacts that are of the highest concern—the

number of stock in the wilderness. This measures all the stock an operator uses in these two wildernesses at one time, including their day rides. As disclosed in the analysis, the number of people being serviced is not as much of a concern as the number of stock used to provide this service.

The stock at one time limitation also minimizes experiential impacts to other visitors on the trails or at shared destinations. This limitation acts as an overall governor of use as it caps stock use and helps to prevent overcrowding during the peak season. The concentration of too many parties at one location can lead to ecological impacts including the creation of new campsites. Overcrowding can lead to disproportionate physical impacts; by controlling crowding we are providing an overall control that protects resource and experiential values. By allowing packers to fully utilize the shoulder season instead of adding more people to a crowded, short season we can help to mitigate the overcrowding that occurs during the peak season.

e) Completing a cumulative impact analysis by December 2005.

This EIS analyzes the activities of 19 pack stations and other users in these two wildernesses collectively. It is estimated that 9% of these wilderness areas are available to commercial pack station services. This is figured by a spatial analysis that buffered all trails, campsites and grazing areas that packers identified as having used (even when they have not used some of these locations for years or decades). Commercial pack station use comprises only 8-10% of total use for these areas.

The degree to which commercial pack operators overlap (the environmental effects of this overlap is documented in the affected environment chapter) is minimal. There were 75 analysis units where pack station operations overlap in their identified operating areas. In 52% of these areas only two pack stations have overlapping operations, while in 45% of the areas 3-5 operators overlap. Although 75 units were identified as overlap, only 17 site specific locations overlap for spot and dunnage services. Most overlap exists as the result of traveling trips going through an operator's primary area for providing spot and dunnage services. These traveling trips comprise only 8% of the commercial pack stock use.

With the current management (Alternative 1) there could be more overlap as considerable freedom of movement is allowed. In Alternative 2 – Modified, the number of locations are limited and controlled by the destination management quota, with an overall limit on the use at these locations. Generally, it is less about how many operators and more about the total number of trips and stock to locations, regardless of how many operators are in a specific area. However, we recognize conflicts and overcrowding are more probable with additional operators. The destination management approach addresses this issue and insures the use levels are site specifically regulated.

The bigger factor with overlap appears to be associated with traveling trips. With alternatives that use service days (Alternative 4) or just trailhead quotas (Alternative 3) to control use there is more potential for traveling trips to increase and, therefore, increase overlap of operators. Alternative 2 – Modified definitively identifies the number of all expense trips and limits the extent of these types of trips in order to control the potential for overlap and cumulative effects of overlapping operations.

Alternative 2 – Modified also includes a methodical wilderness-wide and site-specific cumulative effects analysis in a National Environmental Policy Act (NEPA) context. NEPA

requires that a cumulative impact analysis be structured to assess what additive effects the current actions would have, when viewing the effects of past, present, and reasonably foreseeable actions. Our specialists examined all relevant past, present, and reasonably foreseeable actions in their analysis. A catalogue of these actions can be found in Chapter 4 of the Final EIS. Each specialist assessed these actions at two scales: the wilderness scale and the eight geographic scales (note that a typical programmatic document would not look site-specifically at cumulative effects). The analysis of site-specific cumulative effects was done to ensure that even at a location basis, site-specifically, we were not missing cumulative effects from past or present actions, including other uses, adjacent lands and regional contexts.

As noted earlier, the planning process was designed to include similar or potentially connected actions by incorporating the Trail Plan into the commercial pack stock analysis. This facilitated an analysis of combined impacts which was considered to be essential to completing a cumulative impacts analysis. As a result of this design and with the thoroughness of the analysis, it is with great confidence that we conclude there are not major long-term or short-term adverse effects to any resource or species.

There are instances of minor, short term or locally intensive impacts to resources; some cannot be directly attributable to commercial pack stock. To the greatest extent possible these impacts have been mitigated by our management actions. In addition, we have built into our approach a strategy to monitor and adapt and manage these uses over time should conditions change or assumptions prove to be wrong.

4) Identify the appropriate level of grazing associated with commercial pack stock operations.

Our analysis indicates that the levels of incidental grazing that we are allowing in suitable grazing areas will effectively preserve these meadows' ecosystems, as long as the critical areas are protected. In many high elevation areas, we found meadows to be unsuitable and therefore unavailable for grazing because they are too wet and never reach range readiness. For most suitable grazing areas, we found it is not the utilization of forage that prevents meadow conditions from meeting standards; instead it is the impacts associated with the movement of stock and of the related trampling and chiseling of soil and vegetation that cause unacceptable impacts. We acknowledge in our analysis the long-term ramifications of historic grazing, including sheep, cattle and large pulses of recreational pack and riding stock from trips like the Sierra Club outings of the early to mid twentieth century. With conservative estimates of utilization (measured in stock nights) and a monitoring strategy that makes operators accountable, we are confident that these measures preserve wilderness character in these areas. We limited drift fences to a minimum number used only for resource protection, and the level of development of these primitive fences does not constitute a significant effect to the undeveloped quality of wilderness character. No permanent fencing, caches, or permanent improvements are used to achieve the grazing conditions we desire.

Meadows found with a downward trend in hydrologic functioning condition will be rested from commercial pack stock grazing. While the degraded condition may not have been caused by commercial pack stock, continued grazing would not allow the trend to reverse. Our analysis indicates that trends can change and conditions are dynamic.

Whether we are looking at trends in conditions, or the mosaic character of meadows (intermingling wet and dry portions), or general range readiness determinations, there is a need

to manage for dynamic conditions over time. It is our goal to protect and restore meadows. Establishing conservative estimates of stock nights, as opposed to managing a utilization rate that would require more intensive monitoring, enables us to manage the use more proactively instead of reactively.

5) Identify monitoring requirements to facilitate responsive adaptive management for commercial pack stock operations.

We realize there are risks associated with any of the assumptions made in this analysis. At times it has been difficult to distinguish what the cause of some conditions are; in many cases existing conditions could have been primarily caused by nature, yet appear to have the imprint of human influence. Natural influences and human influences are not easily distinguishable in this wilderness environment. We made our decisions conservatively and cautiously. Over time, natural influence or synergistic effects may have different consequences than we have predicted.

It is for this reason that we have attempted to describe the desired conditions we intend to maintain at destinations, grazing areas and on trails. Over time we will undoubtedly need to take further actions to maintain these conditions. We have developed a comprehensive monitoring and evaluation plan and toolbox that will assist and guide us to consistent applications of adaptive management.

We have approached adaptive management in a responsive way. It is an approach to managing resources where the planning process includes recognizing the uncertainty in existing knowledge related to the resource being managed, and treats management actions as hypotheses to be tested using monitoring specifically designed for the particular action.

It is not our intention to be constantly changing, modifying or reversing the decisions in this document. But the greatest importance and attention must go to managing for the conditions we desire. The actions are merely tools we are using to get to the desired condition.

We understand the need to be realistic in our monitoring goals and objectives. These wildernesses comprise over 800,000 acres of topographically challenging terrain that can only be accessed by foot or horseback. Some destinations take days to reach. We have designed our monitoring goals and objectives around these realities, but have not perceived these as constraints. These considerations have led us toward an integrative approach to monitoring that identifies priorities based on multiple resource objectives, consistent with wilderness management goals to manage wilderness as a composite of resources, not as individually single resources.

We fully expect the pack stations to be fully engaged and accomplish a high level of self-monitoring. We welcome any other interested parties to help us with ongoing management and effectiveness monitoring. These efforts must be accomplished systematically and we will hold ourselves and our partners to a high standard of monitoring, using established protocols.

How the Decision Responds to Public Input

Throughout the development of the Final EIS and Alternative 2 – Modified, we considered public input in developing a scientifically credible, resource sustainable, and legally sufficient plan. In our judgment, the decision we are making will more effectively meet legal

requirements, improve environmental protection measures, and further reduce the potential for environmental harm from human activities in these wildernesses.

A Notice of Intent to prepare an EIS was published in the Federal Register on June 15, 2004. Two Proposed Actions (*Trail Management Plan* and *Commercial Pack Stock Use Authorizations for the Ansel Adams and John Muir Wildernesses*) were distributed to interested parties in June 2004. Public meetings were held to clarify the Proposed Actions in Clovis, California (July 8, 2004) and Bishop, California (July 12, 2004). The public was asked to submit comments to the action from which issues could be determined and alternatives developed. Approximately 300 comments were received for the *Commercial Pack Stock Use Authorizations Proposed Action* and approximately 200 comments were received for the *Trail Plan Proposed Action* (table below provides a summary of these comments). The comments for both of these projects were used to develop the significant issues.

Table 1. Number of Comments received on the Proposed Actions

Project	Agency	Interest Group	Commercial Pack Station	Individual	Form Letter	Total
Commercial Pack Stock Use and Authorization	3	7	6	119	131	266
Trail Management Plan	2	7	3	88	67	167
Total	5	14	9	207	198	433

Using the comments on the Proposed Actions, organizations from the public, other agencies, and (affected) tribes, the interdisciplinary team and Forest Supervisors developed a list of issues. Significant issues directly influence the initiation, development, and technical design of the project; are disclosed in the analysis; and were used to develop alternatives to the proposed action.

On January 25, 2005, a revised Notice of Intent was published in the Federal Register. This notice incorporated the *Trails Management Plan EA* into the *Commercial Pack Stock Use Authorizations EIS*. The project was renamed *Trail and Commercial Pack Stock Management in the Ansel Adams and John Muir Wildernesses EIS* and the purpose and need for the project was clarified. This combined EIS responded to concerns over these two projects being connected actions and better displays the cumulative effects of two projects occurring in the same geographic area.

The Draft EIS was released for public comment on March 29, 2005. The document was placed on the Inyo and Sierra National Forests' websites and was mailed to interested parties. On April 15, 2005, the Draft EIS Notice of Availability was published in the Federal Register. Two public meetings were held. Approximately twenty people attended the May 17, 2005, meeting in Bishop, California and three people attended the May 19, 2005, meeting in Clovis, California. The comment period closed June 15, 2005. Over 400 comments were received on the DEIS, the majority of which were form letters.

Table 2. Summary of Comments received on the Draft EIS

Agency	Interest Group	Commercial Pack Station	Individual	Form Letter	Total
12	10	5	178	224	429

Throughout the process we have engaged the public and responded to what we have heard and there is no doubt that commercial pack stock use is a very polarized issue. There are clearly two sides, with very differing values and opinions that each feels is the “right” way to view these decisions. Both sides engaged in extensive letter writing campaigns that netted no new views or opinions other than the ones that were repeatedly expressed. Engagement at this level is not always productive or constructive and it does not help to facilitate resolution. It is with great regret that we have been unable to bring these two sides together to come to resolution and agreement on the management of these wildernesses.

But we feel our decision, can be seen as a fair approach to managing public use of these lands. We strongly believe there is a public need from commercial services in these wilderness areas and at the levels and conditions prescribed with Alternative 2 - Modified will protect and preserve the wilderness character. While both sides disagree over the means to do this, both sides agree that protecting wilderness character is paramount.

Responses to our Draft EIS led us to reconsider our approach and enhance a number of elements of the analysis. For example, between Draft and Final EIS we developed a new alternative that modified Alternative 2 and designed a specific destination management strategy to help readers understand the synergism of the actions at the destination level. This destination management strategy controls how, when, and where commercial pack stock activity can take place in these wildernesses and responds to the remediation that the courts are anticipating with the Final EIS.

Also, some respondents were very critical of our draft Needs Assessment, and encouraged us to better demonstrate the need for the commercial services. To get a better sense of the public’s use of commercial packing in these wilderness areas, a survey of past commercial clients was conducted between the Draft and Final EIS. In early August 2005, the survey was mailed to 537 pack stock clients from 2004. The names and addresses of the clients were gathered from the Inyo and Sierra National Forests’ Wilderness Permit Databases. The clients contacted were the individuals who identified themselves as the group leader and provided their names and addresses when receiving their wilderness permit. In 2004, 4,015 overnight clients were serviced by commercial pack stock. The average group size was three individuals, so approximately 1,338 commercial packing groups used the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses. A total of 346 surveys were filled out and returned to the forests. In all, data was available from 346 out of the 1,338 commercial groups that utilized commercial pack stock in the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses (approximately 40% of the groups).

The survey revealed the extent to which certain segments of the population rely upon commercial packing services to access the wilderness. Nearly 90% of the groups surveyed had an unqualified obvious need for the service and the vast majority of the need was related to age or physical limitation. A number of the respondents identified themselves as people that enjoyed backpacking at one time, but because of age or physical limitation were no longer able to carry a backpack. Another group of respondents identified themselves as family groups and according

to these individuals, commercial packing was the only way they can bring their children along on the trip. Still, another group of responses came from those with a physical disability who indicated that they would never be able to enjoy the wilderness without commercial packing services. One respondent, for example, said they had a car accident that restricted their ability to carry a backpack. Another survey response came from an individual who said they were bringing a terminally ill family member along with them; commercial pack stock support was vital as the family member did not have the strength to carry a pack. Perhaps the most striking finding in the survey was that 88% of the responses indicated that they would not have taken their trip without commercial pack stock support.

There has also been some skepticism expressed as to how we can do what we say we are going to do; that our plan is too ambitious, and we will not be able to successfully implement all the direction. In addition some believe we will not achieve the conditions we prescribe in our analysis. To respond to these concerns, we spent considerable effort creating adaptive mechanisms and the monitoring and evaluation components for this plan. We believe this greatly strengthens the plan and shows a means and method to be accountable for implementation of the direction and on going management.

Alternatives Considered

Six alternatives were considered and analyzed in detail. The following table summarizes the components of the alternatives comparatively.

Table 3. Comparison of Alternatives

Alternative						
	1 No Action	2 – Modified	2	3	4	5
Use Levels and Stock Numbers						
Day Rides	Allocated by Wilderness Plan in service days.	Day ride locations identified per Pack Station and limited by number of stock at one time in the wilderness. Limits placed on areas where day ride activities have potential for use or resource conflicts.	Allocated per Pack Station location.	Allocated per packer.	Allocate service days per packer with consideration of resource or social issues.	None authorized.
Service Days	Allocated service days with additional temporary service day pool.	No Service Days to Resort Permittees.	No Service Days to Resort Permittees.	No Service Days to Resort Permittees.	Service Days at 20% reduction from Alt 1.	None authorized.

Alternative						
	1 No Action	2 – Modified	2	3	4	5
Quotas	Trailhead quota for people. Borrowing of next days quota allowed. FS writes all wilderness permits.	Destination quotas managed through destination management plans. Stock at one time limit. FS writes all wilderness permits.	Destination quotas. Stock quotas daily/seasonal. FS writes all wilderness permits.	Trailhead quota for people, seasonal. Threshold for clients and stock. Few destination quotas. FS writes all wilderness permits.	Trailhead quota for people, reduction in party size at some trailheads. No borrowing. FS writes all wilderness permits.	None authorized.
Primary Operating Area	N/A	Identified by destination quotas.	Identified operating area.	Identified operating area.	In effect, no overlap of areas for spot and dunnage trips.	None authorized.
Party Size	15/25	15/25 And site specific party size limits.	15/25 And site specific party size limits.	15/25 And site specific party size limits.	12/20 And where trailhead prohibits full party size.	N/A
Trail Management Plan						
General Trail Plan	2001 Wilderness Plan direction and existing inventories.	Designates system of trails and assigns development levels.	Designates system of trails and assigns development levels.	Designates system of trails and assigns development levels.	Designates system of trails and assigns development levels.	Designates system of trails and assigns development levels.
System Trails	Inyo 1988 inventory Sierra 2001 inventory.	Aligns with recreation categories and destination management objectives.	Aligns with recreation categories and commercial destination quotas.	Aligns with recreation categories allowing higher development system than Alt 2.	Aligns with recreation categories allowing lower development system than Alt 2.	Aligns with recreation categories allowing lower development system than Alt 2.
Grazing Management						
Grazing Strategy	Utilization standards. Range readiness standards. Suitability direction not yet implemented.	Utilization standards estimated with stock nights. Range readiness standards same as Alt 1. Grazing suitability	Grazing zones, (stock nights, utilization and meadow closure) 5% impact in critical areas.	Grazing zones, (stock nights, utilization and meadow closure) 5% impact in critical areas.	Grazing zones, (stock nights, utilization and meadow closure) 5% impact in critical areas.	None by commercial pack stock authorized.

Alternative						
	1 No Action	2 – Modified	2	3	4	5
		determinations. Establishment of grazing zones and critical areas.				
Drift Fences	Allow drift fences only where needed for protection of resources or safety of visitors.	Retain 13 drift fences and approve one additional for resource protection.	Retain 11 drift fences and approve one additional for resource protection.	Retain 10 drift fences and approve one additional drift fence for resource protection.	Retain 4 drift fences and approve 1 additional temporary drift fence for resource protection.	None authorized for commercial pack stock.
Trail Suitability						
System Trails Suitable for Comm. Pack stock	Only use on existing system trails as directed by wilderness plan.	Use of system and authorized user trails except system trails identified as “Not Suitable for Commercial Stock.”	Use of system and authorized user trails except system trails identified as “Not Recommended for Stock.”	Use of system and authorized user trails except system trails identified as “Not Suitable for Commercial Stock.” Fewer NSCS trails.	Use of system and authorized user trails except system trails identified as “Not Suitable for Commercial Stock.” Many trail NSCS.	None authorized for commercial pack stock.
User Trails	Require approval Use trails approved in 2004.	Use trail approvals based on destination management.	Use trail approvals based on destination quotas.	Same use trail approvals as in Alt 2.	Very few use trails approved.	None authorized for commercial pack stock.
Campsites						
Campsites	50 feet from water.	Required to use designated stock camps when holding stock overnight with option of reserving site. All designated stock camps will meet BMPs.	Required to use designated stock camps when holding stock overnight with option of reserving site.	Required to use designated stock camps when holding stock overnight with option of reserving site.	All campsites for commercial pack stock designated (not just for overnight holding of stock) and limited to these sites.	None authorized for commercial pack stock.
Campfires						
Campfires	Elevational closures Site specific closures.	Few modifications to elevational fire closure boundary where firewood is available. Allow charcoal fires in areas	Elevational closures and packers allowed to pack in wood and charcoal.	Same as Alt 2 for full service trips in designated sites only.	Elevational closures Site specific closure.	Elevational closures.

Alternative						
	1 No Action	2 – Modified	2	3	4	5
		closed to wood campfires. Case by case wood campfire use by commercial pack stations.				

Description of Alternatives Considered in Detail

Alternative 1 – No Action

The No Action Alternative is the existing management direction from the Final Environmental Impact Statement and Record of Decision for the Ansel Adams, John Muir, Dinkey Lakes Wildernesses (April 2001). Generally, the No Action Alternative reflects the status quo of current management under the direction of the 2001 Plan. The Wilderness Plan programmatic direction has never been fully implemented, in part, because over the last three years resources have been diverted to the court-ordered analysis and/or restricted by the court's injunction from full implementation. For the purpose of this analysis, the No Action Alternative includes the elements of the 2001 Wilderness Plan that have been implemented.

In this alternative, the Trail Management Plan for the Inyo National Forest is based upon the 1988 trails inventory and is consistent with the direction in the Inyo National Forest Land and Resource Management Plan. In the absence of a similar trail inventory associated with the Sierra National Forest Land and Resource Management Plan, Appendix C from the 2001 Wilderness Plan serves as the basis for the Sierra National Forest trail system in this alternative. Direction for managing the trail system, including system and use trail suitability is based on the 2001 Wilderness Plan, but assumes that the designation of a trail system, consistent with the newly designated recreation categories (including identifying trails not recommended for stock) has not yet been fully implemented.

Alternative 2 – Modified

As discussed above, Alternative 2 – Modified is the selected alternative for this project. In this alternative, the emphasis is on destination management and managing for conditions at destinations. The desired condition of each destination is driven primarily by the three recreation categories outlined in the 2001 Wilderness Plan. Seasonal destination quotas will be the starting point for achieving the desired conditions. Grazing will be managed through a determination of suitability and stock night capacity for grazing zones and specific meadows. Critical areas will be protected from grazing impacts.

The proposed system of trails and development levels are based on recreation categories, current and anticipated use, resource impacts, and trail maintenance considerations. These factors are considered to ensure that trail management objectives are consistent with area management objectives.

Alternative 2 – Modified was developed in response to public comments on the Draft EIS and modified Alternative 2, the original Proposed Action.

Alternative 2 – Proposed Action

Alternative 2 is the original Proposed Action that was scoped in June 2004. The proposed action was developed by this project's interdisciplinary team and both Forests' District Rangers. It was designed in response to the interdisciplinary team's assessment of conditions found in locations

where pack stations operate. The central feature of the alternative is managing use through destination quotas. It also identified the system of trails and trail management objectives consistent with the allowable use levels and recreation categories. A grazing management strategy identifies suitable meadows and zones for grazing with estimated use levels measured in stock nights.

Stock thresholds, site-specific party size and campfire allowances are also identified in Alternative 2.

Alternative 3

This alternative uses the trailhead quotas to ration use, establishing separate quotas for commercial packing at trailheads where pack stations are located. It also identifies a threshold for the seasonal number of clients and stock on each trailhead. The system of trails and trail management objectives established in this alternative are consistent with the allowable use levels and recreation categories. Grazing is the same as Alternative 2 except for meadows with downward trends in hydrologic functioning condition are closed to grazing. Site-specific party sizes are the same as Alternative 2. In addition, a number of slight modifications to the recreation category boundaries are made based on further information of the area's conditions.

Alternative 4

This alternative retains the use of service days and reduces overall commercial pack stock use by 20% and trailhead quotas are further reduced to respond more conservatively to resource issues. Party size is 12 people and 20 head of stock and further constrained by trailheads quotas. Trail suitability determinations greatly reduce the areas where commercial pack stock can operate. Grazing is similar to Alternative 3 except that meadows with hydrologic function alteration are closed to grazing. The Trail Plan generally assigns lower trail class levels but manages a very similar system of trails as Alternative 2 and 3.

Alternative 5

This alternative does not allow commercial pack stock services in the two wildernesses. The Trail Plan responds accordingly, typically with lower trail class levels due to the projected type and levels of use. Although Alternative 5 does not meet Purpose #1 (*Provide for needed commercial pack stock services*), it was included in the analysis for two reasons. First, analyzing the environmental effects associated with no commercial pack stock provides a useful baseline to compare to other alternatives. Also, the second environmental analysis addressing commercial pack stock permit issuance, the *Commercial Pack Station and Outfitter/Guide Permit Issuance EIS*, will analyze a No Action Alternative not issuing special use permit to the pack stations. Rather than reanalyze commercial pack station operations in the Ansel Adams and John Muir Wildernesses in the *Permit Issuance EISes*, we determined that the prudent approach would be to analyze the environmental effects of no commercial pack stock in this EIS.

Alternatives Not Considered In Detail

Federal agencies are required by the National Environmental Policy Act “to rigorously explore and objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated” (40 CFR 1502.14). Public comments received in response to the original scoping phase and the DEIS were used to develop the alternatives contained in the FEIS.

Many ideas have been suggested and evaluated during the development of the alternatives considered in detail. Various components were considered, such as additional mitigation measures, changes to quotas and allocations, no grazing, and adjustments to commercial use quotas. Addressing all of the possible permutations would create an unmanageably large number of alternatives that would not be helpful to the decision makers or the public. In addition, some components were determined to be outside the scope of the current wilderness plan revision process, were already represented by one or more of the alternatives considered in detail, or were determined to risk unnecessary environmental harm. Therefore, a number of alternatives were considered but dismissed from detailed consideration.

There was a concerted effort by some who commented on the DEIS to forward what might best be described as “Modified Alternative 4.” This proposal suggested reducing quotas, party size and service days further, and identifying more trails as not suitable for stock. This alternative was not analyzed in detail for three reasons. First, it was determined that Modified Alternative 4 did not meet Purpose # 1 (*Provide for needed commercial pack stock services*) for this project. The levels of service that would have been provided in Modified Alternative 4 would have fallen far short of the public need as identified in the Needs Assessment. Modified Alternative 4 would reduce commercial packing services considerably below what is provided today. Secondly, the proposed reductions were rather capricious and lacked rationale beyond a desire to have less pack stock in the wilderness.

It appeared as though the primary basis for the proposed alternative was to address visitor concerns about encountering stock rather than environmental considerations. We believe that merely reducing commercial services to arbitrary levels below Alternative 4 does not demonstrate a corresponding improvement to the condition of the wilderness and justify the draconian reduction in public access to these wilderness areas. In addition, Modified Alternative 4 was not analyzed because it is believed that the environmental effects associated with this alternative will ultimately closely resemble the effects described for Alternative 5. The alternative did not provide the decision maker or public with an approach to managing commercial pack stock much different than in Alternative 5.

Environmentally Preferred Alternative

The Council on Environmental Quality (CEQ) regulations for implementing the NEPA require that the ROD specify “the alternative or alternatives which were considered to be environmentally preferable” (40 CFR 1505.2(b)). According to the Council on Environmental Quality’s 40 Most Asked Questions concerning NEPA, this direction has been generally interpreted to be “the alternative that will promote the national environmental policy as expressed in NEPA’s Section 101.”

Ordinarily, this means the alternative that causes the least damage to the biological and physical environment; it also means the alternative which “best protects, preserves, and enhances historic, cultural, and natural resources.” Section 101 of the National Environmental Policy Act states that:

...it is the continuing responsibility of the Federal Government to ...

- (1) fulfill the responsibilities of each generation as trustee of the environment for succeeding generations;
- (2) assure for all Americans safe, healthful, productive, and aesthetically and culturally pleasing surroundings;
- (3) attain the widest range of beneficial uses of the environment without degradations, risk to health or safety, or other undesirable and unintended consequences;
- (4) preserve important historic, cultural, and natural aspects of our national heritage and maintain, wherever possible, an environment which supports diversity and variety of individual choice;
- (5) achieve a balance between population and resource use which will permit high standards of living and a wide sharing of life's amenities; and
- (6) enhance the quality of renewable resources and approach the maximum attainable recycling of depletable resources.

It may appear as though Alternative 5 “causes the least damage to the biological and physical environment.” Removing all pack station operations from the wilderness does eliminate a source of impact on the wilderness environment. Alternative 5, however, is not the environmentally preferred alternative if the human environment, including historic and cultural resources are considered. NEPA directs federal agencies to consider the effects of federal actions on not only the physical and natural environment, but also the human and social environment. Alternative 5 falls far short of meeting the federal government’s responsibility #4 above to “preserve important historic, cultural, and natural aspects of our national heritage and maintain, wherever possible, an environment which supports diversity and variety of individual choice.” As discussed in the Final EIS, Alternative 5 will severely limit the ability of a certain percentage of the public to access and enjoy the wilderness areas analyzed in this project. Commercial packing in the Sierra Nevada has a long history of providing access for the public and is recognized as an important cultural and historic resource.

Within this context, Alternative 2 – Modified would also be considered the environmentally preferred alternative in that it maintains a reasonable level of commercial packing service for the public and protects the wilderness character and resources of the area. Alternative 2 – Modified contains a number of site-specific mechanisms that control how, when, and where commercial packing activity can occur in these wildernesses. As discussed earlier in this Record of Decision and in the Final EIS, increased levels of use do not automatically translate into increase impacts to the wilderness. Whereas Alternative 5 provides the highest level of physical and ecological protection at the expense of the human and social environment, Alternative 2 – Modified meets all of the goals in Section 101 in that it “attain[s] the widest range of beneficial uses of the environment without degradations, risk to health or safety, or other undesirable and unintended consequences and preserve[s] important historic, cultural, and natural aspects of our national heritage and maintain[s], wherever possible, an environment which supports diversity and variety of individual choice.”

Relationship of Management Direction to Existing Plans

The Wilderness Goals and Objectives, Desired Future Condition and management direction (Standards and Guidelines) of the existing Land and Resource Management Plans (LRMPs) are amended by this decision for the Ansel Adams and John Muir Wildernesses only. This decision is otherwise consistent with the current LRMPs for the Inyo and Sierra National Forests and with the Sierra Nevada Forest Plan Amendment.

Relationship to State and Local Plans and Proposals

We have reviewed this decision and have determined that it is consistent with tribal, state and local plans.

Relationship to Other Lands

The influences of activities on lands administered by the Bureau of Land Management and the National Park Service were considered in the assessment of cumulative impacts in the FEIS. This decision does not adopt new management direction for those federal lands. Likewise, this decision does not establish direction or regulation for state, tribal, or private lands.

Monitoring and Mitigation

Mitigation Measures Adopted

Extensive measures to avoid or minimize environmental harm are being adopted in the Plan. Some of these measures have been discussed previously. Mitigation measures are an integral part of the management direction. Singularly and collectively, they avoid, rectify, reduce, or eliminate potential adverse environmental impacts of wilderness management activities. Some more significant mitigation measures will be included in the Programmatic Agreement between the State Historic Preservation Office, Advisory Council on Historic Preservation, and the Forest Service and other interested parties.

Monitoring and Evaluation

As described in our rationale, adaptive management and monitoring is integral to this decision. Our actions, such as designating a campsite or resting a meadow from grazing, must be monitored and evaluated for effectiveness. Our monitoring plan identifies the priorities for monitoring based on needs, risks and uncertainties of certain outcomes. We have also identified high priority areas for monitoring with the intention to achieve some integration in our monitoring program.

Evaluation of commercial pack stock management in the Ansel Adams and John Muir Wildernesses will continue indefinitely. The knowledge gained from the current actions is

necessary to inform future pack stock management within the Ansel Adams and John Muir Wildernesses as well as adjacent National Parks and other National Forest Wildernesses.

Integral to the success of adaptive management is site-specific and accurate reporting of commercial pack stock use. An emphasis will be placed on this so we are able to better understand the relationship between this use and impacts. Over time, we believe that we will refine our understanding of the effects of certain management actions, and can inform future management by our critical evaluations of these actions.

Findings Required By Other Laws

The Forest Service manages the Inyo and Sierra National Forests in conformance with many federal laws. In this section some of the more relevant laws pertinent to this programmatic-level decision are discussed.

Wilderness Act

The Wilderness Act (Public Law 88-577) requires that wilderness character be preserved. This section documents our conclusion and finding that wilderness character will in fact be preserved under Alternative 2 – Modified. Section 2(a) of the Act states the designated wilderness areas shall be administered...

...for the use and enjoyment of the American people in such a manner as will leave them unimpaired for future use and enjoyment as wilderness and so as to provide for the protection of those areas, the preservation of their wilderness character.

Wilderness character combines biophysical and experiential qualities, and is never explicitly defined in the Act, however Wilderness is defined in Section 2(c) and through this definition; concepts of wilderness character are expressed as:

an area of undeveloped Federal land retaining its primeval character and influence, without permanent improvements of human habitation, which is protected and managed so as to preserve its natural conditions and which (1) generally appears to have been affected primarily by the forces of nature, with the imprint of man's work substantially unnoticeable; (2) has outstanding opportunities for solitude or a primitive and unconfined type of recreation; (3) has at least five thousand acres of land or is of sufficient size as to make practicable its preservation and use in an unimpaired condition; and (4) may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value.

Impacts are inevitable with recreation use. Impacts often occur rapidly and recover slowly. Many factors that influence the magnitude of impact (amount, timing, and type of use, and spatial distribution of use) can be manipulated by managers to limit impacts (Cole, 2004). The most important attributes of wilderness are that it is natural, wild, un-crowded and free, yet these attributes are in conflict with one another when management attempts to provide for any one of them (Cole, 2000). Wilderness research points to the need to provide for a range of opportunities, settings, and conditions within designated wilderness. Choices between access and protection, wildness and naturalness are value judgments that should reflect society's needs and desires (Cole, 2001). According to Cole (2001):

A broad range of wilderness conditions could be provided by allowing high visitation in carefully selected and delineated wilderness locations, while protecting most wilderness in a lightly used condition. Such a wilderness management zoning approach (Haas et al. 1987) would keep most wilderness close to the low use ideal described in the Wilderness Act and still meet the increasing demand for wilderness experiences.

To evaluate compliance with the Wilderness Act in regards to wilderness character, four factors, or qualities of wilderness character were used to assess the effects of each alternative on wilderness character in Chapter 4. These come directly from the language in the Wilderness Act. Both legislation and agency policy mandate a responsibility to preserve wilderness character, yet no specific process has ever been established.

Current interagency efforts to monitor wilderness character (Landres et al., 2005) define wilderness character as the combination of biophysical, experiential, and symbolic qualities that distinguish wilderness from all other lands. Wilderness character is protected or diminished and sometimes both, by management decisions and actions.

Because wilderness character is multidimensional, composed of both biophysical and social aspects, actions taken to protect one aspect of wilderness character may diminish another aspect. For example, a bridge built to protect a stream bank from erosion caused by people or horses crossing the stream may also diminish the opportunity for people to experience the challenge of crossing a stream, and it may diminish the feeling or experience of a natural setting. Similarly, the required use of hardened or designated campsites to protect the soil and vegetation in an area may diminish the opportunity for unconfined recreation and the sense of freedom from the constraints of society (Landres et al 2004).

As this statement acknowledges, there are competing factors of wilderness character. It is the responsibility of the administering agency to assess these factors in relation to each other.

Here, these four qualities that represent the essence of wilderness character, are identified and defined, and then analyzed in relation to the selected alternative.

Untrammeled

The essence of this factor is that human activities should not control or manipulate wilderness ecosystems. Synonyms for untrammeled include unrestrained, unrestricted, unhindered, unimpeded, unencumbered, self-willed, and wildness. When speaking in terms of effects on the untrammeled quality, this evaluation considers the scale of the control or manipulation. Examples in Landres (2005) of trammeled include dams that impede natural flood cycles, animals or plants that are transplanted or re-established, and fires that are suppressed. These types of actions are intentional and deliberate, and conspicuous in their effects on ecological processes.

In Alternative 2 – Modified, there are no intentional controls or manipulations of ecological processes to facilitate or in conjunction with commercial pack stock use that affect ecosystems at the wilderness scale.

There are remnants of past actions on the wilderness landscape that predate wilderness designation that have nothing to do with commercial pack stock use. The most imposing of these types of actions are water retention structures. A total of ten dams predate the Wilderness Act, three of which would not be noticeable to the average visitor's eye since they are small in scale and/or not visible from a trail. The substantial structures that predate the wilderness do trammel

wilderness and are major adverse effects to the natural ecosystem. Commercial pack stock activities have no additional effect. In relation to these dams, commercial pack stock and noncommercial visitation pale by comparison in their effects on the untrammelled quality.

To the extent that a small percentage of area (9%) is used to camp by clients of commercial pack stock, or trails are used to travel, there is a very minor effect on the untrammelled quality of wilderness with minor water flow diversions, or vegetation loss. This level of impact is minor in scale and intensity and occurs as a result of all recreational visitation as a means to allow the use and enjoyment of wilderness.

The designation of stock camps is intended to reduce effects on water quality and reduce the overall area of impact to vegetation and soil resources. We anticipate that by designating these sites there will be less than 40 acres of disturbed environment in these wildernesses that may be considered light to moderately "trammelled." Considering even this level of obtrusion to be an effect on the untrammelled quality is magnifying the issues beyond what an average person would consider apparent. But even so, this is less than ¼ of 1% of the wilderness that would be directly affected by commercial pack stock activities, most of which may be on a very infrequent basis on generally used by other wilderness visitors.

Natural Conditions

The Wilderness Act makes it very clear that these areas serve as a contrast to modern civilization. They are places where "man and his own work do not dominate the landscape." The agency manages for natural processes to dominate the landscape. Implied is that natural conditions vary over time and evolve. The condition at the time of designation is an important consideration in the evaluation of this factor. If, for example, a road or heavy grazing has had an effect on natural conditions, the effect of subsequent actions may be greater as a result of these past actions. The basic premise of this quality is that humans allow the processes to function on their own and that natural conditions dominate the landscape. It is not the obligation of the agency to manipulate natural processes to restore past damages, as that can become an effect on the untrammelled quality and can become as much a disturbance to natural conditions as the original activity. Each situation needs to carefully consider the best course of action to maintain natural conditions.

These wildernesses still provide a vital contrast to modern civilization. Disturbance to natural process is limited to site specific locations where commercial pack stock activities may contribute to local soil erosion, sedimentation into surface water from pack stock grazing, campsites and trails. Water quality is thought to be good and will remain so except at few very local areas where there may be slight degradation.

Alternative 2 - Modified manages for an increased level of protection for Yosemite toad meadow breeding habitats. Fifty-six meadows approved for commercial packer stock grazing overlap with Yosemite Toad breeding areas. Thirty meadows that have been approved for grazing are determined unsuitable in this alternative, and would be closed to provide full protection for toad breeding habitats.

No significant effect to any species or ecological process occurs as a result of the pack stock activities. There will remain a rich diversity of flora and fauna with interdependencies that exemplifies an unimpeded natural world. This is because the use of system trails, use trails, destinations, and grazing areas is authorized site specifically; and the levels of use assigned are

within an acceptable level that protects species and processes. This is not to say that there is no disturbance, and no effects to natural conditions, but that the disturbance occurs within acceptable locations and where it was determined to have an unacceptable effect, the area was either closed to the use or limited in how much use could occur there.

Undeveloped

This is a basic requirement of wilderness, that it is undeveloped land, void of habitation and other evidence of modern human presence. The physical evidence of humans and human activity should be “substantially unnoticeable.” Trails and campsites, while facilitating the use and enjoyment, can also be considered obtrusive and evidence of human influence. The “minimum necessary” philosophy directs managers to exercise restraint in order to ensure that visitors experience a primitive environment.

The level of development that will ensue with this alternative does not change from current conditions; they are limited to drift fences and trails. The scale of this development is so small as to be hardly discernable to the average visitor.

Campsites will have no level of development other than at most locations a small diameter (less than two feet) rock ring for containing ash, wood and coals and a small locational sign. All other features of campsites are brought in and removed with each trip or series of trips. There are no permanent structures associated with these sites.

The only structures that are allowed and authorized associated specifically with commercial pack stock uses are “drift fences,” which are primitive fences using native posts and wire strung a short distance across a trail, typically in a box canyon or narrow to contain drifting stock. Drift fences are limited in size, scope and obtrusion. There will be fewer of these structures than are allowed currently. Thirteen of these primitive structures will be allowed. Many are being allowed and kept in place to keep the drifting stock out of unsuitable areas for grazing thereby protecting natural conditions in sensitive areas.

Trails facilitate use and travel and are normally a welcome development for most visitors. The level of trail development for the purpose of facilitating commercial pack stock use is moderate in Alternative 2 – Modified. This has a minor to moderate effect on the undeveloped quality of wilderness character. Development of trails occurs to facilitate use and enjoyment of wilderness for commercial and noncommercial visitors. The highest level of trail development in these wildernesses actually occurs on a trail where stock is not allowed (Mt. Whitney). The next highest level of trail development occurs to popular areas for all visitors, and those trails where pack stock use is heavy. Trails do need a higher level of development when they are maintained for riding and pack stock use. The trail is typically more substantial, with more structures on the trail, and more steps and moderate grades. This does have an affect on the quality of wilderness character, however, the level of development that is needed is also responding to protecting resources, such as meadows, steep slopes, and riparian areas.

Actions to develop trails value recreational uses over the undeveloped quality, however the scale of this development is insignificant in contrast to the developments recreation facilities (e.g., ski areas, campgrounds) and urban areas.

Outstanding opportunities for solitude or a primitive and unconfined type of recreation

The experiential component of wilderness is shaped by the other three factors of this evaluation and includes individual's perceptions, responses and opinions. For example, one person may observe a trail as too highly developed and therefore affect their wilderness experience while another person may not even consider the level of development and think that the trail enhances their wilderness experience. These three elements of the wilderness experience attempt to define a wilderness experience in more tangible terms. Evaluating opportunities for solitude considers the ability for a visitor to find and experience a very low density of other visitors. Primitive recreation encompasses concepts of simplicity and reliance on personal skills to travel and camp. Unconfined recreation highlights the importance of freedom and lack of managerial controls, where a visitor takes on their own risk and experiences the consequences of their choices. Together and separately, these experiential elements distinguish wilderness recreation from recreation on other more developed lands or controlled environments.

Alternative 2 - Modified has substantial effects on the unconfined recreation of commercial pack stock visitors. With limits placed on each destination that each pack station uses, there may be visitors that cannot have the trip to the location they desire. Visitation is further regulated by party size, where you can have a campfire, and where you can camp on a traveling or all expense trips. The type of trip that a visitor may want may be limited, specifically the all expense and traveling trips. This could greatly affect the visitor's ability to experience the wilderness entirely on their own terms. It is also a much more controlled experience than the non-commercial visitor, since more restrictions are in place on the commercial pack stock than the non-commercial public. The non-commercial visitor is limited by trailhead quotas, specifically designed to place the restriction on entrance to the wilderness thereby maximizing visitor freedom once inside the wilderness. For the pack stations, we are further limiting the freedom.

These restrictions on visitor freedom come as a price for maintaining natural conditions. In this regard the value of natural conditions is valued and weighed with the value of visitor freedom. Alternative 2 – Modified attempts to maintain a level of use so that the public can still enjoy a wilderness experience, though it may not be the exact location or their first choice in locations. Often the commercial pack stock visitor is merely dropped off at a point and then travels by foot without assistance or support. We considered this factor in limiting the location where the pack stock can travel, yet still allowing the less impacting use to continue.

Solitude will be protected in this alternative by the limitations on the frequency of trips to destinations and the stock at one time limitation. This will make it more likely that non-commercial visitors will not experience an amount of commercial use that is inappropriate for the capacity of the destinations and on the trails. There will still be occasions when the commercial and non-commercial visitors will be in the same locations at the same time, just as there will be times when multiple non-commercial parties will be in the same location. But the chances of commercial - non-commercial conflicts are far less in this alternative, since each destination has a certain level of use allowed, and not more. With each destination receiving a careful assessment of the desired condition, and the capacity and setting, when establishing commercial use levels, there is the greatest chance of maintain high opportunities for solitude for commercial and non-commercial visitors.

In summary, Alternative 2 – Modified preserves and protects wilderness character through various mechanisms that prevent or reduce environmental and social impacts. The diagram below expresses the relationship between public need and wilderness character, and the conditions we are maintaining by the management actions in this EIS. If one were to imagine that the threshold of preserving wilderness character is a constant, controlled through management actions, and that pack stock services will be needed at varying levels over time, depending on demographics and changing population dynamics; our management actions maintain commercial services at a level below the threshold for preserving wilderness character. This is how we perceive this relationship:

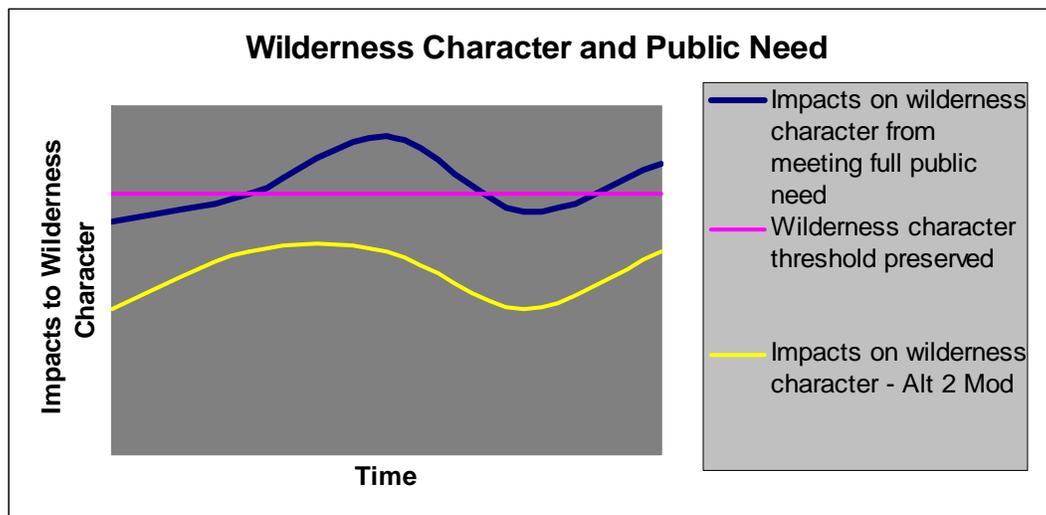

Figure 1. Effects of Alternative 2 – Modified on wilderness character and public need

In this assessment, we can demonstrate and support a finding of preserving wilderness character. Weighing together the four primary factors in relationship to each other, and in relationship to the proposed type and level of commercial pack stock uses allowed by the selected alternative, our assessment indicates that some factors are effected more than others, but all factors collectively and individually do not exceed expectations of the Wilderness Act. Figure 2 displays this finding and shows that effects of Alternative 2 – Modified do not go beyond the minimum thresholds set for the four components of wilderness character: untrammeled, natural conditions, undeveloped, and outstanding opportunities for solitude or a primitive and unconfined type of recreation.

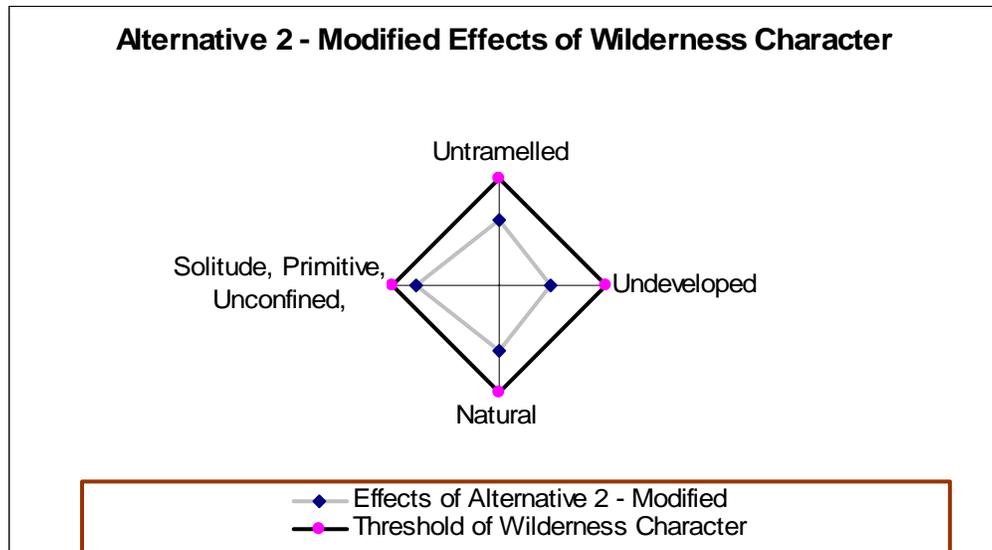

Figure 2. Effects of Alternative 2 – Modified on components of wilderness character.

National Environmental Policy Act (NEPA)

NEPA requires that Federal agencies prepare detailed statements on proposed actions that significantly affect the quality of the human environment. This requirement is designed to serve two major functions: 1) to provide decision makers with a detailed accounting of the likely environmental effects of a proposed action prior to its adoption; and, 2) to inform the public of, and allow comment on, such efforts.

The Inyo and Sierra National Forests have compiled and generated an enormous amount of information relevant to the effects of each of the alternatives considered in the FEIS. Such information builds on the data, analysis, and public involvement set forth in the documents prior to this FEIS, which include the 2001 Final Environmental impact Statement for the Management Direction for the Ansel Adams, John Muir and Dinkey Lakes Wildernesses.

All substantive comments, written and oral, made on the DEIS have been summarized and responded to in the FEIS. Over the course of analysis, this public involvement has led to changes in the alternatives including the selected alternative.

The environmental analysis and public involvement process complies with each of the major elements of the requirements set forth by the CEQ for implementing NEPA (40 CFR 1500-1508).

First, the FEIS considered a broad range of reasonable alternatives.

Second, the FEIS reflects consideration of cumulative effects of the alternatives by evaluating past, present, and reasonably foreseeable future actions in the planning area. Moreover, although non-Forest System lands are outside the scope of this decision, effects from their management have been considered in the Final EIS to a degree appropriate for a programmatic NEPA document at this scale.

Third, the FEIS makes use of the best available information. Application of a geographic information system (GIS) was used to evaluate spatial effects resulting from implementation of the alternatives. The best available science was used to help estimate environmental consequences as evidenced from the bibliography. All of these tools, taken collectively, constitute use of the best available information.

Additional site-specific decisions will be made on projects in compliance with NEPA, ESA, and other environmental laws following applicable public involvement and appeal procedures.

National Forest Management Act (NFMA)

This decision conforms to the 1982 planning regulations (36 CFR 219) that implement the National Forest Management Act. These regulations were recently changed (65 FR 67513). Transition language within the new regulations permits plan revisions and amendments, such as the amendments that are part of this decision, to be completed under the 1982 regulations. Since the rest of the LRMPs will continue to fall under the 1982 regulations, and since there is some uncertainty over the implementation of the new regulations, it is our decision to adopt these amendments under the 1982 regulations.

Diversity and Viability Provisions for Fish and Wildlife

The National Forest Management Act (NFMA) requires the Secretary of Agriculture to “specify guidelines for land management plans developed to achieve the goals of the [RPA] Program which provide for diversity of plant and animal communities based on the suitability and capability of the specific land area in order to meet overall multiple-use objectives” (16 U.S.C. 1604(g)(3)(B)). In accord with this diversity provision, the Secretary promulgated a regulation that provides in part: “[f]ish and wildlife habitat shall be managed to maintain viable populations of existing native and desired non-native vertebrate species in the planning area” (36 CFR 219.19, 1982 edition).

The recently completed SNFPA Record of Decision established land allocations and standards and guidelines to meet all of the diversity and viability provisions for fish and wildlife. This FEIS is consistent with that amendment. Therefore this decision will also provide the fish and wildlife habitat and other ecological conditions necessary to maintain well-distributed viable populations of vertebrate species in the planning area, and maintain the diversity of plants and animals.

Endangered Species Act (ESA)

Consultation requirements under Section 7 of the ESA, have been completed with the Fish and Wildlife Service. The Fish and Wildlife Service reviewed the Biological Assessment for the proposed threatened and endangered species under their regulatory jurisdiction. Consistent with direction in *Memorandum of Agreement, Endangered Species Act Section 7 Programmatic Consultations and Coordination among Bureau of Land Management, Forest Service, National Marine Fisheries Service and Fish and Wildlife Service, August 30, 2000*, the Fish and Wildlife Service (FWS) concluded that this decision is “not likely to jeopardize the continued existence of

threatened and endangered species” occurring on the national forests. Copies of correspondence with the FWS are included in the planning record.

National Historic Preservation Act

Pursuant to Section 106 of the National Historic Preservation Act has been met through the Programmatic Agreement of 2001 for Controlling Impacts on Historic Properties; Management of Ansel Adams, John Muir, and Dinkey Lakes Wildernesses, Sierra and Inyo National Forests. In addition, the Forests are developing a new Programmatic Agreement for site specific actions in the Issuance of the Commercial Pack Stock Special Use Permits and will be , the Forests have consulting extensively with Indian tribes, other users of the wildernesses, the California State Historic Preservation Officer, and the Advisory Council on Historic Preservation about how best to identify and mitigate adverse effects on historic sites, structures, trails, landscapes, Native American spiritual places, and other aspects of the cultural environment, including traditional uses of the wildernesses. This resulted in a Programmatic Agreement among the consulting parties that provides for ongoing studies and consultation over at least the next five years to identify impacts and implement mitigation measures. The Forests will implement the terms of the agreement, which is believed to embrace all practicable measures to mitigate possible impacts on the cultural aspects of the wilderness environment.

Clean Water Act

Full implementation of this decision is expected to maintain and improve water quality and satisfy all State water quality requirements. This finding is based on the standards and guidelines contained in the decision, the application of State approved Best Management Practices specifically designed to protect water quality, and the discussion of water quality and beneficial uses contained in the FEIS. Examples include: (1) camp site containment, (2) destination quotas, (3) trail suitability limitations (4) rehabilitating campsites, (5) grazing strategy for commercial pack stock, and (6) incorporation of established recovery plans. Additionally, project-level analyses for activities subsequent to the decision will be required to demonstrate compliance with Clean Water Act and State water quality standards.

Clean Air Act

At the scale of a programmatic plan such as this, the overall level of activities proposed under this decision is not anticipated to violate ambient air quality standards. This finding is based on information presented in the FEIS. The Inyo and Sierra National Forests are in non-attainment for PM10 while only the Sierra N.F. is in non-attainment for Ozone. Conformity determinations will be made at subsequent levels of planning and analysis where emissions can be more accurately quantified and reasonably forecasted and local impacts assessed.

Flood Plains and Wetlands (Executive Orders 11988 and 11990)

These Executive Orders require Federal agencies to avoid, to the extent possible, short- and long-term effects resulting from the occupancy and modification of flood plains, and the modification or destruction of wetlands. The LRMPs provide standards and guidelines for soil, water, wetlands, and riparian areas to minimize effects to flood plains and wetlands. They incorporate the Best Management Practices of the Soil and Water Conservation Handbook. The standards and guidelines apply to all floodplains and wetlands where less restrictive management might otherwise occur.

Determination of Significance (NFMA)

Forest Service requirements for amending forest plans are included in agency regulations and policies. These require that land uses be consistent with forest plans and that proposed activities which would be in conflict with the forest plan either be denied or modified (so as to be consistent), or that the forest plan be amended. Regulations direct the Forest Service to consider whether a proposed amendment to a forest plan would be considered a significant change.

The Forest Service is authorized to implement amendments to forest plans in response to changing needs and opportunities, information identified during project analysis, or the results of monitoring and evaluation. Forest Service Handbook and Manual direction provides the framework for considering a forest plan amendment, reviewing it for significance, documenting the results, and reaching a decision. An assessment of a proposed amendment's significance in the context of the larger forest plan is a crucial part of this process. It is important to note that the definition of significance for amending a forest plan is not the same as the definition of significance as defined by NEPA. Under NEPA, significance is generally determined by whether a proposal is considered to be a "major federal action significantly affecting the quality of the human environment," or whether the relative severity of the environmental impacts would be significant based on their context and intensity.

The National Forest Management Act (NFMA) requires that proposed forest plan amendments be evaluated for whether they would constitute a significant change in the long-term goods, outputs, and services projected for an entire national forest. Amendments that are not significant may be adopted following disclosure and notification in an environmental document, such as an EA, an EIS, or a supplement to one of these documents. Amendments that are deemed significant must be processed under the more intensive requirements for developing and approving a forest plan, which includes preparation of an EIS.

The criteria to analyze the significance of a forest plan amendment are summarized below from Forest Service Handbook 1909.12, Chapter 5.32. Each of the four criteria for determining significance of the proposed amendment is responded to directly. **Based on an analysis of these criteria, we have determined that these Forest Plan Amendments are non-significant.**

1. Timing. Identify when the change is to take place. Determine whether the change is necessary during or after the plan period (the first decade) or whether the change is to take place after the next scheduled revision of the forest plan. In most cases, the later the

change, the less likely it is to be significant for the current forest plan. If the change is to take place outside the plan period, forest plan amendment is not required.

This action will take place within the next year, towards the end of the current planning period. The Inyo National Forest Land and Resource Management Plan was completed in 1988 while the Sierra National Forest Land and Resource Management Plan was completed in 1992. The Inyo and Sierra National Forest Land and Resource Management Plans are scheduled to be revised in 2010, putting both Forests towards the end of the Forest Plan planning cycle. This action cannot wait for the revision process to be completed, for a number of reasons. For one, the court has ordered this analysis be completed by December 2005. Also, these actions are needed now to ensure environmental protection.

2. Location and Size. Determine the location and size of the area involved in the change. Define the relationship of the affected area to the overall planning area. In most cases, the smaller the area affected, the less likely the change is to be a significant change in the forest plan.

These LRMP amendments only apply to the Ansel Adams and John Muir Wildernesses on the Inyo and Sierra National Forests. These wilderness areas total just over 800,000 acres out of the total of 3.3 million acres that make up these two national forests. This is less than one third of the total acres of both forests. Furthermore, these wilderness areas generally encompass only the higher elevations of these national forests and the area of land within these two wildernesses that are affected by this amendment amounts to approximately 9% of the 800,000 acres.

3. Goals, Objectives, and Outputs. Determine whether the change alters long-term relationships between the levels of goods and services projected by the forest plan. Consider whether an increase in one type of output would trigger an increase or decrease in another. Determine whether there is a demand for goods or services not discussed in the forest plan. In most cases, changes in outputs are not likely to be a significant change in the forest plan unless the change would forego the opportunity to achieve an output in later years.

These LRMP amendments do not alter the long-term relationships between the levels of goods and services projected by the forest plans. An increase in one type of output does not trigger an increase or decrease in another. The changes in outputs are not likely to be a significant change in the forest plan since the changes would not forego the opportunity to achieve an output in later years.

This decision is also consistent with the goals, objectives and outputs set forth in the Inyo and Sierra Forest Plans and the 2001 Wilderness Plan. These additional actions further the goals, objectives and outputs identified in the 2001 amendment and the forests' plans. In the Inyo National Forest's Forest Plan, for example, the Management Direction included in the Designated Wilderness Management Prescription (MP #1) calls for the limitation of "commercial wilderness activities under permit to those that meet public needs and cannot be provided elsewhere." Other Management Direction in this Management Prescription directs the forest to "limit party size and number of stock per party to a level that protects social and natural resource values" and to "redirect and restrict use where necessary to restore impaired wilderness." Commercial pack stock in the Ansel Adams and John Muir Wildernesses will be managed by a Destination Management regime that will provide more specific, updated, and consistent direction for these wildernesses.

4. Management Prescription. Determine whether the change in a management prescription is only for a specific situation or whether it would apply to future decisions throughout the planning area. Determine whether or not the change alters the desired future condition of the land and resources or the anticipated goods and services to be produced.

The changes in the management direction are only for a specific portion of the Forests, and will not apply to future decisions outside the planning area. The amendments do not alter the desired future condition of the land and resources or the anticipated goods and services to be produced.

Land and Resource Management Plan Amendments

Inyo National Forest Land and Resource Management Plan Non-Significant Amendment Number 10:

This amendment is for the Ansel Adams and John Muir Wildernesses only. The Trail Plan and Commercial Pack Stock Management direction contained in Alternative 2 – Modified of the Final Environmental Impact Statement (December 2005) supplements the management direction contained in the LRMP on pages 107 through 112 and the Monitoring Plan on page 257.

Sierra National Forest Land and Resource Management Plan Amendment Number 6:

This amendment is for the Ansel Adams and John Muir Wildernesses only. The Trail Plan and Commercial Pack Stock Management direction contained in Alternative 2 – Modified of the Final Environmental Impact Statement (December 2005) supplements the Standards and Guidelines contained in the Sierra LRMP on pages 4-30 through 4-31.

For both Forests, the following management direction found in the Ansel Adams, John Muir and Dinkey Lakes Wildernesses Plan (2001) is modified:

Page 11: Do not upgrade any trails from maintenance level 1 and 2 solely for the purpose of facilitating stock use. This direction will still apply to Dinkey Lakes Wilderness and will not apply to the Ansel Adams and John Muir Wildernesses.

Page 16: Prohibit wood burning stoves (including “Zip” stoves), charcoal fires, packed in firewood, or firepans within areas closed to wood campfires. This direction will still apply to Dinkey Lakes Wilderness and will not apply to the Ansel Adams and John Muir Wildernesses.

Page 21: Remove specific “Packer” quotas for Big Pine NF; Devils/Graveyard; Jackass/Norris; Walton trailheads. Commercial quotas will remain in place for outfitter guide activities.

Page 27: Identify maximum numbers of stock in the special use permit and condition by site specific needs and objectives. This direction will still apply to Dinkey Lakes Wilderness and will not apply to the Ansel Adams and John Muir Wildernesses.

Page 27: Review and adjust commercial packstock stock allocations every five years. This direction will still apply to Dinkey Lakes Wilderness and will not apply to the Ansel Adams and John Muir Wildernesses.

Page 28: Do not authorize commercial packstock on trails not recommended for stock.

This direction will still apply to Dinkey Lakes Wilderness and will not apply to the Ansel Adams and John Muir Wildernesses.

Page 28: Service days will no longer be used in the Ansel Adams and John Muir Wildernesses for “**Packstock Supported**” and “**Day Rides.**” Modify commercial allocation of service days as follows: Packstock Supported – 145. This is for the Dinkey Lakes Wilderness.

Also, The Trail Plan identified in Alternative 2 – Modified of the Final Environmental Impact Statement (2005) replaces Appendix C of the 2001 Wilderness Plan and the 1988 Inyo National Forest LRMP.

The geographic boundaries of the Recreation Categories are modified with this direction but not the desired conditions of the Recreation Categories.

Geographic boundaries of the elevational fire closure are modified in 8 locations with this direction.

Environmental Justice (Executive Order 12898)

Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, requires that Federal agencies make achieving environmental justice part of their mission by identifying and addressing, as appropriate, disproportionately high and adverse human health and environmental effects of their programs, policies, and activities on minority populations and low-income populations. The issue of environmental justice is analyzed within the Socioeconomic section in Chapters 3 and 4 of the Final EIS.

A qualitative assessment of environmental justice considerations was conducted based on the information in the Final EIS described above. Our conclusion is that the risk of such disproportionate effects on minority or low-income populations from implementation of this decision would be very low.

Civil Rights

The Forest Service manual defines civil rights as “the legal rights of United States citizens to guaranteed equal protection under the law” (USDA Forest Service Manual 1730). Civil rights impact analysis for environmental or natural resource actions are a necessary part of the social impact analysis package in an environmental impact statement and are not a separate report (USDA FSH 1709.11).

The Forest Service is committed to equal treatment of all individuals and social groups in its management programs in providing services, opportunities, and jobs. Because no actual or projected violation of legal rights to equal protection under the law is foreseen for any individual or category of people, no civil rights impacts are reported in the FEIS.

How this Document Relates to Special Use Permit Issuance EIS

This decision on the *Trail and Commercial Pack Stock Management in the Ansel Adams and John Muir Wildernesses* project is being closely followed by a second planning effort, the *Commercial Pack Station and Outfitter/Guide Permit Issuance* project. The *Permit Issuance* project will analyze and disclose the environmental effects of reissuing permits to commercial pack stations and stock-supported outfitters and guides. It will not revisit the decisions made in this ROD for the Ansel Adams and John Muir Wildernesses. In addition, the *Permit Issuance* project will analyze and disclose the environmental effects of reissuing permits to commercial pack stations and stock-supported outfitters and guides which will include an analysis of commercial pack station operations in the front country (or non-wilderness) areas of the respective forests as well as the Golden Trout, South Sierra, Kaiser, and Dinkey Lakes Wildernesses. Unlike the Final EIS for the *Trail and Commercial Pack Stock* project which was completed as a joint effort involving both forests, each forest will issue its own Permit Issuance EIS and decision. Decisions to be made in the *Permit Issuance* project include whether to issue the permits for these operations with modified terms and conditions, or not to authorize the uses and require removal of all facilities from public land.

Implementation Plan

We are providing the following transition language and schedule for implementing the management direction in this ROD. Although the direction will become effective after publication of the Notice of Availability in the Federal Register, we are choosing to phase in this new direction. The main reason is that we will still be under injunctive relief for some elements of this direction. Where we find that new direction is necessary for wilderness protection and not in conflict with the court injunction, we are scheduling immediate implementation. It is important not to allow existing activities that have been identified to harm the environment to continue for several years after the direction is changed. Some items however, are complicated in the timing and implementation due to the time it takes to implement. When changing management direction for such a large area, it is not practical to implement everything at once. The transition period allows for an orderly adjustment that moves management of the wildernesses forward while minimizing costs and disruption.

Table 3: Transition Plan

Alternative 2 – Modified Decision Components	Timing for Implementation
Trail Plan	Immediately.
Trail suitability	2006 operating season.
Use trail authorizations*	2006 operating season. Since the use trail decisions are more refined than the annual decisions made through the Court injunction and the criteria established through Exhibit 2, there will be environmental benefits of implementing this as soon as possible.
Suitability determinations and closure of meadows	2006 operating season.

Alternative 2 – Modified Decision Components	Timing for Implementation
Stock night limits	2006 operating season.
Specific meadow grazing strategies	Work will begin in 2006 but not be fully implemented until 2009 due to the time and personnel required to complete this component.
Permanent transects	2007
Drift fences	2006
Designated stock camps	25% in 2006 and 50% in 2007 and 25% in 2008 due to time and personnel required and timing of implementation.
Campfires	Forest Orders by June 2006.
Baseline data collection	25% in 2006; 50% in 2007 and 25% in 2008 due to time and personnel required to complete this work.
Recreation category adjustments	2006
Replace service day and trailhead quotas with destination quotas*	2007 due to operating season and trip bookings already underway for 2006 season and court injunction specifying service days.
Party size, wilderness wide and site specific*	2007 operating season and end of court injunction.
Day ride control mechanism change*	2007 operating season and end of court injunction to be consistent with control mechanism changes for other services and concurrently with implementation of “stock at one time.”
Stock numbers at one time in wilderness	2007 operating season and end of court injunction to be consistent with control mechanism changes for other services.
<ul style="list-style-type: none"> • <i>All or in part these components are currently controlled by the court injunction. The court injunction must be lifted before implementation. If court injunction does not end prior to the 2007 operating season, then implementation will be the 1st season after end of court injunction.</i> • <i>All items are budget dependent,</i> 	

Appeal Rights

This decision is subject to appeal in accordance with the provisions of 36 CFR 217 by filing a written notice of appeal in duplicate within 45 days of the date of published legal notice of this decision, as provided in 36 CFR 217.5(b) and 36 CFR 217.8(a)(3). The appeal must be filed with the Reviewing Officer:

Bernie Weingardt, Regional Forester
 USDA Forest Service
 Pacific Southwest Region
 1323 Club Drive
 Vallejo, Ca. 94592

The notice of appeal must include sufficient narrative evidence and argument to show why this decision should be changed or reversed (36 CFR 217.9).

Decisions on site-specific projects are not made in this document. Decisions on proposed projects will not be made until completion of environmental analysis and documentation for the specific project, in compliance with the NEPA.

THIS PAGE INTENTIONALLY BLANK

Record of Decision – Appendix A: Commercial Pack Stock Monitoring, Evaluation and Adaptive Management Plan Summary

Goals and Objectives

The 2001 Monitoring Plan developed for the Ansel Adams, John Muir and Dinkey Lakes Wilderness Plan (Appendix H) previously developed monitoring objectives and elements that overlap and also provide data for use in the assessment of trails, and commercial pack stock use as part of a larger multi-user monitoring framework. This monitoring program is designed to specifically address commercial pack stock activities and implement the appropriate components of the 2001 monitoring concept.

The **Destination Management Strategy** provides a framework for viewing management actions comprehensively, organized around the destination. In this framework, the desired conditions of the destinations are articulated and management actions that are expected to maintain the desired conditions are brought forward from the selected alternative. Assumptions will need to be evaluated, and over time, actions may need to be modified to respond to changing conditions and results of monitoring. Or, if conditions that are desired are not achieved, further actions may be needed. Providing a method for managing over time is one of the goals of the monitoring, evaluation and adaptive management plan.

Adaptive management is an approach to managing resources where the planning process includes recognizing the uncertainty in existing knowledge related to the resource being managed, and treats management actions as experiments or as hypotheses to be tested using monitoring specifically designed for the particular action (Williams, 1999; Healey et al., 1998; Walters 1986).

The goal of this monitoring plan is to:

1. Describe the monitoring, evaluation and adaptive management process.
2. Prioritize data collection to validate that the management actions described in Alternative 2 - Modified are being implemented; that these actions are working as designed; that changes in management occur as resource condition assessments warrant.
3. Validate that the commercial pack stock management actions are leading to, or maintaining the desired conditions for the various wilderness resources.

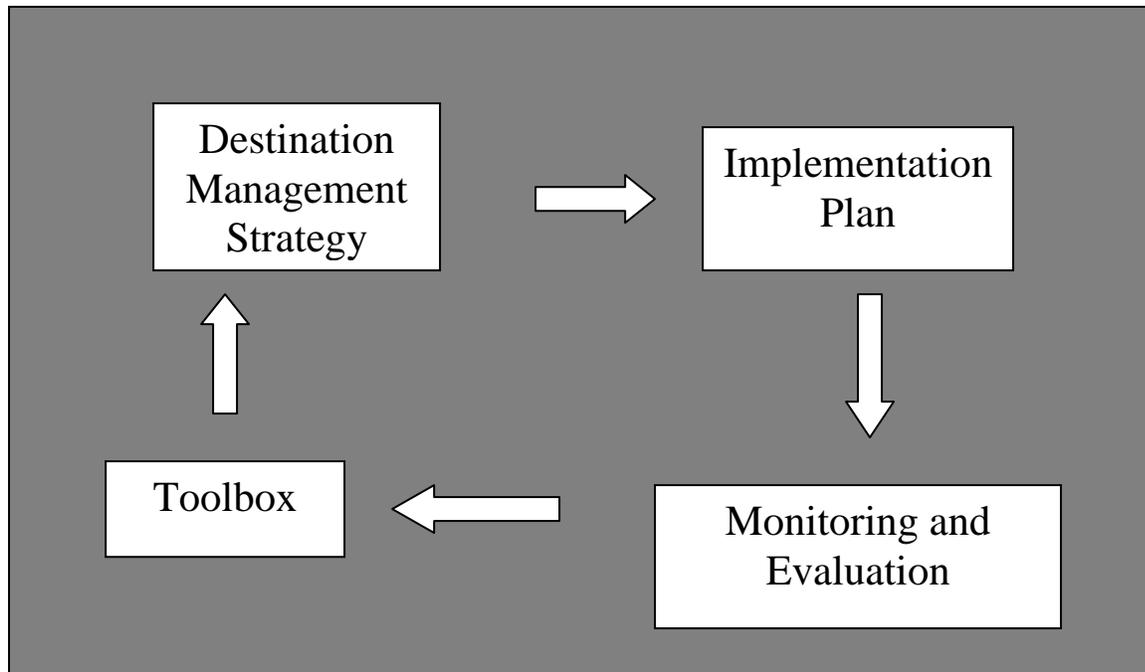

Figure 1: This diagram shows the relationship between the destination management strategy, implementation, monitoring and adaptive management (“Toolbox”).

Priorities

A comprehensive monitoring plan exists in the project files. Due to the complexity, it is not practical to include all components of the monitoring plan in this appendix. Included in the comprehensive plan is a full articulation for each variable of what, when and how to measure, and monitor if full implementation were possible. We recognize that full and extensive monitoring on every element is not realistic. So this plan was developed to provide prioritization for monitoring and evaluation. Three categories of monitoring and evaluation will be implemented.

1. Baseline data collection– acquiring baseline information on destinations, use trails, grazing areas that do not have full interdisciplinary team documentation of conditions.
2. Integrated monitoring of destinations. Locations where multiple resource concerns or risks have been identified and pack stock use is authorized.
3. Single Resource monitoring where less frequent monitoring is needed to understand the effectiveness of management actions and/or the site or feature to be monitored is representative of other sites or features in the planning area.

There are also other programmatic monitoring obligations that intersect this plan, including compliance with requirements for Heritage resource programmatic agreements, and Sierra Nevada Forest Plan Amendment requirements. Where integration with this plan is reasonable or practical, elements of these requirements will be conducted in conjunction with this monitoring.

Data Collection Process

Protocols for all the resources and/or features subject to monitoring have been developed through the interdisciplinary team process and are documented in the Evaluation of Commercial Pack Stock Operations Study Plan (2004). Conditions at meadows, on use trails and at destinations all have designed attribute rating protocols for rapid assessment. More intensive inventory needs are also identified in this study plan, such as stream condition inventory which utilize existing peer reviewed protocols. In addition to the existing protocols, a training, recordation and documentation process is being developed for consistent future applications across the planning area.

Baseline Data Collection:

Objective: To acquire baseline information on destinations, use trails, designated stock camps and grazing areas that do not have full interdisciplinary team documentation of conditions.

A full list of locations is found in the Monitoring Plan in the Project Record

Table 1: Summary of Baseline data collection needs:

Resource or Feature	Protocol	Locations
Grazing Areas	Meadow assessment and PFC (Study Plan)	170
Designated Stock Camps	Camps designed per standards and guidelines and baseline condition documented.	178
Use Trails	Rapid Assessment (Study Plan)	68
Destinations	Attribute rating (Study Plan)	53

Integrated Monitoring

Objective: To monitor and provide evaluation of management actions in locations where multiple resource concerns or risks have been identified and pack stock use is authorized. This type of monitoring will occur frequently (annually or bi-annually) until desired conditions have been reached at which point continued monitoring will be less frequent.

We have identified the following areas (Table 2) as priority monitoring for multiple resources or features. Specialists assessed priorities for range readiness, campsites, grazing, use trails, wildlife habitat critical areas, destinations, fens and sensitive plants. These priorities were then combined to determine areas of multiple concerns. Through a distillation process of evaluating needs, risk factors, use levels and geographic proximity, the following areas have been determined to be the highest need for regular monitoring for effectiveness and implementation of the decision. Where single resource issues exist, or less risk was identified, the area was considered for the ‘single resource’ category of monitoring and evaluation needs.

At each of these locations, following established monitoring protocol, data and photo documentation will be collected on an annual basis unless noted. Designated campsites, use

trails, grazing, range readiness, destinations, fens, wildlife habitat, impacts to heritage resources will be evaluated.

Table 2: Integrated Monitoring Locations

Analysis Unit	Forest	Destinations	Interval
French Canyon	SNF	French Lake; Elba, L, Moon Lakes; “Waterfall” camp, Royce Lake; Merriam Meadow.	Annual
Purple Bench	INF	Purple Lake; Ram Meadow, Purple Bench, Virginia Meadow.	Annual
Silver Divide	SNF	Grassy Lake, Jackson Meadow, Peter Pande Lake, Olive Lake, Wilbur May.	Annual
Cascade Valley	SNF/INF	Iva Belle, Island Crossing, Second Crossing, Third Crossing, Cascade/Purple Junction.	Annual
Fourth Recess	SNF	Fourth Recess Lake, Third Recess Junction, Hopkins Junction, Third Recess Trail, Third Recess Meadow.	Annual
Sadler	SNF	Sadler Lake and grazing area.	Annual
Upper Fish Creek	INF/SNF	Tully Lake, Upper Fish grazing, Horse Heaven, Tully Hole.	Every 2 years
Glacier	SNF	Golden Trout Lakes, Muriel Lake. Wahoo Lake.	Annual
Graveyard	SNF	Lower Graveyard Lake, Graveyard Meadows, Upper Cold Creek Meadows.	Annual
Rush	INF	Clark Lakes, Spooky Meadow, Weber Lake, Alger Lake, Alger Meadow.	Annual
McGee	INF	Round Lake, Martins Meadow, Baldwin, Steelhead Lake, Big McGee Lake.	Every 2 years
Sallie Keyes	SNF	Sallie Keyes Lake, Boot Meadow.	Every 2 years
Silver Peak	SNF	Mott Lake, Silver Pass Meadows, Pocket Meadow.	Annual
Thousand Island	INF	Thousand Island Lake, Meadow, Badger Lake and Meadow, Garnet Lake and inlet.	Annual
Upper Rush	INF	Davis Lake, Rogers Meadow, Marie Lake, Waugh camp, Donahue camp and meadow.	Annual
Bishop creek	INF	Marie Louise Lake, Long lake inlet, Bull Lake.	Every 2 years
Convict	INF	Genevieve/Edith Lake, Cloverleaf Lake.	Every 2 years
Hilton	INF	Second and Davis Lakes, Hilton meadow, Turk Meadow, 3 rd and 4 th Lakes.	Annual
Pine Creek	INF	Upper Pine Lake, Honeymoon Lake.	Every 2 years
Pioneer	SNF	Mudd Lake, Upper Lakes Basin.	Annual
Sabrina	INF	Moonlight Falls, Dingleberry Lake, Baboon Lake.	Every 2 years
Shadow-Ediza	INF	Shadow Trail corridor, Ediza Lake, Laura Lake.	Annual
Triple Divide	SNF	Slab Lakes, Anne Lake.	Every 2 years
Seldon	SNF	Hilgard Branch, Bear Creek, Rosemarie Meadow, Rose Lake, Lou Beverly Lake.	Annual
King Creek	INF	Anona Lake, Ashley Lake, Superior Lake, Holcomb Lake, Fern Lake.	Annual

Single Resource Monitoring

Objective: This category the third priority for monitoring. It includes three distinct purposes. 1) to monitor locations and/or resources only when triggered by certain events or activity. These locations are generally lower priority but for a variety of reasons they may become important for effectiveness or implementation monitoring. Or, 2) to acquire information in areas of low use areas, low risk areas, or areas of single resource concerns with a prediction that use levels will not cause further degradation. And 3) some of these areas have been identified as representative for other locations in the planning area.

Table 3 Single Resource Monitoring

Location	Monitoring or Evaluation Component	Trigger / Reason	Interval
Crater-Deer (INF)	Critical area management.	If use reports indicate grazing activity is occurring.	Based on reported use
Margaret (SNF)	Grazing. North of Fern Lake, Coyote Lake grazing area, north of Frog Lake.	If use reports indicate grazing activity is increasing from current use.	n/a
Minarets (INF)	PFC at Johnston Meadow.	To determine trend in conditions and effectiveness of grazing closure.	10 years
Volcanic (SNF)	Grazing/critical area management.	If use reports indicate grazing activity is substantively increasing from current use.	Evaluated based on reported use.
Glacier Divide (SNF)	Site condition monitoring.	On-going impacts, strong tribal concerns.	Annually
Second Recess (SNF)	Site condition monitoring.	On-going impacts, strong tribal concerns.	Annually
Hopkins (SNF)	Site condition monitoring.	On-going impacts, strong tribal concerns.	Annually
Lee and Cecil (SNF)	System Trail condition	To determine effectiveness of NSCS on trail condition.	3 years
Packsaddle Lake (SNF)	Use Trail	To determine if low use levels maintain low visibility use trail.	3 years
Bishop Creek (INF)	Marie Louise Lake trail	To determine if low levels of use maintain condition of trail.	3 years
Humphreys Basin (SNF)	Mesa, Tomahawk and Humphrey's Lakes	To determine if use levels maintain condition of trail (Humphreys Lake) or if use trail remains low visibility.	3 years
Lake Catherine	Stevenson Meadow	If use reports indicate grazing activity is substantively increasing from current use.	Evaluated based on reported use.
Cargyle	Stairway Meadow, 77 Corral, Middle East Fork Meadow, Cargyle North Meadow.	If use reports indicate grazing activity is substantively increasing from current use.	Evaluated based on reported use.
Emily Lake	System trail condition (trail temporarily NSCS)	To determine if adequate mitigation has been performed to allow reintroduction of commercial stock use.	After work performed, then once every 5 years.

Location	Monitoring or Evaluation Component	Trigger / Reason	Interval
Staniford Lake	Use Trail Condition (Prohibited)	Evaluate effectiveness of removing commercial stock from use trail to Staniford Lake.	3 years
Sallie Keyes – (Senger Creek)	Use Trail Condition (Hunting access)	Determine change in definition and condition of route on Senger Creek hunter route. (Approved for limited use).	3 years

Toolbox

The following table identifies potential tools for an adaptive management approach to be used over time. All the possible outcomes of actions that may need to be modified or adjusted to meet desired conditions, changing conditions or requests for changes, have been considered. The Toolbox provides guidance to staff, pack station operators, the public, and line officers to help provide consistency in approach.

Unless otherwise noted, elements in the “When to use” column do not all need to be present. They represent different situations that may occur that drive either the need for action, or the need to evaluate and consider whether the tool is appropriate. This provides guidance and is not intended to replace the role and discretion of the decision maker to provide appropriate actions.

Table 4 Toolbox for Pack Station Adaptive Management

Tools	When to Use	How to Use
Designated sites		
Additional designated stock camp. Designated spot and dunnage site. Designated temporary hitch line.	<ol style="list-style-type: none"> 1) When more than occasional competition (5 incidences a year) or conflict occur at destinations for the use of a campsite between pack stations, or between general public and pack stations. 2) When a need is identified and potential stock camps exist and no new impacts would occur OR an additional stock camp could be designed without adverse effect to resources. 3) When a need is identified and a suitable location with no identified risk factors and the use of the area would have no adverse effects to physical, biological, heritage or wilderness resources or the desired condition of the area. 4) When requested by operator. 	<p>District Ranger directs an interdisciplinary team to assess campsite, either through reports generated by wilderness ranger, or field visit.</p> <p>Evaluation must include:</p> <p>Heritage clearance,</p> <p>Assessment of trail access so that if risk factors are present they can be mitigated,</p> <p>BMP and assessment of potential compliance of BMPs with expected use levels (BMP Manual, 2000, p. 104), and</p> <p>Wilderness assessment of location's compatibility with recreation category and attributes of solitude, wilderness character and capacity.</p> <p>Designated site must be designed and inventoried according to protocol.</p> <p>Anticipated use level must be identified.</p>
Assigned site (for individual pack stations).	<ol style="list-style-type: none"> 1) When an operator requests to have an assigned site reserved for their use only and it is an existing designated stock camp. 2) When no conflicts between operators would likely result. 	Follow procedures for assigned sites in Forest Service Handbook 2709.11 Section 37.21 (h).
Remove a Designated Stock Camp from use.	<ol style="list-style-type: none"> 1) If BMP compliance cannot be met 2) If site has not been inventoried and designed within two years (2008). 	Prohibit use of site in annual operating plans.
Use Trail Management		
Stabilize use trail.	<ol style="list-style-type: none"> 1) Use trail shows signs of deterioration and instability under current use and this use is otherwise consistent with destination management. 2) Few risk factors are present that would cause continuing impacts once the trail is repaired. 3) Repairs are incidental, (such as primitive barriers and 	<p>Wilderness ranger evaluates UT during normal monitoring cycle, or reports of unusual impacts. Identify key point features or areas of impact, and the presence of risk factors as well as assessment of potential repairs.</p> <p>If repairs are of incidental scale and can be implemented without changing the general undeveloped character of the use trail and there would be minimal off-trail</p>

Tools	When to Use	How to Use
	user redirection/realignment or low-profile drainage or stabilization structures) and these would not change the generally undeveloped character of the use trail.	disturbance, wilderness manager determines prescription for repairs. If work has potential to change character of trail or may disturb off-trail resources, Wilderness Manager consults with appropriate specialists prior to implementation.
Add use trail to system inventory and maintain/manage as system trail.	<ol style="list-style-type: none"> 1) Use trail is showing signs of degradation which require more than incidental management or treatments to stabilize, but could be corrected through standard trail treatments. 2) Use trail is being used by commercial and non-commercial public at moderate to high levels, and is likely to continue. 3) Use is consistent with other management criteria at destination, and is best served with a managed transportation system. 	<p>Wilderness ranger evaluates UT during normal monitoring cycle, or reports of unusual impacts. Identify key point features or areas of impact, and the presence of risk factors as well as assessment of potential repairs.</p> <p>Appropriate specialists assesses trail issues, either through reports generated by wilderness ranger, or field visit if potentially large extent or controversial.</p> <p>Evaluate: Level of current and future work needed; whether this work may have effects on heritage or other resources (if so, conduct appropriate surveys); what level of trail development is appropriate for anticipated use type and levels, recreation category and destination management.</p> <p>Disclose intent of adding trail(s) to system to public, and conduct appropriate planning and environmental process.</p>
Approve a use trail not currently approved.	<ol style="list-style-type: none"> 1) Access is requested to an area within or in close proximity to an existing approved destination (<i>see destination boundary adjustment, below</i>); OR, access is requested on a UT which was previously prohibited. 2) Use to destination is otherwise consistent with desired conditions. 3) Conditions which originally created the need to prohibit use have changed or been corrected. 4) Route is deemed to be stable at the anticipated use level. 	<p>Wilderness ranger evaluates UT after request. Identify key point features or areas of impact, and the presence of risk factors as well as assessment of potential stabilization.</p> <p>Interdisciplinary team assesses trail issues, either through reports generated by wilderness ranger, or field visit if potentially large extent or controversial.</p> <p>Evaluate trail stability and consistency with destination management, and assign appropriate level of use at destination.</p>
Remove use trail from use by Pack Station.	<ol style="list-style-type: none"> 1) Use trail shows signs of deterioration and unacceptable impacts of resources, <i>and</i> 2) Risk factors exist which would make it highly unlikely the use trail could be stabilized without unacceptable changes in the trail character. 3) Impacts to TES, Heritage Resources, or other critical resources cannot be mitigated with continued use. 4) Removal of use by pack station will substantially 	<p>Wilderness ranger evaluates UT during normal monitoring cycle, or because of reports of unusual impacts. Identify key point features or areas of impact, and the presence of risk factors as well as initial assessment of potential mitigation.</p> <p>Interdisciplinary team assesses UT issues, either through detailed reports generated by wilderness ranger, or field visit, if potentially large extent or controversy.</p> <p>IDT evaluates: Extent of physical mitigation and</p>

Tools	When to Use	How to Use
	correct use trail issues. Other non-commercial use types and levels will not likely perpetuate continued problems if pack stock use is removed.	potential change in character needed to stabilize impacts if use were to continue, risk factors, future maintenance considerations, effects on TES, heritage, or other resources, and consistency with Recreation Categories and destination management; also, extent to which commercial stock use is creating the impacts and expectations for improvement with removal of commercial stock.
Destination Quota Adjustment		
Reduce levels of use at a destination.	Impacts at destination, including trails, use trails, grazing areas, campsite conditions etc, are deteriorating. Conflicts become apparent between commercial visitors, and /or between commercial and non commercial visitors.	District Ranger directs an assessment of the destination in question to determine if standards, guidelines and desired conditions are being met. Adjustments should be made based on this assessment. Resource impact ratings from baseline assessment should indicate conditions are deteriorating and commercial pack stock use may be a contributing factor.
Adjust destination quota upward.	Identified work is accomplished as identified in DMS (such as trail is repaired or improved). Desired condition is met and commercial operator identifies an ability to increase use and maintain condition. Requested by operator.	District Ranger directs an assessment of the destination in question to determine if standards, guidelines and desired conditions are being met. Adjustments should be made based on this assessment. Resource impact ratings from baseline assessment should indicate improved conditions.
Destination boundary adjustment.	Commercial operator demonstrates recent past use (within 10 years) occurred outside but adjacent to the current boundary of a destination.	District Ranger should direct an assessment of the locations in question and document conditions including presence of risk factors and determine if standards, guidelines and desired conditions are being met. Adjustments should be made based on this assessment.
Add a new destination.	Upon request by pack station.	Interdisciplinary team assessment, including destination attribute rating, photo-point identification, campsite inventory, and trail and/or use trail assessment.
Allow case by case destination use for hunting.	Upon request by pack station, at least two weeks prior to hunting season.	Wilderness manager assesses location and will need to determine that are no concerns with the level of use, and it will not have any adverse effects to trails, campsites, and/or cross country travel will not lead to trailing impacts.
Modification of Stock at One Time in the Wilderness.	Upon request by pack station or when the FS determines unacceptable impacts to be occurring.	District Ranger will direct an assessment of the locations affected by stock at one time and document conditions including presence of risk factors and determine if

Tools	When to Use	How to Use
		standards, guidelines and desired conditions are being met. Adjustments should be made incrementally based on this assessment.
Trail Suitability		
Designate trail that is currently available to commercial stock use as “Not Suitable for Commercial Stock”.	<ol style="list-style-type: none"> 1) Trail shows signs of deterioration and unacceptable impacts of resources, <i>and</i> 2) Risk factors exist which would make it highly unlikely the trail could be stabilized without unacceptable changes in the trail character. 3) Impacts to TES, Heritage Resources, or other critical resources cannot be mitigated under continued commercial stock use. 4) Removal of use by pack station will substantially correct issues. Other non-commercial use types and levels will not perpetuate continued problems if pack station use is removed. 	<p>Wilderness ranger or trail staff evaluates trail during normal monitoring cycle, or because of reports of unusual impacts. Identify key point features or areas of impact, and the presence of risk factors as well as initial assessment of potential mitigation.</p> <p>Interdisciplinary team assesses trail issues, either through detailed reports generated by wilderness ranger, or field visit if potentially large magnitude or controversial.</p> <p>IDT evaluates: Extent of physical mitigation and potential change in character needed to stabilize impacts if use continues, risk factors, future maintenance considerations, effects on TES, heritage, or other resources, and consistency with Recreation Categories and destination management; also, extent to which commercial stock use is creating the impacts and expectations for improvement with removal of commercial stock.</p>
Make trail which was previously designated NSCS or “NSCS until repaired” available to commercial stock.	<ol style="list-style-type: none"> 1) Use is requested for trail that was formerly designated “NSCS until repaired” or NSCS. 2) Use to destination is otherwise consistent with desired conditions. 3) Conditions which originally created the need to prohibit use have changed or been corrected. 4) Route is deemed to be stable at the anticipated use level. 	<p>Focused field assessment and report by wilderness ranger verifying that trail has been adequately stabilized. Review by IDT.</p> <p>IDT evaluates: mitigation of key impacts has occurred, impacts to TES, heritage and other resources not likely to occur by reopening trail. Limiting factors that determine level of destination use after trail is available.</p> <p>Trails which were designated as NSCS until repaired are cleared in the Operating Plan. Trails that were designated NSCS go through appropriate public process to amend current decision.</p>
Allow early season trail opening (i.e.shoveling, sanding).	<ol style="list-style-type: none"> 1) Request for shoveling, sanding . (This can occur prior to access). 2) Identified concern with trail or destination. 	<p>Identify key locations that indicate destination or trail readiness based on intended trips.</p> <p>Site visit to key locations prior to access being granted.</p>
Grazing Management		

Tools	When to Use	How to Use
Allow grazing outside of an existing key area or grazing zone.	Request by packer or nearby grazing zones at capacity or too far from destination to be used. Destination should be no greater than ½ mile.	Interdisciplinary team visits proposed grazing area, assesses condition and suitability. Team members will as a minimum be wilderness, hydrology, range, botanist, heritage, and wildlife specialist. If determined to be suitable, the IDT completes meadow evaluation, ecological status (Rapid Assessment Process from Wilderness Plan, Assessment of Benchmarks, Appendix G, page 7), Proper Functioning Condition assessment, designates any critical areas, estimates initial stock nights available, and identifies any needed mitigations.
Increase or decrease stock nights temporarily (during a season for the remainder of that season only) within an existing grazing zone.	Change in annual conditions such as wet or dry year or consecutive years indicates productivity may be higher or lower than normal or a request by packer for an increase, and adequate monitoring data shows that utilization and other standards have not yet been reached.	Adequate monitoring data includes photographs and vegetation utilization measurements for key areas (Grazing Response Index method as described in the Wilderness Plan Appendix G, page 10) and streambank alteration measurements (R5 Rangeland Analysis and Planning Guide, Point Method, pages 5-10 to 5-15). Adequate monitoring data also includes photo-points in critical areas and written critical area evaluations.
Increase stock nights in existing key area or grazing zone (long term, for more than one season).	Upon request by pack station.	If current monitoring of vegetation utilization (Grazing Response Index method as described in the Wilderness Plan Appendix G, page 10), critical area protection, stream bank alteration (R5 Rangeland Analysis and Planning Guide, Point method), and trend monitoring (see Assessment of Benchmarks, Appendix G, page 7) shows that standards for stream condition and vegetation composition are obviously being exceeded, then an interdisciplinary team (members will be hydrology, range, and wildlife specialist) re-calculates stock nights of forage available and identifies any management needed to allow allocation. “Degraded meadows and streams will have obvious upward trend in condition and function” (2001, Wilderness Plan ROD, page 17): Therefore, for vegetation, a representative sample indicates that the majority of the meadow (over 50%) must be in high seral condition and no more than some isolated, or patchy changes away from the potential natural plant community, over less than 1/3 of the area. Stream PFC analysis must show an obvious upward trend in stream functional condition. No headcuts can be

Tools	When to Use	How to Use
		deeper than the rooting depth of adjacent potentially stabilizing vegetation or in the lower 1/3 of the meadow. If there is a portion of the meadow with insufficient recovery, it can be excluded from the area able to be grazed. The area with sufficient recovery can be opened, and methods such as fencing, hobbling, etc. can be used to prevent access into the remaining degraded areas.
Reduce stock nights in existing key area or grazing zone or rest meadow.	<ol style="list-style-type: none"> 1) Monitoring shows that grazing area is not meeting standards/desired conditions. 2) More critical areas are found in grazing area. 	<p>If monitoring shows that meadow vegetation or stream condition in downward trend, or utilization or trampling standards are not being met, modify grazing management if possible, or suspend grazing if modification is not sufficient. See monitoring plan for specific monitoring protocols.</p> <p>Use the Grazing Response Index method (Wilderness Plan page 24, and Appendix G) to determine if utilization standards are being met. For trampling, use the Point Method for measuring streambank alteration. For stream condition, use the PFC protocol.</p>
Allow grazing in an area rested due to resource impacts.	Upon request by pack station.	<p>Rest continues until an interdisciplinary team establishes baseline monitoring and then accomplishes subsequent monitoring that quantifies an upward trend with resource conditions sufficient to sustain grazing and stock entry (see Assessment of Benchmarks, Appendix G, page 7). Once this monitoring confirms satisfactory rangeland condition (see Glossary) the IDT then completes a meadow evaluation (including PFC) and identifies any critical areas or mitigations needed. District Ranger reviews information and directs appropriate environmental process.</p> <p>“Degraded meadows and streams will have obvious upward trend in condition and function” (2001, Wilderness Plan ROD, page 17): Therefore, for vegetation, a representative sample indicates that the majority of the meadow (over 50%) must be in high seral condition and no more than some isolated, or patchy changes away from the potential natural plant community, over less than 1/3 of the area.</p> <p>Stream PFC analysis must show an obvious upward trend in stream functional condition. No headcuts can be deeper than the rooting depth of adjacent potentially stabilizing vegetation or in the lower 1/3 of the meadow</p>

Tools	When to Use	How to Use
		in the portion of the meadow where grazing would occur. If there is a portion of the meadow with insufficient recovery, it can be excluded from the area able to be grazed. The area with sufficient recovery can be opened, and methods such as fencing, hobbling, etc. can be used to prevent access into the remaining degraded areas.
Open meadow that is closed due to trail problems.	Trail repair or relocation is completed.	If meadow has been analyzed by ID team and found suitable except for trail issues, open meadow to grazing and calculate stock nights. If meadow has not been analyzed, interdisciplinary team visits meadow and determines suitability and capacity.
Identify additional critical areas.	Surveys, monitoring, or other reports of a previously unknown Yosemite toad population, sensitive riparian plant species population, fen, or other resource concern within a grazing area.	Appropriate specialist confirms presence of a critical area. District Ranger directs and assessment of the impacts and effects to critical areas. If no negative impacts are identified, District Ranger can direct staff to adjust estimated grazing capacity so that critical area is not included in calculation and inform permit administrator and packer(s) of presence of critical area and new capacity. If there are negative impacts, District Ranger works with permit administrator and packer(s) to develop a grazing strategy that will protect the critical area.
Use of Temporary (i.e. Electric Tape Type or “Quick Corral”, but may be barbed wire or other fence type depending upon assessment) Fence for enclosure, enclosure or drift fence.	Packer proposes to use temporary electric “Quick Corral” type fence or other temporary fencing to either exclude stock from a critical area or keep stock within a suitable area or to contain stock as in a drift fence situation. Use may be one time to the entire season.	The Permit Administrator consult with Range and Wilderness Staff and other staff to determine whether additional work is needed (such as Botanical and Heritage Resources) and documents in permit file the resulting determination of the suitability and feasibility of using temporary fence at the proposed location. The fence location and duration are detailed in the Annual Operating Plan, or in a mid-season letter amending the AOP. Staff will consider and identify the location and the shortest time period that will accomplish the stock containment or resource protection needed. Staff will consider and identify the location and the shortest time period that will accomplish the stock containment or resource protection needed. District Ranger directs analysis, evaluates assessment and makes decision. Ensure completion of Section 106 prior to approval.

Tools	When to Use	How to Use
Drift Fences		
Add drift fence.	Packer proposes new fences or, Grazing zones requires resting and fences provide protection for meadow.	District Ranger directs staff to conduct a minimum requirement analysis and appropriate environmental analysis.
Remove drift fence.	No longer serves to protect resources or fulfill stock management objectives or Fence falls into disrepair and/or has not been used for five years or Fence used only for convenience to hold stock for packer, not for resource protection.	District Ranger directs appropriate specialists and permit administrators to prepare evaluation of the effectiveness of the drift fence then determines appropriate course of action. Ensure completion of Section 106 prior to removal of drift fence.
Extend or relocate existing drift fence.	Upon request by operator, and other approved practices have failed (e.g. use of electric fence) or, Significant resource issues occur related to commercial stock grazing or, Where stock management problems lead to unsafe situations for visitors. FS determines unacceptable, unmitigatable resource impacts or conflicts at current site of drift fence and the drift fence has been determined to be necessary.	Appropriate specialists assess need for drift fence vs. other alternative stock management practices. Alternative less intrusive stock management practices have been demonstrated to be unsuccessful. Fence is shown to be last resort and compliant with all current policy and standards. Environmental analysis is completed for construction of new facility in the wilderness. Ensure completion of Section 106 prior to relocation of drift fence.
Campfires		
Allow campfires by pack stations in areas above elevational closure.	Upon request by pack station	District Ranger directs an assessment of proposed area that includes proximity to other visitors camping and potential conflicts.
Adjustments to elevational fire closure.	When firewood availability is abundant enough to support campfires above 10,000 or 10,400 foot elevational closure. When firewood is not available in enough abundance to support continued campfire use When requested by packer	If campsite inventory indicates that enough campsites (at least more than 2 sites rated at a "3" or lower for firewood availability) and no conflicts with adjacent areas or within a destination would occur. When firewood ratings from campsite inventory rate out at "4" and "5" at any given destination, area should be closed to campfire use.
Party Size		
Identify party size limitations.	When reports indicate campsite will not accommodate large number of campers or pack stock without going outside the existing site.	District Ranger directs wilderness manager or permit administrator to evaluate site during normal monitoring cycle, or as a result of reports of unusual impacts. Consider current/recent past tally sheet use reports to

Tools	When to Use	How to Use
		determine appropriate party size.
Historic Properties Management Plan (HPMP)		
Management of heritage resources.	When operations occur in the vicinity of a known heritage resource.	Direction will be provided in the HPMP for each site within the operating area.
	1) Discovery of heritage resources. 2) Inadvertent effect	Modify HPMP.

THIS PAGE INTENTIONALLY LEFT BLANK

Record of Decision – Appendix B: Destination Management

The *Destination Management Strategy* found in this section provides a summary of the management actions at destinations. It is intended to be a strategy whereby managers, field personnel, pack station operators, and other interested parties can understand the integration of actions at each destination. Also, and perhaps most important, this strategy describes conditions that we intend to maintain at each destination. Since the ability to actively manage these activities over time is at the forefront of the selected alternative, this strategy becomes the starting point intended as a working document that describes current conditions and the actions needed to achieve the desired conditions.

ANSEL ADAMS EAST

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
1. Parker				
Destination: Parker Lake	Access	Parker Bench Trail observed Trail Class 3 and generally stable. Used for day rides to wilderness boundary.	Maintain trail stability.	Trail is suitable for commercial pack stock use at proposed levels, primarily day rides and occasional overnight use with pack stock.
	Recreation Category Setting	Recreation Category 1, fair amount of private and commercial use; and in sight and sound of the highway. High day use area.	Recreation Category 2, off primary trail; manage for low levels of use of Recreation Category 2.	Change recreation category from 1 to 2 to be consistent with conditions at lake specifically day use (hiking) of area.
	Use Levels 01-04	None reported, but known use prior to 2001.		Allow up to 4 spot/dunnage trips. Use of area at high end of range during heavy snow years, and for occasional all expense trips. Use level will be consistent with maintaining setting and desired campsite conditions.
	Grazing	No grazing reported or requested.	Maintain current conditions.	No grazing.
	Campsites	Low density of sites, low to	Prevent creation of new camp	Designate 1 stock camp in

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		moderate condition class.	sites, maintain low density.	vicinity of outlet of Parker Lake.
	Other Issues	Area denuded by sheep bedding and flooding.		
2. Rush Creek				
Destination: Clark Zone (Summit Lake / Clark Lakes / Agnew Pass	Access	Summit: Clark Lake Trail observed Trail Class 3, Agnew Pass observed Trail Class 2; Clark: generally stable, Clark Lake Trail observed Trail Class 3, Agnew Pass observed Trail Class 2; Spooky-Clark cutoff observed Trail Class 2. All generally stable. Alternate route down Spooky Canyon in rough condition, too steep to practically maintain. Not safe for stock below wilderness boundary. Agnew Pass: Agnew Pass Trail observed Trail Class 2, steep, generally stable. Clark to PCT Trail Class 3, generally stable.	Summit: Ensure trail stability. Clark: Maintain condition and stability. Keep use to minimum on Spooky Trail. Agnew Pass: Maintain trail stability.	All system trails suitable for commercial stock use at levels prescribed. Minimize use of Spooky Trail to maintain trail stability.
	Recreation Category Setting	Summit Lake Recreation Category 2; low to moderate use and impact, moderate to high opportunities for solitude. Clark Lake Recreation Category 2; moderate to high recreational impacts, moderate opportunities for solitude. (Recreation Impact Rating = 1.6)	Summit: Few, low condition rating campsites, moderate to high opportunities for solitude. Clark: Maintain area as moderately used destination with moderate to high impacts concentrated at few sites. Maintain moderate opportunities for solitude.	
	Use Levels 01-04	Summit Lake: FPT: 0-1 trips, 0-3 stock Clark Lake: 7-14 trips, 62-99 Stock Agnew Pass: none reported		Summit Lake: up to 2 spot and dunnage trips (FPT) will maintain high opportunities for solitude. Clark Lake: up to 15 (FPT) spot/dunnage trips and use of area as full service all expense site, is consistent level of use with Recreation Category 2

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
				popular destination. Agnew Pass: 4 trips (Reds).
Destination: Clark Zone Cont.	Grazing	Associated grazing is in the Spooky Grazing Zone. Reported stock nights (2001/2002/2003) 197/78/119. Low to moderate localized vegetation composition alteration at both Upper and Lower Spooky. Spring with fen characteristics at Upper Spooky with moderate trampling.	Summit Lake: maintain or improve vegetative composition and cover. Maintain functioning of area with fen characteristics.	Allow grazing in Spooky Grazing Zone at 78 stock nights, Lower Spooky 25 stock nights, Upper Spooky 41 stock nights, with 30% allowable utilization, negligible stock impacts in critical area (fen).
	Campsites	Clark Lake: Large designated stock holding campsite meets BMPs. Deep manure at highline. Multiple dead trees at designated site.	Clark Lake: Designated stock holding campsite meets BMPs. Reduce manure accumulation at highline. Reduce total area of impact.	Designated 1 stock camp at Clark Lakes. Reduce total area of designated site. No stock camp at Summit Lake.
3. Rush Creek				
Destination: Alger Lakes	Access	Alger Trail observed Trail Class 2, Resource Rating 1, some instability below lakes. Trail through meadow slightly non-compliant with RCOs. Gem Pass Snow route (non-system), past maintenance as Trail Class 2, Resource Rating 1.	Maintain current stability and low resource ratings.	Trail suitable for commercial stock at use levels prescribed.
	Recreation Category Setting	Recreation Category 2; very low use and overall recreation impacts are minor. Opportunities for solitude are high. Recreation Impact Rating = 1.0.	Maintain low use and overall impacts remain minor. Maintain high opportunities for solitude.	
	Use Levels 01-04	0-6 Trips, 0-62 Stock		Up to 10 spot/dunnage trips and use for all expense trips will maintain low recreation category use levels and conditions.
	Grazing	Alger Lakes: Fen and occupied Yosemite toad habitat with slight to moderate trampling and chiseling impacts; lakeshore sensitive plant potential habitat with no noted impacts. Negligible hydrologic function alteration. Stream is at PFC. Reported use: 332/184/202. Minor localized vegetation impacts.	Maintain functioning fen; maintain good lakeshore condition. Maintain high quality Yosemite toad habitat. Negligible hydrologic function alteration. Stream is at PFC. Vegetation is at high-seral status.	Allow grazing at 332 stock nights with applicable standards, 40% AUF, 20% streambank alteration. Critical areas closed to stock entry and grazing.
	Campsites	Designated stock holding site on east side of lake meets BMPs. Campsite shows moderate compaction, vegetation	Designated stock holding sites and spot/dunnage site meets BMPs. Maintain or decrease existing camp perimeter.	Designate 1 stock camp site.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		loss and total area.		
	Other Issues		Maintain or improve firewood availability condition.	Allow case by case packing in of wood at Alger Lakes.
4. Rush Creek				
Destination: Gem / Waugh Lakes	Access	Rush Creek observed Trail Class 3, stable even with high use. Access trails to camps along primary corridor short. Some instability on inherent camp access trails. Gem Trail observed Trail Class 3, stable even with high use. Access trails to camps at Gem Lake very short. Waugh Trail observed Trail Class 3, stable even with high use. Access trails to camps along primary corridor short, with some instability. Social trails between camp and lake contributing a small amount of sediment to Waugh Lake.	Rush Creek: Ensure camp access trails are stable. Waugh Lake: Ensure camp access trails and social trails from camps are stable.	Rush Creek: Identify best route to "Tractor Camp" (vs. Bill Henry Camp) below Waugh dam.
	Recreation Category Setting	Rush Creek: Recreation Category 2. Moderate impacts at campsites; moderate opportunities for solitude. Waugh Lake: Recreation Category 2. Presence of dam and reservoir has high impact on wilderness character. Recreation impacts moderate, but negligible in comparison to dam. Recreation Impact Rating 1.2.	Maintain moderate opportunities for solitude.	
	Use Levels 01-04	Rush Creek: 23 trips; 52-158 stock Waugh FPT: 0-5 trips, 0-52 stock Reds: 0-2 trips, 0-12 stock		30 trips in zone to one operator, includes Gem Lake, Waugh Lake and Rush Creek for spot/dunnage trips and use for all expense trips consistent with primary trail corridor. Use will maintain moderate opportunities for solitude. Use levels consistent with primary trail corridor of Recreation Category 2.
	Grazing	Rush Creek: none reported Waugh Lake: none reported		Rush Creek: no grazing Waugh Lake: no grazing
	Campsites	Rush Creek: existing campsites have moderate impacts from repeated use, compaction, vegetation loss and bare core are evident.	Rush Creek: use existing campsites for spot and dunnage. Relocate all expense campsite below Waugh dam. Waugh Lake: stock holding and	Rush Creek : designate 3 stock camps. Close and rehabilitate campsite known as "Bill Henry", and relocate to "Tractor Camp". Secondary camp is "Dink's

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		Waugh Lake: 1 stock holding site meets BMPs.	spot/dunnage sites meet BMPs.	Camp". Waugh Lake: designate 1 stock camp at Waugh Lake inlet known as "Bridoff" and contain camp site.
	Other Issues			Maintain 2 high-line sites for day rides at Gem Lake (Crest Creek junction).
5. Rush Creek				
Destination: Weber Lake	Access	Weber Lake observed Trail Class 3, generally stable. Weber Spur use trail (not on system) to campsite at outlet is well-defined, steep, Resource Rating 1. Spur trail appears to be diverting surface water, near junction with system trail. Sullivan Lake use trail: Resource Rating 1, indistinct near Sullivan Lake. Not stock suitable.	Weber Spur use trail should not divert surface water. Ensure stability of Weber Spur use trail at approved use levels. Keep Sullivan use trail low profile and stable.	Weber System Trail downgrade to Trail Class 2. Add Weber Spur use trail to system (Trail Class 2). No commercial stock use on Sullivan Lake use trail.
	Recreation Category Setting	Recreation Category 2; low to moderate recreation impacts, moderate to high opportunities for solitude, low to moderate capacity for camping. Recreation Impact Rating = 1.6.	Maintain for moderate to high opportunities for solitude.	
	Use Levels 01-04	8-12 Trips, 57-84 Stock		Up to 12 spot and dunnage trips consistent with Recreation Category 2 will maintain moderate to high opportunities for solitude.
	Grazing	None reported		No grazing.
	Campsites	Some campsites show moderate to high impact, mutilations, vegetation loss.	Low condition rating at campsites.	No stock camp. Require packer to pack in firewood for clients, set back campsites from water.
6. Rush Creek				
Destination: Crest Creek	Access	Crest Creek use trail not defined, Resource Rating 0 with low-mid risk factors.	No increase in trail visibility or impacts.	Allow limited cross-country travel.
	Recreation Category Setting	No evidence of trail, no impacts visible. High opportunities for solitude.	Maintain high opportunities for solitude.	
	Use levels 01-04	None reported, but known use prior to 2001.		Up to 2 spot and dunnage trips for fall season hunting only. Utilize low stock numbers. Low use level will ensure no

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
				new trail effects and high opportunities for solitude.
	Grazing	None reported.		No grazing.
	Campsites	No visible camps.	No visible camps.	No stock camp.
7. Upper Rush				
Destination: Davis Lake	Access	Davis Lake Trail observed Trail Class 2, Resource Rating 1; Upper Davis use trail Resource Rating 1, lightly defined, light use. Risk factors present. Rodgers use trail (access to grazing) Resource Rating = 2.5, causing slight diversion of spring channel surface flow, becoming more impacted at crossings and meadows.	Prevent change on Upper Davis use trail. Rodgers use trail: remove use from the most fragile areas, stabilize trail at crossings/springs.	Prohibit stock use on Upper Davis use trail. Determine better route to Rodgers grazing.
	Recreation Category Setting	Recreation Category 2. Moderate opportunities for solitude. Recreation Impact Rating = 1.4, riparian concerns and risk factors.	Maintain Recreation Category 2 conditions for destination off primary trail.	
	Use Levels 01-04	0-6 trips, 0-54 stock		Up to 6 spot and dunnage trips and use of designated site for all expense trips will maintain Recreation Category 2 conditions for destination off primary trail.
	Grazing	Davis Rodgers Zone: reported stock nights: 126/168/104. Localized minor vegetation alteration. Yosemite toad breeding habitat critical area in Upper Davis and Rodgers Lakes meadows with light to moderate trampling and chiseling impacts from grazing. Lakeshore potential habitat for Tioga sedge has trampling impacts at Marie and Rodgers Meadows. Streams at PFC and hydrologic function alteration only at the benches east of Davis Lake.	Streams at PFC and no hydrologic function alteration in meadows/grazed areas. Maintain vegetation at desired condition. Maintain high quality Yosemite toad habitat. Maintain Tioga sedge habitat in good condition.	Allow grazing in zone at 128 stock nights 3-year rotation between Davis, Davis benches and Rodgers. Packer manages stock to keep out of critical areas. Critical areas closed to stock entry and grazing.
	Campsites	One stock holding site at the north tip of Davis Lake meets BMPs.	Stock holding and spot/dunnage sites meet BMPs. Contain campsite impacts.	Designate 1 stock camp at Davis Lake. Contain campsite impacts.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
8. Upper Rush				
Destination: Donahue (includes Marie Lake)	Access	PCT Primary access, generally stable. Camp access trail crosses creek at hardened ford. Mountain yellow-legged frog stream habitat critical area in Rush Creek at stock crossing to camp with loss of undercut bank habitat from stock chiseling of streambanks.	Ensure camp access (Donahue) trail stability. No additional undercut streambank habitat loss, maintenance or restoration of existing habitat condition.	Marie Lake Trail NSCS. Stock prohibited on Marie Lakes Meadow use trail (URU02). Monitor stream crossing at Donahue stock to ensure no additional undercut bank loss, implement additional management measures such as re-location if crossing continues to exacerbate undercut bank loss.
	Recreation Category Setting	Recreation Category 2, low to moderate opportunities for solitude.	Maintain moderate opportunities for solitude.	
	Use Levels 01-04	0-2 trips., 0-10 stock		Up to 2 trips for spot and dunnage and use of site for all expense trips. Low commercial use for a Recreation Category 2 primary trail corridor.
	Grazing	Meadow between camp and the creek is severely compacted and stream bank has trampling over about 10% of its length in the meadow. Mountain-yellow-legged frog streambank habitat has collapsed undercut bank areas from stock crossing. Meadows east of camp have good hydrologic function. Localized minor vegetative alteration. Reported grazing: 45/127/36.	Meadow between camp and the creek has only slight compaction and stream bank trampling remains below 20%. Maintain high quality mountain yellow-legged frog undercut streambank habitat. Maintain meadow at vegetative desired condition.	Allow grazing at 127 stock nights, creek crossing and associated meadow identified as a critical area. Apply 40% AUF and 20% streambank standard. Critical areas closed to stock entry and grazing.
	Campsites	Campsite is moderate impact, large barren core area and vegetation loss, moderate in total area.	Contain size of campsite.	Designate 1 stock camp at Marie Meadow and 1 stock camp Donohue. Manage Donahue camp for traveling trips, and Marie for operator at Silver Lake.
9. Upper Rush				
Destination: Lost Lake	Access	Lost Lake use trail: Resource Rating 0, not visible (cross country route).	Ensure trails do not become evident.	Allow limited cross-country travel.
	Recreation Category Setting	Recreation Category 1. No evidence of trail use, high opportunities for solitude.	No visible trail or impacts.	
	Use Levels 01-04	None reported, but known use prior to 2001.		Up to 2 spot and dunnage trips for fall hunting season only. Low use, and season of use, is consistent with Recreation Category 1 and will maintain

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
				high opportunities for solitude and no evidence of trail.
	Grazing	No grazing reported.		No grazing.
	Campsites	No stock camps.	No stock camps.	No stock camps.
10. River				
Destination: River Trail	Access	River Trail observed Trail Class 3, recently repaired, generally stable.		River Trail to Garnet Lake NSCS.
	Recreation Category Setting	Recreation Category 2, high use trail corridor with low opportunities for solitude while traveling, moderate to high while camping.	Maintain for low impacts outside of trail and campsites. Manage for moderate opportunities for solitude while traveling and moderate to high opportunities for solitude while camping.	
	Use Levels 01-04	No reported use.		Up to 10 spot and dunnage trips, relatively low use for Recreation Category 3 high use trail corridor.
	Grazing	PCT junction River Trail and Olaine Meadows have potential habitat for sensitive species. Reported grazing in zone: 0/46/50.	At desired high-seral vegetative condition.	Allow grazing in zone at 78 stock nights, with 30% allowable utilization, 20 percent stream bank alteration, Critical areas closed to stock entry and grazing.
	Campsites	No stock camp.	No stock camp.	No stock camp.
11. Thousand Island				
Destination: Garnet Lake	Access	Garnet Lake camps use trail from PCT observed Trail Class 2, Resource Rating 2.5, awkward, unstable, heavily used by commercial stock and hikers. Garnet-Emerald Trail observed Trail Class 2, Resource Rating 4, (abandoned JMT) poorly maintained, moderate to severe erosion. Garnet grazing use trail, Resource Rating 4, poorly located, through lake, creeks. Meadow between Garnet and Emerald Lakes has local moderate hydrologic function alteration which may be result of trail location.	Reduce erosion and effects of the un-maintained Garnet-Emerald trail. Ensure stable access to camps from PCT. Prevent impacts from grazing trail.	Garnet Lake - Emerald Lake Trail NSCS; Trail Class 1. Install some basic drainage, stabilization structures. Improve trail to camps from PCT.
	Recreation Category Setting	Recreation Category 3. High level of recreation use impact. Recreation Impact Rating = 2.8. Low to moderate opportunities for solitude.	Allow for high levels of use by concentrating impacts and managing sites. Manage for lowering overall resource rating by containing impacts.	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Use Levels 01-04	11-30 trips, 40-296 stock		Up to 20 spot and dunnage trips and use for all expense trips. Decrease commercial use to lower impacts in Recreation Category 3.
	Grazing	Stream determined functional at-risk with a downward trend. Meadow has slight hydrologic function alteration. Localized vegetative composition alteration in lakeshore meadows. Riparian habitat at west shore in fair condition; with current stock trampling and chiseling impacts including fragmented sod and reduced vegetative cover. The majority of the meadows never reach range readiness. Area with fen characteristics at risk due to stream incision.	Condition of the stream improves toward proper functioning with stable banks. No alteration of meadow hydrologic function with no sod fragmentation. Protect wet soils from trampling and sod fragmentation. Vegetative cover increases. Improve habitat condition by reducing trampling and chiseling impacts in wet meadow/wetland types. Fen in functioning condition.	Unsuitable, no grazing allowed.
	Campsites	Stock holding site at the north side of the lake is within 100 feet of water and is causing sediment to enter water.	Stock holding site should be over 100 feet from water, and should not cause sediment to enter water.	Designate 1 stock camp at Garnet Lake. Contain and set back camp site from lake and meadow.
	Other Issues			Implement grazing action.
12. Thousand Island				
Destination: Thousand / Upper San Joaquin	Access	Thousand Island Lake: trail observed Trail Class 2, Resource Rating 3, incised along lakeshore, few to no structures. Badger Lake Spur (to camps): observed Trail Class 2, Resource Rating 1. Stable w/ no risk factors. Badger Meadow grazing use trail, steep, some erosion.	Thousand Island: Stabilize access to approved camps. Badger Lake: ensure stability of grazing access trail from lake. Emerald Lake: meadow should have negligible hydrologic function alteration.	Badger Lake use trail add to system as Trail Class 2.
	Recreation Category Setting	Thousand Island: Recreation Category 3 with crowding and high use. Low opportunities for solitude. Recreation Impact Rating = 2.0. Upper San Joaquin: Recreation Category 3. Badger Lake: Recreation Category 3, moderate impacts, Recreation Impact Rating = 1.8. Emerald Lake: Recreation Category 3. Low opportunities for solitude.	Reduce crowding conflicts and trail encounters in zone. Thousand Island: concentrate and contain recreational impacts. Badger Lake: reduce overall impact rating by improving campsite conditions. Emerald Lake: maintain high use with moderate recreation impacts.	
	Use Levels 01-04	Thousand Island: Reds: 26-58 trips, 150-398 stock. FPT: 0-2 trips, 0-15 stock. Upper San Joaquin: Reds: 0-6 trips, 0-53		Up to 45 trips spot and dunnage to one operator, to 3 destinations within this high use Recreation Category 3 area.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		stock. Badger: 8-13 trips, 28-63 stock Emerald Lake: no data for "Emerald Lake".		Maintain current levels of use at Badger Lake.
	Grazing	Thousand Island: Two streams in meadows were found to be functional at-risk, one with a downward trend, one with a non-apparent trend, with slight overall hydrologic function alteration. See Garnet-Thousand Island Grazing Zone. Yosemite toad and mountain yellow-legged frog breeding habitat critical area in meadows west of Thousand Island Lake with light to moderate trampling and chiseling impacts from grazing. Reported grazing: 390/204/127. Local moderate vegetative composition alteration, moderate to severe alteration at meadows between Garnet and Thousand Island. San Joaquin Grazing Zone: reported stock nights: 0/46/50. Badger Lakes Meadow: minor vegetation alteration, fen with some trampling, stream is functional at-risk with a non-apparent trend, slight hydrologic function alteration meadow-wide. Emerald Lake: wet conditions, low percentage of area reaches range readiness.	Thousand Island: Streams should move toward proper functioning condition, with an upward trend. Meadows should have negligible hydrologic function alteration. Locally increase vegetative cover. Maintain high quality Yosemite toad and mountain yellow-legged frog habitats. Badger Lake: Fen in functioning condition. Stream has an upward trend in functional condition. No hydrologic function alteration. At desired high-seral status. Emerald Lake: At desired vegetative condition.	Thousand Island: allow grazing 127 stock nights available in zone, mostly on benches north of Thousand Island Lake. Critical areas closed to stock entry and grazing. Upper San Joaquin: allow grazing with applicable standards (including a 40% allowable utilization factor), 84 stock nights available in the zone in alternative 2,3; 65 in alternative 4 with a 30% AUF. Badger: allow grazing with applicable standards (including a 40% allowable utilization factor), 84 stock nights available in the zone, 19 stock nights at Badger Lake Meadow, in alternative 2,3; 65 in alternative 4 with a 30% AUF. (Emerald Lake) No grazing.
	Campsites	Thousand Island: one stock holding site at the north end of Thousand Island Lake meets BMPs.	Thousand Island: stock holding and spot/dunnage sites meet BMPs.	Designate 1 stock camp at Thousand Island Lake and 1 in the vicinity of Badger Lake.
	Other Issues	Badger Lake: Mountain yellow-legged frog re-introduction habitat, no current impacts. Emerald Lake: Pack stock trail contours above shoreline of mountain yellow-legged frog unnamed pond between Garnet and Emerald Lakes with minor sedimentation input.	Badger Lake: maintain good condition habitat Emerald Lake: maintain habitat conditions and continue to ensure minimal trail sediment input into pond.	Badger Lake: monitor if stock holding camp is identified. Emerald Lake: monitor and take remedial action if trail erosion increases such as trail re-location.
13. Shadow/Ediza				
Destination: Clarice Lake	Access	Clarice Lake use trail (SHE01), lightly defined, minimal use. Slight risk factors.	Prevent further trail development.	Approve Clarice Lake use trail SHE01.
	Recreation Category	Recreation Category 2 with destination off primary trail. High opportunities for	Maintain high opportunities for solitude,	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Setting	solitude.	lightly defined trail.	
	Use Levels 01-04	0-4 trips, 15-39 stock		Up to 2 spot and dunnage trips for light use to maintain high opportunities for solitude with less than 10 stock a year will not increase visibility of trail.
	Grazing	No grazing.		No grazing.
	Campsites	No stock camps.	No stock camps.	No stock camps.
14. Shadow-Ediza				
Destination: Ediza Lake	Access	Ediza Camp access trail observed Trail Class 1, Resource Rating 3, well-defined, moderate to high use by commercial and public. Issues at creek crossing and incision near camp. Iceberg Lake Trail: Resource Rating 5, causing sediment to enter Ediza Lake; Ediza grazing trail Resource Rating 4.	Ediza camp access trail: Resource Rating 2, Ediza grazing trail: Resource Rating 1.	Stabilize creek crossings; Ediza grazing use trail: prohibit stock use. Mitigate damage when possible.
	Recreation Category Setting	Recreation Category 3; moderate to high use levels; moderate opportunities for solitude; Resource Rating 2.6.	Low-moderate opportunities for solitude during peak season; reduce overall impacts at destination by containing and concentrating impacts.	
	Use Levels 01-04	19-30 trips; 65-137 stock		Limit spot and dunnage trips to 24 trips and do not increase stock numbers.
	Grazing	Closed to grazing above outlet; unsuitable for grazing.	Maintain existing condition.	Maintain grazing closure.
	Campsites	Large impacted camping area at inlet; includes small spot dunnage site at outlet below lake.	Maintain existing condition; no stock holding.	To concentrate stock use in area, designate spot and dunnage site at inlet, set back campsites too close to water.
	Other Issues			No stock camps.
15. Shadow-Ediza				
Destination: Laura Lake	Access	Laura Lake (former "Altha Lake"): Trail observed Trail Class 2, Resource Rating 4, impacts to small meadow, riparian, erosion.	Reduce erosion and impacts on riparian section of trail and stabilize and contain extent of impact on steeper sections that are widening.	Stabilize trail.
	Recreation Category	Recreation Category 2. Recreation Impact Rating = 1.8. Moderate to high	Maintain high opportunities for solitude	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Setting	opportunities for solitude.	and low to moderate impacts at few sites.	
	Use Levels	3-5 trips, 15-39 stock		Up to 3 spot and dunnage trips. Manage for low stock numbers, not more than 15 stock. Up to 5 trips and 20 stock when trail is improved. This use level will maintain high opportunities for solitude and ensure no additional degradation of trail corridor.
	Grazing	Small meadow with some areas never reaching range readiness. In good condition. Reported grazing 0/0/40	Maintain good meadow condition.	Allow grazing, 10 stock nights available.
	Campsites			Designate 1 stock camp.
16. Shadow-Ediza				
Destination: Nydiver Creek	Access	Nydiver Trail observed Trail Class 1.5, Resource Rating 1, generally stable with low use.	Maintain low use and trail stability.	Nydiver Trail Trail Class 1.
	Recreation Category Setting	Recreation Category 1-2. Lakes are Recreation Category 1. Pack station use occurs in Recreation Category 2. Low impact, high opportunities for solitude.	Maintain low impact high opportunities for solitude.	
	Use Levels 01-04	0-2 trips. 0-8 stock		Up to 2 spot/dunnage trips to maintain trail stability and high opportunities for solitude.
	Grazing	No grazing reported.	At desired vegetative condition.	No grazing.
	Campsites	No stock camps.	No stock camps.	No stock camps.
17. Shadow-Ediza				
Destination: Rosalie / Gladys Lakes	Access	JMT(Trail Class 3) provides generally stable access. Short camp access trail - dry/stable. Grazing access use trail is Resource Rating 1, some slight erosion, generally contours dry slope.	Ensure grazing use trail remains stable.	
	Recreation Category Setting	Recreation Category 3. Low to moderate opportunities for solitude.		
	Use Levels 01-04	0-4 trips, 0-38 stock		Up to 6 spot/dunnage trips and use of area for all expense or traveling trips.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Grazing	Possible fen above Rosalie with slight trampling. See Shadow Ediza Grazing Zone. Reported stock nights: 27/0/167 in zone, 0/0/27 at Rosalie/Gladys. Local minor vegetative composition alteration.	Fen trampling <5%. Local minor vegetative alteration is within desired condition.	Allow grazing at 30% AUF and 109 stock nights. Rosalie/Gladys 29 stock nights.
	Campsites	Moderately high impact to stock campsites.	Contain stock campsite and reduce total area.	Designate 1 stock camp at Rosalie Lake and 1 stock camp at Gladys Lake.
18. Shadow-Ediza				
Destination: Shadow Creek	Access	Shadow/Ediza Trail: Trail Class 3, stable. Camp access trail crosses Shadow Creek, some streambank impacts, path in meadow with trampling.	Stabilize camp access trail.	Reroute camp access trail out of meadow. Assess whether structure at creek would improve crossing.
	Recreation Category Setting	Recreation Category 3, low to moderate opportunities for solitude and moderate impacts.	Maintain moderate opportunities for solitude with low to moderate impacts.	
	Use Levels 01-04	4-15 trips, 20-93 stock		Up to 16 spot and dunnage trips and use of area for all expense trips.
	Grazing	Stream in Shadow/Nydiver confluence meadow is functional at-risk. Local moderate to minor vegetative species composition change. Reported stock nights: 27/0/167 in zone. 27/0/110 at Shadow Creek.	Stream should move toward PFC. Vegetation is at desired condition.	Allow grazing at 109 stock nights at Shadow Creek near PCT junction 30 stock nights @ 30% AUF.
	Campsites	Campsite in the Shadow Creek corridor south of Shadow Creek did not meet BMPs, as it was within 50 feet of water and depositing sediment and manure into water. Another nearby stock holding site did meet BMPs.	Stock holding and spot/dunnage sites should meet BMPs.	Designate 1 primary stock camp and 1 secondary for low capacity stock camp. Set campsite back from water.
19. Minarets				
Destination: Trinity Lakes	Access	JMT		
	Recreation Category Setting	Recreation Category 2 along JMT, not a popular destination, high opportunities for solitude while camping low to moderate while traveling.	Maintain current conditions.	
	Use Levels 01-04	0-2 trips, 0-20 stock ("Vivian")		Up to 2 spot and dunnage trips to maintain current low use.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Grazing			Part of the Minaret Creek Grazing Zone.
	Campsites	No stock camp.	No stock camp.	No stock camp.
20. Minarets				
Destination: Emily Lake	Access	Emily Trail observed Trail Class 2, Resource Rating 4. Trail through possible fen with trampling impacts. System trail crossing at Emily Lake outlet appears to be causing unstable banks and sediment to enter the creek. Through meadow, trail is diverting seep flow.	Limit use to reduce deterioration until trail can be stabilized. Fen in functioning condition. Trail should not allow excessive sediment to enter the creek (though some will always enter at stream crossings) or divert seep flow.	NSCS until trail is fixed.
	Recreation Category Setting	Recreation Category 2. Moderate impacts, moderate opportunities for solitude. Recreation Impact Rating = 2.4.	Maintain moderate for solitude and lower reduced recreation impact rating.	
	Use Levels 01-04	0-8 trips, 0-58 stock		No trips until trail is fixed; Up to 8 spot and dunnage when trail is improved.
	Grazing	No grazing reported.		No grazing proposed.
	Campsites	Stock holding campsite at Emily Lake outlet is 100 feet from water, but is allowing sediment to enter the creek and does not meet BMPs.	Stockholding and spot/dunnage sites should meet BMPs.	Prohibit stock use of site on north side of lake; establish (on the east side of creek) 1 stock camp.
21. Minarets				
Destination: Minaret Creek (includes Johnston Meadow)	Access	Minaret Creek Trail and JMT Trail Class 3, generally stable. No use trails, other than grazing-trailing. Minaret Creek Trail: Trail Class 3, generally stable. Short access trails to spot and dunnage campsites.		
	Recreation Category Setting	Recreation Category 2. Moderate impacts and moderate solitude along trail corridor. High capacity for camping and high solitude while camping.	Maintain current conditions.	
	Use Levels 01-04	Johnston: 0-2 trips, 0-60 stock (party size exemption 2003) Minaret: 2-11 trips, 18-45 stock		Up to 20 spot and dunnage trips will maintain experiential qualities. High potential for dispersing use while camping to avoid crowding and maintain high solitude.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Grazing	Johnston Meadow with potential habitat for sensitive species at risk. One reach of stream was found to be functional at-risk with a downward trend. Meadow has overall moderate hydrologic function alteration. Reported grazing: 0/20/12. Local moderate vegetative composition alteration.	Meadow stream move toward PFC. Meadow has negligible hydrologic function alteration. At desired vegetative condition. Improve sensitive plant potential habitat condition.	Rest Johnston Meadow pasture. Re-evaluate in 8-12 years.
	Campsites			Designate 1 stock camp at Minaret Creek and 1 stock camp at Johnston Meadow.
22. King Creek				
Destination: Anona Lake	Access	Fern/Anona Trail observed Trail Class 2&1, Resource Rating 1, lightly defined on mostly dry slopes. One small stream crossing has moderate headcut. Some erosion in steep area near lake.	Ensure trail stability.	
	Recreation Category Setting	Recreation Category 2. Moderate impacts, moderate to high opportunities for solitude. Recreation Impact Rating = 1.8	Maintain at high opportunities for solitude.	Party size limit of 10/20.
	Use Levels 01-04	0-5 trips, 0-28 stock		Up to 6 spot and dunnage trips and use of area for all expense trips.
	Grazing	Meadows are potential habitat for sensitive plants. Meadow stream is at PFC with no hydrologic function alteration. Minor vegetative alteration. Reported grazing: 130/94/42 in King Creek Grazing Zone, 44/0/0 at Anona.	Meadow should remain in good hydrologic condition, at desired vegetative condition.	Allow grazing at outlet, 25 stock nights.
	Campsites	Spot and dunnage site on the benches east of Anona Lake does not meet BMPs. Too close to water.	Stockholding and spot and dunnage sites meet BMPs.	Designate 1 stock camp.
23. King Creek				
Destination: Ashley Lake	Access	Ashley Trail observed Trail Class 2, Resource Rating 1 - rocky and rough, but stable. Some sections ill-defined, but low risk factors.	Current	
	Recreation Category Setting	Recreation Category 2 off primary trail. Moderate impacts and opportunities for solitude. Recreation impact rating = 1.6.	Manage for moderate to high opportunities for solitude of Recreation Category 2 destination off primary trail.	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
Destination: Ashley Lake	Use Levels 01-04	2-14 trips, 14-84 stock		Up to 7 spot and dunnage trips and use of designated site for all expense trips. Limits use to manage for higher opportunities for solitude than current conditions.
	Grazing	Meadow stream is at PFC and overall meadow with no hydrologic function alteration. Poor, steep, erosive soils along access to grazing area.	Meadow stream remains at PFC and in good hydrologic condition. Prevent soil loss along access route.	No grazing approved due to access issues.
	Campsites	Stock holding site on the northeast side of Ashley Lake does not meet BMPs.	Stockholding and spot/dunnage sites should meet BMPs.	Designate 1 stock camp.
24. King Creek				
Destination: Fern Lake	Access	Fern Trail (Trail Class 2 - 1/4 mile) stable, except creek crossing near camp. Slight bank impacts.	Ensure stable crossing and access to camp.	
	Recreation Category Setting	Recreation Category 2 area off primary trail, moderate to high opportunities for solitude but low capacity area. Impacts concentrated at campsites. Recreation Impact Rating = 1.2.	Maintain a low capacity area, minimal party size. Maintain moderate opportunities for solitude.	Party size limit of 10/20.
	Use Levels 01-04	2-8 trips, 12-80 stock		Up to 10 spot and dunnage trips and use of area for small all expense trip parties. Maintain for current stock numbers. This, combined with party size, will ensure continued moderate to high opportunities for solitude.
	Grazing	Meadows are potential habitat for sensitive plants. No grazing reported.		No grazing.
	Campsites	Spot and dunnage site on the northwest side of Fern Lake does not meet BMPs.	Stockholding and spot and dunnage sites meet BMPs.	Designate 1 stock camp at north side of outlet.
25. King Creek				
Destination: Holcomb Lake	Access	Holcomb Trail observed Trail Class 2, Resource Rating 2 to outlet, rocky, rough, but generally stable. Use trail continues on south side of lake. Resource Rating 3.5 with multiple trails, incision. Use trail accessing grazing area above Holcomb lake has caused some soil loss.	Stabilize use trails.	Prevent degradation on use trails until stabilized or rerouted. Prohibit use of Holcomb use trail.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Recreation Category Setting	Recreation Category 2 destination off of primary trail. Moderate to high opportunities for solitude. Moderate impacts that are recovering with elimination of pack stock use at inlet of lake. Recreation Impact Rating = 1.6.	Maintain moderate to high opportunities for solitude. Impacts should be low.	
	Use Levels 01-04	0-6 trips, 0-26 stock		Up to 6 spot and dunnage trips, manage for current levels of stock. This level of use will maintain high opportunities for solitude.
	Grazing	Meadow stream is at PFC and overall meadow has no hydrologic function alteration. Minor local loss of vegetative cover along access trail. Current closure to grazing, no grazing reported.	Meadow stream should remain at PFC and meadow should remain with no hydrologic function alteration. Vegetation at desired condition.	No grazing approved because of access issues.
	Campsites			Designate 1 stock camp north of outlet.
26. King Creek				
Destination: King Creek	Access	Access on King Creek Trail: Trail Class 3, generally stable.		
	Recreation Category Setting	Recreation Category 2, trail corridor with low to moderate use. Moderate to high opportunities for solitude while camping and traveling. Moderate to low impacts.	Maintain moderate to high opportunities for solitude and low impacts.	
	Use Levels 01-04	0-4 trips, 0-14 stock		Up to 8 spot and dunnage trips. Use can be dispersed and will not likely have effects on solitude or camping impacts. Good area for more use to take pressure off Ashley, Anona, Fern, Holcomb and Superior Lakes.
	Grazing			
	Campsites			Designate 1 stock camp at north end of King Creek destination area.
	Other Issues			

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
27. King Creek				
Destination: Lion Point	Access	Lion Point Trail (system) observed Trail Class 1, Resource Rating 0. Use trail from Lion Point to River Resource Rating 0, less than 10% visible.	Keep current primitive condition of system trail with low resource rating. Keep CCD 04 less than 10% visible.	CCD04 use trail for hunting use only.
	Recreation Category Setting	Recreation Category 1. High opportunities for solitude. Impacts not evident.	Maintain current condition.	
	Use Levels 01-04	0-2 trips, 0-18 stock		Up to 2 spot and dunnage trips for fall hunting only. This will ensure no trail becomes visible and high opportunities for solitude are maintained.
	Grazing	No grazing reported.	At desired vegetative condition.	Allow grazing, up to 2 trips annually, as part of Stairway-Cargyle Zone. 25 stock nights available.
	Campsites	No stock camp.	No stock camp.	No stock camp.
28. King Creek				
Destination: Superior Lake	Access	Superior Trail observed Trail Class 2, Resource Rating 3, incision, multiple trailing before lake. Camp access at inlet of lake has bank damage, headcutting.	Stabilize trails - route away from meadow/riparian where possible.	Limit use until both trails are improved.
	Recreation Category Setting	Recreation Category 2, off primary trail, moderate to high opportunities for solitude. Moderate impacts. Recreation Impact Rating = 1.8.	Reduce overall impacts.	
	Use Levels 01-04	7-14 trips, 44-121 stock		Up to 8 spot and dunnage trips. Consider increasing to 14 trips when both trails are improved. Interim use level will ensure no further degradation of trail resources and will maintain moderate to high opportunities for solitude.
	Grazing	Meadow has some local sod fragmentation and compaction, but overall no hydrologic function alteration and stream is at PFC. Local minor vegetative alteration. Reported grazing: 0/12/42.	Meadow should remain without hydrologic function alteration and stream should remain at PFC.	Allow grazing, 87 stock nights.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Campsites	Access to campsites causing soil loss, some alteration of meadow hydrologic function alteration.	Access to campsites should not affect soil or hydrologic function beyond the trail tread.	Designate 1 stock camp at existing site north of inlet. Improve access to stabilize creek crossing.
29. Crater Creek Drainage				
Destination: Deer Creek (includes Deer Lake)	Access	Deer Creek Trail observed Trail Class 2-1 from PCT. Lightly defined in places. Steep sections have slight incision and erosion. Also accessed via Mammoth Crest Trail Class 2 from George Lake. Trail Class 1 trail from lakes to Duck Pass - impractical for stock, ill-defined.	Maintain stability of trails.	Deer Lake to Duck Pass NSCS.
	Recreation Category Setting	Recreation Category 2, very low use for Recreation Category along primary trail (PCT). High opportunities for solitude while camping, moderate while traveling.	Maintain low to moderate use and high opportunities for solitude while camping, low to moderate opportunities while traveling.	
	Use Levels 01-04	Reds: 0-2 trips, 0-18 stock MLPO: 4-12 trips, 27-106 stock McGee: 0-2 trips, 0-16 stock		Up to 14 trips spot and dunnage for two operators and use for all expense trips. This will maintain trails.
	Grazing	Many meadows, most are in good hydrologic condition, one has a stream that was rated non-functional (unknown cause). No to moderate meadow hydrologic function alteration. Local minor vegetative composition alteration. Deer Creek Zone Reported grazing: 60/42/95. Yosemite toad breeding habitat critical areas in meadows with light trampling and chiseling impacts from grazing. Impacts to fens associated with grazing meadows CCD 15, 19a.	All meadows have streams trending toward proper functioning condition. All meadow with negligible hydrologic function alteration. At or trending toward desired conditions. Maintain high quality Yosemite toad breeding habitat.	Allow grazing: 572 stock nights in the zone, with applicable standards; 40% AUF, 20% streambank alteration, critical areas closed to stock entry and grazing. Meadows (CCD 1, 12, 18a, 19a and 15) identified critical areas.
	Campsites			Designate 1 stock camp at Deer Creek and 1 camp at Deer Lakes.

ANSEL ADAMS WEST

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
1. Chiquito/Triple Divide/Sadler				
Destination: Chiquito Pass, Fernandez Pass, Post Peak Pass and Isberg Pass to Yosemite National Park				
	Access	Chiquito: Chiquito Pass (23E01), Chiquito Lake Access (23E02) and Quartz Mountain - Chiquito (23E08) observed Trail Class 2.		
	Recreation Category Setting	Chiquito: Recreation Category 2, moderate to high opportunities for solitude.	Maintain moderate opportunities for solitude.	
	Use Levels 01-04	Data from YOSE 2003-2004: YTPS: spot/dunnage: 2-11 trips, 5-20 stock. MPS: spot/dunnage = 5-20 trips, 15-25 stock.	Use assigned commensurate with actual YOSE use in 2003-2004 and amount of use approved in Incidental Business Permits (IBP) issued by YOSE.	Both operators are authorized by YOSE for all expense/traveling trips. YTPS = 11 trips; or 293 visitor use nights and 457 stock nights. (as authorized by YOSE) MPS = 20 trips; or 250 visitor use nights and 247 stock use nights (as authorized by YOSE). Trips are an estimate of use. Actual use into YOSE will be regulated by NPS.
	Grazing	Chiquito: No grazing requested, no grazing reported. Other passes addressed in corresponding analysis unit.		Chiquito: Do not approve grazing.
	Campsites	Chiquito: Camping only available within YOSE. Other passes addressed in		Chiquito: No stock camps.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		corresponding analysis unit.		
	Other Issues			The use prescribed in this destination will include other access (through use) to YOSE: Isberg, Post Peak, Fernandez and Chiquito.
2. Jackass				
Destination: Jackass Lakes	Access	Norris Lake Trail: sections below standard, but main access to Jackass Lakes. Jackass Lakes Trail: old 4X4 road, erosion, degraded, creek crossings generally stable.		Designate Norris Lake trail as Trail Class 3, Jackass Lake as Trail Class 2, Trail Class 1.
	Recreation Category Setting	Recreation Category 2, moderate opportunities for solitude.	Maintain moderate opportunities for solitude.	
	Use Levels 01-04	2-4 trips, 9-21 stock		Up to 6 spot and dunnage trips will maintain Recreation category opportunities for solitude. Only 4 of the 6 trips to the upper lake.
	Grazing	No grazing reported/requested.		No grazing.
	Campsites	5 sites, some too close to water.	Maintain BMP standards.	No stock camp.
3. Staniford Lakes				
Destination: Staniford Lakes (including Chittenden Trail)	Access	Lillian Lake Loop Trail has awkward section just before lake so use trail STA01 bypasses it, over saddle south of lake. Resource Rating 2+, steep, erosion, no structures, creek crossing has slight bank damage, moderate to high risk factors. Chittenden Lake Trail: Trail Class 1, mostly across bedrock, cairned route, becomes steep extremely awkward for stock at	Stop use of use trail, ensure adequate access to camps without creek crossing.	Prohibit use trail STA01. Identify an interim alternate route into campsites at Staniford Lake, until the Lillian Lake trail is repaired, and permanent access into lakes is established.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		mid-point (before lake).		
	Recreation Category Setting	Recreation Category 2, low to moderate recreation impacts.	Maintain moderate opportunities for solitude.	
	Use Levels 01-04	MPS: 5-23 trips, 23-117 stock High Sierra: 0-3 trips, 0-11 stock		Staniford Lakes: MPS: Limit trips to 14 spot and dunnage trips until trail is fixed and then allow up to 24 spot and dunnage trips. Chittenden Trail: Up to 4 spot and dunnage trips.
	Grazing	No grazing requested. None reported.		No grazing.
	Campsites	Staniford: Trail does not connect to camping opportunities. Chittenden: Very limited camping capacity.	No stock camp.	No stock camp.
4. Staniford Lakes				
Destination: Vandeburg / Lady Lakes	Access	Lillian Loop Trail crosses outlet stream to east. Vandeburg access trail, Resource Rating 2, short cuts across same creek, different crossing, through camps. Moderate impacts at creek crossing. Lady Lake Trail: observed Trail Class 2, Resource Rating 1, appears to have moderate to heavy use, low risk factors, except along creek.	Limit use to Lillian Trail for through trips, allow access to camping from north side of shortcut. Lady Lake Trail: Stabilize trail for current use level, realign away from banks where possible.	South half Vandeburg Lakes access trail is NSCS.
	Recreation Category Setting	Recreation Category 3, moderate opportunities for solitude, low to moderate impacts.	Maintain moderate opportunities for solitude.	Change to Recreation Category 2.
	Use Levels 01-04	Vandeburg Lake: 1-6 trips, 4-88 stock Lady Lakes: 4-18 trips, 10-70 stock		Up to 32 spot and dunnage trips with no more than 12 trips to Lady Lakes.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Grazing	No grazing requested. None reported.		No grazing approved.
	Campsites	Limited capacity for camping at Lady Lakes.		Close sites that do not meet BMPs. No stock camps.
5. Lillian Lake				
Destination: Fernandez Lakes	Access	Fernandez Lakes use trail: LIL02, Resource Rating 1, faint/dispersed, generally low angle, low to moderate risk factors at creek crossings and meadows.	Prevent use trail becoming more obvious and impacted.	Approve use trail (LIL02) for low use only.
	Recreation Category Setting	Recreation Category 2 off of primary trail corridor. High opportunities for solitude. High risk factors (riparian) with recreation use/impact.	Maintain high opportunities for solitude, reduce recreation impacts.	
	Use Levels 01-04	0-1 trips, 0-6 stock		Up to 2 spot and dunnage trips to maintain high opportunities for solitude and to reduce risk factors.
	Grazing	Local moderate alteration of vegetative composition. Meadow northwest of Fernandez Lakes. No grazing reported, grazing requested. Low productivity. Stream rated functional at-risk, and is incised.	Increase recruitment and establishment of late-seral vegetation. Stream moves toward PFC.	Rest until resource recovery.
	Campsites	Low capacity for camping.		No stock camps.
6. Lillian Lake				
Destination: Fernandez Meadow	Access	CAR&H Trail (Fernandez Pass), Trail Class 3 and Post Peak Pass trail, degraded at Jct. Incised, multi-trailing, bank damage.	Repair/reroute	
	Recreation Category	Recreation Category 2, moderate	Maintain moderate to high	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Setting	to high opportunities for solitude.	opportunities for solitude.	
	Use Levels 01-04	0-4 trips, 0-26 stock		Up to 6 spot and dunnage trips and use of area for all expense and traveling type trips, will maintain moderate to high opportunities for solitude.
	Grazing	Local moderate alteration of vegetative composition. Stream rated functional at-risk. Stream is incised, causing severe meadow hydrologic function alteration. Grazing requested, no grazing reported.	Increase recruitment and establishment of late-seral vegetation. Stream moves toward PFC.	Allow light grazing: 24 stock nights.
	Campsites	High density of campsites and high impact campsites.	Reduce campsites development and impacts.	Designate 1 stock camp. Remove/restore stock camp southeast of junction.
7. Lillian Lake				
Destination: Flat / Monument Lakes	Access	Flat Lake Trail: observed Trail Class 1, Resource Rating 1, generally stable, with slight effects at creek crossing, few risk factors. Monument Lake use trail LIL04, Resource Rating 1, not continuous, barely visible, rock slabs, and few risk factors.	Maintain stability with minimal development.	Allow use of use trail LIL04.
	Recreation Category Setting	Recreation Category 2 off of primary trail. High opportunities for solitude; low to moderate impacts associated with camping.	Maintain low use and high opportunities for solitude and low impact.	
	Use Levels 01-04	2-4 trips, 9-38 stock		Up to 6 spot and dunnage trips and use of area for all expense trips will maintain low use and impact and high opportunities for solitude.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Grazing	Flat Lake Meadow: Grazing requested, no grazing reported. Small (1 acre) meadow. Slight soil compaction and local hydrologic function alteration.	Meadow moves toward no hydrologic function alteration.	No grazing.
	Campsites	Low capacity for camping. Campsites impacted and developed.	Reduce campsite development.	Designate 1 stock camp at Flat Lake.
8. Lillian Lake				
Destination: Lillian Lake	Access	Lillian Lake Trail: obvious access trail around north side of lake, few risk factors until near end.	Ensure stability with moderate to high use.	Add to System as Trail Class 2.
	Recreation Category Setting	Recreation Category 2; low to moderate opportunities for solitude.	Maintain moderate opportunities for solitude.	
	Use Levels 01-04	5-21 trips, 33-148 stock		Up to 25 spot and dunnage trips will maintain moderate opportunities for solitude. Use of area for all expense/traveling trips.
	Grazing	No grazing requested. No grazing reported.		Do not approve grazing.
	Campsites	Existing closure: No overnight camping within 400' of the lakeshore outlet northward approximately 1/4 mile. Limited camping capacity. Camping is concentrated into one area. Very intensive camping impacts.	Reduce campsite development.	Designate 1 stock camp. Prohibit spot and dunnage camps within established closure.
9. Triple Divide				
Destination: Anne Lake	Access	Anne Lake Trail: observed Trail Class 2, Resource Rating 3, stable until top of hill, then descends thru small meadow with incision, multi-trails. Steep	Stabilize Anne Lake Trail for moderate use. Allow light use to grazing north of Anne Lake.	Allow use of use trail TRD01.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		section above lake, moderate erosion, sediment to creek. Anne Lake grazing use trail TRD01: Resource Rating 2, continues around lake, then to grazing in "avalanche meadow". Slight impacts on meadows at lakeshore, and slight erosion climbing toward meadow. Risk factors if use increases.		
	Recreation Category Setting	Recreation Category 2, moderate opportunities for solitude, moderate recreation impacts (1.8).	Maintain moderate solitude and reduce overall recreation impacts.	
	Use Levels 01-04	1-4 trips, 12-48 stock		Up to 4 spot and dunnage trips and use of area for all expense traveling trips. Limit stock numbers to 24 stock per season until trail resource issues are addressed.
	Grazing	Meadow north of Anne Lake: Stream rated functional at-risk with an upward trend. Some soil compaction. Minor local alteration of vegetative composition. Reported grazing: 54/0/28	Stream should continue to move toward PFC. Maintain existing vegetative seral status.	Allow Grazing: 46 stock nights available.
	Campsites	Spot/dunnage site on the north side of Anne Lake is in slight non-compliance with BMPs due to access trails causing sedimentation into streams.	All campsites should meet BMPs.	Close sites that do not meet BMPs. Designate 1 stock camp.
10. Triple Divide				
Destination: Rutherford Lake	Access	Rutherford Lake Trail: observed Trail Class 2, Resource Rating 1, trail stable, well-graded to lake, slight impacts to lakeshore in narrow corridor south side lake.		

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Recreation Category Setting	Recreation Category 2, moderate opportunities for solitude,	Maintain moderate to high opportunities for solitude.	
	Use Levels 01-04	0-2 trips, 0-14 stock		Up to 4 spot and dunnage trips.
	Grazing	No grazing requested. None reported.		No grazing.
	Campsites	Spot and dunnage site on the southeast shore of Rutherford Lake does not meet BMPs. Less than 50 feet from water and causing sediment to enter lake. Limited camping opportunities.	All campsites should meet BMPs.	Close campsites that do not meet BMPs. Designate 1 spot and dunnage camp. No stock camp.
	Other Issues	Very sparse downed firewood availability.		Close area to campfires.
11. Triple Divide				
Destination: South of Slab Lakes	Access	Primary access via Slab Lakes Trail: observed Trail Class 1+. Moderately defined with slight erosion and low-mod risk factors up to meadows about 1/2 way to lake. Becomes ill-defined, sporadic to lake. Low grades, slight risk factors, hard to follow upper section.	Do not increase definition of trail above meadows. Maintain stability of lower segment.	Designate trail as Trail Class 1.
	Recreation Category Setting	Recreation Category 2, moderate opportunities for solitude.	Maintain moderate to high opportunities for solitude.	
	Use Levels 01-04	0 trips 1992-95: 0-4 trips to Slab Lake 2-14 stock		Up to 2 spot and dunnage trips and use of area for occasional all expense/traveling trips.
	Grazing	No grazing requested. None reported.	-	No grazing approved.
	Campsites			Designate 1 stock camp.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
12. Triple Divide				
Destination: Isberg Meadow	Access	Primary access via Post Peak Pass Trail: observed Trail Class 2 & 3. Generally stable, substandard maintenance, steep terrain.		Maintain Post Peak Pass trail as Trail Class 3.
	Recreation Category Setting	Recreation Category 2, moderate opportunities for solitude.	Maintain moderate to high opportunities for solitude.	
	Use Levels 01-04	0 trips 1992-97: 1-2 trips to Slab Lake 2-10 stock		Up to 2 spot and dunnage trips and use of area for all expense/traveling trips.
	Grazing	Moderate hydrologic function alteration throughout the meadow and the stream was rated functional at-risk with a non-apparent trend. The effects are attributable to cattle grazing, and likely not associated with commercial pack stock.		Allow grazing; 76 stock nights available.
	Campsites	2 camps requested by packers. None yet analyzed for BMP compliance.		Designate 1 stock camp.
13. Triple Divide				
Destination: Post Creek	Access	Access is via the Post Creek Trail - 24E17 (Trail Class 1)		-
	Recreation Category Setting	Recreation Category 2, moderate opportunities for solitude, mostly hunting use.	Maintain moderate to high opportunities for solitude.	
	Use Levels 01-04	0 trips, 1992-97: 0-2 trips, 0-9 stock		Up to 2 spot and dunnage trips and use of area for all expense/traveling trips.
	Grazing	No grazing requested. None reported.		No grazing approved.
	Campsites	Essentially all of the camping in	No stock camp.	No stock camp.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		this zone is related to hunting. There are at least two large camps that require frequent attention to remove constructed features.		
14. Cora				
Destination: Cora Lakes	Access	Cora Lakes Trail: observed Trail Class 1.5, Resource Rating 1, generally low angle, slight incision at seep crossing westside of lake and at meadows north side. Fades on west side near camps, more pronounced near Isberg.	Maintain stability.	Add to system - Trail Class 1.
	Recreation Category Setting	Recreation Category 2 off of primary trail corridor. Moderate opportunities for solitude, moderate to high recreational impacts. Recreation Impact Rating = 2.0.	Maintain moderate opportunities for solitude.	
	Use Levels 01-04	2-18 trips, 26-93 stock		Up to 18 spot and dunnage trips.
	Grazing	Very small meadow. Local moderate sod fragmentation along trail through meadow. Some trailing through meadow may be affecting local hydrologic function. Grazing reported: 0/15/0.	Increase vegetative cover. Meadow should move toward no hydrologic function alteration.	No grazing (access issues).
	Campsites	Stock holding site on the north side of Lower Cora Lake meets BMPs. Existing closure: No overnight camping within 400' of the lakeshore from the outlet northward approx 1/4 mile.	All campsites should meet BMPs. Avoid campsites with specific resource sensitivity.	No stock camp. Prohibit spot and dunnage camps on south side of Middle Cora Lake, and within established closure.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
15. Cora				
Destination: Chetwood Zone (including Knoblock Meadow and Detachment Meadow)	Access	Primary access via Isberg Trail (observed Trail Class 3) and Chetwood Trail (observed Trail Class 2), generally stable, slight erosion.		
	Recreation Category Setting	Recreation Category 2, low to moderate use, moderate to high opportunities for solitude.	Maintain moderate to high opportunities for solitude.	
	Use Levels 01-04	0-6 trips, 0-48 stock		Up to 12 spot and dunnage and use of area for all expense/traveling trips.
	Grazing	Detachment Meadow has severe hydrologic function alteration, incised channel, and active headcuts remaining. Knoblock Meadow has severe hydrologic function alteration and the stream in the meadow was rated functional at-risk with an upward trend. Chetwood Cabin Meadow also has severe hydrologic function alteration and stream rated functional at risk (non-apparent trend). Condition of meadows likely attributable to recent cattle grazing and not related to commercial pack stock use.	Allow recovery of streams and meadows toward functional condition.	Allow Grazing: 243 stock nights available (in Chetwood, Detachment and Knoblock Meadows combined).
	Campsites		One stock camp is located at Knoblock Meadow and the other is located at Chetwood Meadow or at a suitable site at Detachment Meadow. The purpose of this second stock camp is to support the Cora destination which does not have a designated stock camp.	Designate 2 stock camps.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
16. Cora				
Destination: Cora Creek (includes Lilly Lake, NF San Joaquin River)	Access	Access is via Cora Creek Trail - 25E04 (Trail Class 2). Trail is steep and generally in poor condition for approximately one mile above the North Fork of the San Joaquin River Crossing.		-
	Recreation Category Setting	Recreation Category 2, low to moderate use moderate to high opportunities for solitude	Maintain moderate opportunities for solitude.	
	Use Levels 01-04	0 trips 1997-2000: 0-1 trips, 0-5 stock		Up to 2 spot and dunnage and use of area for all expense/ traveling trips.
	Grazing	No grazing requested. None reported.		No grazing.
	Campsites	The campsite at Cora Crossing is well developed.	Reduce campsite development.	Designate 1 stock camp at Cora Crossing.
17. Cora				
Destination: Lost Lake	Access	Access is via the use trail COR01.		Use trail COR01 is approved.
	Recreation Category Setting	Recreation Category 1, high opportunity for solitude.	Maintain high opportunity for solitude.	-
	Use Levels 01-04	0 trips, 1992-97= 0-1 trips, 0-5 stock		Up to 2 spot and dunnage.
	Grazing	No grazing requested. None reported.		No grazing.
	Campsites	-	No stock camp.	No stock camp.
18. Bench Canyon				
Destination: Long Creek	Access	Unconstructed trail on section from ridge to river.		
	Recreation Category	Recreation Category 1, high opportunities for solitude, low	Maintain high opportunities for solitude.	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Setting	use low impact		
	Use Levels 01-04	0-2 trips 10 stock (1 year of use, 2004)		Up to 4 spot and dunnage trips.
	Grazing	No grazing requested. None reported.		No grazing.
	Campsites			Designate 1 stock camp.
19. Sadler				
Destination: Isberg Lake	Access	Isberg Pass Trail: observed Trail Class 3 (slightly lower at top of pass), generally stable, slight impacts at creek crossings. Accesses YOSE.		
	Recreation Category Setting	Recreation Category 2, moderate to high opportunities for solitude.	Maintain high opportunities for solitude.	
	Use Levels 01-04	0-3 trips, 0-40 stock		Up to 6 spot and dunnage trips only at Lower Isberg Lake.
	Grazing	Minor, local, alteration of vegetative composition. Reported grazing: 0/6/0	Maintain existing vegetative seral status. Fen area in functioning condition.	Allow grazing; 14 stock nights available.
	Campsites			No stock camps.
20. Sadler				
Destination: Joe Crane Lake	Access	Joe Crane Lake Trail: observed Trail Class 2, stable on dry slope, disperses at lake.		
	Recreation Category Setting	Recreation Category 2 off of primary trail. Moderate to high opportunities for solitude.	Maintain high opportunities for solitude.	
	Use Levels 01-04	0-7 trips 0-58 stock		Up to 8 spot and dunnage trips and use of area for all expense

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
				and traveling trips.
	Grazing	Moderate local alteration of vegetative composition. Meadows west of Joe Crane Lake and at Joe Crane Lake: Stream functional at-risk. Severe local hydrologic function alteration due to stream incision.	Streams should move toward PFC and meadows should move toward no hydrologic function alteration. Increased vegetation seral-status.	West of Joe Crane Lakes: Allow grazing, 98 stock nights available. Joe Crane Lake: Allow grazing; 9 stock nights available. Joe Crane zone 178 stock nights.
	Campsites	Stock requested campsite on the southwest shore of Joe Crane Lake does not meet BMPs, within 50 feet of water. Limited capacity for camping.	All campsites should meet BMPs.	Designate 1 stock camp.
21. Sadler				
Destination: Sadler / McClure Lakes	Access	McClure Lake Trail: observed Trail Class 2, Resource Rating 3, accesses camp on south side of Sadler Lake and grazing area below McClure, moderate to severe impacts on south side of lake - multi-trail, incision, stream diversion.	Stabilize trail to camps, south side of Sadler Lake.	Stabilize trail between campsites and small meadow at base of McClure moraine. Repair and restore campsite access trails through meadows along south shore of Sadler Lake.
	Recreation Category Setting	Recreation Category 2 off of primary trail moderate opportunities for solitude, moderate to high recreation impacts (2.2)	Maintain moderate solitude, reduce overall impacts.	
	Use Levels 01-04	MPS Use: Sadler 2-14 trips, 28-141 stock McClure 0-5 trips 0-32 stock HSPS Use: McClure 0-5 trips, 0-32 stock Sadler 0 trips		MPS: Up to 19 spot and dunnage trips with no more than 10 trips to Sadler Lake. Use of area for all expense/traveling trips.
	Grazing	Meadow between Sadler and McClure: Stream rated functional at-risk. Sod fragmentation throughout meadow. Severe to moderate	Increased vegetative cover and seral status. Streams, meadows, and fens should be in PFC.	Sadler to McClure meadow allow 12 stock nights with protection of riparian/spring area. Monitor exclosure. Sadler Lake north meadows, allow grazing,

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		<p>alteration of vegetative composition. Access to meadow has extensive sod fragmentation. Sadler Lake Meadows: On south side of lake, meadow is compacted and has soil erosion related to trails through meadows. Severe to moderate local alteration of vegetative composition. North side of lake is in good hydrologic condition, and with little or not alteration of vegetative composition. Area with fen characteristics in McClure to Sadler Meadow has heavy trampling. Sadler Pond meadow, minor alteration of vegetative composition. Reported grazing: 35/59/0.</p>		<p>53 stock nights available. Sadler Pond meadows, allow grazing, 45 stock nights available.</p>
	<p>Campsites</p>	<p>Existing closure: No overnight camping within 400 ' of the lakeshore from the junction of the Isberg & McClure trails northward approx 1/4 mile. One major stock holding campsite on the south side of Sadler Lake does not meet BMPs. This camp has drainage that was dug to drain the water from the camp into a nearby ephemeral stream, carrying sediment and high flows into the stream. The camp is in the meadow. The stock holding area associated with this camp is in a good location and meets BMPs.</p>	<p>All campsites should meet BMPs.</p>	<p>Close site described in current condition column (on the south side of Sadler Lake) to avoid conflict with ephemeral stream. Prohibit spot and dunnage camps within established closure. Designate 2 stock camps, one at Sadler Pond. .</p>

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
22. Lake Catherine				
Destination: Hemlock / Stevenson (Stevenson Creek, Meadow and Canyon)	Access	LAC01 very steep, followable, no other risk factors besides steep slopes.		Approve use trail to Dike Creek (LAC01).
	Recreation Category Setting	Recreation Category 2, off primary trail, high opportunities for solitude.		
	Use Levels 01-04	MPS: 1-9 trips 0-77 stock Reds: 1 trips -0-5 stock High Sierra: 0-2 trips 0-24 stock		MPS: Up to 10 spot and dunnage trips and use of area for all expense/traveling trips.
	Grazing	Stevenson Meadow stream is at PFC; high production meadow; livestock should be managed to avoid the southwestern portion of the meadow (fen); trail crossing at base of meadow needs some rock armoring; Pond Meadow (2 acres) high forage production; Upper Stevenson (aka. Barrel Camp) is low production; Falls Meadow is a dry meadow with moderate forage production; conifer encroachment evident, Upper Falls Meadow moderate production; Hemlock Meadow has scattered forage amidst dense shrub cover.		For the zone 488 stock nights. Stevenson Meadow: 175 stock nights, Upper Stevenson 28, Pond Meadow 58 stock nights, Falls 126 stock nights. Upper Falls Meadow 70 Stock nights. Hemlock Crossing 31 stock nights.
	Campsites			Designate 1 stock camp at Stevenson Meadow and 1 south of Stevenson Meadow.
	Other Issues	Drift fence in place.		Retain drift fence.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
23. Iron Creek				
Destination: Iron Creek	Access	Access is via the Iron Creek Trail - 25E02 (Trail Class 2)		
	Recreation Category Setting	Recreation Category 2, very low use, high opportunities for solitude.	Maintain high opportunities for solitude.	
	Use Levels 01-04	0-2 trips 20 stock		Up to 4 spot and dunnage trips
	Grazing	None reported, none requested.		No grazing.
	Campsites			No stock camp.
24. Cargyle				
Destination: 77 Corral Zone (77 Corral and Upper and Lower Stairway Meadows)	Access	Mammoth Trail: Trail Class 3. Iron Creek Trail: Trail Class 2. Summit Meadow Trail: Trail Class 3.		Prohibit use of CAR02.
	Recreation Category Setting	Recreation Category 2, low impacts, high opportunities for solitude	Maintain high opportunities for solitude.	
	Use Levels 01-04	Reds 0-3 trips, 0-40 stock MPS 0 trips, 0 stock HSPS: 0-2 trips, 0-22 stock		Reds: Up to 4 spot and dunnage trips and use of area for all expense/traveling trips. MPS: up to 2 spot and dunnage and use of area for all expense/traveling trips.
	Grazing	Fenced public pasture, MPS use limited to one night/trip within fenced pasture.-unknown if same restriction is applied to east side packers, some meadow surface erosion and old headcuts on stream. Likely never reaches range readiness in wet years. Fens present in several meadows.		Cargyle/Stairway Zone = 267 stock nights. 50 stock nights for commercial use in the 77 Corral public pasture.
	Campsites	3 existing campsites, historically used site is too close to water,	All campsites should meet BMPs.	Designate 3 stock camps. Consider additional camp at

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		but is best overnight stock camp		Stairway Meadow. Make sure location of stock camp in section 19 does not impact arch site.
25. Cargyle				
Destination: Spano / Straube Lakes	Access		Maintain low definition of CAR01.	Approve CAR01 for low levels of use.
	Recreation Category Setting	Recreation Category 1, high opportunities for solitude, low impacts.	Maintain high opportunities for solitude.	
	Use Levels 01-04	0-4 trips, 0-28 stock		Up to 4 spot and dunnage trips to maintain high opportunities for solitude. More use allowed if valid state game tag holder requests commercial services. Additional use requires case by case approval. Use of area for all expense/traveling trips.
	Grazing			Part of Cargyle/Stairway Grazing zone.
	Campsites			Designate 1 stock camp at Straube Lake.
26. Cassidy				
Destination: Miller / Cassidy / Rattlesnake (includes Pine Flat)	Access			Approve Pine Flat use trail (JUN01)
	Recreation Category Setting	Recreation Category 1, high opportunities for solitude, low issues and risk factors. Four distinct locations within the zone.	Maintain low use levels, high opportunities for solitude.	
	Use Levels 01-04	2-19 trips, 6-125 stock		Up to 25 trips to the zone, no more than 6 trips to any of one of

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
				the four distinct locations within the zone per year. Use of area for all expense/traveling trips.
	Grazing	Grazing requested. No grazing use reported.	Maintain or improve meadow conditions.	Grazing at Rattlesnake; 25 stock nights.
	Campsites	Campsites limited at Cassidy, Miller and Pine Flat as these are relatively small flat areas surrounded by steep cliffs along the San Joaquin River.		Designate 1 stock camp at Rattlesnake Lake, and 1 at Pine Flat.
27. Bridge Crossing				
Destination: Junction Buttes	Access	Junction Butte Trail Trail Class 1.	Insure stability.	
	Recreation Category Setting	Recreation Category 1 primary trail low to moderate use moderate to high opportunities for solitude.	Maintain low use recreation category.	
	Use Levels 01-04	0-6 trips, 0-26 stock		Up to 6 spot and dunnage trips.
	Grazing	None reported, none requested.		No grazing.
	Campsites	2 campsites on JB flat at river, drop point on trail ~3/4 miles from JB flat, clients may walk to campsites at flat due to poor trail condition. -	-	No stock camp.
	Other Issues	Area not surveyed for Heritage Resources, however area possibly has high archeological sensitivity due to flat topography adjacent to the San Joaquin River. Area is very remote, access is difficult.	Address in programmatic agreement.	

BISHOP/HUMPHREYS

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
1. Horton				
Destination: Horton Lake	Access	Horton Lake Trail observed Trail Class 3, old mining road. No resource concern, stable. Use trail to Upper Horton, along creek, high risk factors. Multiple old mining roads (non-system) on Mt. Tom. Cheatgrass on lower slopes along trail.	Use is low, low development trail. Prevent degradation of use trail HOR03. Prevent spread of cheatgrass.	Maintain trail as Trail Class 2. Prohibit use to Upper Horton. Allow use on old mine roads - Sonny Boy Mine use trail. Maintain low use to minimize cheatgrass spread.
	Recreation Category Setting	Recreation Category 2, low to moderate use and impact, moderate to high opportunities for solitude.	Horton Lake: Maintain for moderate to high opportunities for solitude.	
	Use levels 01-04	Pine Creek: 0-2 trips, 0-11 stock BPO: 0-2 trips, 0-12 stock		Up to 6 spot and dunnage trips to 2 operators. Use primarily as an early season destination. Use level consistent with Recreation Category 2 and will maintain high opportunities for solitude.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	No grazing.
	Campsites		No stock camp.	No stock camp.
2. Pine Creek				
Destination: Pine Creek Zone (not including Honeymoon Lake)	Access	Upper Pine Lake Trail above lake crosses at 200'+ wide ford in poor condition, causing stock to get out of trailway. Occupied Yosemite toad habitat at inlet with observed trampling and chiseling impacts apparently associated with poor trail design at inlet crossing of Upper Pine Lake. Pine Creek Pass Trail Trail Class 3, generally stable, except	Maintain high quality Yosemite toad habitat. Repair and stabilize ford. Ensure trail stability at Lower Pine Lake trail. Prevent development of visible trail to Birchim Lake.	Prohibit use to Birchim Lake on use trail PIN01. Lower Pine Lake use trail PIN05 approve to camp.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		creek crossings, few meadows near pass. Birchim Lake use trail (PIN01) less than 10% visible, steep terrain to lake.		
	Recreation Category Setting	Recreation Category 2 along trail corridor and campsites in drainage. Moderate recreational impacts, moderate opportunities for solitude. Recreation Impact Rating = 1.8.	Pine Creek: Maintain moderate opportunities for solitude.	
	Use levels 01-04	Upper Lake: 2-7 trips, 8-45 stock Pass/Golden Pond: 2-5 trips, 2-60 stock. Lower Pine Lake: 3-8 trips, 14-42 stock		Up to 30 spot and dunnage trips, consistent with primary trail corridor in a Recreation Category 2, multiple destinations within this zone.
	Grazing	Occupied Yosemite toad habitat in meadow with observed trampling and chiseling impacts. No grazing reported, grazing requested at meadows east of pass. Local sod fragmentation, intermingled wetland complex, much of meadow never reaches range readiness. East of Pine Creek Pass meadow has fen characteristics, in good condition.	Maintain moderate to high seral vegetative status. Maintain wetland hydrologic functional condition. Maintain high quality Yosemite toad habitat.	Unsuitable, do not allow grazing.
	Campsites	Stock holding site on the west side of Upper Pine Lake meets BMPs.	All campsites should meet BMPs.	Designate 1 stock camp at Upper Pine Lake.
	Other Issues	Drift fences - one at Pine Lake and one at Pine Creek Pass.	Drift fences allowed for resource protection and not for convenience of packer.	Drift fences - remove drift fence at Lower Pine Lake, maintain drift fence at Pass.
3. Pine Creek				
Destination: Honeymoon Lake	Access	Short spur to Honeymoon Lake observed Trail Class 2, stable. Camp access trails to camp on	Maintain high quality Yosemite toad habitat. Ensure that sensitive areas above	Allow use of Honeymoon Lake spur and access to approved campsites at lake. Designate

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		north/west side near lake, slight incision. Occupied Yosemite toad habitat in meadow may overlap with access routes to camps. Italy Pass Trail continues west from lake - Resource Rating 2+ with many risk factors. Becomes indistinct in Granite Park, extremely awkward west of Pass. Chalfant Lakes use trail GRP01 not found, unlikely that stock route exists - severe terrain.	Honeymoon Lake are not impacted by high risk Italy Pass system trail. Prevent the development of visible trails into Chalfant Lake.	Italy Pass Trail NSCS from Honeymoon to Lake Pass (also designated NSCS west of pass in Italy AU). Prohibit use of GRP 01 Chalfant Lakes use trail.
	Recreation Category Setting	Honeymoon Lake: Recreation Category 2; moderate to high recreation impacts, Recreation Impact Rating = 2.0. Moderate opportunities for solitude.	Honeymoon Lake: Maintain for moderate opportunities for solitude, reduce recreation impacts.	
	Use levels 01-04	14-28 trips, 53-90 stock		Up to 28 spot and dunnage trips, consistent with primary trail corridor destination. Occupy no more than two campsites at one time. This will maintain moderate opportunities for solitude.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status. Management direction is to not approve grazing where it was not requested.	Do not approve grazing.
	Campsites	Dense campsites on the northeast side of Honeymoon Lake. One spot/dunnage site does not meet BMPs.	All campsites should meet BMPs.	Do not allow spot and dunnage trips to access site on the NE side of lake that does not meet BMPs. Designate 2 campsites for spot and dunnage, will reduce recreation impacts.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
4. French Canyon				
Destination: French Canyon (Moon / L Lake junction to Merriam Confluence)	Access	French Trail observed Trail Class 3, Resource Rating 3.5, severely degraded for primary corridor trail.	Improve system trail to reduce off trail impacts associated with degraded trail.	
	Recreation Category Setting	French Canyon Recreation Category 2 on primary trail corridor with moderate opportunities for solitude while traveling and camping. Recreation impact rating = 2.0.	French Canyon: Maintain moderate to high opportunities for solitude along trail corridor while traveling, high opportunities while camping.	
	Use levels 01-04	High Sierra: 0-1 trips, 0-8 stock Pine Creek: 3-5 trips, 18-44 stock McGee: 0-2 trips, 0-10 stock (tribal trip)		Up to 12 spot and dunnage trips to two operators (10 Pine Creek, 2 High Sierra) will maintain moderate to high opportunities for solitude along a primary trail corridor.
	Grazing	Intermingled wetland complex along entire creek corridor. Meadows at confluences are consistently wetlands that never reach range readiness. Meadows above 10,760 feet remain very wet and never reach range readiness. Creek corridor and adjacent forest understory wet to moist meadows do reach range readiness. Overall vegetation is in mid-seral or late-seral condition. Moderate to minor and localized trampling of vegetation and sod fragmentation in wet areas. Occupied Yosemite toad habitat in meadow below Merriam confluence with minor trampling and chiseling impacts observed. Fen with severe trampling	Maintain vegetation at moderate to high seral status. Increase vegetative cover at wetland below "Waterfall" campsite. Prevent alteration of wet meadow/wetland hydrologic function. Improve/maintain fens in functioning condition. Maintain high quality Yosemite toad habitat.	Approve grazing, 735 stock nights available in the French Canyon zone, 40% AUF. No grazing allowed above 10,760 feet. Designate critical areas (for no grazing) at "Waterfall" camp, the Merriam Creek confluence and the Chevaux Creek confluence. Critical areas closed to stock entry and grazing.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		impacts near Waterfall Camp; several other meadows with fen characteristics are in good condition. Reported grazing in French Canyon Zone: 0/13/203.		
	Campsites	"Waterfall" camp covers approximately 4 acres and is within 10 feet of perennial and intermittent streams. The wetland/fen downstream from the camp has been trampled by stock. Sediment and manure found entering intermittent stream.	Reduce area of bare soil to only what is needed. Prevent trampling of wetland downstream of "Waterfall" camp campsite.	Designate "Waterfall" camp as stock holding site. Contain site at least 100 feet from streams. Reduce size of camp. Designate 1 stock camp at Merriam Creek Junction.
	Other Issues	Stock trample fen below waterfall camp during grazing, but do not graze in the fen.	Protect fen from trampling and stock entry.	Use temporary drift fence to protect critical area below "waterfall" camp.
5. French Canyon				
Destination: Elba / Moon / L Lakes	Access	"L" Lake Trail, observed Trail Class 2, Resource Rating 4, two possible routes. Both have moderate to severe incision, multi trailing, and diversions. Various use trails above to Steelhead Lake, Puppet Lake, etc. less than 10% visible. Use trail to Alsace shows some resource concerns.	Stabilize L Lake trail. Select best route. Prevent visible trails to upper basin (Puppet, Alsace, Star Lakes etc).	Identify best route for stock so there's only one route. Stabilize. Prohibit use of use trail FRE27 and others to benches, lakes above. Low use until system trail is repaired and stabilized. Steelhead Lake use trail FRE18 from French Canyon prohibited.
	Recreation Category Setting	Elba/Moon/L Lakes: Recreation Category 2, 1 moderate opportunities for solitude. Recreation Impact Rating = 2.6.	Elba/Moon/L Lakes: Maintain for moderate to high opportunities for solitude. Reduce recreational impacts.	
	Use levels 01-04	2-11 trips, 6-51 stock		Up to 2 spot and dunnage trips until the system trail is repaired to standard.
	Grazing	Moderate to minor and localized trampling of vegetation and sod	Maintain vegetation at moderate to high seral status.	Approve grazing, 735 stock nights available in the French

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		fragmentation in wet areas, along the trail to Elba Lake. Meadows between Elba Lake and Alsace Lake remain wet and do not reach range readiness. These meadows also have local areas of reduced vegetative cover. Reported grazing: 2001/2002/2003 is 0/0/23.		Canyon zone, 40% AUF. Limit planned grazing to 25 stock nights in the Elba/Moon destination and a 30% AUF. Meadows between Elba Lake and Alsace Lake are unsuitable; do not allow grazing. Meadows above the 10,760 foot elevation are unsuitable; do not allow grazing.
	Campsites	Stock holding site on the southeast shore of Elba Lake meets BMPs.	All campsites should meet BMPs.	Designate 1 stock camp between L and Moon Lake.
6. French Canyon				
Destination: French Lake	Access	Cross country travel from Pine Creek Pass to lake. Less than 10% visible. Other use trails from other directions.	Prevent a use trail from becoming defined.	Allow use of FRE60 at low levels. Prohibit other use trails to Lake from Canyon.
	Recreation Category Setting	French Canyon: Recreation Category 1, very low use high opportunities for solitude. Recreation Impact Rating = 0.8.	French Lake: Manage for low use and high opportunities for solitude.	
	Use levels 01-04	0-2 trips, 0-10 stock		Up to 2 dunnage trips with less than 6 stock per season.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status. Management direction is to not approve grazing where it was not requested.	Do not approve grazing.
	Campsites	No stock camp.	No stock camp.	No stock camp.
7. French Canyon				
Destination: Merriam Meadow	Access	Two trails one on each side of creek. Trail north of creek Resource Rating 3, steep, risk	Limit use to one trail.	Allow use of trail south of creek. Designate as Trail Class 2 system trail, stabilize. Prohibit

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		factors. Trail south of creek, Resource Rating 2, steep, risk factors, but higher stability. Use trails continue north to lake and La Salle. Use trail FRE07 to Shepherder Lake less than 10% visible.		use of trail north of creek. Prohibit use trails above meadow. Prohibit use on use trail FRE07 to Shepherder Lake.
	Recreation Category Setting	Merriam Meadow: Recreation Category 2; above Merriam Meadow is Recreation Category 1, very low use high opportunities for solitude. Recreation Impact Rating at Merriam Meadow = 2.0.	Merriam Meadow: Manage for low use and high opportunities for solitude.	
	Use levels 01-04	2-7 trips, 6-40 stock		Up to 4 spot and dunnage trips to maintain trail stability and high opportunities for solitude.
	Grazing	Occupied Yosemite toad habitat in meadow at desired condition. Vegetation overall at high-seral status. Some local fragmentation of sod and reduced vegetative cover near trail in lower section of meadow. Area with fen characteristics in good condition. Much of the meadow never reaches range readiness. Reported grazing: 2001/2002/2003 is 0/0/5.	Maintain high quality Yosemite toad habitat. Maintain vegetation in moderate to high seral status and increase vegetative cover in lower meadow. Maintain fen in good condition.	Approve grazing, 35 stock nights available, in the Merriam zone, including the lodgepole understory, limit grazing at Merriam Lake meadow to 15 stock nights, 30% AUF. Critical areas closed to stock entry and grazing.
	Campsites	Campsites generally far from water, on bench above meadow, and meeting BMPs.	All campsites should meet BMPs.	Designate 1 stock camp on rocks adjacent to meadow east of Merriam Lake.
8. French Canyon				
Destination: Royce Lakes	Access	Lightly defined/sporadic use trail from Pine Creek Pass, Resource Rating 1. Slight erosion near pass, dispersed and no impacts,	Keep trail in lightly defined condition.	Allow use at low levels.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		few risk factors.		
	Recreation Category Setting	Recreation Category 1, very low use high opportunities for solitude. Recreation Impact Rating = 1.0.	Royce Lakes: Manage for low use and high opportunities for solitude.	
	Use levels 01-04	0-2 trips, 0-12 stock		Up to 2 spot and dunnage trips with current stock levels to maintain high opportunities for solitude and to keep trail from being defined.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	Do not approve grazing.
	Campsites			No stock camp.
9. Glacier Divide				
Destination: Hutchinson Meadow	Access	Piute Canyon Trail, observed Trail Class 3, Resource Rating 3, severely degraded for primary corridor trail. Slender moonwort population documented near Piute Canyon Trail below Hutchinson Meadow.	Maintain moonwort habitat near trail.	Primary trail needs to be stabilized.
	Recreation Category Setting	Recreation Category 2, moderate opportunities for solitude, used for stock camps and grazing. Recreation Impact Rating = 2.0.	Reduce overall impacts. Maintain moderate opportunities for solitude.	
	Use levels 01-04	BPO: 0-6 trips, 0-86 stock High Sierra: 0-3 trips, 0-28 stock McGee: 0-2 trips, 0-26 stock (tribal trip) Pine Creek: 0-3 trips, 0-34 stock Rainbow: 0-1 trip, 0-11 stock		Up to 22 spot and dunnage trips to three operators (12 BPO, 6 HS 4 PC). Use of area for all expense type trips.
	Grazing	Area adjacent to large packer camp with altered vegetative species composition, reduced vegetative vigor, and reduced vegetative cover. Reported use:	Increased vegetative cover and vigor in meadow near packer camp.	Approve grazing, 133 stock nights available in the Piute Creek zone. Limit grazing at Hutchinson to 73 stock nights available, 30% AUF.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		2001/2002/2003 is 121/163/290 in Piute Creek zone.		
	Campsites	One stock holding site at Hutchinson Meadow has access trails allowing sediment and manure to enter surface water. A high density of hiker or spot/dunnage camps along creek just downstream from meadow, many do not meet BMPs.	All campsites should meet BMPs.	Designate 3 stock camps.
	Other Issues	Drift fence above Hutchinson Meadow - large and extensive.		Reduce size of drift fence above (east of) Hutchinson meadow
10. Glacier Divide				
Destination: Golden Trout Lakes (including Wahoo Ck, Golden Trout Ck)	Access	Golden Trout Lake system trail from Piute Trail: observed Trail Class 3, Resource Rating 3, highly degraded, formerly primary trail to Piute Canyon, now heavily used to access lakes. Poorly maintained for level of use. Trails east of lake incised and diverting intermittent streams through some meadow areas. Multiple use trails to campsites at lake.	Stabilize system trail. Limit number and extent of use trails at lake. Reduce total number of use trails near Golden Trout Lakes.	Designate camp access routes only. Commercial pack stock would be required to use the Golden Trout Lake spur to access the lake, from the Piute Canyon Trail. Currently used Golden Trout Lake trail NSCS (eventually would be removed from the system and rehabilitated). Designate access routes to camps.
	Recreation Category Setting	Golden Trout Lakes Recreation Category 2, low to moderate opportunities for solitude, moderate to high recreation impacts. Recreation Impact Rating = 2.4.	Golden Trout Lakes: Reduce overall impacts. Maintain use level consistent for Recreation Category 2.	
	Use levels 01-04	31-58 trips, 193 - 388 stock		Up to 40 trips and 300 stock annually.
	Grazing	Occupied Yosemite toad habitat in meadow at desired condition. Vegetation overall at high-seral status. Meadows near Golden	Maintain high quality Yosemite toad habitat. Maintain vegetation in moderate to high seral status and increase vegetative cover in	Meadows near Golden Trout Lakes, to the west and north and to Summit Lake are unsuitable; do not allow grazing. Critical

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		Trout Lakes, immediately to the north and to Summit Lake never reach range readiness. Some local fragmentation of sod and reduced vegetative cover near trails in lower meadows. Reported grazing: 2001/2002/2003 is 0/0/0.	lower meadows, along trail.	areas closed to stock entry and grazing.
	Campsites	Spot/dunnage sites only. Directly adjacent to lake, most sites meet BMPs and are far enough from water, although some hiker sites are on pond shorelines.	All campsites should meet BMPs.	Designate 4 spot and dunnage sites. No stock camps. Prohibit use of the two camps along Piute Creek where access is through wet meadows. Contain "Sierra Club" camp to be over 100 feet from water.
11. Glacier Divide				
Destination: Honeymoon Creek / Lake	Access	Honeymoon Lake Trail, observed Trail Class 1, Resource Rating 1, lightly defined with some slight incision, moderate risk factors - steepness.	Keep trail stable with minimal development.	Low use.
	Recreation Category Setting	Recreation Category 2; low recreation impacts, moderate opportunities for solitude.	Maintain for moderate to high opportunities for solitude.	
	Use levels 01-04	0-4 trips, 0-34 stock		Up to 4 trips at destination, which includes Honeymoon Lake and the junction of Honeymoon Creek and Piute trail. At Honeymoon Lake, only 2 spot and dunnage trips and 10 total stock per year.
	Grazing	No grazing reported or requested. Meadows near confluence with Piute Creek remain wet, very small and fragile lakeshore riparian vegetation areas at lake are at high-seral vegetative condition.	Maintain vegetation at moderate to high seral status.	Unsuitable; do not allow grazing.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Campsites	One spot/dunnage site on the north end of Lower Honeymoon Lake found to meet BMPs.	All campsites used for spot and dunnage should meet BMPs.	No stock camp. Designate spot and dunnage site north of lake, and access route.
12. Glacier Divide				
Destination: Muriel Lake	Access	Muriel Trail, observed Trail Class 2, Resource Rating 2.5, well-defined from just west of Piute Pass, goes through wet meadow benches, moderate risk factors. GLA17 less than 10% visible.	Stabilize Muriel Trail. GLA17 should remain less than 10% visible.	Realign/stabilize trail. Low use until stabilized to prevent further degradation. Approve GLA17 for very low levels of use.
	Recreation Category Setting	Recreation Category 2, moderate to high opportunities for solitude. Recreation Impact Rating = 1.6.	Muriel Lake: Manage area for moderate use destination with moderate impacts to few sites.	
	Use levels 01-04	7-14 trips, 28-74 stock		Up to 4 spot and dunnage trips and limit to 24 stock until the trail is realigned/stabilized. Up to 14 spot and dunnage trips after the trail is repaired. No more than occasional use with low stock numbers to Wahoo Lake.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	No grazing.
	Campsites		No stock camps.	No stock camps.
13. Glacier Divide				
Destination: Packsaddle Lake	Access	Packsaddle Lake use trail GLA02: Resource Rating 1, sporadic, mostly undefined. Moderate risk factors if use increased.	Maintain trail less than 10% visible.	Approve GLA02 to Packsaddle Lake for very low use.
	Recreation Category Setting	Recreation Category 1, low use and high opportunities for solitude. Recreation Impact Rating = 1.4.	Packsaddle Lake: Manage for high opportunities for solitude, low impacts.	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Use levels 01-04	1-4 trips, 2-24 stock		Up to 2 spot and dunnage trips to maintain high opportunities for solitude and trail-less conditions consistent with a Recreation Category 1.
	Grazing	Grazing requested. Meadows near confluence with Piute Creek remain wet; very small, wet, and fragile lakeshore riparian vegetation areas at lake outlet are at high-seral vegetative condition. Reported: 2001/2002/2003 is 12/0/0.	Maintain vegetation at moderate to high seral status.	Unsuitable; do not allow grazing.
	Campsites		No stock camp.	No stock camp.
14. Humphreys				
Destination: Desolation Creek / Lake	Access	Desolation Lake Trail, observed Trail Class 1, Resource Rating 1, low development trail. Portions of trail below Lower Desolation Lake incised through meadows.	Keep stable without changing character, or increasing development.	
	Recreation Category Setting	Desolation Creek/Lake: Recreation Category 2, low to moderate use and impacts, moderate to high opportunities for solitude. Recreation Impact Rating = 0.8.	Desolation Creek/Lake: maintain area as low to moderately used destination with limited sites.	
	Use levels 01-04	4-13 trips, 28-53 stock		Up to 14 spot and dunnage trips. Keeping stock numbers at current levels will maintain moderate to high opportunities for solitude and keep trail with primitive character.
	Grazing	Grazing requested. Wet meadows near and above Desolation Lake to Humphreys Lakes remain too wet to reach range readiness. Upland	Maintain vegetation at moderate to high seral status.	Approve grazing, 60 stock nights available, 30% AUF.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		vegetation low productivity over a large area. Some loss of vegetative cover near and along trails.		
	Campsites		No stock camp.	No stock camp.
15. Humphreys				
Destination: Humphreys Lakes	Access	Humphreys Trail, observed Trail Class 1, Resource Rating 1, lightly defined trail. Visible up to Marmot Lake, and then becomes less defined.	Keep stable without changing character, or increasing development.	Keep use levels low.
	Recreation Category Setting	Recreation Category 1 at upper lakes, Recreation Category 2 at Marmot Lake. Low use and high opportunities for solitude. No Recreation Impact Rating.	Humphreys Lakes: maintain for low use and high opportunities for solitude.	
	Use levels 01-04	3-15 trips, 9-113 stock		Up to 10 spot and dunnage trips. No more than 4 of these trips to Upper Humphreys Lake to be consistent with Recreation Category 1 and to maintain high opportunities for solitude.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	Do not approve grazing.
	Campsites		No stock camps.	No stock camps.
16. Humphreys				
Destination: Tomahawk / Mesa Lakes	Access	Undefined use trail HUM35 to Mesa Lake, Resource Rating 0, slight risk factors. Undefined use trail HUM30 to Tomahawk Lake, Resource Rating 0, slight	Keep undefined, stable without changing character.	Allow cross country travel to Tomahawk Lake until or unless trail becomes defined, then must stay on user trail to Mesa Lake and down to Tomahawk Lake.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		risk factors.		
	Recreation Category Setting	Recreation Category 1, low to moderate use, low to moderate opportunities for solitude.	Mesa Lake: maintain for moderate to high opportunities for solitude. Tomahawk Lake: Maintain as Recreation Category 1 high opportunities for solitude.	
	Use levels 01-04	0-2 trips, 0-6 stock to Mesa 1-8 trips, 3-22 stock to Tomahawk		Up to 4 spot and dunnage trips to each lake. 25 stock per year to Mesa and Tomahawk Lakes, combined. This will maintain high opportunities for solitude in trail-less area.
	Grazing	Grazing Requested. No grazing reported 2001-2003. Thin soil, low productivity, sparse vegetation, easily eroded soil.	Maintain vegetation at moderate to high seral status. No accelerated soil erosion.	Unsuitable; No grazing allowed.
	Campsites		No stock camps.	No stock camps.
17. Lamarck				
Destination: Lamarck Lakes	Access	Lamarck Trail observed Trail Class 3, Resource Rating 1 to Grass Lake, Trail Class 2, Resource Rating 1 above Grass to just below Upper Lake. 1/8 mile below lake, trail in stream channel, potential instability. Lamarck Col trail crosses creek below lake, observed Trail Class 2 & 1, Resource Rating 3, moderate to severe impacts at lower meadows, and meadow below col. Many constructed features in steep sections.	Keep trails stable without changing character or adding substantial structures.	NSCS above Upper Lamarck Lake to Col and on 1/8 mile section below Upper Lamarck Lake.
	Recreation Category Setting	Lamarck Lakes and Col: Recreation Category 2, moderate impacts. Recreation Impact Rating = 1.4.	Lamarck Lakes: Reduce overall impacts; manage for moderate to high opportunities for solitude	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Use levels 01-04	0-6 trips, 0-21 stock (includes Lamarck Lakes and Lamarck Col)		Up to 5 spot and dunnage trips to campsites just above Upper Lamarck Lakes.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status. Management Direction is no grazing allowed when not requested.	No grazing.
	Campsites	Limited camping at Lower Lamarck Lake.		No stock camps. Designate spot and dunnage campsite just above Upper Lamarck Lake.
18. Piute				
Destination: Piute Corridor	Access	Piute Pass Trail: Trail Class 3, generally stable, except at meadow, small stream crossings. Yosemite toad critical area along system trail with minor trampling, water diversion effects from close proximity to trail. Piute Camp Access, use trail PIU01, Resource Rating 1, slight incision, low risk factors. Use trail to snow survey cabin at Loch Leven, short, stable.	Minimal trail effects to Yosemite toad breeding habitat.	Repair trail. Allow use of PIU01.
	Recreation Category Setting	Piute Corridor Recreation Category 3, low to moderate opportunities for solitude. Limited camping within fire closure. Recreation Impact Rating = 1.6.	Piute Lake: Manage as Recreation Category 3 with concentrated impacts areas away from lake and main trail corridor.	
	Use levels 01-04	BPO: 0-4 trips, 0-13 stock		Up to 20 spot and dunnage trips (anywhere in the destination zone), consistent with a Recreation Category 3 high use corridor with adequate capacity.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	Do not approve grazing.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Campsites	Spot/dunnage sites only. Two spot and dunnage sites on the north shore of Piute Lake do not meet BMPs. High density of spot and dunnage and hiker campsites on north side of lake. Spot/dunnage site at the outlet of Loch Leven on the North side of the lake does not meet BMPs, as some tent pads are within 5 feet of water.	All campsites should meet BMPs.	Allow spot and dunnage only at sites that meet BMPs and are over 100 feet from surface water. Designate 1 site for spot and dunnage at Piute Lake and 1 at Loch Leven. Contain the spot and dunnage site at the outlet of Loch Leven away from the lake, do not use this site as a spot and dunnage site.
19. Sabrina				
Destination: Baboon Lake	Access	Baboon Lake Trail: observed Trail Class 1, Resource Rating 2, moderately defined, some incision at seeps, moderate risk factors.	Keep trail stable with minimal development.	
	Recreation Category Setting	Baboon Lake: Recreation Category 2, moderate to high opportunities for solitude.	Baboon Lake: Maintain moderate to high opportunities for solitude.	
	Use levels 01-04	0-1 trip, 0-6 stock		Up to 3 spot and dunnage trips, up to 10 stock per year, consistent with a low use Recreation Category 2, primitive trail. This will maintain high opportunities for solitude.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	No grazing.
	Campsites		No stock camp.	No stock camp.
20. Sabrina				
Destination: Blue Lake	Access	Sabrina Lake Trail: Trail Class 3, steep, stable. Blue Lake camp access trail SAB09, short, stable to upper camp, moderate incision with high risk factors beyond. Inyo beardtongue along Sabrina	Maintain Inyo beardtongue habitat.	Allow use to upper camp only.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		Lake Trail outside wilderness.		
	Recreation Category Setting	Blue Lake: Recreation Category 3, moderate to high opportunities for solitude. High day use area. Recreation Impact Rating = 1.4.	Blue Lake: Manage for low to moderate opportunities for solitude.	
	Use levels 01-04	0-3 trips, 0-9 stock		Up to 6 spot and dunnage trips. Limit trips into this very high use Recreation Category 3 area with limited camping and crowding.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	Do not approve grazing.
	Campsites	Spot/dunnage site near the lake inlet does not meet BMPs, as it is closer than 50 feet to surface water. Sediment from campsite-related social trail entering Blue Lake.	All spot and dunnage and stock holding sites should meet BMPs.	Designate 1 spot and dunnage site on benches above Blue Lake. No stock camps. Prohibit use of campsite at inlet of Blue Lake.
21. Sabrina				
Destination: Dingleberry Lake	Access	Sabrina Lake Trail: Trail Class 3, stable. No use trail found to Fishgut Lake above Dingleberry.	Prevent development of use trail to Fishgut Lake.	Prohibit use to Fishgut Lake (SAB01).
	Recreation Category Setting	Dingleberry Lake: Recreation Category 3, low to moderate opportunities for solitude. Recreation Impact Rating = 1.8	Dingleberry Lake: Manage area for low to moderate opportunities for solitude.	
	Use levels 01-04	4-13 trips, 16-67 stock		Up to 16 spot and dunnage trips. This will maintain opportunities for solitude in Recreation Category 3 primary trail corridor.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	Do not approve grazing.
	Campsites	Spot/dunnage site at the system trail crossing near Dingleberry	All spot and dunnage and stock	Designate 1 spot and dunnage site. Set back campsite from

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		Lake is too close to water and does not meet BMPs.	holding sites should meet BMPs.	water and contain site. No stock camps.
22. Sabrina				
Destination: Emerald Lakes	Access	Emerald Lake Trail: observed Trail Class 1.5 - 2, well-defined, few structures, appears heavily used. Isolated moderate risk factors at stream crossings, short steep sections near lake.	Stable trail.	Maintain trail as Trail Class 2.
	Recreation Category Setting	Emerald Lake: Recreation Category 3, low to moderate opportunities for solitude. Recreation Impact Rating = 1.8.	Emerald Lakes: Manage area for low to moderate opportunities for solitude.	
	Use levels 01-04	15-19 trips, 104-140 stock		Up to 25 spot and dunnage trips consistent with high use Recreation Category 2 area. This will maintain moderate opportunities for solitude.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	No grazing.
	Campsites		No stock camp.	No stock camp.
23. Sabrina				
Destination: Upper Sabrina Basin (includes Hungry Packer, Hell Diver, Moonlight, Midnight, Sailor, Topsy Turvy and Pee Wee)	Access	Topsy Turvy Lake Trail: observed Trail Class 2, Resource Rating 2, ends well below lake at camp near falls. Alternate access to lake via use trail on slabs near Hungry Packer trail. Moonlight Falls Camp trail, observed Trail Class 1, Resource Rating 3, moderate impacts at creek crossing before camp. No trail to Moonlight Lake.	Ensure stability of trail to Moonlight Falls camp. Prevent further expansion of use trails in basin.	Find best alignment for Moonlight Falls trail, add structures to stabilize creek crossing. Allow access to camps along Topsy Turvy Lake trail below falls, but not to lake.
	Recreation Category	Upper Sabrina: Recreation	Upper Sabrina: Manage area for	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Setting	Category 2, low to moderate opportunities for solitude. No Recreation Impact Rating.	moderate opportunities for solitude while camping, low to moderate while traveling.	
	Use levels 01-04	0-33 trips, 0-186 stock		Up to 40 spot and dunnage trips, consistent with high use primary trail corridor. Multiple destinations in this zone will disperse the trips to various locations and maintain moderate opportunities for solitude while camping.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	Do not approve grazing.
	Campsites		No stock camp.	No stock camps.
24. Sabrina				
Destination: Donkey Lake	Access	Donkey Lake Trail observed Trail Class 1.5, Resource Rating 2, well-defined until split with hiker trail, awkward, minimal development, but mostly stable at current use. Risk factors if use increases. Use trails from Baboon Lake to Blue Lake are not evident or likely.	Stable access without adding many structures.	Keep use low. Prohibit use trail from Blue Lake.
	Recreation Category Setting	Donkey Lake: Recreation Category 2, low to moderate opportunities for solitude. Recreation Impact Rating = 1.0.	Donkey Lake: Manage area for moderate to high opportunities for solitude.	
	Use levels 01-04	none reported		Up to 6 spot and dunnage trips, will maintain high opportunities for solitude in Recreation Category 2 area with limited capacity for camping.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	Do not approve grazing.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Campsites	Limited capacity for camping.	No stock camps.	No stock camps.
25. Tyee				
Destination: Tyee Lakes	Access	Tyee Lake Trail: observed Trail Class 2-3 to Tyee Lakes, low Trail Class 2 or Trail Class 1 over Table Mountain, then steep and more developed again into George Lake and Sabrina Lake. Some erosion, mostly stable at current use. Hunting trips on undefined routes on Table Mountain.	Maintain stability without changing trail development.	Allow only low use above Tyee Lakes, limited hunting on Table Mountain.
	Recreation Category Setting	Tyee Lakes: Recreation Category 2, moderate to high opportunities for solitude. No Recreation Impact Rating.	Tyee Lakes: Manage area for moderate to high opportunities for solitude.	
	Use levels 01-04	0-2 trips, 0-9 stock		Up to 2 spot and dunnage trips
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	No grazing.
	Campsites		No stock camps.	No stock camps.
26. Treasure				
Destination: Treasure Lake	Access	Treasure Lake: observed Trail Class 3, generally stable, some widening, moderate bank impacts at creek ford, short section steep w/ slight erosion below lakes. Terminates at creek between two lowest lakes. Evident use trail continues up along stream above.	Stable trail. Ensure no expansion of use trails.	No commercial stock use beyond lower lakes.
	Recreation Category Setting	Recreation Category 2, low to moderate opportunities for solitude (day hikers). Recreation Impact Rating = 1.6.	Manage area for moderate to high opportunities for solitude. Reduce overall impacts.	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Use levels 01-04	0-5 trips, 0-25 stock		Up to 8 spot and dunnage trips.
	Grazing	No grazing reported or requested.	No grazing.	No grazing.
	Campsites			No stock camps. Close campsite near Treasure Lake bench.
	Other Issues	Mountain yellow-legged frog reintroductions occurring in Upper Treasure Lakes.	Commercial pack stock use is coordinated with Mountain Yellow Legged Frog habitat and population recovery objectives.	
27. Bishop Pass				
Destination: Long Lake	Access	Bishop Pass Trail observed Trail Class 3, generally stable. Use trail BIS04, Resource Rating 1, to camps near outlet, slight incision around lake, stable, defined.	Maintain stability of use trail without changing character of trail.	Allow use of use trail at low to moderate levels.
	Recreation Category Setting	Recreation Category 3, high use area both overnight and day hikers. Low opportunities for solitude. Recreation Impact Rating = 2.0.	Manage as a Recreation Category 3 with concentrated impact areas on trails and at lakes.	
	Use levels 01-04	2-6 trips, 4-31 stock		Up to 10 spot and dunnage trips.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	No grazing.
	Campsites	Spot/dunnage site at the outlet of Long Lake is closer than 100 feet to water, and the hillside between camp and lake is denuded of vegetation, allowing sediment to erode off-site into water. Site currently does not meet BMPs.	All spot and dunnage and stock holding sites should meet BMPs.	If the site at the outlet of Long Lake is to continue to be used, a trail around the steep hillside should be designated to access the lake from the site. Otherwise, do not allow spot and dunnage at this site. No stock camps.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Other Issues	Day use tie up site is close to trail and surface water.		Day use tie-up site will be designated on the north side of Long Lake, away from trail.
28. Bishop Pass				
Destination: Bull Lake	Access	Bull Lake Trail: observed Trail Class 2, Resource Rating 1 to inlet. Climbs steeply in riparian habitat, Trail Class 2 & 1, Resource Rating 3 with very high risk factors to Chocolate Lakes. Observed Trail Class 1 above Chocolate Lakes to Ruwau Lake, steep with slight-mod erosion. Congdon's sedge population bisected by Chocolate to Ruwau trail.	Prevent impacts to riparian and at creek crossings near Chocolate Lakes without adding substantial development. Maintain Congdon's sedge population in good condition.	Chocolate Lake Trail NSCS above Bull Lake inlet to Ruwau Lake outlet.
	Recreation Category Setting	Bull Lake: Recreation Category 2, low to moderate opportunities for solitude. Recreation Impact Rating = 1.	Bull Lake: Manage area for moderate opportunities for solitude. Reduce overall impacts around lake.	
	Use levels 01-04	0-2 trips, 0-6 stock		Up to 10 spot and dunnage trips.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	Do not approve grazing.
	Campsites		No stock camps.	No stock camps.
29. Bishop Pass				
Destination: Hurd Lake	Access	Hurd Lake: use trail BIS02, Resource Rating 0, short trail to camps. Stable, no risk factors.	Same.	
	Recreation Category Setting	Hurd Lake: Recreation Category 3, low opportunities for solitude. Recreation Impact Rating = 1.2.	Hurd Lake: Manage area for moderate to high opportunities for solitude (isolated area away from primary trail).	
	Use levels 01-04	0-2 trips, 0-9 stock		Up to 10 spot and dunnage trips. Use of area for all expense/full

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
				service trips.
	Grazing	No grazing reported or requested. Some areas of the meadow have fen characteristics.	Maintain vegetation at moderate to high seral status. Maintain fen in functioning condition.	No grazing.
	Campsites	Good location for campsites. Has been used as a base camp location but not in the past few years.	Maintain campsites proper distance from water.	Designate a campsite with no stock holding for spot and dunnage or all expense type camp.
30. Bishop Pass				
Destination: Marie Louise Lake	Access	Marie Louise Trail: observed Trail Class 2, Resource Rating 2, slight impacts at creek crossing, few structures, moderately steep on dry slope, slight erosion with current use (low).	Maintain character of trail, minimal development.	Allow use compatible with low development trail.
	Recreation Category Setting	Marie Louise Lake: Recreation Category 2, low to moderate opportunities for solitude due to low capacity and high day use. Recreation Impact Rating = 1.8.	Marie Louise Lake: Manage area for moderate opportunities for solitude. Reduce overall impacts around lake.	
	Use levels 01-04	0-2 trips, 0-6 stock		Up to 2 spot and dunnage trips.
	Grazing	No grazing reported or requested.		No grazing.
	Campsites	Current spot and dunnage site meets BMPs. Limited camping, low capacity area.	No stock camps.	No stock camps.
31. Bishop Pass				
Destination: Upper Bishop Creek (Bishop Lake, Saddlerock Lake)	Access	Timberline Tarns use trail BIS08, Resource Rating 0, undefined route, slight risk factors at meadows, seeps if much use. Saddlerock Lake use trail BIS09 to campsites from outlet, lightly defined, few risk factors. Ledge Lake use trail	Limit impacts and expansion of use trails.	Approve use trail BIS09. Prohibit use of use trails BIS08, BIS03, BIS06.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		BIS03 risk factors near tarns, wet areas. Margaret Lake use trail BIS06, Resource Rating 1.5, lightly defined, slight impacts at creek crossing, slight incision in meadow, moderate risk factors if use increased.		
	Recreation Category Setting	Upper Bishop Creek: Recreation Category 3, low opportunities for solitude. Recreation Impact Rating = 2.0.	Upper Bishop Creek: Manage as a Recreation Category 3 with concentrated impact areas on trails and at lakes.	
	Use levels 01-04	10-19 trips, 30-88 stock		Up to 25 spot and dunnage trips.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	No grazing.
	Campsites		No stock camps.	No stock camps.
32. Bishop Pass				
Destination: Bishop Pass to SEKI	Access	No trail issues.		
	Recreation Category Setting	Bishop Pass to SEKI: Recreation Category 3, low opportunities for solitude. Recreation Impact Rating = 2.0.	Bishop Pass to SEKI: Manage as a Recreation Category 3 with concentrated impact areas on trails and at lakes.	
	Use levels 01-04	RPO: 48-58 trips, 180-232 stock MLPO: 0-1 trip, 0-4 stock		Up to 58 spot and dunnage trips.
	Grazing			
	Campsites		No stock camps.	No stock camps.

FISH CREEK/CONVICT/MCGEE

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
1. Cold Duck				
Destination: Coldwater Corridor	Access	Duck Pass: observed Trail Class 3, heavy stock and public use, generally stable. Snow bypass north of pass - duplicate, stable. Emerald to Skelton Trail: observed Trail Class 2, Resource Rating 3, moderate erosion, incision, high risk factors. Sky Meadows trail observed Trail Class 2 & 1, Resource Rating 4, moderate-severe impacts to stream and riparian, high risk factors. Woods Lake Trail: observed Trail Class 2 to first lake, Trail Class 1 to upper lake, Resource Rating 3 with risk factors.	Prevent further impacts to degraded trails.	Emerald to Skelton NSCS. Sky Meadow Trail NSCS. Allow use of Duck Pass snow bypass only when snow blocks main trail. Limit use to low numbers on Woods Lake trail.
	Recreation Category Setting	Recreation Category 3.	Day rides to Emerald, Barney, Heart, Crystal Lakes manage for moderate levels of use to these locations. Woods Lake, Skelton use for spot and dunnage.	
	Use Levels 01-04	MLPO: 1-8 trips, 4-39 stock McGee: 0-4 trips, 0-50 stock		Up to 12 spot and dunnage trips to two operators to maintain low commercial pack stock use relative to Recreation Category 3. Crowding occurs with high levels of day hikers, day rides, and overnight use in basin. Good alternative for early season use. Woods Lake - manage for infrequent use to lower lake only.
	Grazing	Not reported or requested.		No grazing.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Campsites			No stock camps.
2. Purple Bench				
Destination: Purple Lake	Access	Purple/Ram Lake Trail observed Trail Class 2, (high impacts in 2001, mostly stabilized in 2003) to camps. Use trail short cuts between PCT/Cascade trail near outlet. Camp access issues at Purple Bench camps - creek crossing with moderate impacts. There are areas with fen characteristics near High Camp and Ram Camp.	Stabilize trail to camps. Reduce unnecessary use trails. Maintain functioning fens.	Stabilize crossing at Purple Bench camp access. Prohibit use on PPB08.
	Recreation Category Setting	Recreation Category 2.	Reduce impacts associated with use trail proliferation and campsite impacts.	
	Use Levels 01-04	13-31 trips; 61-126 stock		Up to 24 spot and dunnage trips a year. Use of area for moderate to high level of all expense type trips.
	Grazing	2001: Moderate altered vegetative composition, bare areas (dusting pits), reduced vegetative cover, fragmented sod, PFC at risk with downward trend on local stream segments, with a few headcuts. 2004 and 2005: A few stream segments remain functional at-risk, but with an upward trend, due to revegetation after 2 years of rest. stream segment nearest camp remains straightened relative to other segments. Reported stock nights in 2001/2002/2003/2004: 218/438/47/0. Purple Bench Meadow has some areas with fen characteristics.	Provide adequate vegetation species and cover to protect from soil and stream bank erosion. All streams move toward proper functioning condition (PFC). Do not exceed more than 20% stream bank trampling in reach near camp.	Purple Lake Zone: Allow grazing, 90 stock nights. Enforce all applicable standards but especially readiness and streambank trampling limits. Repair headcut above Ram Tarn pond, protect springs at Ram Tarn pond. Utilize existing crossing of Deer Creek. Prohibit impacts along stream across meadow from "Deer Camp" and along stream at "Deer Camp". Purple Bench: approve grazing. 12 stock nights available.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Campsites	Three high impact sites with access concerns. One old highline location near water, so site not meeting BMPs, but highline has been moved.	Sites meet BMPs.	Maintain and contain 3 stock camps at Purple Lake. Improve and stabilize access to sites. Rehabilitate old highline near water to prevent sediment entry into water. Limit camping when not with clients to no more than 5 nights a year. Designate 1 stock camp at Purple Bench.
	Other Issues	Campfires - lake is just at 10,000 feet, some sites below some above the fire closure	Reduce confusion of various fire closures.	Open to campfires, modify elevational boundary.
3. Purple Bench				
Destination: Ram Bench	Access	Ram Lake Trail (from Purple Lake camps) observed Trail Class 1, no structures, some headcuts entering meadow. Risk factors in meadows. Light stock use, high risk factors. Use trails from Ram Lake to Virginia (PPB14) & Franklin (PPB13). Subalpine fireweed along trail near Purple Bench.	Stable trail with minimal structure/development. Stabilize headcuts entering meadow. Maintain population of subalpine fireweed.	Limit commercial stock on segment to bench to low numbers. NSCS from bench to Ram Lake. Prohibit use on PPB14 & PPB13.
	Recreation Category Setting	Recreation Category 2.		
	Use Levels 01-04	0-4 trips; 0-10 Stock		Up to 4 spot and dunnage trips only with low stock numbers (10), consistent with a low visibility trail in Recreation Category 2. Limit use to bench below Ram Lake.
	Grazing	Reported grazing, likely in zone but actually occurs closer to Purple Lake. Low vegetative productivity and resiliency and poor access to grazing at Ram lake.	Vegetation is likely at desired condition but with low productivity and low resiliency. Limit trampling in fen.	Unsuitable, prohibit grazing.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Campsites	Ram Camp site causing sediment entry into Purple Creek, not meeting BMPs.	All campsites meet BMPs.	No stock camps.
4. Purple Bench				
Destination: Lake Virginia	Access	PCT observed Trail Class 3, generally stable. Use trail PPB14 (see Ram Destination). Camp access routes generally dry/stable.	Prevent expansion of new use trails.	Prohibit use of use trail past grazing zone (PPV14) to Franklin, Glennette Lakes.
	Recreation Category Setting	Recreation Category 2, low to moderate opportunities for solitude along primary trail corridor, moderate opportunities for solitude while camping.	Maintain moderate opportunities for solitude for camping.	
	Use Levels 01-04	0-4 trips; 0-24 stock		Up to 10 spot and dunnage trips. Consistent with high use corridor Recreation Category 2. Encourage use shift from Purple to Virginia. Use of area for occasional all expense trips and traveling trips.
	Grazing	Low productivity, thin easily fragmented sod, highly erosive soils, and low resiliency. Sod fragmentation, decreased vegetative cover. Reported grazing: 24/60/0.	Increase and maintain vegetative soil cover and litter.	Allow 20 stock nights of grazing.
	Campsites	Low to moderate impacted sites.	Maintain low impact sites.	Designate 2 stock camps in durable areas.
5. Purple Bench				
Destination: Duck Lake / Pike Lake / Duck Creek	Access	Duck Pass observed Trail Class 3, heavy stock and public use, generally stable. Duck Pass to Deer Lake Trail observed Trail Class 1, lightly defined, rocky awkward conditions.	Ensure stability of Duck/Deer trail without adding structural development.	Duck Pass to Deer Lake Trail NSCS.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Recreation Category Setting	Recreation Category 3. Camping closure in effect at outlet.		Maintain camping closure, allow commercial pack stock use at Duck Creek.
	Use Levels 01-04	MLPO: 6-21 trips; 18-87 stock Reds: 0-1 trips; 0-5 stock		Allow up to 20 spot and dunnage trips to Duck Lake, consistent with Recreation Category 3, no overnight stock. Allow up to 6 trips to Pika Lake with no more than 10 stock. Allow low use for all expense trips below outlet area.
	Grazing	Minor and localized reduced cover especially on access slopes between lake-side trail and benches to the north-northeast of lake. Overall moderate productivity. Streams and meadow at PFC. Reported grazing stock nights: 12/16/0, likely on benches rather than lakeshore terraces. Occupied Yosemite toad habitat in meadow along northeast shore in desired condition.	Adequate vegetative cover with desired species to protect meadow and streambanks. Maintain streams and meadow at PFC. Maintain high quality Yosemite toad habitat.	North of Duck Lake: Allow grazing, at high recent historical levels, 16 stock nights. Critical areas closed to stock entry and grazing.
	Campsites	Small capacity site at Duck Creek.	Maintain existing size of site, do not allow site to expand.	Designate 1 stock camp below Duck Lake outlet along Duck Creek. Do not hold more than 20 stock. No stock camp at Pika Lake.
6. Silver Divide				
Destination: Grassy Lake	Access	Minnow Creek Trail: observed Trail Class 3, slight to moderate erosion & degraded conditions in steep areas. Slight instability, diversions at creek crossing. Use trail SIL16 accesses grazing in box canyon above Grassy Lake, Resource Rating 3,	Keep use light on use trail SIL04, to prevent degradation.	Stabilize access on use trail SIL16.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		moderate to severe headcutting, incision. Brave Lake use trail (SIL04) Recreation Category 2, lightly defined at first, but more evident closer to lake. Many small ephemeral streams, some slight-moderate risk factors.		
	Recreation Category Setting	Recreation Category 2, high impacts from recreation use, primarily grazing and campsite impacts. Access from west and east, popular for traveling and all expense trips.	Recreation Category 2. Moderate impacts that are not easily noticeable.	Cap use levels for all expense trips and consider reductions if high impacts to sites persist. One night stay only in Silver Divide.
	Use Levels 01-04	D&F: 0-2 trips; 0-20 stock MLPO: 0-1 trips; 0-3 stock		Up to 8 spot and dunnage trips. D&F= 2 trips. MLPO= 4 trips. HS=2 trips
	Grazing	Moderate altered vegetative composition, active unstable banks, active headcuts, reduced vegetative vigor, abundance, and cover. Stream reaches assessed are functioning at risk with downward trend. Reported grazing: 306/447/199 stock nights. Occupied Yosemite toad habitat has associated hydrologic instability associated with headcuts. Unstable access to box canyon above Grassy Lake.	Stream moves toward PFC. Provide adequate vegetative cover, composition, and vigor to provide watershed protection, to trap and hold sediment, and to stabilize stream banks. Reduce sediment input (upstream trail erosion sites are the likely sources). Stabilize and maintain toad habitat area hydrologic condition. Stable conditions along access to box canyon.	Grassy Lake Meadow, rest from grazing. Establish both Stream Condition Inventory (SCI) and vegetation baseline monitoring; re-assess within 5 or fewer years with repeated monitoring to determine if grazing may be resumed. Limit use of grazing in Box Canyon to 2 trips to limit use of trail.
	Campsites	BMP analysis completed on three stock holding campsites. One site, on northeast shore of lake is a good location for stock holding. Other two, one on the northwest side of lake, and one along the inlet stream south of the meadow, do not meet BMPs.	All campsites should meet BMPs.	Designate 2 stock camps, over 100 feet from water and the meadow. The designated site along the inlet stream needs to be contained so it does not contribute sediment to water.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
7. Silver Divide				
Destination: Chief / Papoose / Lone Indian / Squaw Lakes	Access	Minnow Creek Trail: observed Trail Class 3, generally stable, confusing creek crossing at Papoose. Goodale Pass Trail observed Trail Class 2, Resource Rating 2, awkward, unstable in places. Goodale Pass use trail SIL15, steep, awkward with erosion near Lake of Lone Indian. Papoose to Lone Indian use trail SIL17 steep, eroded, parallels creek - short cuts system trail.	Increase stability of system trails. Reduce impacts on riparian from use trail.	Only approve use of Goodale use trail SIL15 during snow blockage on system trail. Prohibit use of use trail SIL17.
	Recreation Category Setting	Recreation Category 2 along a primary trail corridor (PCT/JMT).	Allow for moderate to high use and contained impacts along trail corridor.	
	Use Levels 01-04	HSPS: 0-3 trips; 0-20 stock MLPO: 0-1 trips; 0-7 stock		Up to 6 spot and dunnage trips to two operators. Allow occasional use of Chief Lake for all expense trips. Use of area for all expense/traveling trips with a one night stay only in Silver Divide.
	Grazing	Reported grazing: 9/0/0 stock nights. Fragmented sod, reduced vegetative cover, associated with trailing and trail erosion especially between Warrior Lake trail junction and Grassy Lake Meadow, also including the along the trail to Peter Pande on the Minnow Creek side of the hill. Occupied Yosemite toad habitat at Papoose, Lone Indian, and Squaw Lakes meadows in desired condition.	Increase vegetative cover, decrease bare soils and erosion, especially at the outlet of Squaw Lake, in the meadows between the Warrior Lake junction and Papoose Lake, at the inlet side of Papoose, between Papoose and Lone Indian and between Lone Indian and Grassy Lake Meadow. Maintain high quality Yosemite toad habitat.	No grazing. Unsuitable.
	Campsites	Few campsite with moderate	Contain campsites and insure	Designated 1 stock camp at

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		impacts.	proper distance from water.	Chief Lake.
8. Silver Divide				
Destination: Wilbur May Lake	Access	Wilbur May Trail observed Trail Class 2, Resource Rating 1, stable with current use.	Maintain current condition.	No remedy needed if use levels remain low.
	Recreation Category Setting	Low capacity for camping.		Limit party size of 8 persons suitable to capacity of camping.
	Use Levels 01-04	MLPO: 0-2 trips, 0-18 stock HSPS: 0-2 trips, 0-18 stock		Up to 4 trips shared between two operators. Olive, Long Canyon, Wilbur May, Grassy, Jackson will be managed as a zone for westside packers.
	Grazing	No grazing requested.	Management direction is no grazing approved where not requested.	No grazing approved.
	Campsites	No stock camp.	No stock camp.	No stock camp.
9. Silver Divide				
Destination: Olive Lake	Access	Olive Lake Trail observed Trail Class 2, Resource Rating 1, generally stable with low risk factors. Use trail SIL08 grazing access to benches, lightly defined, Resource Rating 1.	Maintain existing trail conditions without excessive structural development.	No remedy needed if use levels remain low.
	Recreation Category Setting	Recreation Category 2 moderate to high opportunities for solitude. Low capacity for camping.	Maintain existing conditions.	
	Use Levels 01-04	0-2 trips, 0-40 stock		Up to 6 spot and dunnage and use of area for all expense/traveling trips no more than 2 times a year. Olive, Long Canyon, Wilbur May, Grassy, Jackson will be managed as a zone for westside packers.
	Grazing	At Olive Lake: Very small and	Olive Lake: Protect wet	Olive Lake: Unsuitable, prohibit

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		wet meadows on Olive Lakeshore. Benches west of Olive Lake: Rocky, moist to dry meadows. No water, soil, or vegetation changes observed.	meadows along lakeshore. Benches west of Olive Lake: Maintain current good vegetation condition and good soil condition.	grazing. Benches west of Olive Lake: Allow grazing 40% vegetation utilization for 114 stock nights.
	Campsites	Stock holding site east of Olive Lake near the outlet does not meet BMPs because the hitch-line is within 10 feet of the stream. Site at inlet site meets BMPs.	All campsites should meet BMPs.	Obliterate stock holding site at outlet. Designate 1 stock camp.
10. Silver Divide				
Destination: Peter Pande Lake	Access	Peter Pande Trail, observed Trail Class 2, Resource Rating 4, degraded, incision, affecting hydrology. Peter Pande Tarn use trail (SIL13) lightly used, slight incision in meadows, risk factors. There are areas of Peter Pande Tarn with fen characteristics.	Reduce rate of degradation. Limit fen trampling.	Limit stock numbers until trail can be repaired or rerouted. Approve use trail SIL13
	Recreation Category Setting	Recreation Category 2, off primary trail. High impact along trail to lake.	High opportunities for solitude. Improve trail.	Limit party size to 10/15.
	Use Levels 01-04	0-4 trips; 0-26 stock		Until Peter Pande Trail is repaired, allow 1 trip each to MLPO and HSPS. Allow up to 3 trips each when trail is fixed.
	Grazing	Fragmented sod, low productivity, low resiliency, active headcuts, meadow damage along access trail. Reported grazing: 92/14/26 stock nights. Yosemite toad critical area below Peter Pande Lake in desired condition. Un-named tarn on bench above Peter Pande Lake has Occupied Yosemite toad	Stabilize headcuts, increase vegetative cover. Maintain high quality Yosemite toad habitat.	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		habitat in meadow with observed trampling and chiseling impacts.		
	Campsites	Limited camping. One stock-related site (likely spot/dunnage) does not meet BMPs; sediment reaching lake.	Campsites meet BMPs.	No stock camps.
11. Silver Divide				
Destination: Long Canyon	Access	Long Canyon Trail to Beetlebug Lake (last 1/2 mile) has large jump offs, awkward, has sections that are incised and unstable.	Prevent further degradation.	Trail to Beetlebug Lake(last 1/2 mile) NSCS.
	Recreation Category Setting	Recreation Category 2, high opportunities for solitude.	Maintain high opportunities for solitude.	
	Use Levels 01-04	Minarets: 0-2 trips, 0-34 stock. Use of area for occasional all expense/traveling trips.		Up to 4 spot and dunnage trips per year and use of area for all expense/traveling trips. Olive, Long Canyon, Wilber May, Grassy, Jackson will be managed as a zone for westside packers.
	Grazing	Stream was assessed to be at PFC. Moderate productivity. Some trampling of springs, headcuts in spring channels, and a few headcuts within dry forested area near meadows . High utilization (estimated near 40%) in some portions of the meadow in 2004 with 140 reported stock nights. Grazing reported 2001-2004: 130/68/0/140.	Allow headcuts in spring and stream channels to revegetate and stabilize. Protect springs and wet areas.	Allow grazing. 130 stock nights available. Springs are critical areas where negligible trampling is allowed.
	Campsites	One stock holding site below Beetlebug Lake does not meet BMPs, too close to stream and meadow.	All campsites must meet BMPs.	2 stock camps: 1 at the lower part of Long Canyon, 1 approximately one mile up the canyon.
12. Silver Divide				

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
Destination: Jackson Meadow	Access	Minnow Creek Trail, Trail Class 3, generally stable. Pick & Shovel Mine use trail (SIL14) low risk factors, lightly defined but evident to old cabin.		
	Recreation Category Setting	Recreation Category 2 along primary trail corridor. Impacts to riparian, and risk factors. Used for all expense/traveling trips.		One night stay only in Silver Divide.
	Use Levels 01-04	none reported		All expense and use of stock camp for 2 day spot and dunnage trips, with clients dropped elsewhere. Allow up to 5 spot and dunnage trips (MLPO). Olive, Long Canyon, Wilber May, Grassy, Jackson will be managed as a zone for westside packers.
	Grazing	Vegetative composition varies from high to low similarity to desired composition. Reduced vegetative cover, especially associated with active headcuts and channel incisement. Reduced vegetative cover, vigor associated with stock trails in upper end of meadow along Minnow Creek. Active headcuts and stream channel incision with collapsing banks in upper meadow. Two of 3 stream reaches assessed were rated functional at-risk with a downward trend. Lower west portion of meadow has vegetation and soil condition near desired condition. Reported grazing: 318/168/363 stock nights.	Increased vegetative cover, especially in the vicinity of active headcuts and along streambanks. Streams and meadow move toward PFC.	Develop an annual grazing management plan for Jackson meadow. Establish SCI and vegetation monitoring to confirm trend. Allow grazing in western portion between trail and creek (15 acres), 300 stock nights available. Enforce range readiness. Limit to one night grazing per trip.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Campsites	One stock holding campsite on the east side of Jackson Meadow is not meeting BMPs. It is 70 ft from water and rills are carrying sediment from the site to water.	All campsites should meet BMPs.	Designate 3 stock camps on west side of meadow, both at least 100 feet from water. Rehabilitate sites on east side of meadow near Lagoon Lake.
13. Silver Divide				
Destination: Lost Keys Lake	Access	Lost Keys Trail observed Trail Class 1, lightly defined, with some slight erosion.	Maintain trail stability without adding substantial structures/development.	Managing low use at destination.
	Recreation Category Setting	Recreation Category 1. Low impact and low use.	Maintain low use/impact.	
	Use Levels 01-04	None reported.		Up to 2 trips spot and dunnage.
	Grazing	None reported.		
	Campsites	No stock camps.	No stock camps.	No stock camps.
14. Cascade Valley				
Destination: Cascade Valley	Access	Fish Creek Trail observed Trail Class 3, generally stable. Camp access trail at Second Crossing use trail CAS04 stable, dry. Grazing access to meadow at 2nd crossing has moderate to severe impacts and high risk factors.	Reduce resource impacts of use trails.	Allow use of use trail CAS04 to campsite only. Prohibit grazing access use trail.
	Recreation Category Setting	Recreation Category 2 along primary trail corridor.	Maintain use levels consistent with Recreation Category 2 along primary trail corridor.	
	Use Levels 01-04	MLPO: 3-4 trips; 4-28stock Reds: 0-1 trips; 0-2 stock		Up to 10 spot and dunnage trips to two operators and use of areas as all expense/traveling trips.
	Grazing	Meadows near Purple and Minnow Creeks have been closed to grazing and exhibit low vegetative cover and altered vegetative composition. There are locations with understory	Retain annual vegetative growth to maximize vegetative growth, vigor, and restoration potential at confluence of Purple Creek and Minnow Creek. Maintain existing conditions at Third	Rest every other year. 20 stock nights at Purple Creek/Minnow Creek. Allow grazing, 214 stock nights in zone (between Sharktooth and Third), with one night grazing per trip. Allow

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		<p>vegetation and available forage for grazing between and including Sharktooth Creek confluence and Third Crossing. High gradient wetland at Second crossing is at risk due to stock use trails channeling water and associated headcuts. Meadow vegetation is moderately affected by trampling, compaction and reduced in size by a landslide at Island Crossing. Reported stock nights in zone: 293/271/447. Second Crossing grazing area is a large fen. Third Crossing: Small stream through meadow assessed to be in PFC. Fish Creek is incised through the meadow. A large portion of the meadow never reaches range readiness and has fen characteristics. Some sod fragmentation and spring trampling.</p>	<p>Crossing. Improve vegetative cover and vigor at Island Crossing. Maximize vegetative growth and retention at Second Crossing. Third Crossing: Reduce spring trampling and sod fragmentation, especially in wet portions of the meadow.</p>	<p>grazing and limit planned grazing at Third Crossing, 52 stock nights and Island Crossing, 12 stock nights, remainder of grazing is in the Cascade Valley Grazing Zone between and Sharktooth Confluence and Third Crossing. Prohibit grazing at 2nd crossing. Third Crossing: Allow grazing. 52 stock nights available. Avoid very wet areas and fragile Fish Creek streambanks.</p>
	Campsites	<p>Campsite at Third Crossing large total area and high level of impact. Second Crossing campsite moderate impact close to trail.</p>	<p>Reduce impacts at campsites at both Second and Third Crossing. Reduce overall total area of Third Crossing.</p>	<p>Designate 3 stock camps in Cascade Valley including Third Crossing. Designate 1 stock at Second Crossing.</p>
15. Cascade Valley				
Destination: Lower Fish Creek	Access	<p>Use trail issues at Iva Belle Hot Springs, mostly from public, but exacerbated by spot/dunnage drops at springs. Use trail CAS01 to Pond Lily Lake, lightly defined, Resource Rating 1, mostly in low risk factor areas.</p>	<p>Reduce contributing impacts at Iva Belle Hot Springs. Keep current trail stability of use trail CAS01 without increasing structures/development.</p>	<p>Prohibit commercial stock use at Iva Belle Hot Springs. Approve use trail CAS01 with low use levels.</p>
	Recreation Category Setting	<p>Recreation Category 2. Use concentrated at Iva Belle Hot</p>		

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		Springs, low opportunities for solitude at Iva Belle.		
	Use Levels 01-04	HSPS: 0-2 trips, 0-12 stock Reds: 13-22 trips, 86-149 stock To Pond Lily Lake: 0-1 trips, 0-6 stock		No spot and dunnage trips to Iva Belle Hot Springs (Sharktooth Creek camp okay). Up to 20 trips to other destinations in Lower Fish Creek. Maintain low use to Pond Lily Lake.
	Grazing	Grazing currently not allowed near Iva Bell Hot Springs. Fox Meadow/Island Crossing reported grazing 40/159/99. Moderate vegetation composition alteration.		Prohibit grazing at Iva Bell Hot Springs. Fox Meadow limit to 12 stock nights in meadow and 100 stock nights in zone. Remove deteriorated drift fence.
	Campsites			Designate 3 stock camps. 2 stock camps in vicinity of Island Crossing and 1 at Sharktooth Creek.
16. Upper Fish				
Destination: Tully Hole	Access	McGee Pass Trail & PCT primary access, both observed Trail Class 3, stable. Use trail UFC01 accesses camp on north side of Tully Hole. Generally stable, with one creek crossing.	Ensure camp access trail remains stable, if camp approved.	Prohibit use trail on north side of Tully Hole.
	Recreation Category Setting	Recreation Category 2 along primary trail corridor. Low capacity for camping.	Maintain use levels consistent with low capacity of the area.	
	Use Levels 01-04	0-2 trips; 0-12 stock		Up to 6 spot and dunnage trips. Manage for occasional use of stock camp.
	Grazing	Vegetation exhibits good vigor, mid-seral composition, with low cover. Moderate to high productivity and resiliency. Stream assessed to be functional at-risk with a non-apparent trend.	Maintain or improve vegetation composition. Stream should move toward PFC.	Allow grazing, 72 stock nights available.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		Grazing reported: 30/105/0.		
	Campsites	Stock holding campsite at east side of Tully Hole Meadow does not meet BMPs; within 50 feet of water.	Campsites should meet BMPs.	Designate 1 stock camp.
17. Upper Fish				
Destination: Horse Heaven	Access	McGee Pass Trail observed Trail Class 3, primary access mostly stable.	Ensure camp access trail is stable.	
	Recreation Category Setting	Recreation Category 2. Along main trail corridor.	Maintain use level consistent with Recreation Category 2 along primary trail.	
	Use Levels 01-04	MLPO: 0-3 trips; 0-9 stock McGee: 2-6 trips; 19-36 stock		Up to 9 spot and dunnage trips to two operators and use of area as all expense traveling trips.
	Grazing	Vegetative cover and composition mid-seral. Some hummocks and stream bank trampling, but stream at PFC. Marshy area has extensive hoof punching. Reported grazing: 156/56/36 stock nights.	Vegetation is at desired condition. Stream should remain at PFC. Reduced sod fragmentation in marshy area.	Allow grazing, 65 stock nights estimate for wet years and 150 in normal and dry years. Replace drift fence with drop fence.
	Campsites	High impact stock camp, large area of impact, fence present.	Reduced size of stock camp impact.	Designate 2 stock camps, contain impacts and reduce size of northern site. Establish a secondary site at southeast end of meadow.
18. Upper Fish				
Destination: Tully Lake	Access	McGee Pass Trail primary access, stable. Two spur trails to lake, one at outlet, one from northeast -- both have risk factors, unclear which is managed as system. Outlet trail use trail UFC08, Resource Rating 2.5 with many risk factors	Reduce multiple routes to lake. Stabilize camp access trail.	Define one route from McGee Pass Trail north/east to lake. Make this the system trail (Trail Class 2), stabilize at high risk areas. Remove sign from outlet trail to discourage use.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		does not access main pack camp. Trail from northeast, not developed, moderate risk factors, accesses pack camp.		
	Recreation Category Setting	Recreation Category 1, moderate to high opportunities for solitude	Manage for high opportunities for solitude with use levels consistent with Recreation Category 1.	
	Use Levels 01-04	0-3 trips, 0-16 stock		Up to 4 spot and dunnage trips consistent with a Recreation Category 1 area. Reduce use if trail access issues not improving.
	Grazing	None reported or requested.	Management direction is no grazing approved where not requested.	No grazing approved.
	Campsites	Low capacity camp sites.	No stock camp.	No stock camp. Party size limit of 8 people.
19. Upper Fish				
Destination: Upper Fish	Access	McGee Pass Trail Primary access, stable. Lee Creek Trail observed Trail Class 2, Resource Rating 5, severe degradation in meadows in trail corridor. Cecil Lake use trail UFC02 from Lee Lake, low-angle, through meadows near lake, but slight impacts. Accessed from Lee Creek Trail. Use trail UFC07 to Red and White Lake, short trail lightly defined.	Remove use (and grazing) from the Lee Creek trail. This precludes use of sue trail UFC02 to Cecil Lake. Ensure that UFC07 does not become more defined or degraded.	Lee Creek trail NSCS. UFC02, prohibited. Prohibit use on Red and White use trail.
	Recreation Category Setting	Recreation Category 2 along main trail corridor. Use of this area as overnight location for long spot and dunnage trips over McGee pass.	Manage for moderate opportunities for solitude along trail corridor and high opportunities while camping. Manage for no visible trail to Red and White Lake.	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Use Levels 01-04	6-14 trips, 63-109 stock		Up to 18 spot and dunnage trips. Low to moderate use of stock camps for traveling trips or overnight spot and dunnage trips.
	Grazing	See Horse Heaven, and Tully Hole. Tully Lake Meadow, adjacent to Upper Fish Creek near trail junction to Tully Lake. High-seral vegetation with localized sites of altered vegetation, primarily associated with stock watering access from trail to and including the right bank of Fish Creek. Impacts to riparian vegetation associated with active erosion and incisement of access trail to Lee and Cecil Lakes include reduced cover, bare areas, altered vegetative species composition, and adjacent water table lowering and water capture. High elevation meadows immediately west of McGee Pass exhibit low productivity and low resiliency.	Vegetation overall at desired condition, with localized moderate to severe, mostly associated with access and trailing impacts. Trails should not capture surface or ground water flow.	Allow grazing in Tully Lake Meadow 60 stock nights in lower most meadow between system trail and Fish Creek. Prohibit grazing at meadows near Lee and Cecil Lakes, the Lee Cecil trail junction meadow, and the higher elevation meadows immediately west of McGee Pass.
	Campsites	Moderate impacts at stock camps in area. One site has some development.	Reduce impact and development at campsites.	Designate 3 stock camps.
20. McGee				
Destination: Big McGee Lake	Access	McGee Canyon Trail primary access, generally stable. Camp access at Big McGee Lake Trail Class 2, former Hopkins Pass Trail, slight incision, moderate risk factors. Hopkins Pass trail not maintained many years, still defined, steep, rocky, no risk factors. "CCC Camp" trail access	Ensure stability on camp access trails. Maintain primitive condition of Hopkins Pass Trail.	Add Big McGee camp trail to system (Trail Class 2) ensure stable alignment. (MCG08). Hopkins Pass Trail Class 1, NSCS.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		(MCG08) Resource Rating 2, steep, but dry/rocky, low risk factors.		
	Recreation Category Setting	Recreation Category 2 along primary trail corridor.	Big McGee Lake: Manage for moderate opportunities for solitude while hiking and camping.	
	Use Levels 01-04	5-15 trips, 16-60 stock		Up to 20 spot and dunnage trips consistent with recreation category area along primary trail corridor. Monitor occupied campsites and reduce use if crowding is facilitated by pack stock dunnage trips.
	Grazing	Low productivity, low resiliency. Stream was assessed to be functional at-risk with a non apparent trend in 2001. Reported grazing in Big McGee Meadow 7/0/0. Occupied Yosemite toad breeding habitat in desired condition.	Vegetation is at desired condition. Stream channel needs to move toward PFC. Maintain high quality Yosemite toad habitat.	Allow grazing. 20 stock nights available. Critical areas closed to stock entry and grazing.
	Campsites	Concentration of campsites due to low capacity of accessible areas. "CCC Camp" has concerns with access.		Designate 1 stock camp. Relocate "CCC Camp".
21. McGee				
Destination: Grass Lake	Access	Steelhead Lake Trail, observed Trail Class 2, Resource Rating 2, lower section in steep riparian. Then Grass Lake Spur observed Trail Class 2, Resource Rating 1, short, flat, stable.	Keep Grass Lake Trail stable.	
	Recreation Category Setting	Recreation Category 2 along lower use trail corridor.	Low to moderate use and impacts at camping areas. Moderate to high opportunities for solitude.	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Use Levels 01-04	3-10 trips, 8-46 stock		Up to 10 spot and dunnage trips consistent with a Recreation Category 2 off of primary trail corridor.
	Grazing	Wet meadow associated with lake remains wet throughout summer (fen characteristics). Occupied Yosemite toad habitat in desired condition.	Vegetation is at desired condition. Maintain high quality fen and Yosemite toad habitat.	Unsuitable, prohibit grazing.
	Campsites		No stock camp.	No stock camp.
22. McGee				
Destination: Meadow Lake (Golden)	Access	Use trail MCG04, Resource Rating 3, goes west from Steelhead Trail toward Golden Lake - high risk factors (meadows, seeps, creeks), ill-defined, steep with many risk factors above Meadow Lake.	Prevent impacts to high risk areas near Meadow Lake. Prevent further development of use trails toward Golden Lake.	Allow use on MCG04 only to Meadow Lake. Stabilize or reroute where possible. Keep use low. Prohibit use to Golden Lake.
	Recreation Category Setting	Recreation Category 2. High opportunities for solitude, low recreation impacts.	Maintain high opportunities for solitude.	
	Use Levels 01-04	0-2 trips, 0-6 stock		Up to 2 trips with no more than 6 stock. Manage for use not occurring every year.
	Grazing			
	Campsites	No stock camp.	No stock camp.	No stock camp.
23. McGee		(Including a portion of Baldwin Canyon)		
Destination: McGee Canyon	Access	McGee Pass Trail, observed Trail Class 3, some moderate impacts to Yosemite toad habitat and meadow/hydrology at Martin's Meadow. Use trail MCG03 Accesses Campsite at Round Lake. Causing	Keep use to most stable trails. Stable trail at Martin's Meadow, with reduced effects on Yosemite toad and hydrology. Ensure trail is in good location and stable to approved site. Stabilize trail and resource	Keep stock on trail, stabilize trail. Reroute use trail MCG03 to Round Lake site. Baldwin Trail: Trail Class 1 NSCS above pond, (1/2 mile above Cutoff junction). Encourage use on Baldwin

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		disturbance to meadow from trampling. Baldwin Canyon Trail, observed Trail Class 2 to lower meadow, Trail Class 1 to mine, Resource Rating 3. Former road, degraded, rocky but generally stable to pond below meadow. Above, overgrown, severe incision, affecting Yosemite toad habitat. Baldwin Cutoff use trail MCG02, Resource Rating 3, impacts at creek crossing, duplicates McGee Pass trail, accesses camp from both north and south.	degradation on upper Baldwin Trail. Keep stock to one trail or other on Baldwin Cutoff or McGee Canyon.	Canyon Trail and Baldwin Cutoff rather than McGee Pass Trail to just above Steelhead junction. Stabilize creek crossing on Baldwin Cutoff.
	Recreation Category Setting	Recreation Category 2 along primary trail corridor. Steep and long canyon accessing Fish creek drainage and multiple destinations. Baldwin Canyon: Recreation Category 1.	Manage for moderate opportunities for solitude while hiking and moderate to high opportunities for solitude while camping.	
	Use Levels 01-04	McGee Canyon: 2-9 trips, 11-65 stock Round Lake: 7-20 trips, 68-159 stock Baldwin: 0-2 trips, 0-19 stock		Up to 20 spot and dunnage trips in McGee Canyon. Use level is not expected to cause crowding or overuse of any destinations, as use will disperse. Round Lake: Allow 12 spot/dunnage trips until access to camp is improved, then allow up to 20 spot and dunnage trips.
	Grazing	All meadows: Little to no grazing reported 2001-2003 due to Yosemite Toad Habitat Management. Chute meadow: Vegetation in high-seral status. No recent use. Occupied Yosemite toad habitat in desired condition. Much of the meadow never reaches range readiness.	Vegetation remains at desired condition. Hydrologic and soil condition should remain good. Protect wet areas from trampling. Maintain high quality Yosemite toad habitat in Chute Meadow. Martin's Meadow: Vegetation is at desired condition. Stream should move toward proper	Allow grazing, 30 stock nights at Chute Camp Meadow in wet years (150% of normal precipitation at nearest snow sensor site), 90 stock nights in normal or dry years. Critical areas closed to stock entry and grazing. No grazing at Cable Meadow. Martin's Meadow:

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		No known soil or hydrologic effects. Cable Meadow, a turn-around point for day rides, is flooded by a beaver pond. No grazing reported. Martin's Meadow: Vegetation is mid-seral to high-seral. Stream incisement and severe active headcuts (4 feet deep) in lower meadow. Headcuts possibly trail related. Reported grazing: 5/0/0. Occupied Yosemite toad habitat in desired condition. Baldwin Canyon: No grazing reported. Round Lake: Martin's meadow sediment deposition, mid-seral to low-seral vegetative status. Reported grazing: 15/0/0.	functioning condition, with headcuts stopping their advance. Maintain high quality Yosemite toad habitat. Baldwin Canyon: Vegetation is at desired condition. Round Lake: Stable soils, increased vegetative cover and improved composition toward high seral.	Rest from grazing until headcuts stabilize. Stabilization will likely require active rehabilitation, including structures. Critical areas closed to stock entry and grazing. Baldwin Canyon: Prohibit grazing due to access issues (gullied trail). Re-assess if access issues resolved. Round Lake: Unsuitable, prohibit grazing.
	Campsites	Round Lake: stock holding camp within 15 feet of creek, does not meet BMPs.	All campsites should meet BMPs.	Designate 1 stock camp at Round Lake. Improve access and BMP compliance with Round Lake campsite.
	Other Issues	Round Lake: Occupied Yosemite toad habitat with observed sediment deposition problems related to trail impacts at Martins Meadow.	Round Lake: Restore high quality Yosemite toad habitat.	Stabilize Martin's Meadow headcuts and reduce or eliminate unacceptable sediment transport.
24. McGee				
Destination: Steelhead Lake	Access	Steelhead Trail observed Trail Class 2, Resource Rating 2, lower section in steep riparian, above two routes because of poor alignment on a reroute. Steep, erosion, but mostly dry slopes.	One stable route to Steelhead Lake.	Keep use on western of two routes to Steelhead Lake, stabilize with structures.
	Recreation Category Setting	Recreation Category 2 off main trail corridor. Moderate to high opportunities for solitude. Low capacity for camping.	Manage for low to moderate use levels to maintain opportunities for solitude and not facilitate crowding.	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Use Levels 01-04	2-12 trips, 8-70 stock		Up to 16 spot and dunnage trips. Manage so not more than 1 party at one time.
	Grazing	None reported or requested.	No grazing.	No grazing.
	Campsites	Two spot/dunnage camps where BMPs were evaluated. One caused sediment to reach Steelhead Lake and does not meet BMPs.	All campsites should meet BMPs.	No stock camp. Spot and dunnage sites must meet BMPs.
	Other Issues	Moderate downed firewood available around lake.		Modify elevational closure to allow campfires at Steelhead Lake.
25. Convict				
Destination: Cloverleaf Lake	Access	Convict Canyon trail destroyed by landslides, not passable to stock, difficult to hikers. All destinations in Convict Canyon accessed by Laurel Lake Trail, observed Trail Class 2, Resource Rating 3, stable, dry until above Genevieve Lake, moderate impacts near Edith Lake, along stream. Mapped system not consistent with ground. Two trails from near Edith Lake to Cloverleaf Lake, both with high resource impacts and risk factors.	One stable trail from Edith Lake to Cloverleaf Lake. Correct map and inventory inconsistencies.	Keep commercial stock to system trail on south/east side of creek. Limit stock numbers until trail can be repaired. Designate use trail to Genevieve via Edith as system trail. Abandon trail east of Genevieve Lake. Designate Convict Creek Trail below Mildred Lake as NSCS.
	Recreation Category Setting	Recreation Category 1, off primary trail, high opportunities for solitude.	Manage for high opportunities for solitude and infrequent use.	
	Use Levels 01-04	MLPO: 0-2 trips, 0-12 stock McGee: 2-10 trips, 6-103 stock		Up to 4 (2 McGee/2 MLPO) spot and dunnage trips and party size limit of 8 head of stock to maintain low use, low impact to trail.
	Grazing	Inlet meadow at high-seral	Vegetation is at desired	No grazing.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		vegetative status. Localized trail impacts along lakeshore terraces include compaction and reduced vegetative vigor and reduced cover. Never reaches range readiness. None reported. Occupied Yosemite toad habitat in desired condition.	condition. Maintain high quality Yosemite toad habitat.	
	Campsites	No stock camp.	No stock camp.	No stock camp.
	Other Issues			
26. Convict				
Destination: Genevieve / Edith Lakes	Access	See "Cloverleaf" for general Convict trail info. Laurel-Genevieve Trail observed Trail Class 2, Resource Rating 3 mod resource impacts at Edith Lake, and creek crossings. Use trail CON04 accesses camp at Genevieve Lake outlet. Slight meadow impacts, mod risk factors. Trail on map east of Genevieve Lake unmaintained, abandoned trail.		Designate use trail to Genevieve Lake via Edith as system trail. Abandon old system trail east of Genevieve. Prohibit use of CON04 (camp not approved).
	Recreation Category Setting	Recreation Category 1. Not a primary trail. Low use and high opportunities for solitude.	Maintain low end of recreation Category 2 conditions, moderate to high opportunities for solitude, some impacts at primary campsites.	Change to Recreation Category 2 at Genevieve and Edith Lakes.
	Use Levels 01-04	MLPO: 0-4 trips, 0-30 stock McGee: 0-5 trips, 0-45 stock		Up to 20 trips for Edith Lake Genevieve Lakes: 6 trips to MLPO, 14 trips to McGee.
	Grazing	Two ponds and adjacent marsh near stock holding site. Associated wet meadow remains wet season long. Reported grazing: 0/14/0. Occupied Yosemite toad habitat at Edith	At desired vegetative condition. Maintain high quality Yosemite toad habitat.	Unsuitable, prohibit grazing.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		Lake inlet meadow with observed trampling and chiseling impacts.		
	Campsites	Moderate impact at campsites, particularly Genevieve Lake.	Reduce impacts at campsites and insure proper distance form water.	Designate 1 stock camp at Edith Lake and 1 at Genevieve Lake.
	Other Issues			Modify elevation closure to allow campfires at Genevieve and Edith Lakes.
27. Convict				
Destination: Dorothy Lake	Access	See Cloverleaf Destination for general Convict trail info. Access to this destination via Laurel Lake Trail, then segment of Convict Creek Trail. Camp accessed by Dorothy Lake Spur, observed Trail Class 1.5, Resource Rating 2, slight incision, moderate risk factors. Bighorn use trail CON07 ill-defined, high risk factors.	Ensure stability of Dorothy Spur. Prevent expansion of impacts on Bighorn trail.	Prohibit use of Bighorn Lake use trail. Designate Convict Creek Trail below Mildred Lake as NSCS.
	Recreation Category Setting	Recreation Category 2 off primary trail.	Manage for moderate to high opportunities for solitude.	
	Use Levels 01-04	1-3 trips, 2-20 stock		Up to 4 spot and dunnage trips.
	Grazing	None reported. Fragmented sod and reduced vegetative cover near inlet. Small lakeshore meadows. Thin sod, highly erosive soils.	Overall vegetation is at desired condition. Soil erosion should not be accelerated, reduce sod fragmentation.	Unsuitable, prohibit grazing.
	Campsites	Moderate to high impacted campsites and high density of sites at outlet of lake.		No stock camps.
28. Margaret				
Destination: Margaret	Access	Margaret Lake Trail observed Trail Class 3, Resource Rating 2	Reduce instability around Rainbow without substantial	Relocate drift fence from Coyote Lake down to bottom of steep

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
Lakes		to Big Margaret Lake, Trail Class 2, Resource Rating 2.5 beyond Big Margaret Lake. Trail beyond Big Margaret (and around Rainbow Lake), lower development, moderate incision, diversion. Descends granite cliff band below Baby Lake, extremely awkward. Silver Creek trail observed Trail Class 2, Resource Rating 3.5, from Coyote Lake to Baby Lake Junction, steep, soil loss, trail damaged by grazing stock (at meadow near Coyote Lake). Silver Creek Trail below to Fish Creek, overgrown, very awkward, rarely maintained. Use trail MAR02 Saddle Mountain to Fern Lake, Resource Rating 2, lightly defined, moderate to high risk factors. Rainbow to Sedge Lake use trail MAR01, not evident, low use.	structures, development. Use trail MAR01, ensure that use trail does not become more evident. Stabilize Coyote to Baby Lake Junction trail.	section if feasible. Stabilize trail with structures after drift fence moved. Keep low use levels on Rainbow/Baby Lakes area. NSCS on system trail from Baby Lake to Silver Creek Junction. Trail between Big Margaret Lake and Rainbow Lakes is closed to commercial stock until the incised trail/meadow south of Rainbow Lakes is repaired. Prohibit use of use trails MAR01 and MAR02.
	Recreation Category Setting	Recreation Category 2.		
	Use Levels 01-04			20 spot and dunnage trips in the destination zone.
	Grazing	Coyote Lake Grazing area: Trampled throughout meadow, much of meadow does not reach range readiness, some bare areas under trees around the edge of the meadow. However, meadow appears to be in PFC. There is a headcut on the trail north of the meadow moving into the meadow. Trail between this grazing area and drift fence at	All meadows and streams should be in proper hydrologic functioning condition. Increased vegetation cover near trails and increase stability of trail tread so it is not affecting vegetation composition by diverting surface water. Trail between Coyote Lake and Coyote Lake grazing area should become more stable and soil loss should be reduced	Coyote grazing area: 62 stock nights. Frog Lake Meadow, north: 60 stock nights. Coyote Lake: Unsuitable, no grazing allowed. Fern Lake: 63 stock nights. Frog Lake Meadow: Unsuitable, no grazing allowed. Rainbow to Margaret Meadow: 127 stock nights available once trail is repaired. Until trail is repaired, no stock use of trail and

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		Coyote Lake is loose and structures are not holding in place, due to stock traveling between grazing meadow and drift fence. High reported stock use 84 stock nights. Adjacent to Coyote Lake: low productivity, high percentage of bare area, streams have low vegetation cover on banks. No use reported. Other areas (Fern, Rainbow to Margaret, Frog Lake) - All meadows have some local vegetation composition change related mainly to trails. Some headcuts associated with trail within meadows.	to near background levels.	therefore grazing is not approved.
	Campsites			Designate 2 stock camps, 1 at Coyote Lake and 1 at Big Margaret Lake.
	Other Issues	Drift fence at Coyote Meadow.		

FLORENCE/BEAR

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
1. Apollo				
Destination: Cirque Zone (including Bear Dome, Marcella)	Access	Cirque Lake observed Trail Class 1, minimal development trail. Slight incision at steep slopes, few risk factors.	Maintain current stability without changing trail character.	Low use levels. Approve use.
	Recreation Category Setting	Recreation Category 2, mostly trail-less area, high opportunities for solitude, very low impact.	Maintain trail-less, high opportunities for solitude and very low impact of area.	
	Use Levels 01-04	0-5 trips, 0-29 stock		Up to 8 spot and dunnage trips to

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
				two operators. No more than two trips a year to Orchid and Apollo.
	Grazing	Not assessed.	Not assessed.	Allow grazing 15 stock nights until assessed.
	Campsites			Designate 1 stock camp at Cirque Lake, 1 stock camp at Orchid Lake and 1 stock camp at Marcella Lake.
	Other Issues			
2. Bolsillo				
Destination: Corbett	Access	Corbett Lake Trail: observed Trail Class 2, generally stable, low-mod risk factors, meadows and creek crossings; Cunningham Lake use trail, BOL01. Kings Castle use trail BOL02.		
	Recreation Category Setting	Recreation 2 for Corbett and Recreation Category 1 other destinations.	Maintain for high and moderate opportunities for solitude.	
	Use Levels 01-04	none reported		Up to 4 spot and dunnage trips to one operator will maintain low use and high opportunities for solitude.
	Grazing	Unknown		No grazing.
	Campsites		No stock camp.	No stock camp.
3. Dutch				
Destination: Dutch/Hidden/Crater	Access	Crater Lake Trail: observed Trail Class 2.		
	Recreation Category Setting	Recreation Category 2: moderate to high opportunities for solitude, off primary trail.	Maintain for moderate opportunities for solitude.	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Use Levels 01-04	High Sierra: 0-2 trips, 0-20 stock D&F: 0-1 trips, 0-4 stock		Up to 12 spot and dunnage trips to two operators will maintain moderate to high opportunities for solitude.
	Grazing	Not assessed.	Not assessed.	Allow grazing, 25 stock nights until assessed.
	Campsites			Designate 1 stock camp at Dutch Lake.
4. Dutch				
Destination: Thompson Lake	Access	29E57 from either north or south depending on pack station.		
	Recreation Category Setting	Recreation Category 2: High to moderate opportunities for solitude.	Maintain high to moderate opportunities for solitude.	
	Use Levels 01-04	Low recent use prior to 2001		4 spot and dunnage between two pack stations.
	Grazing	Included with Thompson Lake/Burnt Corral grazing zone		
	Campsites		No stock camp.	No stock camp.
	Other Issues	Easily accessible from Dusy-Ershim OHV road.		
5. Dutch				
Destination: Rodeo Meadow	Access			
	Recreation Category Setting	Recreation Category 2 off of primary trail; moderate opportunities for solitude.	Maintain moderate to high opportunities for solitude, low impact area.	
	Use Levels 01-04	0-2 trips, 0-14 stock		Up to 4 spot and dunnage trips to maintain moderate to high opportunities for solitude.
	Grazing	Grazing requested, no use reported 2001-2003.		Allow up to 25 stock nights.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Campsites			Designate 1 stock camp .
6. East Florence				
Destination: Shooting Star Meadow	Access	Blayney Hot Springs trail.		
	Recreation Category Setting	Recreation Category 3 along primary trail corridor. Low to moderate opportunities for solitude.	Maintain in a condition compatible with Recreation Category 3.	
	Use Levels 01-04	D&F: 0-2 trips, 0-6 stock High Sierra: 0-1 trips, 0-6 stock Lost Valley: 0-2 trips, 0-4 stock		18 spot and dunnage trips to three operators.
	Grazing	Blayney Meadow: Used as a pasture and for private recreational pack stock use. Unknown stock nights used, only 60 reported. Stream appears functional at-risk (2004) and some sections of stream have over 20% stream bank disturbance. This meadow is part private land. Double Meadow: Currently being used as a pasture, with up to 1000 stock nights estimated use (but we do not have use records). Stream is in good condition.	Blayney Meadow: Stream should move toward proper functioning condition, less than 20% stream bank disturbance on all stream reaches. Double Meadow: Maintain stream in good condition, maintain non-altered vegetation composition and continuous sod cover.	Blayney Meadow: Forest Service portion of the meadow only: 544 stock nights. Attempt to enter into an agreement with private landowners to distribute use more evenly and prevent concentrated impacts along fence lines. Double Meadow: Allow grazing. 1,250 stock nights available.
	Campsites			Designate 2 stock camps at Shooting Star Meadow.
	Other Issues	There is a population of prairie wedge grass at Blayney Hot Springs.	Maintain rare plant population.	Monitor population.
7. Hooper				
Destination: Gordon/Hooper Lakes	Access	Access is via 28E45, Trail Class 2.		

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Recreation Category Setting	Recreation Category 2, Infant Buttes is Recreation Category 1. High opportunities for solitude.	Maintain high opportunities for solitude.	
	Use Levels 01-04	0-5 trips, 0-41 stock		Up to 8 spot and dunnage trips.
	Grazing	Jackass Meadow: 135 acres (of which approximately 15 acres is in the wilderness), 7,200 feet, 75% suitable, no concerns noted by IDT, Native American basketry plant material gathering exclosure, 2025 stock nights recommended, another 120 stock nights in Forest Service administrative pasture portion. Poison: 20 acres at 6,800 feet, used as pasture; 80% suitable, some isolated vegetation composition changes, 320 stock nights. Hell Hole: 16 acres at 6,800 feet, used for brood mares and foals, 95% suitable, dominant willow community, 442 stock nights.	Maintain or improve vegetative composition.	Allow grazing: Jackass Meadow 2025 stock nights; Poison Meadow 320 stock nights; Hell Hole Meadow 442 stock nights.
	Campsites		No stock camps.	No stock camps.
8. Italy				
Destination: Hilgard Meadow	Access	Lake Italy Trail: observed Trail Class 2, Resource Rating 1, to Hilgard Meadow camps; Trail Class 1, Resource Rating 3 above, steep, meadows, riparian, moderate to high risk factors.	Prevent further degradation of trail and off-trail resources above Hilgard Meadow.	Italy Pass Trail above Hilgard NSCS.
	Recreation Category Setting	Recreation Category 2, low to moderate opportunities for solitude in peak season.	Maintain moderate opportunities for solitude.	
	Use Levels 01-04	D&F: 0-5 trips, 0-28 stock High Sierra: 1-8 trips, 3-27 stock		Up to 14 spot and dunnage trips between two operators and use of area for all expense type trips

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
				will maintain moderate opportunities for solitude.
	Grazing	Low productivity, moderate vegetation composition change. Stream is functional at-risk and there is moderate alteration of hydrologic function due to compaction, incised stream and bare soil. Reported Grazing: 0/0/66 (Was open even years only until early 2000s)	Increase late seral vegetation over time. Stream should move toward proper functioning condition, and meadow should move toward no hydrologic functional alteration.	Approve grazing: 57 stock nights. Recommend the rotation with Rosemarie continue. The rest year of rotation would help with vegetation recruitment, if not allowing increased utilization when grazed.
	Campsites	Stock holding site at Hilgard Meadow is causing minor contribution of sediment surface water. Does not meet BMPs.	All campsites should meet BMPs.	Add logs or other structures to prevent sediment from entering stream. Minor sedimentation could be reduced without moving the camp, because it is a good location with a few adjustments. Designate 2 stock camps at Hilgard Meadow.
9. Sallie Keyes				
Destination: Senger Creek	Access	Senger Creek use trail SAK08 from PCT to deer camp west of creek/meadow, Resource Rating 1, lightly defined, few risk factors. Stable with current low use.	Maintain low visibility trail.	Low use levels to maintain undefined character of trail. Do not allow trail condition to degrade.
	Recreation Category Setting	Recreation Category 1, high opportunities for solitude; low impacts.	Maintain low impacts and high opportunities for solitude.	
	Use Levels 01-04	1-9 trips, 2-64 stock		Up to 10 spot and dunnage trips. Limit use above junction into Senger creek to no more than 4 trips and or 20 stock will insure that use trails remains mostly undefined.
	Grazing	Grazing requested. Reported use 0/8/0.		In Sallie Keyes Grazing Zone, 420 stock nights allowable.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Campsites			Designate stock camp along PCT north of Senger Creek.
10. Sallie Keyes				
Destination: Sallie Keyes Lake	Access	PCT, observed Trail Class 3, but degraded with moderate resource impacts to meadows, stream crossings.	Stabilize the trail.	
	Recreation Category Setting	Recreation Category 2 along primary trail corridor. Low to moderate opportunities for solitude. Low to moderate capacity for camping.	Maintain moderate opportunities for solitude, reduce impacts of camping.	
	Use Levels 01-04	High Sierra: 0-4 trips, 0-52 stock Lost Valley: 0-1 trips, 0-2 stock		Up to 11 spot and dunnage trips by three operators and use of area for all expense and traveling trips. MTR = 4 HS = 4 LV=3
	Grazing	Minor vegetation alteration, minor decreased cover. Meadow streams in Boot Lake Meadow and "old trail" meadow near Sallie Keyes Lake are in proper functioning condition. There is some trampling of springs and stream banks, but meadow hydrologic function remains good. Grazing reported: 28/18/0.	Increase vegetation cover, increased late-seral vegetation. Protect springs from trampling and alteration of spring channel morphology.	Allow Grazing: 196 stock nights in all meadows around Sallie Keyes Lakes. Springs and very wet areas are critical areas that are not to be grazed. Manage to avoid use along old trail.
	Campsites	Two of three stock holding campsites near Sallie Keyes Meadow found to be out of compliance with BMPs.	All campsites should meet BMPs.	Close sites that do not meet BMPs. Designate 2 stock camps at Sallie Keyes Lake and insure they are setback from water to meet BMPs. Prohibit use of site at Old Trail Meadow for overnight holding of stock.
11. Sallie Keyes				
Destination: Piute Creek to SEKI Boundary	Access	Access via 27E81.		

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Recreation Category Setting	Recreation Category 2, low to moderate opportunities for solitude. Main trail for pack stock use.	Maintain use to concentrated stock locations. Increase opportunities for solitude.	
	Use Levels 01-04	D&F: 0-1 trip, 0-2 stock HSPS: 13-26 trips, 48-126 stock Muir Trail Ranch 0 trips		Up to 35 spot and dunnage trips between three operators.
	Grazing	No grazing reported or requested.	Maintain vegetation at moderate to high seral status.	Do not approve grazing.
	Campsites			Designate 1 stock camp west of boundary with SEKI.
	Other Issues			
12. Selden				
Destination: Bear Creek/PCT corridor (includes Twin Falls, Lower Bear Ck, Selden/JMT, Rosemarie)	Access	JMT/PCT observed Trail Class 3, mostly stable, but under-maintained, with moderate, isolated severe impacts at creek crossings, meadows. Seldon Pass use trail SEL04: direct line to Marie Lake from pass, does not exist. Marie Lake Cutoff SEL03, mostly undefined, potential risk factors, meadows, creek crossings. Marie Lake to Sandpiper Lake, SEL06, does not exist. Rosemarie Lake: PCT parallels east side of meadow, Trail Class 3, stable. Use trail SEL07 moderate incision, risk factors. Bear Ridge Trail, observed Trail Class 3. Bear Cr Cutoff, observed Trail Class 3. Bear Creek Trail observed Trail Class 2. Bear Creek Trail and Bear Creek Cutoff bisect populations of Mono Hot Springs evening primrose, no	Prevent development of unnecessary use trail. Keep use on system trails, which access all destinations. Maintain stability. Maintain Mono Hot Springs evening primrose populations in good condition.	Prohibit use of SEL04. Prohibit use from Twin Falls to PCT junction. Prohibit use of use trails SEL03, SEL06 and SEL07.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		reported problems.		
	Recreation Category Setting	Recreation Category 2 along primary trail corridor. Low to moderate opportunities for solitude.	Maintain moderate opportunities for solitude while camping.	
	Use Levels 01-04	D&F:2-18 trips, 11-32 stock High Sierra:7-16 trips, 40-112 stock		Up to 38 spot and dunnage trips by two operators (24 - High Sierra and 14 - D&F) and use of area for all expense/traveling trips. Rosemarie Lake: Up to 4 trips for each operator.
	Grazing	Marie: High elevation, low productivity, thin sod, erosive soils, highly visible along PCT, stream in proper functioning condition. Reported grazing: 2/0/0. Rosemarie: Moderate vegetation productivity, locally severe plant composition change. Stream in meadow was rated functional at-risk with an upward trend. Stream is widened and incised, but banks have revegetated. Slight hydrologic function alteration. Reported grazing: 18/0/38. Past management was grazing only in odd years. Bear Ridge grazing zone and Kip Camp Grazing Zone: existing condition not assessed outside of Kip Camp. Meadow with fen characteristics at Kip Camp appears to be in good condition. Reported grazing: 2001/2002/2003 is 0/34/32.	Rosemarie: Increase vegetation cover, increased late-seral vegetation. Stream and meadow continue to move toward proper functioning condition.	Marie: No grazing allowed. Rosemarie: Allow 93 stock nights of grazing with rest rotation between Rosemarie and Hilgard Meadows. The rest year of rotation would help with vegetation recruitment, if not allowing increased utilization when grazed.
	Campsites	Stock holding site at Kip Camp is slightly non-compliant with BMPs.	All stock holding and spot/dunnage sites should meet BMPs.	Designate 1 stock camp at Rosemarie Meadow.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
13. Selden				
Destination: Rose Lake	Access	Rose Lake Trail: observed Trail Class 2, Resource Rating 2.5, steep, with minimal structures, moderate incision. Moderate risk factors. Use trail SEL05 around lakeshore, unstable with many risk factor; proximity to lake, meadows.	Stabilize trail. Prevent degradation of use trail SEL05.	Low use on Rose Lake Trail. Prohibit use of use trail SEL05.
	Recreation Category Setting	Recreation Category 2 off of primary trail, moderate opportunities for solitude. Moderate impacts noticeable Recreation Impact Rating = 2.2.	Maintain as moderate to high opportunities for solitude. Reduce recreation impacts.	
	Use Levels 01-04	none reported		Up to 2 spot and dunnage trips.
	Grazing	Not fully analyzed for grazing. Meadow had some wet areas and trail to and through meadow causing sod fragmentation and erosion. Use reported: 33/0/0	Meadow and stream in meadow should remain in proper functioning condition. Reduce sod fragmentation and erosion in meadow outside the trail tread, or cause more than minimal soil erosion.	Allow grazing: 33 stock nights available.
	Campsites	Spot/dunnage site that appears to be used meets BMPs, but trail access is through wet meadow and is causing sod fragmentation. Low capacity for camping.	All campsites meet BMPs. Access routes to campsites are stable and not causing erosion.	Limiting spot and dunnage drop to area around outlet.
14. Selden				
Destination: Lou Beverly Lake / Sandpiper Lake	Access	Sandpiper Lake Trail:, observed Trail Class 2, Resource Rating 2 around Lou Beverly Lake; Resource Rating 3 above with moderate to severe impacts to springs, creeks. Moderate to high risk factors. Use trail SEL01 to Three Island Lake, not visible, many risk factors --	Stabilize trail. Prevent development of use trail to 3- Island Lake.	Trail above Lou Beverly Lake is NSCS until repaired. Prohibit use on use trail SEL01.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		meadows, stream crossings, springs.		
	Recreation Category Setting	Recreation Category 2 off of primary trail. Moderate to high opportunities for solitude, low to moderate impacts.		
	Use Levels 01-04	0-2 trips, 0-16 stock		Up to 4 spot and dunnage trips and use of areas for all expense/traveling trips. Prohibit use beyond Lou Beverly Lake until trail is fixed.
	Grazing	Stream in Lou Beverly Meadow is in proper functioning condition, and the meadow has no hydrologic function alteration. No vegetation composition alteration. Occupied Yosemite toad habitat in meadow above lake.	Stream and meadow should remain in proper functioning condition. Maintain vegetation cover. Maintain high quality Yosemite toad breeding habitat.	Allow Grazing: 39 stock nights available.
	Campsites	Stock holding site at Lou Beverly meets BMPs.	All campsites must meet BMPs.	Designate 1 stock camp at Lou Beverly Lake.
15. Ward Mountain				
Destination: Ward Mountain Lake	Access	Ward Mountain Lake use trail WAM01.		
	Recreation Category Setting	Recreation Category 1.	Maintain high opportunity for solitude.	
	Use Levels 01-04	Infrequent use prior to 2001.		Up to 2 spot and dunnage trips to one operator.
	Grazing	Not assessed.	Not assessed.	Allow grazing; 25 stock nights until assessed.
	Campsites		No stock camp.	No stock camp.

MONO ROCK CREEK/ROCK CREEK

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
1. Tamarack				
Destination: Tamarack Basin	Access	Tamarack Lake Trail: Trail Class 3, generally stable, slight impacts at streams, meadows. Trail Class 2 to Tamarack Lake, rough, few risk factors. Dorothy Lake Loop: observed Trail Class 2, Resource Rating 2, moderate incision, impacts at creek crossings. Francis Lake Trail observed Trail Class 2, Resource Rating 2, steep, stable with low use. Multiple use trails through basin.	Improve stability of Dorothy Loop Trail. Keep Francis Trail stable without addition of substantial development. Prevent expansion of use trails.	If trail conditions deteriorate, consider day ride management. Approve one use trail from Dorothy Loop to Kenneth Lake. Prohibit all other use trails.
	Recreation Category Setting	Dorothy Lake: Recreation Category 2 low to moderate opportunities for solitude.	Manage for moderate to high opportunities for solitude throughout basin.	
	Use Levels 01-04	0-12 trips, 0-57 stock		Up to 16 spot and dunnage trips. Manage for low use to the Upper Basin (Tamarack and Francis Lakes).
	Grazing	Moderate to minor localized vegetation composition change mostly at riparian crossings. No grazing reported, grazing requested. Lower area within 1 hour of pack station, grazing is not needed.	Vegetation overall is at desired condition. Minor need to stabilize trail creek and wetland crossings and approaches.	Do not approve grazing.
	Campsites		No stock camps.	No stock camps.
	Other Issues	Moderate downed firewood available around Kenneth Lake.		Modify elevational closure to allow campfires at Kenneth Lake.
2. Hilton				

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
Destination: Hilton (Davis / Second Lake)	Access	Hilton Creek Trail observed Trail Class 3, generally stable with moderate impacts at Davis Meadow. Above 2nd Lake to 4th Lake, trail steep with risk factors, Resource Rating 3. Duplicate access to Davis Lake from Hilton Ridge Trail. Davis Spur to inlet camps and peninsula is stable. Use trail HIL05 at Davis outlet accesses camps, slight impacts at creek. Population of Inyo beardtongue outside wilderness on Hilton Creek trail in good condition.	Keep use to one trail into Davis Lake. Maintain population of Inyo beardtongue in good condition.	Prohibit use of Hilton Ridge Trail. Allow trail use to designated campsites, including use trail HIL05. Do not allow stock use on the Davis Spur trail past peninsula at Davis Lake inlet. Reduce Trail Class above 2nd Lake to Class 2.
	Recreation Category Setting	Hilton (Davis and Second Lake): Recreation Category 2 low to moderate opportunities for solitude (close proximity to trailhead, high day use). High stock use with early season access by three pack stations. Recreation Impact Rating = 2.2 and 2.0.	Hilton (Davis and Second Lake): Manage area for moderate opportunities for solitude.	Change Davis and Second Lakes to a Recreation Category 3.
	Use Levels 01-04	PC: 0-4 trips, 0-18 stock McGee: 4-12 trips, 33-84 stock Rock Creek: 34-51 trips, 222-349 stock		Up to 60 spot and dunnage trips (between 3 operators), and manage area for intensive all-expense trip use.
	Grazing	Local moderate to minor vegetative alteration along trails between Second Lake and Lake 4 and at Davis lakeshore meadows. Small, wet, and fragile meadows along trail from Lakes 5 to 6. Minor trampling of riparian vegetation and associated sod fragmentation at Turk Meadow and Davis Pond Meadow. Sensitive spring heads with minor trampling damage in	Increase vegetative cover and vigor around Davis Lake, increased vegetative cover along trails between Second lake and Lake 5. Maintain high-seral status of vegetation at Turk Meadow springs. Maintain population of Blandlow's feather moss and fen area in good condition.	Approve grazing, 419 stock nights available in the grazing zone, allowable use factor (AUF) is 30%. Manage Turk Meadow springs/fen/sensitive plant habitat as a critical area.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		upper Turk Meadow. Blandlow's feather moss population in upper Turk Meadow in area with fen characteristics currently in good condition. Reported grazing: 2001/2002/2003 is 0/0/7.		
	Campsites	High campsite density and Davis Lake. Many sites, including a holding site, do not meet BMPs because they are too close to water. Abandoned goshawk territory in south shore high use camping area.	All stock holding and spot and dunnage campsites should meet BMPs. Reduce campsite density and contain individual sites. Manage for intensive use of sites. Goshawk territory habitat suitability maintained for occupancy.	6 stock camps at Davis Lake and 4 at Second Lake. Utilize only these sites for all full service trips to contain impacts, even if stock is not held overnight. 1 stock camp designated at Turk Meadow. Monitor goshawk territory and implement camping restrictions as needed through biological evaluation process.
	Other Issues			Stock holding area for day rides to tie up in the vicinity of Davis Lake peninsula/waterfall camp.
3. Hilton				
Destination: Hilton Upper Lakes	Access	Hilton Lakes Trail: Trail Class 3, stable to junction with Hilton Creek Trail, then observed Trail Class 2, steep, soil movement, moderate impacts to stream banks, terminates at 4th Lake. Use trail HIL17 from 3rd to 5th Lake, lightly defined, steep, riparian effects. There is a population of subalpine fireweed below 3rd Lake.	Maintain subalpine fireweed population in good condition.	Prohibit use of use trail HIL17. Monitor subalpine fireweed population.
	Recreation Category Setting	Hilton Upper Lakes: Recreation Category 2 low to moderate opportunities for solitude.	Maintain area as low to moderate use destination with low to moderate impacts concentrated at few sites. Maintain moderate to high opportunities for solitude.	
	Use Levels 01-04	1-19 trips, 5-104 stock		Up to 6 spot and dunnage trips to maintain moderate to high

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
				opportunities for solitude consistent with Recreation Category 2, off primary trail.
	Grazing	No grazing reported or requested.	Maintain high-seral vegetative status. Management direction is no grazing allowed when not requested.	No grazing.
	Campsites		No stock camps.	No stock camps.
4. Little Lakes Valley				
Destination: Chickenfoot / Long Lakes	Access	Chickenfoot Lake Spur observed Trail Class 2, Resource Rating 1, dry, stable to lake. Use trail LLV03 accesses from south side, duplicate access. Little Lakes Valley Trail observed Trail Class 3, generally stable. Long Lake Spur lightly developed trail accesses camps on bench south of lake.	One route to lake.	Limit stock to system spur. Prohibit use trail LLV03.
	Recreation Category Setting	Chickenfoot Lake: Recreation Category 3. High use, low opportunities for solitude, high day use. Recreation Impact Rating = 1.6. Long Lake: Recreation Category 3. High day use low opportunities for solitude. Recreation Impact Rating = 2.0.	Chickenfoot Lake: maintain moderate opportunities for solitude. Long Lake: maintain moderate opportunities for solitude.	
	Use Levels 01-04	Chickenfoot Lake 0-6 trips, 0-32 stock Long Lake 0-2 trips, 0-4 stock		Up to 12 trips to Long, Chickenfoot to prevent additional crowding.
	Grazing	No grazing reported or requested. Some local moderate loss of riparian vegetation along trails and creek access points, trail along north side of	Increased vegetative cover along trails. Maintain high-seral status of vegetation.	No grazing.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		Chickenfoot Lake.		
	Campsites	Low capacity for campsites.	No stock camps.	No stock camps.
5. Little Lakes Valley				
Destination: Ruby Lake	Access	Ruby Spur Trail Class 2, stable, close to creek, light development. Some local moderate loss of riparian vegetation along trails and creek access points, such as at the junction of the Ruby Lake and Mono Pass Trails.	Keep stable with minimal development.	Snow bypass below Ruby Lake is prohibited for commercial pack stock use. Snow bypass trails over Mono Pass are approved.
	Recreation Category Setting	Ruby Lake: Recreation category 3. High day use low opportunities for solitude. Recreation Impact Rating = 1.4.	Ruby Lake allow for moderate level of use by concentrating impacts and managing sites. Manage for lowering overall resource ratings by containing impacts.	Adjust to a Recreation Category 2.
	Use Levels 01-04	0-2 trips, 0-8 stock		Up to 6 spot and dunnage trips.
	Grazing	No grazing reported or requested.	Increased vegetative cover along trails. Maintain high-seral status of vegetation.	No grazing.
	Campsites	Low capacity for camping.		No stock camps.
6. Volcanic				
Destination: Volcanic	Access	Volcanic Knob Trail, observed Trail Class 2 to meadow, then Trail Class 1 to upper basin. Resource Rating 1. Generally stable, low impacts, low risk factors. Use trail VOL01 continues above 10,800 to lakes below Recess Peak.	Maintain current stability without adding substantial development.	Keep use levels low on trails. Approve use trail VOL01.
	Recreation Category Setting	Volcanic: Recreation Category 1. Low use high opportunities for solitude. No Recreation Impact Rating. Cabin, snow sensor site.	Volcanic: maintain high opportunities for solitude.	Change Recreation Category to 2 due to cabin and snow survey site.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Use Levels 01-04	0-5 trips, 0-21 stock		Up to 4 spot and dunnage trips.
	Grazing	Intermingled wet to moist meadow complex. Vegetation meets desired condition. Minor and local hoof punching and sod fragmentation near and along trail to snow survey cabin. Some areas of the meadow have fen characteristics. Occupied Yosemite toad habitat in good ecological condition. Reported grazing: 0/0/0.	Maintain current vegetative conditions. Maintain areas with fen characteristics in functioning condition. Maintain high quality Yosemite toad breeding habitat.	Approve grazing, 250 stock nights available, AUF is 40%, Protect critical areas (fens).
	Campsites	Campsite around snow survey cabin, low to moderate impact.	Maintain low to moderate impact at campsite at cabin.	Designate 1 stock camp.
7. Devils				
Destination: Devils Bathtub	Access	Devils Bathtub Trail observed Trail Class 2, Resource Rating 3.5, erosion, incision, proximity to water.	Long-term, improve trail.	Keep use levels low. Limit use to outlet of lake and prohibit commercial pack stock use to inlet.
	Recreation Category Setting	Devils Bathtub: Recreation Category 2. Low to moderate opportunities for solitude. Potential opportunities for high day use.	Devils Bathtub maintain moderate to high opportunities for solitude.	
	Use Levels 01-04	0-4 trips, 0-56 stock		Up to 8 spot and dunnage trips
	Grazing	Requested for grazing. No use reported 2001-2003.	Maintain mid-seral to high-seral vegetative status.	Allow 25 stock nights of grazing, 40% AUF.
	Campsites		No stock camp.	No stock camp.
8. Second Recess, Silver Pass, Graveyard, Laurel Analysis Units				

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
Destination: Lower Mono Creek (including Quail Meadow)	Access	Mono Creek Trail: Trail Class 3, generally stable with poor drainage and moderate impacts at creek crossings. Population of Mono Hot Springs evening primrose near boat landing on northeast side of Edison Lake.	Perform maintenance to increase stability. Maintain population of primrose in good condition.	Monitor evening primrose population.
	Recreation Category Setting	Lower Mono: Recreation Category 2. Moderate to high opportunities for solitude. Area adjacent to JMT and PCT. Recreation Impact Rating = 1.2.	Lower Mono: maintain for moderate to high opportunities for solitude.	
	Use Levels 01-04	0-3 trips, 0-34 stock (Quail: 0-1 trip, 0-5 stock)		Up to 18 spot and dunnage trips to one operator.
	Grazing	Overall vegetation is high-seral. Intermingled wetland complex. Some areas have fen characteristics. Quail meadow has areas of bare soil in trees and in upper, dry meadow, and sod fragmentation in wet portion of meadow. Reported use in 2001/2002/2003 is 0/48/45, only reported at Quail Meadow.	Maintain current vegetative conditions. Maintain any areas with fen characteristics or wetland characteristics in functioning condition.	Approve grazing, 323 stock nights available in Mono Creek zone. Limit planned trips to Quail Meadow to 48 stock nights. AUF is 40%. Critical area (fens) trampling <5%.
	Campsites	Stock holding campsite at Mono Creek/Second Recess confluence does not meet BMPs. There is some sediment entering the creek.	All stock holding and spot and dunnage sites should meet BMPs.	Designate 3 stock camps in this zone. Relocate stock camp at junction of Second Recess.
9. Second Recess				
Destination: Second Recess Canyon	Access	Second Recess Trail, observed Trail Class 2, Resource Rating 2, rarely maintained, with many obstacles. Difficult crossing at high water. Use trail SEC02 to Mills Lake, lightly defined, high risk factors. Many downed trees	Maintain trail to prevent multiple trailing.	Prohibit use on SEC02. Remove logs to prevent users from going off trail.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		across the system trail.		
	Recreation Category Setting	Second Recess: Recreation Category 2. Low use, moderate to high opportunities for solitude. Recreation Impact Rating = 1.3.	Second Recess maintain for moderate to high opportunities for solitude.	
	Use Levels 01-04	High Sierra: 0-7 trips, 0-45 stock Rock Creek: 0-2 trips, 0-28 stock		10 spot and dunnage trips.
	Grazing	Overall vegetation is high-seral. Intermingled wetland complex. Meadow has areas with fen characteristics. Reported use: 2001/2002/2003 is 0/23/27.	Maintain current vegetative conditions. Maintain fen in functioning condition.	Approve grazing, 278 stock nights available in zone. AUF is 40%. Protect critical areas.
	Campsites		All stock holding and spot and dunnage sites should meet BMPs.	Designate 1 stock camp
10. Fourth Recess				
Destination: Fourth Recess Lake	Access	Fourth Recess Trail, observed Trail Class 2, Resource Rating 1, slight impacts at creek crossings. Terminates at lake.	Needs improved structures at crossings.	
	Recreation Category Setting	Fourth Recess: Recreation Category 2. Low to moderate opportunities for solitude. Concentrated impacts at outlet of lake. (Recreation Impact Rating = 1.2)	Fourth Recess: manage for overall resource rating by containing impacts. Maintain moderate opportunities for solitude.	
	Use Levels 01-04	8-28 trips, 57-164 stock		Up to 28 spot and dunnage trips.
	Grazing	No grazing reported or requested. Reported grazing: 0/0/0. No reported alterations of vegetative composition or cover.	Mid-seral to high-seral vegetative status.	No grazing.
	Campsites	Limited camping, crowding potential at outlet of lake. One site is suitable for large parties.		No stock camp at lake, but down at Mono Creek. Designate 1 spot and dunnage campsite for large

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
				parties (over 8 people) at the north end of lake.
11. Fourth Recess				
Destination: Upper Mono Creek (Trail Lake, Upper Mono Corridor)	Access	Mono Creek Trail, observed Trail Class 3, degraded in steep sections, meadows, creek crossings. Use trail FOR02, access to camps near Mono Creek below 3rd, 4th Recess.	Maintain/stabilize primary trail.	Determine best route to camps, maintain stability. Golden Lake Trail is NSCS. Third Recess Trail is NSCS.
	Recreation Category Setting	Upper Mono Creek: Recreation Category 2. Low to moderate opportunities for solitude. High use along trail corridor. (Recreation Impact Rating = 1.4)	Upper Mono Creek: maintain moderate to high opportunities for solitude outside of trail corridor, moderate opportunities for solitude on trail corridor. Manage to lower overall resource rating.	
	Use Levels 01-04	1-20 trips, 2-111 stock		Up to 35 spot and dunnage trips to two operators (30 Rock Creek 5 High Sierra), and use for all expense/traveling trips.
	Grazing	Meadow north of Mono Rock, near shortcut to Mudd Lake, Reported grazing: 0/5/7. Meadow is wet throughout the summer, with local trampling and moderate sod fragmentation especially near the trail crossing at the west end and on the south side. Area with fen characteristics and occupied mountain yellow-legged frog habitat has moderate spring impacts.	Mid-seral to high-seral vegetative status. Fen in functioning condition, and mountain yellow-legged frog spring channel habitat in good ecological condition.	Meadow north of Mono Rock is unsuitable for grazing. Approve grazing in the Mono Creek zone. 323 nights in the zone. Protect critical area (fen).
	Campsites			Designate 5 stock camps.
12. Pioneer				
Destination: Pioneer Basin	Access	Pioneer Basin Trail past Mudd	Keep use to most stable trails.	No use of system trail to Lake

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		Lake to Lake 10,860, observed Trail Class 2, Resource Rating 3.5, degraded, severe incision, high risk factors. Various use trails to Camp Meadow (PIO09) Resource Rating 2, duplicates system; to Lake 10,900 (PIO16), Resource Rating 4, severe resource impacts. Use trail PIO06 from Mudd Lake to Mono Creek camps (Resource Rating 3) shortcuts system trail, used for grazing.	Enhance trails most sustainable network, and close/rehab unneeded or unstable trails. Prevent further degradation of use trails.	10,860 above Mudd Lake until the trail is repaired. Long term, repair trail to Lake 10,860 past Lake 10,840 at Trail Class 2. Prohibit use trail PIO09 and use trail PIO16. Use on system trail to the northeast of Mudd Lake is allowed only to designated campsite. Allow use of PIO06 only to access dispersed upland grazing.
	Recreation Category Setting	Pioneer Basin: Recreation Category 2. Moderate opportunities for solitude, moderate impacts. (Recreation Impact Rating = 1.4, Lake 10,900 Recreation Impact Rating 2.4)	Pioneer Basin maintain moderate to high opportunities for solitude. Manage for lower overall resource rating by containing impacts.	
	Use Levels 01-04	High Sierra: 0-1 trip, 0-7 stock Rock Creek: 13-27 trips, 96-210 stock		Up to 22 spot and dunnage trips to 2 operators (20 Rock Creek, 2 High Sierra) to lower lakes in basin.
	Grazing	No grazing reported (closed to grazing), grazing requested. Locally moderate vegetative species composition alteration, near inlet and outlet of Mudd Lake. Camp Meadow has fen characteristics and incised trail has caused changes to hydrologic condition. Occupied Yosemite toad habitat at north end of lakeshore in good ecological condition.	Maintain mid-seral to high-seral vegetative status. Fen in functioning condition. Maintain high quality Yosemite toad breeding habitat.	Approve grazing SE side of Mudd Lake only, 30 stock nights available, 30% AUF. No grazing in Camp Meadow.
	Campsites	Some spot and dunnage sites at Pioneer Basin Lakes do not meet BMPs.	All spot and dunnage and stock holding campsites should meet BMPs.	Do not allow spot and dunnage or stock holding at sites that do not meet BMPs. Designate 3

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
				stock camps, 2 in vicinity of Mudd lake and 1 above Mudd at trail/creek crossing to upper basin.
13. Hopkins				
Destination: Lower Hopkins Basin	Access	Hopkins Pass Trail, observed Trail Class 2, Resource Rating 3. Has moderate to severe incision at meadows, water diversion. Becomes indistinct, but stable last 1/8 mile from pass. Hopkins spur goes to lake, similar condition. Use trail HOP01 continues north from lake to meet Hopkins Pass Trail, duplicate access, degraded.	Reduce rate of degradation, repair trails. Prevent duplication.	Prohibit use on HOP01. Keep use levels low. Hopkins Pass Trail NSCS the last mile before the pass (above small lake south of Upper Hopkins Lake).
	Recreation Category Setting	Lower Hopkins: Recreation Category 2. Moderate to high opportunities for solitude. (Recreation Impact Rating = 2.0)	Lower Hopkins maintain moderate to high opportunities for solitude.	Identify stock camps.
	Use Levels 01-04	0-6 trips, 0-57 stock		Up to 10 spot and dunnage trips for use by two operators (8 Rock Creek; 2 HSPS) and use of area for all expense traveling trips.
	Grazing	Locally moderate sod fragmentation and altered vegetative species composition. Overall, at desired condition. Reported grazing: 2001/2002/2003 is 0/26/12.	Maintain vegetation at moderate to high seral status. Prevent local sod fragmentation and altered vegetative species composition from expanding.	Approve grazing, 159 stock nights available, 30% AUF.
	Campsites	Two sites at Lower Hopkins Lake (out of 7 evaluated) do not meet BMPs.	All stock holding and spot and dunnage sites should meet BMPs.	Do not allow stock holding or spot and dunnage at sites less than 100 feet from lake. Designate 1 stock camp at lake and 1 at junction of basin and Lower Hopkins Lake.
14. Laurel				

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
Destination: Laurel Canyon	Access	Laurel Lake, observed Trail Class 2, then Trail Class 1, Resource Rating 1. Rough trail with obstacles near bottom. Very steep, could be risk factor if use increased.	Maintain stability without addition of substantial development.	Use trail to Grinnell Lake prohibited for commercial stock use.
	Recreation Category Setting	Laurel Lake: Recreation Category 2. Moderate to high opportunities for solitude. No Recreation Impact Rating.	Laurel Lake maintain for high opportunities for solitude.	
	Use Levels 01-04	None reported (spot & dunnage)		Manage for occasional use on traveling and all expense trips.
	Grazing	No grazing reported. Grazing requested. High-seral vegetative status. Historical sod fragmentation and trail ruts patterns and local minor creek crossing impacts noted.	Maintain mid-seral to high-seral vegetative status. Maintain or improve creek crossings to prevent stream capture or excessive erosion into creeks.	Approve grazing, 92 stock nights available in lower meadow on Laurel Bench and one meadow north of bench, 40% AUF.
	Campsites	Very old campsites with low impacts at Laurel Bench.		Designate 1 stock camp at south end of Laurel Bench.
15. Graveyard				
Destination: Arrowhead/Feather Lakes	Access	Arrowhead Trail observed Trail Class 2, Resource Rating 1. Feather Trail observed Trail Class 1, Resource Rating 1, low risk factors.	Maintain stability without addition of substantial development.	Keep use levels low to Feather Lake.
	Recreation Category Setting	Arrowhead/Feather Lakes: Recreation Category 2. Moderate to high opportunities for solitude. No Recreation Impact Rating.	Arrowhead/Feather Lakes: maintain high opportunities for solitude, low development trails, low impact ratings.	Change Feather Lake to Recreation Category 1.
	Use Levels 01-04	2-6 trips, 8-50 stock		Up to 5 trips. Only occasional trips to Feather Lake, no more than 1 trip a year.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Grazing	No grazing reported or requested. High-seral vegetative status. High elevation wetland complex meadows with wet fragile inlet and outlet meadows at Feather Lake, meadows limited to small lakeshore riparian patches/meadows at Arrowhead Lake. Fen at Arrowhead Lake in good condition.	Maintain high-seral vegetative status. Maintain fen in functioning condition. D127	Unsuitable; do not allow grazing.
	Campsites	Stock holding site at Arrowhead Lake meets BMPs.	All stock holding and spot and dunnage campsites should meet BMPs.	No stock camp at Feather Lake; 1 stock camp at Arrowhead Lake north of the lake.
16. Graveyard				
Destination: Goodale Pass	Access	Goodale Pass Trail (observed Trail Class 3 to Graveyard Junction, Trail Class 2 above). Generally stable, with slight impacts at creeks, meadows. Trail on north side of pass deteriorated.	Maintain stable trail.	
	Recreation Category Setting	Goodale Pass: Recreation Category 2. Low to moderate opportunities for solitude along trail corridor. Moderate to high opportunities for solitude outside trail corridor. No Recreation Impact Rating. Graveyard Meadows: Recreation Category 2, moderate opportunities for solitude.	Goodale Pass: maintain for moderate opportunities for solitude. Concentrate impacts along trail corridor. Graveyard Meadows: maintain moderate opportunities for solitude.	
	Use Levels 01-04	0-6 trips, 0-25 stock		Up to 6 trips to Goodale Pass.
	Grazing	No grazing reported, grazing requested. Intermingled wetland	Maintain mid-seral to high-seral vegetative status. Fen in	Approve grazing, part of Graveyard zone, 400 stock nights

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		complex, some historical local and minor alteration of vegetative composition. Occupied Yosemite toad habitat in upper Graveyard Meadows. Gooddale Pass Meadow has a fen with headcuts in the spring channel. There are several fens in this drainage in good condition with little use. Stream in Middle Graveyard Meadow was rated functional at-risk, and the meadow has areas of severe compaction. It is currently grazed by cattle.	functioning condition. Allow stream in Middle Graveyard Meadow to move toward proper functioning condition. Maintain high quality Yosemite toad habitat.	available in entire Graveyard zone, 40% AUF. Limit planned grazing in Upper Cold Creek near Gooddale Pass to 200 stock nights, in Upper Graveyard meadow to 127 stock nights, Middle Graveyard Meadow to 41 stock nights. Prohibit stock entry and grazing in critical areas.
	Campsites			Designate 1 stock camp at Upper Graveyard Meadow.
17. Graveyard				
Destination: Graveyard Lakes	Access	Graveyard Trail observed Trail Class 2, heavily used compared to development, needs repair, but in mostly low-risk area up to first lake. Upper trail observed Trail Class 1.5, Resource Rating 3, incision, risk factors - proximity to creek, steepness, diversions, no development. Above Upper Graveyard Lake, trail not visible, used only to access saddle north of lake by foot.	Prevent further deterioration of trail above Lower Graveyard Lake.	NSCS past Lower Graveyard Lake inlet. Prohibit use trail GRA01 above Big Graveyard.
	Recreation Category Setting	Lower Graveyard Lakes: Recreation Category 1. Moderate to high use, low opportunities for solitude at lower lake. Camping impacts evident.	Lower Graveyard Lakes low to moderate opportunities for solitude during peak season; reduce overall impacts at destination by containing and concentrating impacts.	Change to Recreation Category 2.
	Use Levels 01-04	High Sierra: 0-34 trips, 0-228 stock D&F: 0-6 trips, 0-64		Up to 30 trips by two operators to lower lake only, to keep

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		stock		opportunities for solitude moderate and respond to low capacity of area.
	Grazing	None reported, grazing requested. Moist understory meadows between trail junction at Cold Creek and lower lake, moist to dry meadows on benches to southeast of lakes. Few impacts noted, other than minor sod fragmentation in lakeshore meadows.	Maintain mid-seral to high-seral vegetative status.	Approve grazing, part of Graveyard zone, 400 stock nights available in Graveyard zone. Limit planned grazing in Graveyard Lakes area to 32 stock nights, 40% AUF.
	Campsites			No stock camps.
18. Silver Peak				
Destination: Mott Lake	Access	Mott Lake Trail observed Trail Class 2, Resource Rating 2.5, Trail degraded, but only moderate resource effects on isolated sections. Some bypasses of wet areas between Mott Lake and the meadow. Very awkward in rocks just below Mott Lake.	Maintain trail to prevent off-trail degradation.	Allow low-moderate use to lake.
	Recreation Category Setting	Mott Lake: Recreation Category 2. Moderate to high opportunities for solitude. Used only for spot and dunnage trips. No Recreation Impact Rating.	Mott Lake: maintain for moderate to high opportunities for solitude.	
	Use Levels 01-04	High Sierra: 2-10 trips, 4-64 stock D&F: 0-2 trips, 0-10 stock		Up to 10 trips spot and dunnage to Mott Lake to two operators.
	Grazing	No grazing reported. Requested for grazing below Mott Lake along trail. Meadow stream in proper functioning condition.	Protect soda spring function. Protect hydrologic function of wetland areas.	Allow 13 stock nights of grazing in the area below Mott Lake. Spring and wetlands are critical areas.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		Contains a unique soda spring and over half of the meadow never reaches range readiness.		
	Campsites	High density of impacted sites		Designate 1 stock camp below lake.
19. Morgan Lakes				
Destination: Morgan Lakes	Access	Morgan Pass Trail observed Trail Class 3 from old mining road on Pine Creek side. Use trail MRG01 to Bear Lake, lightly defined, few risk factors.	Keep Morgan Pass Trail stable.	Use trail to Bear Lake (MRG01) prohibited for commercial stock use.
	Recreation Category Setting	Morgan Lakes: Recreation Category 2. Moderate opportunities for solitude. (Recreation Impact Rating = 1.4)	Morgan Lakes: maintain for moderate to high opportunities.	
	Use Levels 01-04	Rock Creek: 0-2 trips, 0-7 stock Pine Creek: 0-2 trips, 0-10 stock		Up to 8 trips by two operators to maintain high opportunities for solitude.
	Grazing	None requested or reported. Small lakeshore meadows and small riparian areas associated with creek above upper lake.	Maintain mid-seral to high-seral vegetative status.	Unsuitable; do not allow grazing.
	Campsites			No stock holding.
20. Silver Peak				
Destination: Pocket / Silver Pass Meadows	Access	PCT/JMT Trails Class 3.		
	Recreation Category Setting	Recreation Category 2. PCT/JMT trail corridor low to moderate opportunities for solitude.	Maintain low opportunities for solitude along JMT/PCT trail corridor.	
	Use Levels 01-04	Use for all expense trips.		Use for all expense trips.
	Grazing	Silver Pass Meadow has vegetation composition change,	Silver Pass Meadow should move toward no alteration of	Silver Pass Meadow: rest until the stream is functional at-risk

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		incised channels, streams are functional at-risk, hydrologic function alteration. Grazing reported: 0/67/127. Meadows at Silver Pass Lake are low productivity and have no current use. Pocket Meadow has an incised channel and there is some vegetation composition change, likely drying due to creek incisement.	hydrologic function, stream move toward proper functioning condition, and vegetation should be mid to high seral. Meadows at Silver Pass Lake should remain with no hydrologic function alteration and streams should remain in proper functioning condition. The stream in Pocket Meadow should move toward proper functioning condition, if possible.	with an upward trend and vegetation composition recovery toward mid-high seral. Silver Pass Lake: allow grazing 124 stock nights (moderate priority for monitoring). Pocket Meadow: 48 stock nights.
	Campsites			Designate 3 stock camps. 1 at Pocket Meadow, 1 at Silver Pass Meadow, 1 below Silver Pass Lake.

JOHN MUIR SOUTHEAST

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
1. North Fork Big Pine				
Destination: Black Lake/Summit Lake	Access	Black Lake Loop Trail observed Trail Class 3, generally stable. Use trail NFB01 to Coyote Ridge, stable with current use, low risk factors, and generally dry slopes.	Ensure continued stability of NFB01.	Approve use of use trail NFB01.
	Recreation Category Setting	Recreation Category 2, off primary trail, moderate opportunities for solitude.	Manage for moderate to high opportunities for solitude.	
	Use Levels 01-04	Black: 8-16 trips, 34-121 stock Summit: 7-14 trips, 25-68 stock		Up to 30 spot and dunnage trips to maintain moderate-high opportunities for solitude.
	Grazing	None requested, none available.		No grazing.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Campsites		No stock camps.	No stock camps.
2. North Fork Big Pine				
Destination: North Fork Big Pine	Access	North Fork Big Pine Trail: observed Trail Class 3 to 4th Lake, Trail Class 2 to 6th Lake, well-developed, stable; low to moderate commercial use, high public hiker use. 6th Lake hiker trail: observed Trail Class 2, steep with high risk factors, alternate route to stock trail. Various use trails: Heidi Cabin NFB05, 2nd Lake Snow Cabin NFB06, 4th/5th Lake spur NFB07, 5th Lake Camps NFB08, Snow Survey site NFB09 - all generally stable with current low use.	Ensure use trails do not increase or degrade. Identify best route to 6th Lake.	Approve use trail at current levels. Heidi Cabin use trail NFB05 for hunting season use only. Prohibit commercial stock on 6th Lake hiker trail. Allow access on primary 6th Lake trail.
	Recreation Category Setting	Recreation Category 3, high use corridor to 5th Lake, popular day hiking, mountaineering and backpacking destination. Low to moderate opportunities for solitude, moderate impacts concentrated at sites and trails.	Manage as high use corridor, concentrate impacts.	
	Use Levels 01-04	66-115 trips, 260-564		Up to 125 spot and dunnage trips. Use levels should not facilitate additional crowding at campsites.
	Grazing	None requested, none available.		No grazing.
	Campsites	High density campsites around lakes, all spot and dunnage or hiker camps.	All camps should meet BMPs.	No stock camps.
3. Coyote				
Destination: Baker Lakes	Access	System trail access from Baker Lake Trail, Trail Class 2. Stable,	Keep use limited to prevent degradation of use trails.	Approve COY01 to Thunder and Lightning Lake. Approve

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		lightly used, rarely maintained. Use trail access from Black Lake NFB01, faint, low use, few risk factors. Use trail COY01 from system trail to Thunder and Lightning Lake.		use of NFB01 to Coyote Flat.
	Recreation Category Setting	Recreation Category 2, off of primary trail, low use high opportunities for solitude.	Maintain high opportunities for solitude.	
	Use Levels 01-04	Baker Lake/Ridge 0-2 trips, 12-13 stock		Up to 6 spot and dunnage will maintain high opportunities for solitude.
	Grazing	None requested. Potential grazing.		No grazing.
	Campsites		No stock camps.	No stock camps.
4. South Fork Big Pine				
Destination: South Fork Big Pine	Access	South Fork Big Pine Trail: observed Trail Class 2 to Willow Lake, steep, rocky in places, with slight impacts at stream crossings near Willow Lake. Trail Class 1 above. Climbs steeply near creek. Population of Father Crowley's lupine and Inyo beardtongue near South Fork Big Pine Trail.	Keep trail stability without adding further structural development. Maintain populations of rare plants.	NSCS above Willow.
	Recreation Category Setting	Recreation Category 2, not a primary trail, has moderate opportunities for solitude, low to moderate impacts. Limited camping.	Manage for high opportunities for solitude.	
	Use Levels 01-04	None reported.		Up to 2 spot and dunnage trips with very low stock numbers will maintain high opportunities

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
				for solitude.
	Grazing			No grazing.
	Campsites	No stock camps.	No stock camps.	No stock camps.
5. Birch				
Destination: Birch Creek	Access	Birch Creek Trail: observed Trail Class 2, generally stable to just below lake, dissipates into willows. Three use trails used for hunting, two are near system trail (BIR01,BIR02), lightly defined to camps. Use trail BIR03 follows old trail to spring east of Kid Mountain. Indistinct, dry slope with few risk factors at current use levels.	Maintain system trail stability without adding substantial structures; keep commercial stock use low. Ensure that use trails do not become more evident, by limiting use to low levels.	Top 1/3 mile of Birch Creek Trail NSCS. Approve use trails BIR01 and BIR02 and BIR03 for hunting trips.
	Recreation Category Setting	Recreation Category 1, very low use high opportunities for solitude.	Manage for low use and high opportunities for solitude.	
	Use Levels 01-04	4-14 trips, 15-93 stock		Up to 5 spot and dunnage trips for hunting trips only. Consider up to 10 trips if state game tag capacity. Limit stock numbers to current numbers per party. This use level will maintain high opportunities for solitude.
	Grazing			No grazing.
	Campsites		No stock camps.	No stock camps.
6. Taboose				
Destination: Taboose to SEKI	Access	Taboose Pass Trail: observed Trail Class 2. Steep, awkward, generally stable. Snow bypass below pass. Populations of Raven's milkvetch, Inyo beardtongue, and alpine jewel-flower on the Taboose Trail	Keep all stock use on trail when trail is in adequate condition. Maintain rare plant populations in good condition.	Repair trail, so bypass not needed.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		have no reported negative impacts.		
	Recreation Category Setting	Recreation Category 2, primarily providing access to SEKI, limited camping, moderate to high opportunities for solitude.	Manage primarily as travel corridor, moderate opportunities for solitude. Manage use consistent with SEKI's desired conditions.	
	Use Levels 01-04	Sequoia Kings: 2-8 trips, 10-49 stock Mt. Whitney: 0-5 trips, 0-24 stock Rock Creek: 0-3 trips, 0-12 stock		Up to 13 spot and dunnage and resupply trips for pass through use to SEKI.
	Grazing	None requested, none available.		No grazing.
	Campsites		No stock camps.	No stock camps.
7. Sawmill				
Destination: Sawmill to SEKI	Access	Sawmill Pass Trail: observed Trail Class 2, steep, sandy, generally stable. Snow bypass SAW01 below pass. There is a population of Raven's milkvetch on the Sawmill Pass Trail with no reported negative impacts.	Keep all stock use on trail when trail is in adequate condition. Maintain Raven's milkvetch population in good condition.	Approve use trail SAW01 for bypassing snow until system trail is relocated.
	Recreation Category Setting	Recreation Category 1, Bighorn Zoological Area. Primarily used to access SEKI. Very low use and high opportunities for solitude.	Manage for very low use and high opportunities for solitude. Manage use consistent with SEKI's desired conditions.	
	Use Levels 01-04	0-2 trips, 0-15 stock		Up to 3 spot and dunnage trips to two operators to maintain low use and high solitude of area.
	Grazing	Current light use is not causing resource concerns. Reported use	Maintain or improve meadow conditions.	45 stock nights.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		9/0/0.		
	Campsites			Designate 1 stock camp at meadow below Sawmill Lake.
8. Kearsarge				
Destination: Gilbert/Matlock/Bench/Flower Lakes	Access	Kearsarge Pass Trail: observed Trail Class 3, recently repaired, stable. Matlock Lake Trail: observed Trail Class 2.5, stable. Two use trails to Bench Lake- Matlock to Bench use trail KEA06, dry slope, steep, but few risk factors; Flower to Bench use trail KEA05, less stable, longer off-system approach.	Ensure use is on most stable use trail.	Matlock Lake, Trail Class 2. Allow use of Matlock to Bench KEA06. Prohibit use trail KEA05.
	Recreation Category Setting	Recreation Category 3, high use area with low to moderate solitude and concentrated impacts at campsites and trails. Limited camping without being in sight and sound of others at each of these lakes.	Manage as a Recreation Category 3, continue to concentrate impacts.	
	Use Levels 01-04	None reported		Up to 16 spot and dunnage trips. Distribute use to various lakes within destination to prevent overcrowding or overusing any one lake.
	Grazing			
	Campsites	There are populations of Mt. Whitney draba and Sharsmith's stickseed within 0.1 mile of camp and use trails with no known adverse impacts.	Maintain populations of rare plants in good condition.	No stock camps.
	Other Issues	Mountain Yellow Legged Frog Restoration habitat	Pack stock use should be consistent with MYLF habitat restoration (State Fish and	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
			Game project).	
9. Kearsarge				
Destination: Kearsarge to SEKI	Access	Kearsarge Pass Trail, observed Trail Class 3, stable.		
	Recreation Category Setting	Recreation Category 3, high use area with low to moderate solitude and concentrated impacts at campsites and trails. Limited camping without being in sight and sound of others at each of these lakes.	Manage as a Recreation Category 3, continue to concentrate impacts. Manage use consistent with SEKI's desired conditions.	
	Use Levels 01-04	SKPT: 20-32 trips, 110-125 stock MLPO: 0-2 trips, 0-6 stock Mt. Whitney: 0-1 trip, 0-3 stock Rock Creek: 0-1 trip, 0-3 stock Pine Creek: 0-5 trips, 0-20 stock		Up to 36 spot and dunnage trips to access the SEKI. Consistent with SEKI desired conditions and Recreation Category 3 conditions along primary trail corridor. Use of area for all expense trips.
	Grazing			No grazing.
	Campsites			No stock camps.
10. Shepherd				
Destination: Shepherd to SEKI	Access	Shepherd Pass Trail: observed Trail Class 2 to base of headwall, trail very degraded on final 1/2 mile, due to severe terrain. Junction Pass Trail: observed Trail Class 1, no resource concern, limited use after Forester Pass constructed. Rough, steep, rocky, rarely maintained. There are populations of Dedecker's clover and marble rock mat on the Shepherd Pass Trail, with no known adverse impacts.	Continue to maintain Shepherd Trail from base of headwall to Pass as primitive trail. Maintain Junction Pass as primitive trail. Reduce use to prevent excessive maintenance needs. Maintain rare plant populations.	Shepherd Pass: designate upper section as Trail Class 2, with low priority for maintenance. Require pack stations in operating plans to scout and clear trail prior to first guided trip over pass. Allow loose-herding below pass to Pothole section only. Junction Pass is NSCS.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Recreation Category Setting	Recreation Category 2 (Shepherd), Recreation Category 1 (Junction Pass). Use primarily as a pass through to SEKI. Moderate opportunities for solitude.	Manage use consistent with Park's desired conditions.	
	Use Levels 01-04	SKPT: 2-12 trips, 14-59 stock MLPO: 0-1 trips, 0-3 stock Mt. Whitney: 1-6 trip, 3-28 stock Pine Creek: 0-1 trips, 0-4 stock		Up to 18 spot and dunnage trips to two operators.
	Grazing	Anvil Camp Meadow closed to grazing in early 1990's due to stock related impacts.		No grazing.
	Campsites			Stock camp at Anvil camp for occasional use (less than 3 nights a year).
11. Whitney				
Destination: Trail Crest	Access	Stock access is via NPS trails.		Whitney Trail is NSCS (closed to all stock use).
	Recreation Category Setting	Recreation Category 3. Use is coming over from SEKI and clients hike down Mt. Whitney trail. Very high use area, impacts concentrated, low opportunities for solitude.	Manage use consistent with Park's desired conditions.	Reduce use if SEKI indicates the facilitated use is not acceptable.
	Use Levels 01-04	Cottonwood: 1-7 trips, 7-58 stock SKPT - 1 trip		Up to 14 trips a year (two operators SKPT/Cottonwood: 4:10) Unguided. Consistent with SEKI desired condition.
	Grazing			No grazing.
	Campsites			No stock camps.
12. Cottonwood				

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
Destination: Cottonwood Basin	Access	Cottonwood Lakes Trail: Trail Class 3 to Lake 3, Trail Class 2 to Lake 4/5, recently repaired, stable. Cottonwood Lake 2 Cutoff lightly defined on south, severe impacts along Lake 3 banks. Muir Lake Trail: Trail Class 2, stable, dry until lake outlet on southwest end, then riparian and stream impacts. Cirque Lake: observed Trail Class 3 & 2, generally stable, but risk factors at creek crossings and meadows. South Fork Trail: observed Trail Class 2, (mostly in Golden Trout Wilderness - only 3/4 mile in John Muir Wilderness) degraded, affecting stream, meadows, duplicates access of stable Cottonwood Lakes Trail. Hidden Lake use trail COT05, lightly defined, stable. Use trail COT01 around 4th/5th Lakes, unstable, close to lakeshores. Use trail COT08 to Frog Pond Camp, lightly defined access from CA Department of Fish and Game cabin.	Keep stock on most stable routes. Eliminate duplicate access. Ensure Muir Trail stability with minimal added development or structures. Keep Hidden Lake use trail stable without adding structures.	Cottonwood Lake 2 Cutoff - NSCS. Muir Lake Trail: designate best access to camp on west side of lake (avoid riparian at outlet, if possible). South Fork Creek Trail: NSCS above South Fork Meadow. Use Cirque Lake trail from New Army Pass Trail to access Cirque Lake. Keep use low on Hidden Lake use trail and on Muir Lake Trail. Prohibit use on use trail COT01 around 4th/5th Lake. Define best route to "Frog Pond Camp" from CA Department of Fish and Game cabin.
	Recreation Category Setting	Recreation Category 3 , high use area, concentrate impacts at campsites and trails. Low opportunities for solitude	Manage as Recreation Category 3 with concentrated impact areas at lakes.	
	Use Levels 01-04	14-32 trips, 73-215 stock		Up to 50 spot and dunnage trips consistent with Recreation Category 3. Low use and stock numbers to Hidden Lake.
	Grazing	Windy Gap Meadow is a relatively high elevation. fragile	Windy Gap - stream in proper functioning condition, meadow	Long term rest.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		meadow that is severely degraded from historic multiple headcuts, and stream and spring channel incision events. The meadow is in a long-term floodplain rebuilding process.	in late seral vegetative condition with water table restored to allow for wet meadow restoration.	
	Campsites	Sweet-smelling monardella population near Lakes 4 and 5 with no known negative impacts.	Maintain sweet-smelling monardella population.	No stock camps. Allow access to Muir Lake west shore campsites on designated system trail only.
13. Cottonwood				
Destination: New Army Pass	Access	New Army Pass Trail: Trail Class 3, generally stable.		
	Recreation Category Setting	Recreation Category 2. Access to SEKI.	Manage consistent with SEKI's desired conditions.	
	Use Levels 01-04	0-4 trips, 0-34 stock		Up to 4 spot and dunnage trips a year to maintain current use level consistent with SEKI desired conditions.
	Grazing	None requested, none reported.		No grazing.
	Campsites			No stock camps.
14. Cottonwood				
Destination: Cirque and South Fork Lakes	Access	Cirque Lake, South Fork Lake reached by primary New Army Pass Trail and Cirque Lake trails from the North Fork -- well-developed, generally stable. South Fork Trail (observed Trail Class 2 to South Fork Meadow, Trail 1 above) provides duplicate access, with isolated moderate to severe risk factors, minimum development.	Prevent degradation on undeveloped trail above South Fork Meadow.	Prohibit use of South Fork Trail above South Fork Meadow (John Muir Wilderness segment). Require the use of North Fork trails to access Cirque and South Fork Lakes.
	Recreation Category	Recreation Category 2, moderate use and moderate to	Maintain moderate to high	

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Setting	high opportunities for solitude.	opportunities for solitude.	
	Use Levels 01-04			Up to 6 spot and dunnage trips.
	Grazing	South Fork Meadow has reaches that are incised, with an active headcut. Stream segment rated functional at-risk. Requested as pasture.	Stream moves toward PFC.	No grazing. Rest for 8-12 years.
	Campsites		No stock camps.	No stock camps.

JOHN MUIR SOUTHWEST

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
1. Bench				
Destination: Bench Valley	Access	Blackcap Trail (Trail Class 3) to Bench Valley Trail (Trail Class 2, Resource Rating 3, Observed Trail Class 1), no system trail beyond Horsehead Lake. Bench Valley Trail in poor condition, severe erosion on switchbacks below McGuire Lake. Multiple trailing through at least one meadow above Guest Lake on Bench Valley Trail.	More stable Bench Valley Trail. More frequent maintenance on Bench Valley Trail.	Major rockwork needed on switchbacks below McGuire Lake (Bench Valley Trail). Regular maintenance needed on remainder of Bench Valley Trail.
	Recreation Category Setting	Recreation Category 2; a portion of upper basin is Recreation Category 1.	Maintain limited recreational impacts.	
	Use Levels 01-04	2-5 trips, 14-31 stock		Up to 6 spot and dunnage trips, consider additional (not to exceed 10) when trail is improved to standard.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Grazing	Some trailing related sod fragmentation and hoof punching are documented at McGuire Lake. Stream found to be in PFC. No grazing reported by pack station, but requested for grazing. Fall Creek grazing area: meadow less than 1 acre. Stream was rated at PFC. Stock nights reported at Fall Creek: 0/38/0	Retain stream in PFC.	McGuire Meadow: Wet areas (15%) of meadows need to be excluded from grazing. Allow grazing: 160 stock nights available. Fall Creek grazing area: allow grazing. 22 stock nights available.
	Campsites	1 stock camp at McGuire. 1 stock camp at Guest.	Stock holding and spot/dunnage sites should meet BMP's.	Designate 1 stock camp.
2. Basin				
Destination: Blackcap Basin	Access	Blackcap Trail (Trail Class 3 to junction with Bench Valley Trail, Trail Class 2 beyond), then user trails towards Ambition Lake and Maxson Lake.		Approve BAS01. Prohibit Bench to Blackcap use trail.
	Recreation Category Setting	Recreation Category 1. Remote with opportunities for solitude. Limited human impacts.	Maintain remoteness with high opportunities for solitude, low impacts.	
	Use Levels 01-04	4-5 trips, 23-24 stock		Up to 5 spot and dunnage trips.
	Grazing	Grazing at Lightning Corral Meadow reported 27/24/0 stock nights. Site not visited recently.		Allow grazing. 27 stock nights available.
	Campsites	No current packer camps in this area.		Designate 1 stock camp at Upper Lightening Corral Meadow. Stock holding and spot and dunnage sites should meet BMP's.
3. Basin				

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
Destination: Pearl/Portal Zone	Access	Blackcap Trail (Trail Class 3 to junction with Bench Valley Trail, Trail Class 2 beyond), then use trail (BAS02) towards Pearl Lake		Approve BAS02. Approve CRB01 for occasional use to Hummingbird Lake
	Recreation Category Setting	Recreation Category 1.	Maintain low use, high opportunities for solitude, low impacts.	
	Use Levels 01-04	1-4 trips, 4-20 stock		Up to 8 spot and dunnage trips per year. No more than 2 trips to Hummingbird Lake.
	Grazing	Grazing occurs in between Portal and Pearl Lakes or Crown Basin Camp. Reported grazing at Pearl Lake: 62/0/0		Pearl Lake Grazing Zone: allow grazing. 62 stock nights available.
	Campsites	Two packer camps exist at junction to Crown Basin.		Designate 2 stock camps in zone.
4. Bench				
Destination: Crabtree Lake	Access	Blackcap Trail (Trail Class 3) to Bench Valley Trail (Trail Class 2, Resource Rating 3, observed Trail Class 1, no system trail beyond Horsehead Lake, prohibited use trail to Crabtree Lake. BEN02 use trail less than 10% visible.	Maintain low visibility use trail to Crabtree Lake.	Approve BEN02 for low levels of use.
	Recreation Category Setting	Recreation Category 1.	Maintain high opportunities for solitude, low impacts, low visibility trail.	
	Use Levels 01-04	2 trips, 10-12 stock		Up to 2 spot and dunnage trips per year will maintain low visibility trail and setting of a Recreation Category 1.
	Grazing	Stock does not remain at Crabtree Lake, moved to Upper Fall Creek. Upper Fall Creek	Maintain current light grazing impacts.	Crabtree Lake: No grazing approved. Upper Falls Grazing

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		Grazing Area. 1.5 acres, low productivity. No grazing reported.		area, 12 stock nights available.
	Campsites	Little use occurring in this area. Spot and dunnage drop campsite on NE side of lake. High opportunity for solitude with very little camping available.	No stock camp.	No stock camp.
5. Basin				
Destination: Maxson Lake	Access			Approve BAS03 use trail.
	Recreation Category Setting	Recreation Category 1, very low use, high opportunities for solitude.	Maintain very low use, high opportunities for solitude.	
	Use Levels 01-04	No use reported.		Up to 2 spot and dunnage trips per year.
	Grazing	No grazing reported. Grazing requested.		Allow 25 stock night at meadow east of Maxson Lake.
	Campsites			Designate 1 stock camp.
6. Big Maxson				
Destination: Halfmoon Lake	Access	Blackcap Trail (Trail Class 3) to Halfmoon Cutoff (Trail Class 3).		
	Recreation Category Setting	Recreation Category 2. Low to moderate use, moderate to high opportunities for solitude, low impacts.	Maintain high opportunities for solitude.	
	Use Levels 01-04	1 trip, 6 stock		Up to 3 spot and dunnage trips per season.
	Grazing	No grazing requested or reported.		No grazing.
	Campsites	No packer camps in this area. Client drop off site only.	No stock camp.	No stock camp.
	Other Issues			

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
7. Big Maxson				
Destination: North Fork Kings River	Access	Blackcap Trail (Trail Class 3). Incision on Blackcap Trail at west end of Post Corral Meadow.	Reduce incision at west end of Post Corral Meadow on Blackcap Trail.	
	Recreation Category Setting	Recreation Category 2.		
	Use Levels 01-04	4-6 trips, 15-30 stock		Up to 6 trips spot and dunnage trips.
	Grazing	South side of the North Fork Kings River at the confluence of Fleming Creek. Site has high productivity and the stream within the meadow properly functioning.		Grazing allowed. Allow 400 stock nights.
	Campsites	South side of the Kings River at the confluence of Fleming Creek and the North Fork of the Kings River. BMP's were properly implemented and effective.		Designate 1 stock camp near gauging station/cabin.
	Other Issues			
8. Big Maxson				
Destination: Big Maxson Meadow	Access	Blackcap Trail (Trail Class 3). A small section of the Blackcap Trail below Big Maxson Meadow is in poor condition with instable tread and erosion issues.	Stabilize short section of Blackcap Trail that has unstable tread and shows erosion issues.	Rockwork needed on this section of the Blackcap Trail.
	Recreation Category Setting	Recreation Category 2, moderate to high use area, moderate opportunities for solitude.	Maintain as moderate opportunities for solitude.	
	Use Levels 01-04	1 trip, 14 stock		Up to 4 spot and dunnage trips.
	Grazing	Packer rarely grazes stock here, has not used since 2001. High public use in this area for		It is suitable for grazing, allocated to non-commercial pack stock users only.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		grazing. Meadow was rated functional at risk with an upward trend during field visit in 2002.		
	Campsites	There are several campsites around the meadow. This is a popular area for public stock users.		No stock camp.
	Other Issues			
9. Crown Lake				
Destination: Crown/Scepter Lakes	Access	Blackcap Trail (Trail Class 3) to Halfmoon Cutoff (Trail Class 3) to Crown Valley Trail (Trail Class 3), user trail to Scepter Lake.		Approve CRL01.
	Recreation Category Setting	Recreation Category 2, moderate use, moderate opportunities for solitude.		
	Use Levels 01-04	2 trips, 11 stock		Up to 6 spot and dunnage trips.
	Grazing	Clients are dropped at lake. Pack station moves stock 1/4 mile south of the lake to graze. Requested to graze area around and north of the lake.		Allow grazing at meadow near Scepter Lake. 25 stock nights.
	Campsites	No packer camp at lake. Clients are dropped at campsites. Very low use at this destination.		Designate 1 stock camp at Scepter Lake. Stock holding and spot and dunnage sites should meet BMP's.
10. Finger				
Destination: Chain / Duck Lakes	Access	Rancheria Trail (Trail Class 3) to Hoffman Mountain Trail (Trail Class 2). Severe erosion problems along sections of the Hoffman Mountain Trail. Trails receive low use and infrequent maintenance.	Stabilize gullied sections of the Hoffman Mountain Trail.	Significant water diversion and erosion control structures needed on Hoffman Mountain Trail.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Recreation Category Setting	Recreation Category 2. Low to moderate use, moderate to high opportunities for solitude, low impacts.		
	Use Levels 01-04	1 trip, 12 stock		Up to 4 spot and dunnage trips to one operator.
	Grazing	No grazing reported. Grazing requested at Duck Lake and Chain Lake.		Allow 25 stock nights at Duck and 25 stock nights at Chain Lake.
	Campsites			Designate 1 stock camp at Duck Lake and 1 stock camp at Chain Lake.
11. Fleming Mountain				
Destination: Dale Lake	Access	Blackcap Trail (Trail Class 3) to Hell For Sure Trail (Trail Class 2, RR 2.5, Observed. Trail Class 2) to Dale Lake Trail (Trail Class 2, RR 2.5, formerly user trail) is well defined but rocky in areas. Minor to moderate erosion and gullies on Dale Lake Trail.		Stabilize erosion and gullies on Dale Lake Trail.
	Recreation Category Setting	Recreation Category 2.	Maintain moderate to high opportunities for solitude.	
	Use Levels 01-04	1 trip, 4-5 stock		Up to 3 spot and dunnage trips.
	Grazing	Currently graze stock at Fleming Meadow or site North of Devils Punchbowl.	Retain streams in PFC.	Allow grazing. 621 stock nights available in the Fleming/Dale/Lower Indian Grazing Zone. Above Fleming Meadow (flee): Allow grazing; 77 stock nights available. Indian Lake Meadow: Allow grazing; 237 stock nights available. Upper Dale Meadow: 280 stock nights available.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Campsites	Packer drops clients at lake but does not remain with stock. One stock drop-off camp evaluated with BMP's. Primitive latrine present.		Designate packer drop off camp at Dale Lake. Remove latrine installed by CPO. Stock holding and spot and dunnage sites should meet BMP's.
12. Fleming Mountain				
Destination: Fleming Lake	Access	Blackcap Trail (Trail Class 3) to user trail that drops into Fleming Creek.		
	Recreation Category Setting	Recreation Category 2. Low use, High opportunities for solitude.		
	Use Levels 01-04	1-2 trips, 3-6 stock		Up to 6 spot trips.
	Grazing	Currently graze at Fleming Meadow. Meadow rated proper functioning condition.		Allow grazing. Fleming Meadow: 77 stock nights available.
	Campsites	Camps exist at lakes but are only used by private stock. Packer drops clients at lakes but does not remain.		Designate 1 stock camp above Fleming Lake. Stock holding and spot and dunnage sites should meet BMP's.
13. Fleming Mountain				
Destination: Rae Lake	Access	Blackcap Trail (Trail Class 3) to Hell For Sure Trail (Trail Class 2, Resource Rating 2.5, Observed. Trail Class 2) to Rae Lake Trail (Trail Class 2, Resource Rating 2, observed. Trail Class 2). Use trail from north side of Rae Lake to Reddys Hole trail is prohibited.		
	Recreation Category Setting	Recreation Category 2. Moderate use and moderate opportunities for solitude. Moderate recreational impacts.	Maintain moderate opportunities for solitude, reduce overall impacts.	
	Use Levels 01-04	3-4 Trips, 24-25 Stock		Up to 4 spot and dunnage trips.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Grazing	No grazing at Rae Lake. Graze stock at Fleming Meadow, Lower Indian or site near Devils Punchbowl trail depending on suitability.		No grazing at Rae Lake. 621 stock nights available in the Fleming/ Dale/ Lower Indian Grazing Zone. Above Fleming Meadow (flee): Allow grazing; 77 stock nights available. Indian Lake Meadow: Allow grazing; 237 stock nights available. Upper Dale Meadow: 280 stock nights available.
	Campsites	Packer drops clients at lake but does not remain. Limited camping capacity.	Stock holding and spot/dunnage sites should meet BMP's.	No stock camp.
14. Hobler				
Destination: Burnt Corral Zone	Access	Blackcap Trail (Trail Class 3) to Burnt Corral Trail (Trail Class 2)		Approve HOB01.
	Recreation Category Setting	Recreation Category 2.		
	Use Levels 01-04	2-6 Trips, 8-58 Stock		Up to 6 spot and dunnage trips.
	Grazing	Pack station grazes stock at Burnt Corral Meadow or Reddys Hole Meadow. Grazing reported at Burnt Corral: 8 stock nights.		Burnt Corral Meadow: Allow 25 stock nights.
	Campsites	No issues identified.		Designate 1 stock camp at Burnt Corral Meadow. Stock holding and spot and dunnage sites should meet BMP's.
15. Hobler				
Destination: Red Rock Basin	Access	Blackcap Trail (Trail Class 3) to Burnt Corral Trail (Trail Class 2) to Reddys Hole Trail (Trail Class 1) - possible shortcut via Hobler Lake Trail (Trail Class		

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		2) or Reddys Hole user trail. Reddys Hole system trail and user trail are very faint, often contain no discernable tread and receives very little use.		
	Recreation Category Setting	Recreation Category 1.		
	Use Levels 01-04	2-4 trips, 12-66 stock		Up to 4 spot and dunnage trips.
	Grazing	No grazing reported or requested.		No grazing approved.
	Campsites		No stock camp.	No stock camp.
16. South Woodchuck				
Destination: Chimney/Woodchuck Lakes	Access	Woodchuck Trail (Trail Class 3) to Woodchuck Lake Loop (Trail Class 2). Access to Chimney/Marsh Lake trail 28E39. Use trail to Chimney Lake is prohibited.		Prohibit Chimney Lake use trail (SOW03) Prohibit use trail (SOW02) to Marsh Lake.
	Recreation Category Setting	Recreation Category 2.		
	Use Levels 01-04	2-11 trips, 10-99 stock		Up to 15 spot and dunnage trips to one operator.
	Grazing	Stock is grazed 1/4 mile south of Chimney Lake.		Allow 25 stock nights south of Chimney Lake.
	Campsites	Pack station drops clients off at Chimney and Woodchuck Lake but moves stock to camp 1/4 mile south of Chimney Lake.	Stock holding and spot/dunnage sites should meet BMP's.	Designate 1 stock camp south of Chimney Lake.
17. South Woodchuck				
Destination: Moore Boy	Access	Woodchuck Trail (Trail Class 3) to Woodchuck Lake Loop (Trail		

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
Meadow		Class 2).		
	Recreation Category Setting	Recreation Category 1.		
	Use Levels 01-04	2-4 trips, 14-16 stock		4 trips.
	Grazing	Does not hold stock overnight. No grazing requested.		No grazing.
	Campsites	Pack station drops clients and returns.	Stock holding and spot/dunnage sites should meet BMP's.	No stock camp.
18. Post Corral				
Destination: Niche	Access	Blackcap Trail (Trail Class 3). Incision on Blackcap Trail at west end of Post Corral Meadow.	Reduce incision at west end of Post Corral Meadow on Blackcap Trail.	
	Recreation Category Setting	Recreation Category 2.		
	Use Levels 01-04	3-5 trips, 14-21 stock		Up to 6 spot and dunnage trips.
	Grazing	Does not hold stock overnight. No grazing requested or reported.		Grazing is not approved.
	Campsites	Pack station drops clients and returns.		No stock camps.
19. Red Mountain				
Destination: Disappointment Lake	Access	Blackcap Trail (Trail Class 3) to Hell For Sure Trail (Trail Class 2, RR 2.5, observed. Trail Class 2). Sections of Hell For Sure Trail in poor condition with erosion issues.	Stabilize erosion issues on Hell For Sure Trail.	NSCS trail from Disappointment Lake to SEKI boundary.
	Recreation Category Setting	Recreation Category 2.		

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Use Levels 01-04	4-6 trips, 6-40 stock		Up to 6 spot and dunnage trips.
	Grazing	Northwest of the junction of the Hell for Sure (29E52) and Meadowbrook (29E21). (Named North of Devil's Punchbowl (ramble). Meadow stream rated properly functioning.	Due to the high elevation should receive light grazing during the later part of the grazing season.	Allow 27 stock nights of grazing North of Devils Punchbowl. No grazing at Disappointment Lake.
	Campsites	Pack station drops clients off at Lake and moves stock to grazing location.		Designate 1 stock camp.
20. Red Mountain				
Destination: Devils Punchbowl / Little Shot Lake	Access	Blackcap Trail (Trail Class 3) to Hell For Sure Trail (Trail Class 2, Resource Rating 2.5, Observed. Trail Class 2), use trail to Little Shot Lake. Sections of Hell For Sure Trail in poor condition with erosion issues.	Stabilize erosion issues on Hell For Sure Trail.	Approve use trail RMB05.
	Recreation Category Setting	Recreation Category 2.		
	Use Levels 01-04	4 trips, 24 stock		Up to 4 spot and dunnage trips.
	Grazing	Northwest of the junction of the Hell for Sure (29E52) and Meadowbrook (29E21). (Named North of Devils Punchbowl). Meadow stream rated properly functioning.	Due to the high elevation should receive light grazing during the later part of the grazing season.	Allow 27 stock nights of grazing North of Devils Punchbowl. No grazing at Little Shot Lake itself.
	Campsites	Pack station drops clients off at Lake and moves stock to grazing location.	It is recommended that no packer camps be established in this location.	No stock camp.
21. Rodgers				
Destination: Crown Valley	Access	Crown Valley Trail (Trail Class		

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
		3) to Crown Valley.		
	Recreation Category Setting	Recreation Category 2.		
	Use Levels 01-04	2 trips, 11 stock		Up to 10 spot and dunnage trips.
	Grazing	No grazing, private land.		No grazing approved.
	Campsites			Designate 1stock camp.
	Other Issues			
22. Rodgers				
Destination: Geraldine Lake	Access	Crown Valley Trail (Trail Class 3) to Spanish Lake Loop (Trail Class 2) to Geraldine Lakes Trail (Trail Class 1). Steep, rocky trail leads to Geraldine Lakes.	Stabilize trail to Geraldine Lakes.	Rockwork needed on Geraldine Lakes Trail.
	Recreation Category Setting	Recreation Category 2, low use and high opportunities for solitude.	Maintain high opportunities for solitude.	
	Use Levels 01-04	3-5 trips, 22-23 stock		Up to 4 spot and dunnage trips.
	Grazing	No grazing requested or reported.		Grazing not approved.
	Campsites		No stock camps.	No stock camps.
23. Spanish				
Destination: Spanish Lakes	Access	Crown Valley Trail (Trail Class 3) to Statham Trail (Trail Class 2).		
	Recreation Category Setting	Recreation Category 2.		
	Use Levels 01-04			Up to 4 spot and dunnage trips.

Analysis Unit/ Destination	Feature	Current Condition	Desired Condition	Remedy Proposed / Operating Guidelines
	Grazing	No grazing requested.		No grazing approved.
	Campsites		No stock camps.	No stock camps.
24. Post Corral				
Destination: Fleming Creek	Access	User Trail RMB07 Fleming Creek trail departs off of the Blackcap Trail (29E03).		
	Recreation Category Setting	Recreation Category 1.	Based on limited trips authorized area will maintain opportunities for solitude.	
	Use Levels 01-04	1-2 trips, 3-6 stock		2 trips per year. Trail is only used 1-2 times a year by one individual party.
	Grazing	No grazing requested, none reported.		No grazing.
	Campsites	One campsite along Fleming Creek.

Trail and Commercial Pack Stock Management In the Ansel Adams and John Muir Wildernesses

**Final
Environmental Impact Statement**

Volume 1 – Chapters 1-3

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, age, disability, and where applicable, sex, marital status, familial status, parental status, religion, sexual orientation, genetic information, political beliefs, reprisal, or because all or part of an individual's income is derived from any public assistance program. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at (202) 720-2600 (voice and TDD). To file a complaint of discrimination, write to USDA, Director, Office of Civil Rights, 1400 Independence Avenue, S.W., Washington, D.C. 20250-9410, or call (800) 795-3272 (voice) or (202) 720-6382 (TDD). USDA is an equal opportunity provider and employer.

Chapter 1 Purpose and Need for Action

Chapter 1 – Purpose and Need

1.1 Background

Analysis Area

The analysis area includes the Ansel Adams and John Muir Wildernesses and covers 810,581 acres extending in the eastern portion of the analysis area from west of Lone Pine, California in the south to State Highway 120 in the north. The western portion of the analysis area extends from the southern boundary of Yosemite National Park to west of Sequoia Kings Canyon National Park. The planning area lies within Madera, Fresno, Inyo, and Mono Counties (see Location and Vicinity Map, Figures 1.1 and 1.2).

The Ansel Adams Wilderness was originally established as the Minarets Wilderness in 1964 and was enlarged by 119,000 acres and renamed the Ansel Adams Wilderness by the California Wilderness Act of 1984. The Ansel Adams Wilderness is a total of 231,005 acres, with 78,775 acres on the Inyo National Forest and 151,483 acres on the Sierra National Forest. A small portion of the Wilderness (747 acres) is located in Devils Postpile National Monument (not included in this analysis). The Wilderness extends from Highway 120 in the north to Lake Thomas A. Edison to the south.

The John Muir Wilderness was established in 1964 by the original Wilderness Act and enlarged 81,000 acres by the 1984 California Wilderness Act. The John Muir Wilderness extends from Mammoth Lakes, California in the north, forks around the Sequoia Kings Canyon Wilderness, and extends some 100 miles to the south with its southern most boundaries just west of Lone Pine, California. The John Muir Wilderness is one of the most heavily visited wildernesses in the National Wilderness Preservation System. There are 580,323 acres within the Wilderness, with 228,366 acres on the Inyo National Forest and 351,957 acres on the Sierra National Forest. Approximately 26,000 acres in the northern portion of the Fish Creek watershed are Sierra National Forest lands administered by the Inyo National Forest.

History

With the completion of the Ansel Adams, John Muir and Dinkey Lakes Wilderness Plan in 2001, new direction for the management of these wildernesses was incorporated into the Land and Resource Management Plans for the Inyo and Sierra National Forests. The plan established a need for types of commercial services, levels of commercial use (measured in service days), controls on commercial use with quotas at trailheads for all commercial operations, limitations on pack stock travel, grazing standards for all recreational stock, and desired conditions for the wildernesses through the creation of three recreation categories. Recreation categories are a strategy for managing recreation use in the Ansel Adams, John Muir and Dinkey Lakes Wildernesses. The three recreation categories are explained in more detail in the Glossary in Appendix A.

The Wilderness Plan's Record of Decision set objectives and desired conditions for managing these wildernesses and established limitations and controls on authorized commercial operations. This proposal adds and modifies direction pertaining to commercial stock supported outfitter and guiding.

In April 2000, a lawsuit filed against the Sierra and Inyo National Forests alleged violations of the National Forest Management Act, National Environmental Policy Act (NEPA), and the Wilderness Act. The judge found in favor of the plaintiffs on the NEPA claim. The Court determined that in authorizing the special use permits for the pack stations, the Forest Service failed to adequately document environmental impacts as required by the NEPA. A Court Order was issued that required the Forest Service to re-evaluate the existing management direction and impacts of commercial pack stock operations in the Ansel Adams and John Muir Wildernesses. This proposal will establish management direction. Proposals for individual pack stock special use permits will be considered through a subsequent NEPA analysis to be completed by December 2006.

Nineteen pack station operations continue to be authorized, with specified conditions and restrictions imposed by the court. The restrictions will remain in place until the NEPA analysis is completed and new special use permits are issued. Most of the special use permits issued to existing commercial pack stock operations have expired or are due to expire in the next few years. For all of these pack stations, their use in the Ansel Adams and John Muir Wildernesses reflects only a portion of their overall operation. Many pack stations provide service on lands outside these wildernesses and in some cases in other adjacent wildernesses—the Kaiser, Dinkey Lakes, Golden Trout, and South Sierra Wildernesses.

The Forest Service assessed resource conditions where pack stock operations occur, and compared that condition with current Forest Land and Resource Management Plan standards, applicable laws, and policies. Where differences between existing conditions and standards, guidelines, laws, and policies were found, a need for change and corrective actions were identified.

This proposal will also establish a Trail Management Plan for the Ansel Adams and John Muir Wildernesses. Both forests have maintained various trail inventories during the past 40-50 years; including the most recent list of trails in Appendix C of the 2001 Wilderness Plan, a 1987 Recreation Information Management (RIM) Inventory maintained by the Inyo National Forest, and a remnant inventory from the 1960s and 1970s, once used by the Sierra National Forest.

The 2001 Wilderness Plan's Record of Decision directs the forests to adjust trail maintenance levels to be consistent with the desired conditions of the three recreation categories. Designations in the proposed trail management plan are intended to meet this direction for the two wilderness areas.

1.2 Proposed Action

The Forest Service proposes to amend the Land and Resource Management Plans for the Sierra and Inyo National Forests which includes the 2001 Ansel Adams, John Muir, and Dinkey Lakes Wildernesses Management Plan. This amendment will provide further standards and guidelines for commercial pack stock activities. The proposed action would modify existing Wilderness Plan direction related to use levels (numbers of stock and numbers by use type), locations of

commercial use, party size, trail suitability for commercial pack stock operations, grazing suitability and utilization levels, and designation of campsites and use of campfires. The Proposed Action also establishes a Trail Management Plan for both wildernesses. The Trail Management Plan establishes the trails that will be maintained on the Forests' inventories, and how they will be managed. The specifics of the proposal are detailed in Chapter 2, Alternative 2 – Proposed Action.

1.3 Purpose of and Need for Action

The need for the Trail and Commercial Pack Stock Management Direction for the Ansel Adams and John Muir Wildernesses is as follows:

There is a need for additional guidance for managing commercial pack stock operations in the Ansel Adams and John Muir Wildernesses in order to achieve and maintain desired resource and experiential conditions identified in the 2001 Wilderness Plan and Record of Decision. Stock impacts can cause substantial damage to vegetation and soils particularly in sensitive environments (McClaren and Cole, 1993; Newsome et al., 2004; DeLuca et al., 1998). Overall stock use can also affect other wilderness visitor experiences, both on trails and at campsites. The 2001 Wilderness Plan relies upon external controls to manage use and impact. Field assessments indicate more direct actions (internal controls) are needed to manage commercial pack stock impacts and maintain the desired resource and experiential conditions of the 2001 Plan.

There is a need for a trail plan that accurately identifies a system of trails for all users, and appropriate trail management objectives for each system trail, consistent with the desired condition of areas within the two wildernesses as identified in the 2001 Wilderness Plan and Record of Decision. Past trail system inventories (2001 Sierra N.F.; 1988 Inyo N.F.) are incomplete, have a variety of inaccuracies, and in many cases are inconsistent with the management of the areas that they access. The 2001 Wilderness Plan directs the Forests to adjust trail maintenance levels to implement the three category recreation strategy.

In meeting these needs, the proposal must also achieve the following purposes:

1. Comply with the Wilderness Act by preserving wilderness character. The Wilderness Act (16 U.S.C. 1131-1136) provides overall direction to Federal land management agencies that administer wilderness areas. Federal agencies are required to manage wilderness areas so as to preserve wilderness character. Elements of wilderness character include: untrammled, natural, undeveloped and outstanding opportunities for solitude or a primitive and unconfined type of recreation.

2. Provide for needed commercial pack stock services. There is a substantial need for commercial pack stock services by segments of the population who wish to engage in legitimate wilderness activities, but can only do so with commercial pack stock support. A purpose of this decision is to preserve wilderness character while meeting that need. The public's need for commercial pack stock services is documented in the Needs Assessment (Appendix D).

3. Comply with the January 10, 2002, court order from the United States District Court for the Northern District of California granting injunctive relief in *High Sierra Hikers Association v. Powell* (No. C-00-01239) by:

- **Identifying appropriate group size limits for commercial stock operations.** There are both social and resource considerations with the current party size of 15 persons and 25 stock. Party size limitations are in place wilderness wide and many locations do not have the capacity for a full party size. Social impacts of large groups can affect other visitor's wilderness experience and their expectations of few encounters with others. Large parties can also create larger campsites and a proliferation of larger campsites.
- **Establishing camping limitations on commercial pack stock operations.** Pack stock impacts can be more severe on vegetation and soils than hiking parties. The size and impacts of stock camps can be noticeable and intrusive in some locations.
- **Identifying which trails are suitable for use by commercial pack stock.** There are a variety of factors including resource impacts, management objectives, allowable levels of use and trail maintenance objectives that require considering the appropriateness of commercial stock on certain trails.
- **Identifying an appropriate level of stock to be used in conjunction with the commercial operations.** Stock impacts can cause substantially more damage to vegetation and soils particularly in some sensitive environments. Overall stock numbers on trails can also affect other wilderness visitor experiences, both on the trail and at campsites. Managerial actions in the past have focused on regulating the numbers of people with very coarse limits on stock.
- **Completing a cumulative impact analysis by December 2005.** The 2001 Wilderness Plan identified separate NEPA processes for the issuing of multiple pack station special use permits in the two wildernesses. The District Court of San Francisco issued injunctive relief that included direction that the Forest Service prepare a cumulative impact analysis by December 2005 followed by a second NEPA process to issue individual special use permits.

4. Identify monitoring requirements to facilitate responsive adaptive management for commercial pack stock operations. In recognition that conditions change and need to be managed over time, it is important to have clear, responsive guidelines for those operations through the term of the permits.

5. Identify the appropriate level of grazing associated with commercial pack stock operations. It is a common practice to allow commercial pack stock to graze meadows and other forage producing areas within these wildernesses. Some meadows used by pack stock exhibit varying historical and current impacts such as soil compaction, bare soil, and stream alternations which affect hydrologic function, and vegetation composition.

Scope of the Proposal

The topics to be addressed in the EIS are relatively narrow in scope, specifically designed to respond to the above mentioned court order and establish a Trail Management Plan for the Ansel Adams and John Muir Wildernesses. The recent 2001 Wilderness Plan set forth programmatic management direction for these two wildernesses and this analysis will not revisit the following decisions that have already been made: party size limits for non commercial pack stock visitors, hiker only trails, the strategy of desired conditions as identified by the recreation category definitions, and that the Forest Service (or authorized contractor) will issue all wilderness permits. These issues have already been adequately addressed through full NEPA processes, and

it would divert scarce agency resources to revisit these issues, and it would produce little benefit. Therefore, the range of alternatives in this EIS is limited to the focused purpose and needs described above.

While the above discussion goes beyond the strict parameters of the purpose and need, this is done to provide greater context for the decision to be made and to address specific concerns raised by the public. NEPA itself, the regulations implementing it, and the case law interpreting NEPA all make clear that the range of alternatives is defined by the purpose and need. NEPA and its implementing regulations also make clear that the agency should focus its discussion on significant issues only. That is what we have tried to do with this EIS. While we believe we have succeeded in achieving this goal, it should also be noted that the agency has been under a strict court-imposed deadline, so has only had limited time to address all the issues at hand.

1.4 Decision Framework

Decision to be Made

The decision to be made is whether or not to continue commercial pack stock operations in the Ansel Adams and John Muir Wildernesses and, if so, to determine the extent of the operations, which includes the amount, type, and locations where these activities would occur. A decision will also be made that establishes a Trail Management Plan for both wildernesses. This will determine the trails that will be maintained on the Forest's inventories, and how they will be managed.

Related Laws, Regulations, and Agency Policies that Influence the Scope of the EIS

1964 Wilderness Act: This law provides for the establishment of designated wilderness lands that are to be protected for their ecological, geological, recreational, historical, scientific, educational and scenic values. Managing agencies are to preserve the wilderness of the designated lands, yet the Act does not establish standards for this to occur. This Act designated a National Wilderness Preservation System and the Ansel Adams and John Muir Wildernesses were two of the original areas designated as wilderness.

The National Forest Management Act (1976) requires that a plan be prepared for the management of each National Forest. Among other direction, it also directs National Forests to prevent irreversible watershed damage and to prevent detrimental impacts to streams and wetlands.

Endangered Species Act: The Endangered Species Act (1973) and amendments to the Act (1978, 1979, and 1982) was passed by Congress to prevent the extinction of any species that is in danger of extinction throughout all or a significant portion of its range. Section 7 of the Act outlines procedures for interagency cooperation to conserve Federally listed species and designated critical habitats. Section 7(a)(1) requires Federal agencies to use their authorities to further the conservation of listed species. Section 7(a)(2) requires Federal agencies to consult with the National Marine Fisheries and/or the U. S. Fish and Wildlife Service to ensure they are not undertaking, funding, permitting, or authorizing actions likely to jeopardize the continued existence of listed species or destroy or adversely modify designated critical habitat.

Clean Water Act: The Clean Water Act (33 U.S.C. 1251 et seq.), a series of Acts passed from 1948 to 1987, was passed to restore and maintain the chemical, physical, and biological integrity of the nation's waters, and to protect beneficial water uses. It requires compliance with state and federal pollution control measures. The Clean Water Act is enforced by the California State Water Resources Control Board (SWRCB). The Forest Service developed Best Management Practice (BMP) guidelines (Water Quality Management for Forest System Lands in California – Best Management Practices, USDA Forest Service, Sept. 2002) as part of the Management Agency Agreement between the Forest Service and the SWRCB. These BMPs are guidelines for prevention of water quality degradation on National Forest Lands in California.

Clean Air Act: The Clean Air Act (1967) and amendments to the Act (1972, 1977) were established to enhance the quality of the Nation's air resources and protect public health and welfare. Section 118 of the Clean Air Act requires the federal government to comply with all federal, state, tribal, interstate, and local air quality standards and requirements. The Act established National Ambient Air Quality Standards and gave the States primary responsibility for air quality management. States carry out this responsibility through development of a State Implementation Plan. Federal and State land managers must ensure that their actions comply with all procedural and substantive requirements contained in Federal, State and local air pollution control regulations.

The 1977 Clean Air Act Amendment: Areas of the country were designated as Class I, II, and III air sheds for the prevention of significant deterioration purposes. Class I areas include national parks and wilderness areas designated before 1977 and over 5,000 acres in size. The Ansel Adams and John Muir Wildernesses are Class I airsheds. Class I provides protection to pristine lands by severely limiting the amount of additional human-caused air pollution that can be added to these areas.

Executive Orders 11988 and 11990 direct federal agencies to avoid to the extent possible the impacts associated with the destruction or modification of floodplains and wetlands. Agencies are directed to avoid construction and development in flood plains and wetlands whenever there are any feasible alternatives.

Water Quality Management for Forest Lands in California: Best Management Practices (Sept. 2000) provides guidance for protecting water quality, as directed by the Lahontan Regional Water Quality Control Board (LRWQCB) Central Valley Regional Water Quality Control Board (CVRWQB).

Inyo National Forest Land and Resource Management Plan (1988) and Sierra National Forest Management Plan (1991) as Modified by the Sierra Nevada Forest Plan Amendment (2004): The Ansel Adams and John Muir Wildernesses fall under the jurisdiction of individual plans—Sierra (1991) and Inyo (1988). Each Forest Plan contains general management direction applicable to all wildernesses within each Forest. This direction includes multiple use goals and objectives, forest-wide standards and guidelines, management area direction (prescriptions), and monitoring and evaluation requirements.

The Sierra Nevada Forest Plan Amendment Record of Decision 2004 (2004 ROD) amended both of these forest plans. The 2004 ROD established Riparian Conservation Objectives (RCOs); a set of six objectives and their associated standards and guidelines that establish management direction for Riparian Conservation Areas (RCAs). RCAs are defined as areas near water bodies and wetlands. The RCOs were developed to protect water quality, aquatic and riparian habitats,

and stream, floodplain and watershed condition. The applicable RCOs and RCA standards and guidelines are described in the document and are available in the project record. There is also direction to maintain and restore habitat of riparian dependent plant and animal species.

A number of wildlife related standards and guidelines are also in the 2004 ROD. These include standards and guidelines for willow flycatcher, wolverine, great grey owl, northern goshawk, California spotted owl, fisher, marten, and Sierra Nevada red fox.

The Record of Decision for Management Direction for the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses 2001 (Wilderness Plan) amended both forest plans and establishes management direction for the Ansel Adams, John Muir and Dinkey Lakes Wildernesses. Desired conditions for visitor use are described through the recreation categories assigned to the landscape. The recreation categories establish standards and guidelines for the experiential components and resource conditions that are to be maintained. They allow for some areas to be heavily managed with high visitor use while other areas are managed for very low use and pristine conditions. These categories and desired conditions are in place to prevent the slow degradation of areas over time. Campsite, use trails, and trail management direction were also established in relation to the recreation category. Standards and guidelines were established for recreational stock grazing, including utilization, range readiness and hydrologic conditions. Allocations of use and a rationing mechanism to maintain the desired use levels for both commercial and non commercial visitors were established.

The Wilderness Plan states that the Forests will “provide a transportation system that ensures suitable access for the types and numbers of trail users, protection of resources, and is consistent with management objectives for the areas accessed.” It further states that the Forests will maintain an inventory of system trails with designated “service levels” (nationally known as “Trail Classes”), which consider the three recreation categories for the areas that the trail accesses.

Specific direction from the Wilderness Plan relevant to the current planning effort is detailed in the project record.

1.5 Public Involvement

A Notice of Intent to prepare an EIS was published in the Federal Register on June 15, 2004. Two Proposed Actions (*Trail Management Plan* and *Commercial Pack Stock Use Authorizations for the Ansel Adams and John Muir Wildernesses*) were distributed to interested parties in June 2004. Public meetings were held to clarify the Proposed Actions in Clovis, California (July 8, 2004) and Bishop, California (July 12, 2004). The public was asked to submit comments to the action from which issues could be determined and alternatives developed. Approximately 300 comments were received for the Commercial Pack Stock Use Authorizations Proposed Action and approximately 200 comments were received for the Trail Plan Proposed Action (table below provides a summary of these comments). The comments for both of these projects were used to develop the significant issues.

Table 1.1 Number of comments received on the Proposed Actions

Project	Agency	Interest Group	Commercial Pack Station	Individual	Form Letter	Total
Commercial Pack Stock Use and Authorization	3	7	6	119	131	266
Trail Management Plan	2	7	3	88	67	167
Total	5	14	9	207	198	433

On January 25, 2005, a revised Notice of Intent was published in the Federal Register. This notice incorporated the Trails Management Plan EA into the Commercial Pack Stock Use Authorizations EIS. The project was renamed *Trail and Commercial Pack Stock Management in the Ansel Adams and John Muir Wildernesses EIS* and the purpose and need for the project was clarified. This combined EIS responds to concerns over these two projects being connected actions and will better display the cumulative effects of two projects occurring in the same geographic area.

The Draft EIS was released for public comment on March 29, 2005. The document was placed on the Inyo and Sierra National Forests' websites and was mailed to interested parties. On April 15, 2005, the Draft EIS Notice of Availability was published in the Federal Register. Two public meetings were held. Approximately twenty people attended the May 17, 2005, meeting in Bishop, California and three people attended the May 19, 2005, meeting in Clovis, CA. The comment period closed June 15, 2005. Over 400 comments were received on the DEIS, the majority of which were form letters. The table below summarizes the comments received on the Draft EIS; the response to comment is in Appendix E.

Table 1.2 Summary of comments received on the Draft EIS

Agency	Interest Group	Commercial Pack Station	Individual	Form Letter	Total
12	10	5	178	224	429

1.6 Scope of the Analysis

Issues Studied in Detail

Using the comments on the Proposed Action from the public, organizations, other agencies and (affected) tribes, the interdisciplinary team and Forest Supervisors developed a list of issues. Issues are points of discussion, debate or dispute about environmental effects.

The Forest Service separates the issues into two categories: significant and non-significant. The Council on Environmental Quality regulations state:

NEPA documents must concentrate on the issues that are truly significant to the action in question, rather than amassing needless detail. (40 CFR 1500.1(b))

Using the scoping process, not only to identify significant environmental issues deserving of study but also to deemphasize insignificant issues narrowing the scope of the EIS process accordingly. (40 CFR 1500.4(g))

Significant issues directly influence the initiation, development, and technical design of the project; are disclosed in the analysis; and were used to develop alternatives to the proposed action. Issues are significant because of the extent of their geographic distribution, the duration of their effects, or the intensity of interest or resource conflict.

Non-significant issues are identified as those: 1) outside the scope of the proposed action; 2) already decided by law, regulation, Forest Plan, or other higher level decision; 3) unrelated to the decision to be made; or 4) conjectural and not supported by scientific or factual evidence. The Council for Environmental Quality (CEQ) NEPA regulations require this delineation in Sec. 1501.7, "...identify and eliminate from detailed study the issues which are not significant or which have been covered by prior environmental review (Sec. 1506.3)..." A list of the non-significant issues and reasons regarding their categorization as non-significant may be found in the project file.

These significant issues directly influence the initiation, development, and technical design of the project; are used in the analysis; and were used in the development of alternatives to the proposed action.

Issue #1: Use Levels

There is disagreement on the amount of commercial pack stock use that is acceptable in these wildernesses. Some believe that the proposed level of commercial pack stock use will cause degradation of resources including wilderness values. Others believe the proposed action is overly restrictive and that more commercial stock use should be allowed.

How the issue was addressed:

- Evaluation of each alternative's use levels on the four components of wilderness character.
- Evaluations of effectiveness of various control mechanisms on resource impacts.
- Evaluation of impact of various use level control mechanisms on wilderness experience of pack stock visitors.
- Development of different alternatives with varied numbers of stock and locations where commercial stock use occurs.
- Development of different alternatives with varied control mechanisms, numbers of stock, and locations where commercial stock use occurs.

Issue #2: Party Size

There is disagreement on the appropriate party size for commercial pack stock. Some publics feel the proposed party size is too high and proposed site specific party size limitations do not go far enough in responding to the effects that large stock parties have on both the resource (trails, camps and meadows) and the experience of the non-pack stock visitor.

How the issue was addressed:

- Locations where party size is less than wilderness-wide standard of 15 persons and 25 stock.
- Objective evaluation of research on effects of party size on ecological and experiential resources.
- Development of an alternative with lower overall people and stock limits.

Issue #3: Trail Suitability

There are concerns that some destinations and trails may incur further impacts as a result of continued commercial pack stock use. The current conditions of the proposed system and use trails are not capable of sustaining repeated use by commercial pack stock due to terrain, grade and maintenance limitations. Conversely, commercial stock operators believe there should be no trail restrictions for commercial pack stock users.

How the issue was addressed:

- Miles of System Trail available to commercial stock and resource condition ratings of trails.
- Percent of System available to commercial.
- Miles of Use Trail available to Commercial Stock.
- Development of alternatives with variations on numbers of miles and types of trails that are not suitable for commercial stock.

Issue #4: Grazing Management

There is disagreement over the level of grazing that is sustainable and the level of grazing that is appropriate. Some believe the proposed grazing practices will lead to unacceptable resource impacts. Drift fences may support poor grazing practices by allowing loose grazing and a determination on the role of drift fences in managing stock is needed. Others believe that all forage should be available for pack stock grazing.

How the issue was addressed:

- Number of meadows grazed and their condition (Proper Functioning Condition rating).
- Number of meadows grazed and their Hydrologic Function Alteration Severity rating.
- Estimated number of key areas, and percent of total assessed, predicted to exhibit a downward trend in the vegetation needed to protect the watershed over the long term.
- MIS riparian meadow and meadow edge habitats with improved habitat conditions and reduced potential for human disturbances.

Issue #5: Campfires

It is believed by some publics that the current elevation fire closures do not accurately reflect firewood availability at some locations and that campfire closures should be based on site specific conditions, not generic elevation closures. By bringing firewood from outside the wilderness into areas closed to collecting firewood and allowing campfires as proposed, the proposal commercial pack stock users could bring pathogens, spread weeds, and possibly encourage unauthorized campfires from non-packer supported wilderness users.

How the issue was addressed:

- Number of campsites where firewood may be brought into the wilderness.
- Assessment of risk associated with packing in firewood.
- Development of alternatives with variations on campfire limits.

Issue #6: Economic and Operational Effects

There is disagreement as to the extent that economic factors should be considered when deciding levels and appropriateness of commercial activities in the wilderness. The proposed action includes additional restrictions on commercial pack stock in the Ansel Adams and John Muir Wildernesses and will limit the flexibility of pack station operators. One perspective on this issue is that the additional restrictions may irreparably harm the financial viability of these operations. These potentially negative economic impacts to commercial pack stations would also lead to adverse economic effects on local communities.

How the issue was addressed:

- Regional economic contribution (in terms of labor income and employment) related to wilderness commercial pack stock activities.

Issue #7: Trail Development

Some comments on the Proposed Action stated that the proposed trail management plan does not protect wilderness values. The higher development trails have characteristics and management intrusion which adversely affects visitors' experience of wilderness. On the other hand, other comments contend that the low development trails will not support the allowable use types and levels and may cause greater resource effects leading to exclusion of stock from trails that are not adequately maintained. Trails need to be designated to accommodate the allowable types and levels of use.

How the issue was addressed:

- Miles of trail by trail class.
- Miles of Trail Class 1 open to commercial stock.
- Miles of system trail and use trails available to commercial stock.
- Miles of trails by trail class indicators.
- Cost analysis of maintaining trails to standards.
- Development of alternatives with variations on trail class assignments.

1.7 Applicable Regulatory Requirements, Required Coordination, Licenses, and Permits

Consultation with United States Fish and Wildlife Service

Forest Service Manual direction found in 2671.45 describes the direction and procedures for Consultation with the U. S. Fish and Wildlife Service (USFWS) as required under the Section 7 of the Federal Endangered Species Act of 1973, as amended.

The Forest Service is required to consult with the USFWS when a proposed action will result in a “may affect” determination that the Forest Service has concluded through a biological evaluation process for a federally listed species, or designated critical habitat. Consultation through a Biological Assessment can be informal when a determination of “may affect not likely to adversely affect” is concluded, or the consultation process moves to formal consultation when the determination is a “may affect, likely to adversely affect.”

Conference is a legally required “informal consultation” with the USFWS. It is mandatory whenever an agency program or activity that is likely to jeopardize the continued existence of any species proposed for listing or result in the destruction or adverse modification of proposed critical habitat.

The USFWS reviews the Forest Service findings of affect in the biological assessment/consultation process to determine if it concurs with the findings, or to determine if further conservation actions are necessary to prevent the action from jeopardizing the continued existence of a listed species, or to avoid adverse effects to a proposed species.

No consultation is required with the U. S. Fish and Wildlife Service under Section 7 of the Act if a determination of “no affect” is concluded.

Consultation with the Advisory Council on Historic Preservation (Council) and the State Historic Preservation Office (SHPO)

Compliance with Section 106 of the NHPA requires that the agency afford the Council the opportunity to comment on actions that have the potential to impact heritage resources. The majority of this work is done through the SHPO. The forests have consulted with the Council and the SHPO on this undertaking.

Government-to-Government Consultation

The Forests will work with tribal governments and tribal communities to develop mutually acceptable protocols for government-to-government and tribal community consultations. Vegetation community conditions will be assessed where a specific area has an identified importance to an affected tribe or tribal community. The Forests will consult with affected tribes and or tribal communities to consider traditional and contemporary uses and needs and to identify areas of new or worsening weed infestations and develop plans for appropriate weed control. The Forests will maintain appropriate access to sacred and ceremonial sites, and to tribal traditional use areas. All sensitive and proprietary information to the greatest extent permitted by law will be protected (Sierra Nevada Framework ROD 2001).

Under the U.S. Constitution and Federal law, and in some cases under treaty, federally recognized Indian Tribes have certain rights that do not extend to tribal groups that are not so recognized, and federal agencies have certain obligations toward federally acknowledged Tribes that they do not have toward other groups. As a result, there may be occasions on which the Forests will necessarily have to consult with and otherwise interact with the federally recognized Tribes in a manner different from that in which they interact with the other groups regarded as Tribes for purposes of the Wilderness PA.

The Wilderness Programmatic Agreement

The Inyo and Sierra National Forests developed the *Programmatic Agreement: Controlling Impacts on Historic Properties; Management of Ansel Adams, John Muir, and Dinkey Lakes Wilderness, Sierra and Inyo National Forests* (Wilderness PA) in accordance with Section 106 of National Historic Preservation Act (NHPA) and 36 CFR Sec. 800.14(b) of its implementing regulations. The Wilderness PA has a five year time span, ending on January 1, 2006. Work done in the wildernesses during this period was carried out under its stipulations.

A Strategy for Compliance with Section 106 of the National Historic Preservation Act for Issuance of Special Use Permits for Pack Station Operations on the Inyo & Sierra National Forests (Strategy) was submitted by the Inyo and Sierra National Forests to the Council and the SHPO for comment with the release of the DEIS. The Strategy covers the CEA and the Trails Plan, as well as the upcoming Special Use Permit issuance.

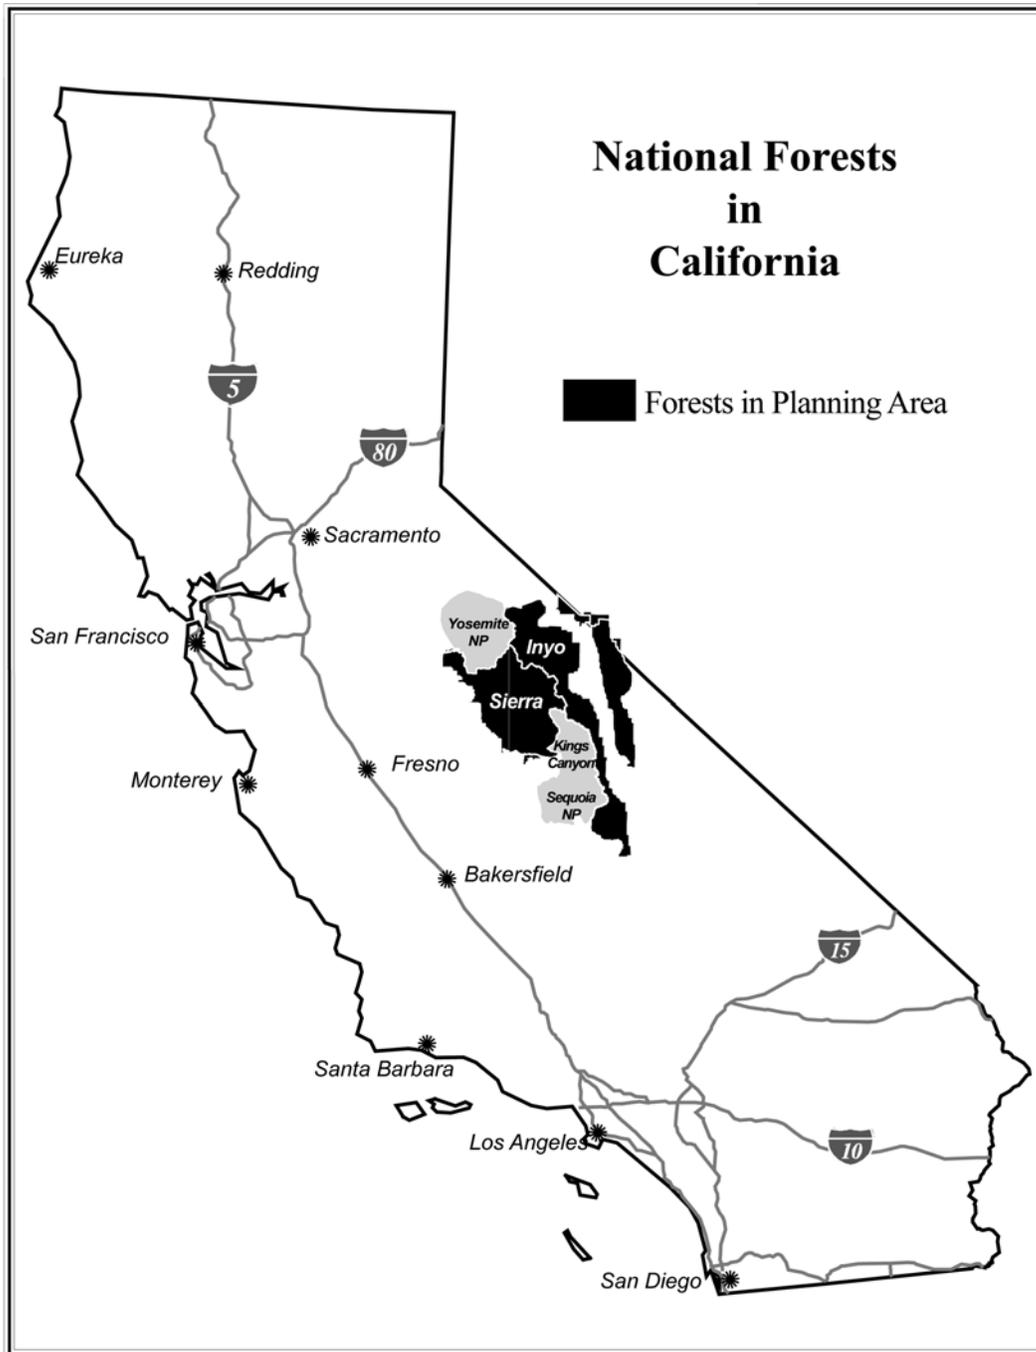

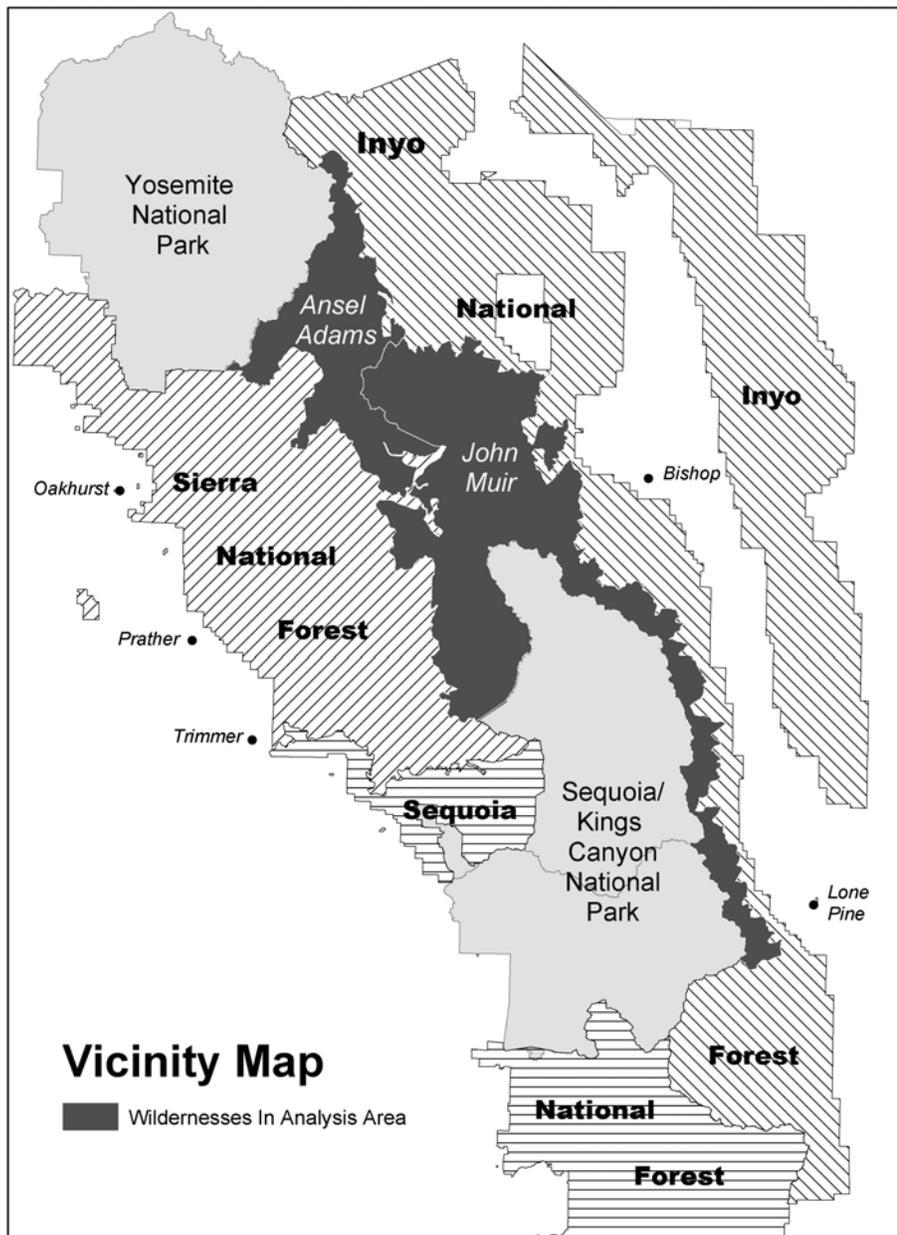

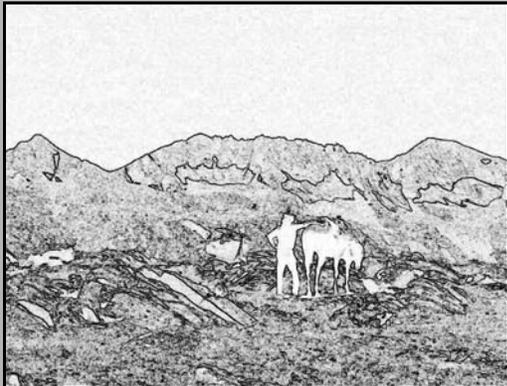

Figure 1.2 Vicinity map

Chapter 2 Alternatives, Including the
Proposed Action

CHAPTER 2 – ALTERNATIVES, INCLUDING THE PROPOSED ACTION

INTRODUCTION

This chapter describes and compares the alternatives considered for the Trail and Commercial Pack Stock Management in the Ansel Adams and John Muir Wildernesses plan. Section 2.1, *Process Used to Develop the Alternatives* describes the development of the proposed action and the process used to define and develop the range of alternatives.

The description and comparison of the six alternatives begins with Section 2.2, *Elements Common to All Alternatives*. This section is followed by a description of each alternative. At the end of the chapter are more detailed tables that show the trails inventory, use trail approvals, destination quotas, day rides, drift fences, grazing actions, and designated campsites in a comparative format. The chapter concludes with a comparison of effects, as required by the National Environmental Policy Act, as well as discussion of the environmentally preferred alternative.

2.1 PROCESS USED TO DEVELOP THE ALTERNATIVES

Alternatives were developed for this environmental analysis to meet the purpose and need while addressing issues and concerns raised during public involvement. Initially, a proposed action was developed by assessing the current situation in these wildernesses. Specifically, commercial pack stock use, the activities and the conditions on the trails, campsites and grazing areas the commercial pack stations use were identified. The interdisciplinary team identified changes needed to meet current standards and guidelines and applicable laws and policies. The interdisciplinary team worked with the District Rangers from the Inyo and Sierra National Forests to identify actions to include in the proposed action. The team also proposed additional standards they considered necessary to manage commercial pack stock.

As described in Chapter 1, this proposal is the result of a court ordered analysis of the cumulative impacts of commercial pack stock operations in the Ansel Adams and John Muir Wildernesses. The Court expressed concerns “*that the cumulative impacts of the pack station permits may be substantial, with some packers operating in the same sensitive areas.*” The order required the agency to consider limits on numbers of stock animals used in conjunction with commercial operators, limits on group size (both numbers of people and numbers of stock on and off trail), trail suitability for various use types, and designation of campsites for use by commercial pack stations. Magistrate LaPorte further stated that “*the purpose of requiring these specific considerations in the environmental analysis is to pinpoint issues that directly affect the degradation of the wilderness.*”

In addition to this court direction, a subsequent ruling from the 9th Circuit Court of Appeals asserted that the 2001 Needs Assessment did not go far enough in assessing the need for

commercial services. This Court expressed concerns over the preservation of wilderness character as a result of the existing commercial authorizations. An amendment to the 2001 Needs Assessment accompanies this document (Appendix D) and forms a basis of need for commercial services from which these alternatives assess different levels and extent of commercial services.

Alternatives to the proposed action were developed, responding to the issues raised during the public scoping process (see Chapter 1 – Public Involvement). These alternatives represent a reasonable range of alternatives. Given the scope of the analysis as described in the Purpose and Need, there could be literally hundreds of permutations of alternatives for each of the elements that are subject to actions: grazing, overnight use levels, day rides, use trails, system trails, campfires etc. It is simply not possible to address every person's individual concerns on every element. The six alternatives, ranging from the No Action to five variations on use levels and control mechanisms with compatible grazing and trail management techniques adequately addresses the significant and relevant issues. In addition, and most important to note, each alternative described in this section was developed to comply with the requirements of the Wilderness Act to preserve wilderness character and provide use and enjoyment in a manner that protects these lands as wilderness.

After receiving public comment on the Draft EIS in June 2005, a fifth alternative was developed, Alternative 2 – Modified. The central component of the Proposed Action (Alternative 2), destination quotas, is used in this alternative, thus leading to its identification as a modified Alternative 2. The quota numbers themselves change in this alternative, with more thorough analysis of use levels and resource effects. The trail system was also re-considered with attention to comments on trail suitability and similarly the grazing actions, use trail authorizations, drift fences, day rides, campfires were all considered in relation to the central component, destination quotas.

2.2 ELEMENTS COMMON TO ALL ALTERNATIVES

This section defines management guidelines that will be common to all action alternatives.

TRAIL MANAGEMENT PLAN

General Guidelines

Maintain an inventory of system trails to assigned service levels. Maintain system trails to meet management objectives for visitor use and resource protection. Also, consider the recreation categories for the areas that a trail accesses and adjust trail maintenance levels to match the three recreation categories.

Review trail development levels (trail classes) when monitoring indicates inconsistency with destination management.

Actively restore and/or stabilize trails that have been abandoned (due to realignment or closure) that will not heal naturally. Some examples include abandoned trails that alter local hydrology, deeply compacted soils, and sites with continued inappropriate traffic, increased entrenchment or widening.

Do not construct new trails.

Do not add use trails to the system, or conduct major reconstruction to trails on the forest trail system solely for the purpose of providing improved or easier access to an area. Add use trails to the system only when there is an overriding benefit to the protection of the wilderness resource.

When adding or removing trails from the forest trail inventory, NEPA analysis, including public involvement, will be conducted.

Consider removing trails from the system (with appropriate public involvement) when concerns are identified, such as limited or no use, catastrophic natural event, unmitigable resource impacts, change from original need (ie: unneeded mining road/trail), or others. Evaluate the need for physical closure or allow natural recovery, depending on the expected resource impacts.

The Mt. Whitney and Meysan Lakes Trails will be closed to all stock use.

Trail design targets for the Ansel Adams and John Muir Wildernesses (Table 2.29) provide guidelines by trail class. These will be considered when maintaining, repairing or reconstructing trails. Variations from these guidelines may occur due to circumstances unique to each trail.

Routine Maintenance

Routine maintenance will be conducted on all system trails in the inventory, dependent upon on funding or other available maintenance resources. Routine maintenance includes cleaning and repairing drainage structures (i.e., water bars and rolling dips) and berm removal; clearing the trail tread of obstacles such as rock, slough, trees, and brush; clearing obstacles from the trail tread to target width and grade; blocking and naturalizing multiple trails or shortcuts, and incidental replacement or repair of trail structures such as steps, walls, and causeways.

Commercial pack stock is required to stay on system trails, unless otherwise approved by the Forest Service. Examples of approved bypasses include circumstances when an impassable obstacle or severe safety issue exists which cannot be reasonably removed by the packer.

Reconstruction Guidelines

Reconstruction projects beyond routine maintenance will require an appropriate planning and NEPA process, including field clearances, completion of the Section 106 process and consultation with affected tribes.

Generally, repair and reconstruction projects will be prioritized using the following considerations:

- Trails where the location or deteriorated condition is causing substantial effects to riparian, watershed, threatened, endangered or sensitive species, or significant cultural resources.
- Trails with health and safety problems out of character with the designated trail class.
- Trails with deteriorated conditions that substantially hinder the intended use or purpose, or will likely lead to this condition within the short-term (<5 years).
- Primary trails where use is relatively high. (Generally repairs of short spurs associated with the primary trail will also be integrated into projects when conducting major reconstruction.)

USE TRAIL MANAGEMENT

Reduce or eliminate resource impacts associated with use trails.¹

Where suitable, allow a low density of use trails that meet management objectives.

Discourage the creation of additional use trails and limit the impacts associated with existing use trails.

Emphasize managing or eliminating use trails in riparian, meadow, and streamside areas.

Evaluate the need to allow, eliminate, stabilize, or add use trails to the forest trails system.

If a use trail is not specifically identified or is not otherwise approved through campsite or grazing approvals, it is considered prohibited to commercial pack stock.

Use trails will be monitored to ensure that the resource condition does not deteriorate from the current condition from which the approval was based. If the use trail is found to exceed standards and guidelines or incidental physical treatments cannot mitigate identified resource concerns, use will be limited, suspended or disapproved.

Commercial pack stock may travel off-trails when requested by the Forest Service or County Sheriff officials during search and rescue, fire, or other emergencies and to access and support approved research, studies, or projects.

Packers supporting clients with valid game tags may leave trails with stock to retrieve game.

¹ A “use trail” is a path or route that is not on the forest inventory so is not a “system” trail. It is therefore not subject to maintenance or improvement. It is generally created by repeated hiker or equestrian use.

COMMERCIAL PACK STOCK GRAZING

The grazing actions are intended to allow maintenance of, or a trend toward, desired conditions as described in the Record of Decision for the 2001 Wilderness Plan and the Inyo and Sierra National Forest's Land and Resource Management Plans. An adaptive management strategy will be used to adjust the grazing actions based on the results of monitoring. Monitoring will be directed at compliance with standards in key and critical areas.

Grazing will be managed by using *Grazing Response Index* methods and forage utilization standards in conjunction with rangeland suitability criteria, range readiness and recreation strategy objectives, to maintain or reach desired conditions (2001 Wilderness Plan and Appendix G, Pack Stock Management Guide).

Prevent disturbance to meadow-associated stream banks and lake and pond shorelines caused by human activities (for example, pack stock grazing and dispersed recreation) from exceeding 20 percent of stream reach or 20 percent of lake and pond shorelines. Disturbance includes bank sloughing, chiseling, trampling, and other means of exposing bare soil or cutting plant roots.

The Authorized Officer may approve changes to the grazing direction based on monitoring results. Changes may include adjustments in stock numbers (increase or decrease); changes in stock management; identification of range readiness dates, stock nights, critical areas, and areas to be rested until resource recovery; and determinations of suitability by an interdisciplinary team.

WEED AND PATHOGEN PREVENTION

To prevent spread of weeds and plant pathogens, it is recommended that stock have their hooves cleaned before entering the wilderness. If stock is held in the 14 counties with quarantine for sudden oak death (SOD)², their hooves must be cleaned before entering the wilderness.

It is recommended that certified weed free hay and straw be used in the AA/JM Wildernesses when feed is brought in. When the California certification program for weed free hay and straw is operational and certified feed becomes available, certified hay and straw will be required for all wilderness users.

COMMERCIAL PACK STOCK MONITORING

Pack stock operations will be monitored through reports provided by commercial pack stock operators as follows:

- Each day of service will be recorded on a commercial report or "tally sheet." This includes each day of a multi-day trip.

² For a list of the 14 counties see USDA APHIS, Dec. 21, 2004. Emergency Federal order restricting movement of nursery stock from California, Oregon, and Washington nurseries. [www.aphis.usda.gov/ppq/ispm/sod/faqprorder\(\)11305.html](http://www.aphis.usda.gov/ppq/ispm/sod/faqprorder()11305.html).

- Reports will include as a minimum: wilderness permit number, number of clients, number of employees, number of stock, trailhead entry, trailhead exit, destination of the service provided, stock or designated camp used, and grazing activity by grazing zone and/or meadow.

Wilderness permits will be written by the Forest Service. In the event that wilderness permits or reservation services are contracted out, the contractor will be performing the function of the US Forest Service.

2.3 ALTERNATIVES, INCLUDING THE PROPOSED ACTION

Table 2.1 Alternative summary. This table summarizes the various components contained in the six alternatives.

Alternative						
	1- No Action	2 - Modified	2	3	4	5
Use Levels and Stock Numbers						
Day Rides	Allocated by Wilderness Plan in service days.	Day ride locations identified per Pack Station and limited by number of stock at one time in the wilderness. Limits placed on areas where day ride activities have potential for use or resource conflicts.	Allocated per Pack Station location.	Allocated per packer.	Allocate service days per packer with consideration of resource or social issues.	None authorized.
Service Days	Allocated service days with additional temporary service day pool.	No Service Days to Resort Permittees.	No Service Days to Resort Permittees.	No Service Days to Resort Permittees.	Service Days at 20% reduction from Alt 1.	None authorized.
Quotas	Trailhead quota for people. Borrowing of next days quota allowed. FS writes all wilderness permits.	Destination quotas managed through destination management plans. Stock at one time limit. FS writes all wilderness permits.	Destination quotas. Stock quotas daily/seasonal. FS writes all wilderness permits.	Trailhead quota for people, seasonal. Threshold for clients and stock. Few destination quotas. FS writes all wilderness permits.	Trailhead quota for people, reduction in party size at some trailheads. No borrowing. FS writes all wilderness permits.	None authorized.

Alternative						
	1- No Action	2 - Modified	2	3	4	5
Primary Operating Area	N/A	Identified by destination quotas.	Identified operating area.	Identified operating area.	In effect, no overlap of areas for spot and dunnage trips.	None authorized.
Party Size	15/25	15/25 And site specific party size limits.	15/25 And site specific party size limits.	15/25 And site specific party size limits.	12/20 And where trailhead prohibits full party size.	N/A
Trail Management Plan						
General Trail Plan	2001 Wilderness Plan direction and existing inventories.	Designates system of trails and assigns development levels.	Designates system of trails and assigns development levels.	Designates system of trails and assigns development levels.	Designates system of trails and assigns development levels.	Designates system of trails and assigns development levels.
System Trails	Inyo 1988 inventory Sierra 2001 inventory.	Aligns with recreation categories and destination management objectives.	Aligns with recreation categories and commercial destination quotas.	Aligns with recreation categories allowing higher development system than Alt 2.	Aligns with recreation categories allowing lower development system than Alt 2.	Aligns with recreation categories allowing lower development system than Alt 2.
Grazing Management						
Grazing Strategy	Utilization standards. Range readiness standards. Suitability direction not yet implemented.	Utilization standards estimated with stock nights. Range readiness standards same as Alt 1. Grazing suitability determinations. Establishment of grazing zones and critical areas.	Grazing zones, (stock nights, utilization and meadow closure) 5% impact in critical areas.	Grazing zones, (stock nights, utilization and meadow closure) 5% impact in critical areas.	Grazing zones, (stock nights, utilization and meadow closure) 5% impact in critical areas.	None by commercial pack stock authorized.
Drift Fences	Allow drift fences only where needed for protection of resources or safety of visitors.	Retain 13 drift fences and approve one additional for resource protection.	Retain 11 drift fences and approve one additional for resource protection.	Retain 10 drift fences and approve one additional temporary drift fence for resource protection.	Retain 4 drift fences and approve 1 additional temporary drift fence for resource protection.	None authorized for commercial pack stock.

Alternative						
	1- No Action	2 - Modified	2	3	4	5
Trail Suitability						
System Trails Suitable for Comm. Pack stock	Only use on existing system trails as directed by wilderness plan.	Use of system and authorized user trails except system trails identified as “Not Suitable for Commercial Stock.”	Use of system and authorized user trails except system trails identified as “Not Recommended for Stock.”	Use of system and authorized user trails except system trails identified as “Not Suitable for Commercial Stock.” Fewer NSCS trails.	Use of system and authorized user trails except system trails identified as “Not Suitable for Commercial Stock.” Many trail NSCS.	None authorized for commercial pack stock.
User Trails	Require approval Use trails approved in 2004.	Use trail approvals based on destination management.	Use trail approvals based on destination quotas.	Same use trail approvals as in Alt 2.	Very few use trails approved.	None authorized for commercial pack stock.
Campsites						
Campsites	50 feet from water.	Required to use designated stock camps when holding stock overnight with option of reserving site. All designated stock camps will meet BMPs.	Required to use designated stock camps when holding stock overnight with option of reserving site.	Required to use designated stock camps when holding stock overnight with option of reserving site.	All campsites for commercial pack stock designated (not just for overnight holding of stock) and limited to these sites.	None authorized for commercial pack stock.
Campfires						
Campfires	Elevational closures Site specific closures.	Few modifications to elevational fire closure boundary where firewood is available. Allow charcoal fires in areas closed to wood campfires. Case by case wood campfire use by commercial pack stations.	Elevational closures and packers allowed to pack in wood and charcoal.	Same as Alt 2 for full service trips in designated sites only.	Elevational closures Site specific closure.	Elevational closures.

ALTERNATIVE 1 – NO ACTION (WILDERNESS PLAN DIRECTION)

SUMMARY

The No Action Alternative follows the existing management direction in the *Final Environmental Impact Statement and Record of Decision for the Ansel Adams, John Muir, Dinkey Lakes Wildernesses* (April 2001). For more detailed direction refer to the 2001 Wilderness Plan and Record of Decision.

Generally, the No Action Alternative reflects the status quo of current management under the direction of the 2001 Plan. The Wilderness Plan programmatic direction has never been fully implemented, in part, because over the last three years resources have been diverted to the court-ordered analysis and some management actions were delayed until this analysis is completed. For the purpose of this analysis the No Action Alternative includes the elements of the 2001 Wilderness Plan that have been implemented.

This direction establishes a level of commercial pack stock use measured in service days that is consistent with the average of the high two years of use from 1996-2000. It established a trailhead quota system for commercial operators that limit the location and timing of their use.

Direction in the 2001 Wilderness Plan established utilization levels, range readiness standards and a suitability evaluation process for recreation pack stock grazing. Although meadow suitability determinations are a reasonable foreseeable action under the 2001 Wilderness Plan, they have not yet been made and are not considered in the No Action.

The Trail Management Plan for the Inyo National Forest is based upon the 1987 trails inventory and is consistent with the direction in the Inyo National Forest Land and Resource Management Plan. In the absence of a similar trail inventory associated with the Sierra National Forest Land and Resource Management Plan, Appendix C from the 2001 Wilderness Plan serves as the basis for the Sierra N.F. in this alternative. Direction for managing the trail system, including system and use trail suitability is based on the 2001 Wilderness Plan, but assumes that the designation of a trail system, consistent with the newly designated recreation categories (including identifying trails not recommended for stock) has not yet been fully implemented.

1. TRAIL MANAGEMENT PLAN

The trail system inventory for this alternative is shown in Table 2.26.

The inventories reflect the 2001 Wilderness Plan for the Sierra N.F. and the “service levels” concept. The Inyo N.F. uses the 1987 inventory with the “maintenance levels” concept which refers to the frequency and priority of maintenance rather than the level of development. Descriptions of service levels and maintenance levels are available in the project record.

2. USE LEVELS AND STOCK NUMBERS

A. Day Rides

Day rides are services that do not include any overnight use or equipment.

Day rides are approved as a distinct allocation measured in service days³, with locations approved in annual operating plans. Where areas of congestion or concerns occur, the Forest Service will work with the operators to identify alternate locations for day rides. The service day allocation for day rides can be found in Table 2.33.

B. Overnight Use

Upper limits allowed for overnight services (spot, dunnage and all expense type trips) provided by commercial pack stock operations are allocated by service days as shown in Tables 2.2 and 2.3.

Table 2.2 Service day allocations for pack stock support, non traditional pack stock and day rides by forest.

Activity	West side entry Allocation (Service Days)	East side entry Allocation (Service Days)
Pack stock supported	2,855*	13,300
Non-traditional pack stock	200	500
Day Rides	600	4,100**

*Allocation reflects the reduction of service days for the Dinkey Lakes Wilderness because it is not addressed in this planning effort.

**Allocation was corrected from 5000 to 4100 by an errata. Mistake attributed to error in Reds Meadow's allocation.

Table 2.3: Overnight service day allocation by pack station location

Location	Wilderness Plan Allocated Overnight (Service Days)
North Lake	1082
Silver Lake	1881
Cottonwood Lakes	261
North Fork Big Pine	640
Various. John Muir south of North Fork Big Pine	156
Edison Lake	893
Reds Meadow	3005
Lakes Basin	1731
McGee Creek	636
Clover Meadow	997*
Pine Creek	666
Onion Valley	263
South Lake	466

³ A service day is a day or part of a day for each individual accompanied or provided services including transportation services, by an outfitter or guide.

Location	Wilderness Plan Allocated Overnight (Service Days)
Rock Creek	2308
Double Meadow	38
Blayne Meadow	135***
Fish Camp	102**
Various, John Muir Inyo NF	119
Tule Meadow	507
Huntington Lake	342

*Tabulation of service days in the 2001 Wilderness Plan for Minarets Pack Station inadvertently omitted certain classes of use (e.g., re-supply of non-stock commercial operators). The value shown corrects this error for the high two years used in the Wilderness Plan (1996-97), and is based on an actual hand count of all existing records.

**The 2001 Wilderness Plan showed no service days for Yosemite Trails Pack Station due to lack of reliable data to estimate high two at that time. The value shown is based on 2003 and 2004 data.

***Tabulation of service days for Muir Trail Ranch was incorrect in the 2001 Wilderness Plan. Overnight use traveling through the National Forest to the National Park was recorded as day use. The value shown corrects this error.

C. Quota

The rationing system includes three types of trailhead quotas:

Single Quotas - A single quota is to be used in areas with low commercial use and/or the desired condition for the area prescribes low levels of use.

Case-by-Case Itinerary Approvals - Entry points where the Forest Service has not identified a compelling reason for commercial services to be provided is approved only on a case-by-case basis using the following criteria:

- Use must meet a need identified in the needs assessment.
- Trips in these areas will not be advertised in brochures or other media.
- Service is occasional in nature and not part of a yearly, repeated operation.
- Use must fit within the quota system.
- In areas where limiting factors have been identified, the appropriate resource specialists must review the proposed use to assure it is consistent with resource objectives.

Multiple Quotas - Where there is high demand for visitor use, including commercial service providers, there are multiple quotas, a quota for commercial providers and a separate quota for the general, non-commercial public.

All guides and employees of operators must have an authorized wilderness permit for overnight use.

Table 2.4: Alternative 1 single quotas

Inyo NF Entry	Quota
Beck	15
Big Pine SF	12
Deer Lake	10
Fern Lake	10
Fern/Yost	8
George Lake	10
Gibbs	8
Glacier Canyon	8
Horton Lakes	10
JMT/PCT South	10
Mammoth Pass	20
Meysan	10
Parker Creek	10
Red Cones	15
Sawmill	10
Shepherd	15
Taboose	10
Upper Buttermilk	8
Sierra NF Entry	Quota
Badger	10
Bear Creek	10
Bear Ridge	10
Cassidy	10
Chiquito	35
Cliff Lake	20
Crown/Rancheria	10
Hells Half Acre	10
Logan Meadow	10
Mammoth	25
Miller	10
Mono Creek	30
Onion Springs	10
South Fork	10
Squaw Dome	10
Woodchuck	20

In addition to the single quotas listed, there were eleven entry points that were inadvertently omitted from the 2001 Wilderness Plan. Table 2.5 lists these trailheads. with Each is managed for a single daily quota. Overall they represent a small proportion of the total use entering on the Sierra National Forest (4.7% in 2004) and almost no pack station use (17 visitors in 2004). Due to the low use, quotas were set at minimum levels.

Table 2.5: Sierra N.F. additional single quota trailheads

Isberg	22		8	8
Jackass/Norris	10	8		
Maxson	25		8	8
Walton	9	8		

D. Primary Operating Areas

No direction on where commercial pack stock operators can operate.

E. Party Size

The party size for commercial pack stock supported parties is 15 persons and 25 stock wilderness-wide.

3. GRAZING MANAGEMENT

A. Grazing Strategy

Grazing management as described in the Wilderness Plan and the Sierra Nevada Forest Plan Amendment includes utilization standards by vegetation types using key species and key area concepts, annual range readiness determinations, and protection of riparian resources including stream bank and shoreline trampling standards. Most meadows/meadow complexes are open for grazing, except for the few meadows that were previously closed or under rest-rotation grazing due to resource conditions (see Table 2.30).

For the purposes of analyzing this “No Action” Alternative the assumption is that suitability and utilization standards have not been implemented even though it is a reasonably foreseeable future action that management direction would eventually be implemented.

B. Drift Fences

Allow drift fences only where the protection of resources or safety of visitors is of concern; not solely for the convenience of the visitor, outfitter or guide.

See Table 2.34 for locations of approved drift fences.

4. TRAIL SUITABILITY FOR COMMERCIAL PACK STOCK

A. System Trails

The plan provides for the future designation of system trails as “Not Recommended for Stock” (NRFS) when conditions warrant. As directed in the plan, trails so designated would be closed to commercial stock use. No specific trails have yet been identified as NRFS in this alternative.

Seven miles of system trails are closed to commercial operators in annual operating plans, based on known resource or management conflicts. These are:

- **Marie Louise Lake** (*INF – Bishop/Humphreys Geographic Unit*)
- **Bull Lake to Ruwau** (*INF – Bishop/Humphreys Geographic Unit*)

- **Gable Lakes** (*INF – Bishop/Humphreys Geographic Unit*)
- **Grass Lake outlet** (Lamarck area); and (*INF – Bishop/Humphreys Geographic Unit*)
- **South Fork Cottonwood Creek** above South Fork Meadow (*INF – John Muir Southeast Geographic Unit*)

B. Use Trails and Routes

All commercial use off existing system trails must be approved by the Forest Service. Following the guidance in the Wilderness Plan, use trails are requested for use by operators and approved or disapproved. A list of the use trails approved under the various alternatives is in Table 2.27.

5. CAMPSITES

Campsites will be located 100 feet from water. In areas where terrain does not permit a campsite to be 100 feet from water, sites will be no closer than 50 feet from water.

Designated campsites can be implemented under this direction. Commercial pack stock camps are currently designated in the Rush Creek drainage.

6. CAMPFIRES

Prohibit wood campfires in areas above 10,000-foot elevation in the northern portion of the planning area and 10,400 feet in the southern portion.

Permit gas, propane, and multi-fuel stoves and heaters in areas closed to wood campfires.

Prohibit wood burning stoves (including “Zip” stoves), charcoal fires, packed in firewood, or fire pans within areas closed to wood campfires.

7. RECREATION CATEGORIES

Recreation categories will be used to manage recreation use as described and mapped in the 2001 Wilderness Plan direction.

ALTERNATIVE 2 - MODIFIED

SUMMARY

This alternative allows commercial pack stock activities with the following standards and guidelines:

- Emphasis is on destination management and managing for conditions at destinations. Desired condition of destinations is driven primarily by the three recreation categories outlined in the 2001 Wilderness Plan. Seasonal destination quotas will be the starting point for achieving the desired conditions.
- The destination management concept will be applied through an implementation plan that describes desired condition by destination. Desired condition includes recreation category setting, access, grazing, use levels, campsites and impacts that require remediation actions.
- Maximum stock in the wilderness at one time will limit the potential for overcrowding, provide temporal controls on commercial stock use and provide overall management for total amount of commercial pack stock use.
- The alternative includes a monitoring plan to manage destinations over time and a “toolbox” describing how and when to take further action.
- Party size limit would be 15 persons and 25 stock wilderness-wide with 14 site specific destinations with smaller maximum party size.
- Ten locations have limitations on stock numbers per season to maintain or improve conditions.
- Campsites will be designated for all locations where operators hold stock overnight and operators will be required to use these sites.
- Grazing will be managed through a determination of suitability and stock night capacity for grazing zones and specific meadows. Critical areas will be protected from grazing impacts.
- Some site specific modifications to the elevational fire closure respond to firewood availability and inconsistencies at destinations.
- The proposed system of trails and maintenance levels are based on recreation categories, current and anticipated use, resource impacts, and trail maintenance considerations. These are considered to ensure that trail management objectives are consistent with area management objectives.
- Trail suitability determinations for commercial pack stock are based on the suitability of destinations, trail infrastructure stability, resource conditions, and potential impacts of continued commercial pack stock use due to risk factors.

- In evaluating the extent of commercial pack stock use that was necessary, “Not Suitable for Commercial Stock” determinations were made to exclude commercial stock use into areas.

1. TRAIL MANAGEMENT PLAN

The trail system inventory responding to the direction for this alternative is shown in Table 2.26. See Section 2.2, *Actions Common to All Alternatives* for overall direction for trail management.

Not Recommended for Stock

This alternative does not identify “Not Recommended for Stock” (NRFS) trails. Trails will be identified as NRFS as needed and will be merely an educational consideration for private equestrians. NRFS has no regulatory effect; it serves as an educational and informational tool.

2. USE LEVELS AND STOCK NUMBERS

A. Day Rides

Day rides will be authorized in locations listed in Table 2.33. Day rides will be limited in locations where there are resource concerns or potential or known user conflicts. Initially, Reds Meadow (specifically rides to Rainbow Falls) and rides in the Mammoth Lakes Basin will be allocated a specific level of use.

In all other locations day rides are identified and limited by the location and type of ride and the number of guest horses available for these rides. For a full description of the allocations, see Table 2.33, *Day Rides Alternative Comparison*.

The Forest Service will emphasize opportunities outside wilderness to allow expansion of day ride business.

B. Overnight Use

Use will be controlled by seasonal destination quotas, maximum stock at one time in the wilderness, designated stock camps, party size limitations, and trail suitability determinations.

The outfitter and guides (non-resort permits) will be allocated service days and operate through trailhead quotas, not destination quotas. Annual operating plans will approve use of trailheads to insure consistency with desired conditions of area and to reduce conflicts with other types of use. The service day allocation for llamas will be 250. The service day allocation for a burro operator will be 119.

C. Quota

Destination quotas are the method of limiting and distributing commercial pack stock use in this alternative. These quotas are estimates of use for commercial stock operators to meet the desired resource and experiential condition of the area, considering the recreation category and the resource capacity of the destination. Quotas are placed on the number and type of trips per season:

- Spot and dunnage type trips have quotas on each destination, for each operator. No additional quota is allocated for unassigned or additional trips, (or ½ trips for small parties) as is proposed in Alternative 2.
- In addition, each operator has a set number of all expense and traveling type trips.

Quotas were based on an assessment of the capacity of the locations for commercial stock use. All locations where commercial pack operators identified current, proposed and past use were assessed. Tally sheets (the self-reported record of commercial use) were analyzed to calculate the number of trips, people and stock use at destinations.

The assessment of capacity was determined by reviewing the level of use at each recorded destination over the last three years (2001-2003). Three criteria were applied to determine if this level of use was the appropriate capacity for the future:

1. **Resource Condition:** The resource condition rating of the destinations as evaluated by the interdisciplinary team by assessing recreational impacts, access issues, riparian concerns, camping potential, and risk factors at destinations;
2. **Capability:** Assessment of current levels of use and sustainability of the resource at that level of use (factoring in prescribed actions such as designated sites, meadow management, use trail prohibitions, and stock number limits) and a determination of whether the destination could accept more use, or if the area was already at an appropriate level of use or needed to be reduced; and
3. **Consistency with Recreation Category:** Whether that level of use is consistent with the recreation category, given considerations of other uses (overnight use by general public, other outfitters and guides, day hiking, and day riding).

The following describes how various pack station trips will be accounted for in the destination quota system:

- For spot and dunnage, a trip is defined as a one-way service.
- A one-way spot trip will count for one trip.
- Trips that hold stock in the backcountry overnight in conjunction with an all expense, traveling or base camp type service are considered “all expense” for the purposes of the quotas. A trip that involves services (such as a cook or camp tender and wrangler) throughout the duration of a client’s trip is considered an all expense trip. All expense trips have a specific quota that cannot be exchanged or otherwise counted as a spot and dunnage trip. Each operator is authorized a specific number of all expense trips. All expense trips will be further regulated by the designated site requirement and allowable grazing constraints.

Destination quotas will not be adjusted (lowered) based on lack of use. They can be lowered based on future assessments of capacity or resource conditions. Quotas are designed to accommodate fluctuations at various destinations over the years. There will be no borrowing, trading or otherwise sharing the destination quota assigned to an operator.

It is assumed that the combination of destination quotas and limits on number of stock at one time in the wilderness will serve an estimated 3,000 - 5,500 clients and utilize 6,000 - 10,000 stock per season for overnight use and 3,000 - 4,000 clients and 3,000 - 4,000 stock for day rides.

This level of use is considered to be within the extent necessary for preserving wilderness character.

At the conclusion of each season, actual use will be compared to the use levels identified above for clients and stock. If these levels are reached or exceeded, the responsible officer will make an assessment of the potential resource implications. If any evaluation indicates that conditions do not meet standards and guidelines or desired conditions, corrective actions—including reduced use levels, reduced destination quotas and/or campsite or other site specific closures—will be considered.

For a full listing of all destination quotas see Table 2.31.

Any use identified for travel into or through the adjacent National Parks (Yosemite National Park, Devils Postpile National Monument and Sequoia/Kings Canyon National Park) will comply with authorizations or use level limitations by the National Parks. If the National Parks wish to increase use into the Park and no other resource concerns exist, the Forest Service will support Park allocations.

Wilderness permits are required for all parties and commercial pack stock operators will obtain the proper wilderness permits from the Forest Service (or its contractor). Tally sheets for reporting the service will continue to be required. Each day of use will be recorded for all expense and traveling trips to improve monitoring of use and conditions.

In cases of administrative use, including approved research permits, support of functions such as search and rescue, tribal walks, the authorizing officer can allow use of areas previously unidentified as a destination. This is on a case-by-case basis, and is not considered a reoccurring use.

Use of areas not identified by destinations for hunting activities will be subject to case-by-case approval similar to that described above for administrative use. Hunting areas will change based on availability of State Game tags and are typically low use and minimal impact activities.

The *Destination Management Strategy* in the Record of Decision provides a framework for the direction found in this alternative. The strategy is intended to guide management over time.

D. PRIMARY OPERATING AREAS

Specific primary operating areas are not assigned. The assignment of destination quotas provides delineation of pack station operations. Overlap of operators will primarily occur as a result of traveling trips. Very few areas of overlapping spot and dunnage services are proposed. All areas of overlap will be monitored through the destination management approach to determine if additional separation of use is needed.

E. PARTY SIZE

Party size for commercial pack stock parties is 15 persons and 25 stock wilderness-wide. In 14 site specific locations the party size varies, based on the physical capacity, setting and management objectives for the area. These are in Table 2.8 and included in the *Destination Management Strategy* (available in the Record of Decision).

Table 2.8. Site-specific party size limitations

Geo Unit	Analysis Unit	Location/Person/Stock limit
Ansel Adams East	King Creek	Fern Lake: 10 persons/20 stock
	King Creek	Anona Lake: 10 persons/20 stock
	Rush Creek	Weber Lake: 10 persons/20 stock
Bishop/Humphreys	Bishop Creek	Ruwau Lake: 8 persons/15 stock
	Bishop Creek	Marie Louise Lake: 6 persons/10 stock
	French	Merriam Meadow: 10 people/20 stock
	French	Steelhead Lake: 6 persons/6 stock
	Glacier Divide	Honeymoon Lake : 6 persons/12 stock
	Glacier Divide	Packsaddle Lake: 6 persons/6 stock
Fish Creek/ Convict /McGee	Sabrina	Baboon Lake: 8 persons/15 stock
	Convict	Cloverleaf Lake: 15 persons/8 stock
	Purple Bench	Above Ram Camp: 8 stock
	Silver Divide	Peter Pande: 10 persons/15 stock
	Upper Fish	Tully Lake: 8 persons/15 stock

F. STOCK NUMBERS

Commercial pack stock operators are subject to a maximum number of stock in the wilderness at one time to limit temporal spikes and address overcrowding. These stock numbers were derived from an analysis of recent stock use on trails, current resource concerns, visitor capacity considerations, cumulative impacts and management objectives. These limits are listed in Table 2.9.

Table 2.9. Alternative 2 – Modified stock at one time limits

Pack Station Located at	Stock at One Time
North Lake	60
Cottonwood Creek	35
Silver Lake	75
North Fork Big Pine	35
Lakes Basin	75
McGee Creek	60
Pine Creek	50
South Lake	35
Reds Meadow	90
Rock Creek	90
Onion Valley	35

Pack Station Located at	Stock at One Time
Blayne Meadow	35
Huntington Lake	35
Tule Meadow	35
Double Meadow	25
Edison Lake	60
Clover Meadow	60
Fish Camp	25

The following locations have seasonal limits on stock numbers. Specific direction for the destination is in the *Destination Management Strategy*, (available in the Record of Decision).

- **Clarice Lake** (*Ansel Adams East*)
- **Holcomb Lake** (*Ansel Adams East*)
- **Fern Lake** (*Ansel Adams East*)
- **Honeymoon Lake** (*Bishop/Humphreys*)
- **Muriel Lake** (*Bishop/Humphreys*)
- **Desolation Lake** (*Bishop/Humphreys*)
- **Mesa/Tomahawk Lakes** (*Bishop/Humphreys*)
- **Baboon Lake** (*Bishop/Humphreys*)
- **French Lake** (*Bishop/Humphreys*)
- **Cloverleaf Lake** (*Fish/Convict/McGee*)

In addition, the following locations have limits on stock numbers until a condition is repaired or otherwise corrected. Specific direction for the destination is in the *Destination Management Strategy*.

- **Ediza Lake** (*Ansel Adams East*)
- **Anne Lake** (*Ansel Adams West*)
- **Golden Trout Lake** (*Bishop/Humphreys*)

3. GRAZING MANAGEMENT

A. Grazing Strategy

Grazing is to be managed in “grazing zones” that include one or more meadows and their surroundings. Grazing is only allowed within these identified grazing zones. Meadows within the grazing zones were assessed for determinations of suitability and estimated grazing capacity. Within suitable meadows, key areas and critical areas were identified. Critical areas include fens, Yosemite toad breeding habitat, and other important hydrologic features such as springs, seeps, and unstable areas.

No stock entry or use will be allowed in areas identified as critical or unsuitable. The stock user is expected to manage stock to avoid stock entry. Operators planning on using meadows with identified critical areas, must describe the techniques they plan to use to avoid entry. This must be approved in the annual operating plans.

Monitoring of vegetative utilization and streambank disturbance will occur at selected key areas as described in the 2001 Wilderness Plan Final EIS, Appendix G (pp. 7-10) and the *R5 Rangeland Analysis and Planning Guide* (pp. 5-10 to 5-15).

An overall estimate of stock nights was assigned to each grazing zone and key areas within the grazing zones. These estimates are based on calculated suitable meadow area, vegetative productivity for the key areas and reported stock use (2001-2003) (see Table 2.30). The estimated stock nights are intended as a pre-season trip planning guide to be used during annual operating plan development. Operators will not be allowed to schedule itineraries that intentionally exceed stocking rates.

Specific allocations and grazing terms and conditions will be approved in the annual operating plan.

If, later in the season, the permittee requests additional use, and monitoring data shows that utilization and other standards have not yet been reached, then additional grazing may be approved for a specific amount for that season only.

Before any permanent change is made in estimated stock nights (increase or decrease) or in grazing zone boundaries, there will be a review of existing monitoring data and/or collect additional data and re-calculate stock nights or change management as described in the *Monitoring Plan* (found in the Record of Decision).

Meadows with streams categorized as Functioning at Risk with a downward trend or with access issues such as unstable trails will be rested from grazing. This period of rest from grazing and grazing associated impacts will continue until recovery of identified resource indicators. These resource indicators include recruitment and establishment of stabilizer plant species on point bars, on stream banks, and on headcuts adequate to meet the Recreation Stock Forage Goals and Objectives, as defined in the *2001 Wilderness Management Plan for the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses* (p. 23).

This rest for resource recovery will continue until an interdisciplinary team establishes baseline monitoring and then accomplishes subsequent monitoring that quantifies an upward trend in resource conditions and confirms that resource conditions are sufficient to sustain grazing and stock entry.

In general, monitoring will typically be done at identified key areas. The entire area within a grazing zone, however, may be managed as needed by applying standards described in the Wilderness Plan for range readiness, vegetation utilization, and streambank and soil disturbance.

B. Drift Fences

Existing drift fences that provide for resource protection and visitor safety are approved. Resource protection includes the prevention of stock drifting or moving to areas where grazing is rested or not suitable. Drift fences are also considered to be appropriate in situations where visitor safety is of concern, such as on steep trail passages where drifting stock may be a danger to visitors on the trail. Drift fences that do not facilitate resource protection or visitor safety but only provide convenience for commercial pack stock operators will be removed.

For a list of approved drift fences see Table 2.34.

Whenever possible, temporary or electric rather than permanent fencing will be used and encouraged to keep stock out of critical areas, sites that are not range ready, or to keep stock in approved areas. The commercial pack stock operator may request, and the Authorized Officer may approve, an alternative method of controlling stock to minimize the risk of impacts to critical areas.

4. TRAIL SUITABILITY FOR COMMERCIAL PACK STOCK

A. System Trails

In this alternative, trails designated as “Not Suitable for Commercial Stock” (NSCS) are closed to commercial stock use. There are 89 miles of system trails designated as NSCS in this alternative. Determinations for trails designated as NSCS in this alternative considered trail conditions, development level, capability of the trail, resource conditions including risk factors, and the suitability of the destination. Trails which are generally resource-stable with no risk factors and access a destination suitable for commercial pack stock use are generally open to commercial stock use.

B. Use Trails and Routes

All commercial pack stock use off existing system trails must be approved by the Forest Service. Use trails are not intended to be used or managed as system trails, because they typically do not require recurring maintenance. A list of the use trails and routes that will be approved under the various alternatives is in Table 2.27.

On approved use trails that are used primarily by commercial pack stock operators, mitigation of resource impacts and removal of seasonal obstacles may be performed, such as the removal of downed trees where bypasses would otherwise impact resources. Mitigation is limited to the minimum necessary, so that the character of the use trail does not change.

Campsite access trails that are directly associated with designated commercial pack stock camps (see Table 2.32) are approved as an inherent part of the designation of stock camps and are generally not addressed as “use trails.” Mitigation of resource impacts and maintenance is the responsibility of the operator and will be managed through annual operating plans.

Trails accessing spot and dunnage campsite or drop off locations, will be managed through the *Destination Management Strategy*. Any such trails will be short in length and will access an established campsite or drop off location.

Cross country travel that is authorized in this alternative occurs only in areas where the level of use will not lead to any defined or visible trail. In physically durable areas such as expanses of granite or decomposed granite with little to no vegetation, low levels of riding and pack stock can travel and not leave evidence of use.

C. Early Season Access and Trail Readiness

Where trail or destination readiness concerns exist, key areas will be identified and a monitoring program initiated. Concerns with early season access include saturated soils, surface flows on trails, snow drifts or other factors which may cause accelerated erosion or disturbance.

Monitoring of key area conditions will be used to determine when trail or destination conditions are ready and commercial pack stock use will not contribute to unacceptable deterioration.

Shoveling, sanding or otherwise treating a trail to obtain access over snow or obstacles must be approved in advance. These occurrences will be infrequent and access will be approved when trail and destination readiness is determined. No such treatments will occur into the National Parks unless Park approval is provided. Sanding material and sources must be approved and weed-free.

5. CAMPSITES

All overnight holding of stock by commercial operators will take place at a designated stock camp. All party members on an all expense, base camp or traveling trip must stay in a designated stock camp. These sites will be signed as stock camps.

As identified in Forest Service policy, assigned sites are designated stock camps that, upon request by the operator, can be reserved for the exclusive use of that operator. These sites are subject to a reserved site fee (as specified in Forest Service Handbook Chapter 2709.11, Section 37.21 (h)).

All designated campsites must be 100 feet from water, already established, durable and adequate for loading and unloading stock, and have acceptable access from the system trail. Designated campsites will not be located where sensitive resources (e.g., heritage, sensitive plants, etc.) may be affected.

These designated sites will have identified stock holding areas, identified access into and out of the camp, and will be contained in a manner that is consistent with Best Management Practices. Features and allowances will be made in these sites to ensure and facilitate resource protection. All designated sites will be brought up to this standard within two years of permit issuance.

If a stock camp has not been identified, and an operator requests use of an area where overnight holding of stock is needed, the Authorized Officer may approve that use consistent with the destination management strategy for that area. If an operator plans to use sites repeatedly through the term of the permit, the site should be approved and designed in accordance with the guidelines above.

Any legal campsite may be used for spot and dunnage trips except where specifically prohibited or prescribed in the list of designated sites found in Table 2.32.

6. CAMPFIRES

On a case-by-case basis, approval will be considered for wood fires in areas above the elevational closure. The fire must be in a fire-pan and the ashes must be packed out. Wood must be brought in from outside or an approved source. These allowances will be managed through annual operating plans. Areas that may be considered appropriate for such uses are areas that are not often used by the non commercial public or are at sites that have some separation from areas where non commercial parties typically camp. These allowances will be site and/or seasonal specific.

For all visitors, charcoal fires with a fire-pan will be approved above the elevational fire closure. The charcoal fire must be in a fire-pan and the ashes must be packed out.

If non-compliance with the campfire policy is documented or there is an increase in trash, ash, charcoal, fire-rings, mutilations of standing trees or any indication that resources are not protected as a result of charcoal or wood fires, then site specifically the approval may be revoked. Monitoring will be conducted with existing campsite condition inventory monitoring protocol. Adequate documentation and rationale must accompany any revocation.

Areas that are at or just above the elevational fire closure, and have firewood available, will be subject to adjustments in the elevational fire closure boundary. Areas to be considered are locations where more than one site indicates dead and downed fuel wood availability rated at “3” or below. Sierra/Inyo N.F. campsite inventory monitoring protocol will be used for these ratings.

The following adjustments to elevation closure will be made to reflect adequate downed wood sources at areas near the elevation closure.

- **Purple Lake** (*Fish/Convict/McGee Geographic Unit*)
- **Genevieve** (*Fish/Convict/McGee Geographic Unit*)
- **Deer Lakes** (*Fish/Convict/McGee Geographic Unit*)
- **Steelhead Lakes** (*Fish/Convict/McGee Geographic Unit*)
- **Kenneth Lake** (*Mono/Rock Creek Geographic Unit*)
- **Lower Sallie Keyes Lake** (*Florence/Bear Geographic Unit*)
- **French Canyon** (*Bishop/Humphreys Geographic Unit*)
- **Piute Canyon** (*Bishop/Humphreys Geographic Unit*)

In addition, **Rutherford Lake** (Ansel Adams West) is identified as not having fuel wood available and the elevation will be adjusted to exclude campfires from this location.

7. RECREATION CATEGORIES

The following changes will be made in the assignment of recreation categories. These areas were determined to be consistent with the proposed recreation category. These are not areas that have changed in condition since 2001, but were improperly categorized and are more consistent with the new category.

Table 2.10. Alternative 2 – Modified recreation category changes

Location	Geographic Unit	Analysis Unit	Recreation Category	
			Current	Change to:
Deadhorse Lake	Ansel Adams East	Minaret	RC2	RC 1
Cabin Lake	Ansel Adams East	Shadow-Ediza	RC3/2	RC 1
Cecile Lake	Ansel Adams East	Shadow-Ediza	RC2	RC 1

ALTERNATIVE 2 – PROPOSED ACTION

SUMMARY

As discussed in the introduction, the proposed action was developed by the interdisciplinary team and Forests' District Rangers. It was designed in response to the interdisciplinary team's assessment of conditions in locations where pack station operations had been identified. The assessment focused on the issues identified by the court in the injunctive relief. The team identified a need for change where conditions warranted further direction, change in direction or specific actions to implement existing direction. A comprehensive and detailed proposed action was scoped in June 2004.

This alternative allows commercial pack stock activities with the following standards and guidelines:

- Use is rationed through seasonal destination quotas combined with daily and seasonal stock quotas (totals) set at levels similar to the past three years.
- Destination quotas respond to a determination of capacity for the destination, utilizing the desired condition of the area (recreation category), resource capability, and a consideration of risk factors.
- Party size limit is 15 persons and 25 stock wilderness-wide with some site specific decreases in party size.
- Campsites are designated for all locations where operators hold stock overnight and operators will be required to use these sites.
- Grazing is managed through a determination of suitability and stock night capacity for grazing zones and specific meadows.
- The proposed system of trails and development levels are based on an analysis of current and anticipated use, resource impacts, and trail maintenance considerations. Destination recreation categories and commercial stock quotas are considered to ensure that trail management objectives are aligned with area management objectives.
- Trail suitability for commercial pack stock is based on an analysis of anticipated trail infrastructure stability, current resource impacts and potential impacts due to a variety of risk factors (if commercial pack stock use were to occur or continue). These same trails would also be posted as not recommended for private stock due to perceived severity of trail conditions and safety concerns.

1. TRAIL MANAGEMENT PLAN

The trail system inventory responding to the direction for this alternative is shown in Table 2.26.

2. USE LEVELS AND STOCK NUMBERS

A. Day Rides

A total of 5,500 day rides will be authorized in locations listed in Table 2.33, *Day Rides Alternative Comparison Table*.

B. Service Days

No service days are assigned to pack station operations. Use is controlled by destination quotas, primary operating areas, designated campsites, grazing restrictions and party size limitations.

Pack stock operators with O/G Special Use Permits (no facilities on forest lands) will be assigned service days as follows:

Table 2.11 Alternative 2 outfitter/guide service days allocations

Operator	Allocation
Burro Operator	119
Horse and Mule Operator	156
Llama Operator	100

C. Overnight Use

Quotas on number of trips per season by destinations will replace trailhead quotas and service day allocations.

Quotas were based on an assessment of the capacity of the locations for continued commercial use. All locations where commercial pack stock identified their current, proposed and past operations were assessed. Tally sheets (the self-reported record of commercial use) were analyzed and the number of trips, people and stock use at destinations was calculated.

Calculations were done to the best of the agencies ability, given a small margin of error for imprecise recording of destinations by permittees. Records are not available consistently across the planning area prior to 2001.

The assessment of capacity was done by looking at the highest level of use to each recorded destination from 3 years (2001-2003). Three criteria were applied to determine if this level of use was the appropriate capacity:

- 1) The resource condition rating of the destinations as evaluated by the interdisciplinary team by assessing recreational impacts, access issues, riparian concerns, camping potential, and risk factors at destinations;
- 2) Determination if the destination could accept more use, or if the areas was already at or exceeded capacity and needed to be reduced; and
- 3) Whether that level of use is consistent with the recreation category, given considerations of other uses (overnight use by general public, other outfitters and guides, day hiking, and day riding).

These quotas are estimates of use for commercial operators that would meet the desired resource and experiential condition of the area, considering the recreation category and the physical capacity of the destination.

In addition to the quota assigned to destinations and quota assigned for all expense trips, each operator would be assigned five trips that can be used (pending approval from the line officer) for either unidentified or unassigned destinations or, if needed and approved, for exceeding destination quotas for the season. This accommodates fluctuations and allows a small amount of flexibility to the operators.

Quotas would be managed over time to adapt to changing conditions. If conditions at destinations deteriorate or do not meet the desired condition, the number of trips would be reduced. If conditions improve or stay the same and a determination is made that an increase in use is sustainable, the number of trips may increase. Increases and reductions will be incremental and monitored for effectiveness. Both the Forest Service and the commercial pack stock operator must respond to resource concerns in a prompt and appropriate manner. Destination quotas are only one mechanism in this alternative that allows for the management of the resource quality of the wilderness.

Primary operators (the primary operating concept is explained below) would have priority for available destination quotas. Traveling trips or trips by operators who are not the primary operator would be the first to be reduced if resource conditions warrant reduction.

The following describes how various pack station trips would be accounted for in the destination quota system:

- For spot and dunnage, a trip is defined as a one-way service ⁴
- A one-way spot trip will count for one trip.
- A one-way dunnage that utilizes less than five stock will count for a ½ trip. This provides incentive for a type of trip (dunnage) that utilizes less stock per person. Due to data collection concerns of National Park managers, trips accessing the National Parks will not be counted as ½ trip, regardless of the number of stock.
- Trips that hold stock in the backcountry overnight in conjunction with an all expense, traveling or base camp type service are considered “all expense” for the purposes of the quotas. These all expense trips will be considered one trip for the duration of the service provided on that trip. All expense trips will be further regulated by the designated site requirement and allowable grazing constraints.

Destination quotas will not be adjusted (lowered) based on lack of use. Quotas are designed to accommodate fluctuations at various destinations over the years.

Any use identified for travel into or through the adjacent National Parks (Yosemite National Park, Devils Postpile National Monument and Sequoia/Kings Canyon National Park) will comply with authorizations or use level limitations set by the National Parks.

⁴ A spot trip is where the party rides and pack stock is used to carry the dunnage. A dunnage trip is where the party walks in and pack stock is used to carry the dunnage.

Wilderness permits are required for all parties, commercial pack stock operators will obtain the proper wilderness permits from the Forest Service (or its contractor). Tally sheets for reporting the service will continue to be required as described in Alternative 1.

For a full listing of all destination quotas see Table 2.31.

D. Primary Operating Areas

Pack station operators are assigned a primary operating area. This is defined by the area an operator can reasonably service with a one to two day spot or dunnage trip from their base pack station facility where past use records show service has regularly been provided. These areas are defined in the site-specific section by the destination/zone quotas assigned to each operator in Table 2.31.

In areas where two or more pack stations can access the same destination through spot and dunnage trips, primary operating areas may be shared. With the exception of the shared primary areas, no overlap of services in these primary operating areas will be assigned for spot or dunnage trips. Allocations for occasional trips can be authorized in another operator's primary area, but the Authorized Officer must approve such trips. (Note: "approval" for any occupancy or use, for primary operating areas and other actions common to all analysis units constitutes a written statement regarding the status and terms of the approval, signed by the Authorized Officer.)

E. Party Size

Party size for commercial pack stock parties is 15 persons and 25 stock wilderness-wide. In 15 site specific locations the party size varies, based on the physical capacity, setting and management objectives for the area. These are listed in Table 2.12.

Table 2.12. Site-specific party size limitations

Geo Unit	Analysis Unit	Location: Person/Stock limit
Ansel Adams East	King Creek	Fern Lake: 10 persons/20 stock
	King Creek	Anona Lake: 10 persons/20 stock
	Rush Creek	Weber Lake: 10 persons/20 stock
Bishop/Humphreys	Bishop Creek	Ruwau Lake: 8 persons/15 stock
	Bishop Creek	Marie Louise Lake: 6 persons/10 stock
	French	Merriam Meadow: 10 persons/20 stock
	French	Steelhead Lake: 6 persons/6 stock
	Glacier Divide	Honeymoon Lake: 6 persons/12 stock
	Glacier Divide	Packsaddle Lake: 6 persons/6 stock
Fish Creek/Convict/McGee	Sabrina	Baboon Lake: 8 persons/15 stock
	Convict	Cloverleaf Lake: 15 persons/8 stock
	Purple Bench	Above Ram Camp: 8 stock
	Silver Divide	Peter Pande Lake: 10 persons/15 stock

Geo Unit	Analysis Unit	Location: Person/Stock limit
	Upper Fish	Tully Lake: 8 persons/15 stock
Mono Creek/Rock Creek	Little Lakes Valley	Gem Lake: 8 persons/10 stock

F. Stock Numbers

Commercial pack stock operators are subject to seasonal and daily stock number limits. These limits were derived by an analysis of recent stock use on trails and current resource concerns, visitor capacity considerations, and management objectives and are listed below.

Table 2.13: Alternative 2 - seasonal and daily stock limits

Pack Station Location	Stock Limit
North Lake

3. GRAZING MANAGEMENT

A. Grazing Strategy

Grazing is managed in “grazing zones” that include one or more meadows and their surroundings. Grazing is only allowed in the 82 grazing zones that are based on areas requested for grazing by the commercial pack operators. Key meadows were visited within the grazing zones for determinations of suitability and estimated grazing capacity. Within those key meadows, some critical areas were identified based on resource concerns, such as fens, Yosemite toad breeding habitat, and important hydrologic zones such as springs, seeps, and unstable areas.

An overall estimate of stock nights was assigned to each grazing zone based on calculated suitable meadow area, vegetative productivity, and reported stock use in the last three years (see Table 2.30). This estimate will be used as an initial stocking rate to be adjusted either up or down based on monitoring of progress toward or maintenance of desired conditions. Of 178 meadows

analyzed within grazing zones, 127 meadows were determined to be suitable and 51 unsuitable. If no meadows in a requested area were determined to be suitable, no grazing zone was established. Twenty meadows determined to be unsuitable are in this category. An additional eight meadows outside of areas requested for grazing by commercial pack outfitters were analyzed and determined to be unsuitable.

Most monitoring will focus on the key meadows; however, the entire area inside the grazing zone will be managed by applying standards described in the Wilderness Plan. These include standards for range readiness, vegetation utilization, and streambank and soil disturbance. Critical areas and areas identified as unsuitable will be managed for no use, and the stock user will be expected to avoid stock entry, although there is an inadvertent ground disturbance limit of 5% allowed in these areas.

Monitoring of utilization, and trampling at selected critical areas, will occur as described in the Wilderness Plan.

B. Drift Fences

Existing drift fences are allowed for resource protection and where identified by, and agreed to by the Forest Service, for stock management. Stock management includes the prevention of stock drifting or moving to areas where grazing is not suitable, particularly in situations where the drifting could lead to loose, unattended stock on the trail thereby causing unsafe situations for visitors. Drift fences that do not facilitate resource management or stock management but only provide convenience for commercial pack stock operators will be removed. Whenever possible, temporary rather than permanent or electric fencing will be used and encouraged to keep stock out of critical areas, sites that are not range ready, or to keep stock in approved areas. The commercial pack stock operator may request, and the Authorized Officer may approve, an alternative method of controlling stock to minimize the risk of impacts to critical areas. For a list of drift fences see Table 2.34.

4. TRAIL SUITABILITY FOR COMMERCIAL PACK STOCK

A. System Trails

The 2001 Wilderness Plan provides direction to identify trails that are not suitable for commercial stock as “Not Recommended for Stock” (NRFS). Commercial stock use is not authorized on trails that are NRFS. The NRFS has no regulatory effect on private stock use, and is used for public educational and advisory purposes only.

Management of trails designated as “Not Recommended for Stock” will include gradually signing trails, identifying them on agency recreational maps, and working with private map producers to identify these trails appropriately. Other educational efforts will be implemented as appropriate. The trails will continue to receive basic maintenance and stabilization to keep them from degrading and causing excessive resource impacts. In most cases work will not be undertaken which changes the current character of the trail.

This alternative identifies 73.8 miles of system trails that are designated as “Not Recommended for Stock” (listed in Table 2.26). The identification of these trails is based on the direction in the 2001 Wilderness Plan that closure is appropriate where repetitive commercial pack stock use on trails not maintained at a higher level results in further degradation of the trail. In addition, the

closure provides benefits to soils, vegetation, and biophysical resources and reduces maintenance and reconstruction costs.

B. Use Trails and Routes

The 2001 Wilderness Plan requires that all commercial use off existing system trails be approved by the Forest Service. Alternative 2 implements this guidance and designates the use trails and cross county routes appropriate for use by commercial pack stock, taking into consideration commercial uses at destinations, grazing areas, and designated camps. Certain undefined (cross-country) routes that had limited risk factors and no notable existing resource degradation under current use levels were considered for approval if not in conflict with other commercial stock direction in this alternative. If some risk factors exist, limitations are placed on the number of approved trips to these areas. A list of the use trails and routes that will be approved under the various alternatives is in Table 2.27.

Mitigation of resource impacts and removal of seasonal obstacles can be performed on use trails (such as removal of downed trees where bypasses would otherwise impact resources), but are limited to the minimum necessary, so that the character of the use trail does not substantially change.

Campsite access trails that are directly associated with designated commercial pack stock camps (see Table 2.32) and are used for access to the site are approved as an inherent part of the designation of stock camps and are generally not addressed as “use trails.” Mitigation of resource impacts and basic trail opening to ensure that multiple routes do not form is allowed and is generally the responsibility of the primary operator.

5. CAMPSITES

All overnight holding of stock by commercial operators can only take place at a designated stock camp. These sites will be signed as stock camps. The general public is not excluded from using these sites, but the intent is for a stock party to have priority over a non-stock party for use of the site.

These sites will have designated stock holding areas, designated access into and out of the camp, and will be contained in a manner that is consistent with Best Management Practices.⁵ Features and allowances will be made in these sites to ensure and facilitate resource protection. The Forest Service and commercial pack stock operators will bring all designated sites up to this standard within five years of permit issuance.

As identified in Forest Service policy, assigned sites are designated stock camps that, upon request by the operator, can be reserved for the primary operator for the area. These sites are subject to a reserved site fee (as specified in Forest Service Handbook Chapter 2709.11, Section 37.21 (h)). Assigned sites are not mandatory.

If a stock camp has not been identified, and an operator requests use of an area where overnight holding of stock is needed, the Authorized Officer may approve that use. If an operator plans to

⁵ Best Management Practices (BMP) is a practice or combination of practices that are the most effective and practical means of preventing or reducing water pollution from non-point sources.

use sites repeatedly through the term of the permit, the site should be approved and designed in accordance with the guidelines above.

Any legal campsite may be used for spot and dunnage trips except where specifically prohibited or prescribed in the list of designated sites found in Table 2.32.

Table 2.14 describes camping limitations in twelve locations. These limitations are intended to facilitate resource protection objectives.

Table 2.14. Alternative 2 camping limitations

Geo Unit	Analysis Unit	Management Action
Fish Creek/Convict/McGee	Silver Divide	One night grazing per trip in Cascade Valley and Silver Divide analysis units.
Fish Creek/Convict/McGee	Purple Bench	Purple Lake: limit camping when not with clients to no more than five nights a year.
Florence/Bear	Sallie Keyes	Prohibit use of site at Old Trail Meadow for overnight holding of stock.
John Muir Southeast	Cottonwood	Allow access to Muir Lake west shore campsites on designated system trail only.
John Muir Southeast	Shepherd	Anvil Camp: allow overnight camping with pack stock (remove current restriction).
Mono Creek/Rock Creek	Fourth Recess	Prohibit camping (through trail use only) below Third Recess to Fish Camp (Second Recess).
Mono Creek/Rock Creek	Hilton Creek	Close campsites in vicinity of goshawk nests at Davis Lake.
Bishop/Humphreys	Sabrina	Prohibit use of campsite at inlet of Blue Lake.
Bishop/Humphreys	Sabrina	Set back campsite at Dingleberry Lake from water and contain.
Bishop/Humphreys	Treasure	Close campsite near Treasure Lakes bench.
Ansel Adams East	Rush Creek	Designate stock holding area for day rides at Crest Creek.
Ansel Adams West	Staniford	Vandeberg: Limit pack stock access to sites at north shore of lake. Contain campsites, and set back from water.

6. CAMPFIRES

In areas that are closed to campfires by the elevational closure in the 2001 Wilderness Plan commercial stock operators are allowed to pack in wood and charcoal from outside the wilderness for campfires. This applies to all types of trips including dunnage, spot, and full service. All campfires in areas otherwise closed by the elevational restriction will only occur in a fire-pan and the ash and coals from these fires will be packed out of the wilderness.

The following are requirements associated with firewood use in the Ansel Adams and John Muir Wildernesses.

- Get firewood locally, particularly no wood from the 14 counties with quarantine.

- No use of wood that has been left in woodpiles over winter.
- Clean any equipment used in gathering firewood.

7. RECREATION CATEGORIES

Recreation categories are used to manage recreation use as described and mapped in the 2001 Wilderness Plan direction.

ALTERNATIVE 3

SUMMARY

- Use is rationed through trailhead quotas and a threshold concept for limiting seasonal stock and clients on each trailhead.
- Party size limit is 15 persons and 25 stock wilderness-wide with some site specific decreases in party size.
- Campsites will be designated for all locations where operators hold stock overnight and operators are required to use these sites.
- Grazing will be managed through a determination of suitability and stock night capacity for grazing zones and specific meadows. Meadows with hydrologic function conditions on a downward trend will be closed to grazing.
- The proposed system of trails and development levels are based on an analysis of current and anticipated use, resource impacts, and trail maintenance considerations. Destination recreation categories and commercial stock quotas at certain locations are also considered to ensure that trail management objectives are aligned with area management objectives.
- Trail suitability for commercial pack stock is based on an analysis of anticipated trail infrastructure stability, current resource impacts and potential impacts due to a variety of risk factors, if commercial pack stock use were to occur or continue. Trails which are awkward for most equestrian use, but are otherwise generally resource-stable and not likely to degrade may be allowed for commercial stock use.
- “Not Recommended for Stock” determinations in this alternative are a public advisory, and do not directly restrict commercial operations.

This alternative responds to Issues #1- Use Levels and #6 – Economic and Operational Effects with a different rationing system than destination quotas. Trailhead quotas on people combined with annual thresholds on stock and clients allow for more flexibility to operators while at the same time providing definitive capacities to protect desired conditions. Additional protections are provided with some destinations that will also have a limit on the number of trips per season.

Issue #4- Grazing Management is addressed by considering all meadows with a rating of functional at risk with a downward trend to be unsuitable for grazing.

Issue # 5 – Campfires is addressed by limiting where the commercial operators can have a campfire above the elevation closure to designated sites only.

Issue #7 – Trail development is addressed by providing a stable trail system in light of the anticipated allowable uses. This alternative proposes a Trail Management Plan implementing the direction in the 2001 Wilderness Plan and is compatible with this alternative’s proposed direction for the management of commercial pack stock. The proposed system of trails, along with the assigned Trail Management Classes are based on analysis of recreation categories, current and anticipated use, resource impacts, and trail maintenance considerations to ensure that trail management objectives are consistent with area management objectives.

1. TRAIL MANAGEMENT PLAN

Implements direction as described in Alternative 2. In addition the following changes or clarifications would apply:

This alternative proposes the “Not Recommended for Stock” (NRFS) concept. NRFS refers to those trails or trail segments where the Forest Service wishes to communicate and educate to both public and commercial stock users that a condition exists that warrants their consideration when using stock on that trail. Trails identified as NRFS in this alternative are open to all stock users with appropriate caution. There are approximately 135 miles of trail designated as NRFS in this alternative.

The criteria for identifying a trail as NRFS include:

- Conditions present which could be especially awkward or impractical to most riders or pack and saddle animals.
- Conditions or hazards which are not likely to be repaired in a stock-suitable manner.
- Obstacles or hazards that are severe, prolonged, or out of character with the trail class and/or the rest of the trail.
- Consistently awkward condition which may require frequent or continuous dismounting and leading of animals.
- Issues surrounding destination and desired conditions of area and management of the trail that make it highly unlikely that the trail condition and hazards will be repaired to a stock-suitable condition.

The trail system inventory responding to the direction for this alternative is shown in Table 2.26.

2. USE LEVELS AND STOCK NUMBERS

A. Day Rides

Allow 5,500 day rides in 45 analysis units as described in Table 2.34.

B. Overnight Use

No service days will be assigned to pack station operations that are under resort term permits. Use will be controlled by daily commercial quotas, primary operating areas, designated campsites and party size limitations, and overall thresholds on commercial stock numbers and clients.

Pack stock operators under Outfitter/Guide (O/G) Special Use Permits will be counted in existing daily trailhead quotas on visitors.

Pack stock operators with O/G Special Use Permits (no facilities on Forest Lands) will be assigned service days as follows:

Table 2.15 Alternative 3 outfitter/guide service days allocations

Operator	Allocation
Burro Operator	119
Horse and Mule Operator	156
Llama Operator	100

C. Quota

Trailhead Quotas

Wilderness permits will be required for all parties serviced by commercial pack stock operations for overnight use. Operators must obtain the proper wilderness permits to enter the wilderness from the Forest Service, or a contractor authorized to issue the permits. Tally sheets for reporting the service will continue to be required as described in Alternative 1.

Trailhead quotas in conjunction with identified primary use areas will provide temporal and spatial controls on pack station use. Specific commercial packstock quotas will be put in place on trailheads where commercial pack stations are located. Existing commercial quotas will remain for use by non pack stock outfitter guides. Quotas for the general public will not be modified.

Daily trailhead quotas on people spending the night in the wildernesses will be in effect. This includes any overnight employees of the commercial operator.

The total number of stock will be counted for each trip. Re-entering the wilderness to pick up a party is a trip and the number of stock used for that service will be counted. Re-supplying a camp or a party will also count against the annual stock and client threshold. When the re-supply service is for a commercial outfitter/guide then the stock will be counted but not clients.

For all multiple quota trailheads, thresholds are established for both stock and clients. These thresholds provide general guidance for total use in a season. Single quota trailheads will only have a seasonal stock threshold and will regulate number of clients through the daily trailhead quota.

At the conclusion of each season, actual use will be compared to the established thresholds. If thresholds are reached or exceeded, the responsible officer will make an assessment of the causative factors and potential resource implications. If conditions are within standards and guidelines, the responsible officer can allow the threshold to be raised with definitive monitoring goals and objectives identified. If any evaluation indicates that conditions do not meet standards and guidelines or desired conditions, corrective actions—including reduced thresholds, additional destination quotas and/or campsite or other site specific closures—will be considered. Any adjustments to thresholds would require NEPA compliance.

Commercial quotas will be modified as follows:

Table 2.16. Alternative 3 Inyo N.F. trailhead quotas and thresholds

Multiple quota trailheads

Trailhead	DAILY Packer Quota (People)	DAILY Outfitter/Guide Quota (People)	SEASONAL Stock Threshold	Seasonal Client Threshold
NF Big Pine	15	8	765	450
Bishop Pass	15	8	385	350
Cottonwood Lakes	15	8	300	200
Duck Lake	15	8	600	450
Fish Creek	8	8	350	200
High Trail	15	8	700	400
Hilton	15	8	700	400
Hilton Creek	Shared quota with Hilton		100	100
JMT north	8		150	100
Kearsarge	8	8	180	200
Lamarck	8	8	25	25
Little Lakes Valley	8	8	40	50
McGee	15	8	500	450
Minaret	15	8	90	150
Mono Pass	15	8	800	400
Pine Creek	15	8	500	450
Piute Creek	15	8	600	450
River trail	8	8	130	200
Rush Creek	15	8	1200	700
Sabrina Lake	15	8	280	300
Shadow	15	8	280	300
Tamarack	8	8	125	150
Treasure	8	8	25	25

Single quotas as identified in the Wilderness Plan will remain the same. Pack station operators will compete with the general public for the quota on these trails. Primary operators will be identified based on pre-Wilderness Plan operating areas.

Single quota trailheads

Trailhead	Single Quotas DAILY (People)	SEASONAL Stock Threshold
Bloody	8	0
Glacier Canyon	8	0
Gibbs	8	0
Parker Ck	10	25
Fern/Yost	8	0
Beck	15	150
Fern Lake	10	160
JMT/PCT South	10	0
Red Cones	15	50
Deer Lake	10	35
Laurel	8	80
Horton Lakes	10	15
Upper Buttermilk	8	5
George Lake (via Sabrina)	10	0
SF Big Pine	12	0
Taboose	10	50
Sawmill	10	15
Shepherd	15	100
Meysan	10	0

Trailheads that have “0” as a seasonal stock threshold and case-by-case trails are trailheads that have no or very little recorded stock use. Unless a trail is identified as “Not Suitable for Commercial Stock,” these trails will be managed on a case by case approval basis for allowing incidental use. Incidental use is considered to be irregular, unadvertised, infrequent, and small parties that may meet a need not currently being met.

Trail Crest will be managed to allow for visitors that have been provided spot and dunnage pack stock support for entry, but are currently unguided and unsupported to exit Trail Crest. 40% of the quota (10) will be available for commercial packstock clients in advance.

Table 2.17. Alternative 3 Sierra N.F. trailhead quotas and thresholds

Multiple quota trailheads

Trailhead	DAILY Packer Quota (People)	DAILY Outfitter/Guide Quota (People)	SEASONAL Stock Threshold	Seasonal Packer Client Threshold
Maxson	8	8	260	285
Florence	15	8	630	430

Trailhead	DAILY Packer Quota (People)	DAILY Outfitter/Guide Quota (People)	SEASONAL Stock Threshold	Seasonal Packer Client Threshold
Devils/Graveyard	10	8	440	295
Isberg	8	8	510	310
Walton	8	8	25	60
Fernandez	8	12	480	285
Jackass/Norris	8	8	25	20

In addition, on the Sierra National Forest six trailheads would be changed from their current management as Single Quota to Multiple Quota, creating a separate commercial quota that includes both commercial pack stock operators as well as commercial non-stock operators.

Trailheads changing from a single quota to a multiple quota

Trailhead	DAILY Packer Quota (People)	DAILY Outfitter/Guide Quota (People)	SEASONAL Stock Threshold	Seasonal Packer Client Threshold
Onion Springs	10	Included in Packer Quota	25	20
Crown/Rancheria	10	Included in Packer Quota	55	80
Woodchuck	10	Included in Packer Quota	125	85
Bear Creek (Diversion)	10	Included in Packer Quota	30	130
Bear Ridge	10	Included in Packer Quota	200	85
Margaret Lakes	8	Included in Packer Quota	150	80

Single quotas as identified in the Wilderness Plan will remain the same. Pack station operators will compete with the general public for the quota on these trails. Primary operators will be identified based on pre-Wilderness Plan operating areas.

Single quota trailheads

Trailhead	Single Quotas DAILY (People)	SEASONAL Stock Threshold
*Mono Meadow	10	25
*Doris/Tule	10	25
*Mono Hot Springs	10	25
*Portal Forebay	10	25

Trailhead	Single Quotas DAILY (People)	SEASONAL Stock Threshold
*Rattlesnake	10	25
*Crater	10	25
Logan Meadow	10	25
Hells Half Acre	10	25
South Fork	10	25
Squaw Dome	10	25
Cassidy	10	80
Miller	10	55
Mammoth	25	105
Chiquito Lake	35	245
*Statum/Spanish	10	30
*Corbet	10	25
*Dutch	10	50
*Hooper	10	45
Mono Creek	30	140

* See Alternative 1; Trailheads inadvertently omitted from Wilderness Plan

Destination quotas

In addition to trailhead quotas, the following destinations will be limited to a maximum number of trips per season. This includes stops on a traveling all expense trip.

Table 2.18 Alternative 3 destination quotas

Geographic Unit	Area	Number of Trips
Ansel Adams East	Superior	8
	Emily (temporary until trail is fixed))	0-4
	Laura	2
	Ediza (temp)	24
Ansel Adams West	Sadler	10
	Staniford	20
Bishop/Humphreys	Muriel	4
	Packsaddle	2
	Mesa, Tomahawk	4
	Treasure	8
	Chocolate	4
	Elba, Moon, L (temp)	2
	Royce	4
	Merriam	4

Geographic Unit	Area	Number of Trips
	French	2
	Wahoo	4
Fish Creek/Convict/McGee	Woods Lake	4
	Cloverleaf	4
	Pika	4
	Peter Pande	4
	Convict destinations (other than Cloverleaf)	18
	Tully Lake	4
John Muir Southeast	Birch	5
Mono Creek/Rock Creek	Hilton #3	6
	Pioneer Basin	20
	Ruby	6

D. Primary Operating Areas

Pack station operators will be assigned a primary operating area. This is defined by the area an operator can reasonably service with a one to two day spot or dunnage trip from their base pack station facility (pack station) where past use records show service has regularly been provided.

In areas where two or more pack stations can access the same destination through spot and dunnage trips, primary operating areas may be shared. With the exception of the shared primary areas, no overlap of services in these primary operating areas will be assigned for spot or dunnage trips. Allocations for occasional trips can be authorized in another operator's primary area, but the Authorized Officer must approve such trips. (Note: "approval" for any occupancy or use, for primary operating areas and other actions common to all analysis units constitutes a written statement regarding the status and terms of the approval, signed by the Authorized Officer.)

E. Party Size

Party size is 15 persons and 25 head of stock throughout the two wildernesses. In addition party size is limited at the same destinations as in Alternative 2.

3. GRAZING MANAGEMENT

A. Grazing Strategy

Allow grazing at the utilization, range readiness, inadvertent use/impact critical area 5% standard, and other standards as for Alternative 2. Initial identified stock nights available are the same as for Alternative 2 for areas that are assessed as Fully Functional or Functional at Risk with an upward trend.

No use will be authorized on key areas determined to be Functional at Risk with a downward trend.

Some locations where assessments were not accomplished prior to the Proposed Action have changes in identified initial stock nights available as a result of site visits in 2004. This affects

locations visited in 2004 such as Davis Lake Benches, Coyote Lake, Margaret Lake, Graveyard Meadows/Cold Creek, Silver Divide (Olive Lake, Box Canyon above Grassy, Chief Lake), Silver Pass Analysis Unit, Stevenson Meadow, Crater Meadow, Deer Creek, Blayne Meadow, Jackass Meadow, Hells Hole Meadow, and Poison Meadow.

B. Drift Fences

Drift fence management for Alternative 3 can be found in Table 2.34.

4. TRAIL SUITABILITY FOR COMMERCIAL PACK STOCK

A. System Trails

This alternative redefines the term “Not Recommended for Stock” (NRFS) from the Wilderness Plan and replaces the NRFS designation in Alternatives 1 and 2 with the term “Not Suitable for Commercial Stock” (NSCS). In this alternative, trails designated as NSCS are closed to commercial stock use.

There are 62.8 miles of system trails designated as “Not Suitable for Commercial Stock” based on an analysis of compliance with the Wilderness Plan management direction, trail and resource condition, and compatibility with the commercial pack stock direction in this alternative.

Overall guidance for the identification of trails designated as NSCS remains the same as trails designated as NRFS in Alternative 2. It is based on the direction in the 2001 Wilderness Plan that closure is appropriate where repetitive commercial use on trails not maintained at a higher level will result in further degradation. Also, the results of the closure will be beneficial to soils, vegetation, and biophysical resources as well as reducing maintenance and reconstruction costs. The distinction between criteria used in Alternative 2 and this alternative is that trails which are notably awkward for most equestrian use, but are generally resource-stable and not highly likely to degrade may be allowed for commercial stock use. This assumes that the commercial operators are familiar with the travel conditions of the trail, and will use appropriate judgment regarding the capability of each packer, pack and saddle animals, and their clientele.

B. Use Trails and Routes

The rationale for approving use trails in this alternative is modified from Alternative 2 to account for differences in the anticipated use resulting from the specific management direction contained in this alternative for commercial pack stock. Certain undefined (cross-country) routes that had limited risk factors and no notable existing resource degradation under current use levels were considered for approval if not in conflict with other commercial stock direction in this alternative.

A list of use trails and routes approved in this alternative is in Table 2.27.

C. Pass Sanding

Passes may be sanded with approval from the appropriate line officer.

5. CAMPSITES

All overnight holding of stock by commercial operators must take place at a designated stock camp. These sites will be signed as stock camps. The general public will not be excluded from using these sites, but the intent is for a stock party to have priority over a non-stock party for use of the site.

All designated campsites must be 100 feet from water, already established, durable and adequate for loading and unloading stock, and have acceptable access from the system trail. Designated campsites will not be located where sensitive resources (e.g., heritage, sensitive plants, etc.) may be affected.

These sites will have designated stock holding areas, designated access into and out of the camp, and will be contained in a manner that is consistent with Best Management Practices to ensure and facilitate resource protection. The Forest Service and pack station operators will have all designated sites up to this standard within five years of permit issuance.

Assigned sites will be designated stock camps that, upon request, will be reserved for the primary operator for the area. These sites will be subject to a reserved site fee (as specified in Forest Service Handbook Chapter 2709.11, Section 37.21 (h)). Assigned sites will not be mandatory.

If a stock camp has not been identified, and an operator requests use of an area where overnight holding of stock is needed, the Authorized Officer may approve that use. If an operator plans to use sites repeatedly through the term of the permit, the site should be designated and designed in accordance with the guidelines above.

Any legal campsite may be used for clients engaged in spot and dunnage trips except where specifically prohibited or as prescribed in the table below.

Table 2.19. Alternative 3 site-specific camping limitations

Geographic Unit	Analysis Unit	Camping Limitations
Fish Creek/Convict/McGee	Cascade	Prohibit all spot and dunnage to Iva Belle Hot Springs.
Fish Creek/Convict/McGee	Purple Bench	Purple Lake: limit camping when not with clients to no more than five nights a year.
Florence/Bear	Sallie Keyes	Prohibit use of site at Old Trail Meadow for overnight holding of stock.
John Muir Southeast	Cottonwood	Allow access to Muir Lake west shore campsites on designated system trail only.
John Muir Southeast	Shepherd	Anvil Camp: allow overnight camping with pack stock (remove current restriction).
Mono Creek/Rock Creek	Fourth Recess	No camping from Third Recess to below Second Recess in Mono creek. Close Fish Creek camp.
Mono Creek/Rock Creek	Hilton Creek	Close campsites in vicinity of goshawk nests at Davis Lake.
Bishop/Humphreys	Sabrina	Prohibit use of campsite at inlet of Blue Lake.
Bishop/Humphreys	Sabrina	Set back campsite at Dingleberry Lake from water and contain.
Bishop/Humphreys	Treasure	Close campsite near Treasure Lakes bench.

6. CAMPFIRES

In areas that are closed to campfires by the elevational closure in the 2001 Wilderness Plan, commercial packers will be allowed to pack in wood and charcoal from outside the wilderness for campfires. All campfires in areas otherwise closed by the elevational restriction must occur in a fire-pan and the ash and coals from these fires must be packed out of the wilderness after each trip. This allowance will be made for full service (all-expense and/or traveling trips) in designated sites only.

The following are requirements associated with firewood use in the Ansel Adams and John Muir Wildernesses:

- Get firewood locally, particularly no wood from the 14 counties with quarantine
- No use of wood that has been left in woodpiles over winter
- Clean any equipment used in gathering firewood

If monitoring indicates that a changed condition occurs as a result of this allowance, including increased depletion of wood or if there is demonstrated continual non compliance at a location, then this privilege will be revoked site specifically.

7. RECREATION CATEGORIES

The following changes will be made in the assignment of recreation categories. These areas were determined to be consistent with the proposed recreation category. These are not areas that have changed in condition since 2001, but were improperly categorized and are more consistent with the new category.

Table 2.20. Alternative 3 – Modified recreation category changes

Location	Geographic Unit	Analysis Unit	Recreation Category (RC) Change to:
Deadhorse Lake	Ansel Adams East	Minaret	RC 1
Cabin Lake	Ansel Adams East	Shadow-Ediza	RC 1
Cecile Lake	Ansel Adams East	Shadow-Ediza	RC 1
Altha Lake	Ansel Adams East	Thousand Island	RC 1
Marie Lake	Ansel Adams East	Upper Rush	RC 1
Slab Lakes	Ansel Adams West	Triple Divide	RC 1
Chalfant Lakes	Bishop/Humphreys	Granite Park	RC 1
Goethe Lake	Bishop/Humphreys	Glacier	RC 1
Lower Honeymoon Lake	Bishop/Humphreys	Glacier	RC 1
Moonlight Lake	Bishop/Humphreys	Sabrina	RC 1
Golden Lake (McGee Creek)	Fish/Convict/McGee	McGee	RC 1
Beetlebug Lake	Fish/Convict/McGee	Silver Divide	RC 1
Medley/Three Island Lakes	Florence/Bear	Seldon	RC 1

Location	Geographic Unit	Analysis Unit	Recreation Category (RC) Change to:
Blackrock Lake	John Muir Southwest	Red Mountain	RC 1
Third Recess	Mono/Rock Creek	Fourth Recess	RC 1
Golden Lake (Mono Creek)	Mono/Rock Creek	Fourth Recess	RC 1
Feather Lake	Mono/Rock Creek	Graveyard	RC 1
Grinnell Lake	Mono/Rock Creek	Laurel	RC 1
Laurel Lake	Mono/Rock Creek	Laurel	RC 1
Second Recess	Mono/Rock Creek	Second Recess	RC 1
Vandeberg Lake	Ansel Adams West	Staniford	RC 2
Anona Lake	Ansel Adams East	King	RC 2
Badger Lake	Ansel Adams East	River-High	RC 2
Iceberg Lake	Ansel Adams East	Shadow-Ediza	RC 2
Rosalie Lake	Ansel Adams East	Shadow-Ediza	RC 2
Marie Meadow	Ansel Adams East	Upper Rush	RC 2
Lady Lake	Ansel Adams West	Staniford	RC 2
Edith Lake	Fish/Convict/McGee	Convict	RC 2
Dorothy Lake	Fish/Convict/McGee	Convict	RC 2
Genevieve Lake	Fish/Convict/McGee	Convict	RC 2
Volcanic Knob	Florence/Bear	Volcanic	RC 2
Guest Lake	John Muir Southwest	Bench	RC 2
Graveyard Lake	Mono/Rock Creek	Graveyard	RC 2
Ruby Lake	Mono/Rock Creek	Little Lakes Valley	RC 2

ALTERNATIVE 4

SUMMARY

- Use is rationed through trailhead quotas. Quotas are lowered in this alternative for trailheads accessing interior destinations with resource concerns.
- Party size limit is lowered to 12 persons and 20 stock wilderness-wide.
- Campsites will be designated and required for all locations where operators hold stock overnight and drop parties on spot and dunnage type trips.
- Grazing will be managed through a determination of suitability and stock night capacity for grazing zones and specific meadows. Meadows with hydrologic function conditions on a downward trend as well as meadows with severe hydrologic function alteration will be closed to grazing.
- The proposed system of trails, along with the assigned trail management classes are based on analysis of recreation categories, anticipated reduced commercial use levels, the increased number of trails that are prohibited to commercial stock because of destination concerns, and attempts to maximize the undeveloped character on trails.
- Trail suitability for commercial pack stock is based on an analysis of anticipated trail infrastructure stability, current resource impacts and potential impacts due to a variety of risk factors, if commercial pack stock use were to occur or continue. Additionally, perceived social and experiential conflicts with other wilderness users in more remote wilderness locations were considered, with an emphasis on separating conflicting user groups.
- “Not Recommended for Stock” determinations in this alternative are purely a public advisory, and do not directly restrict commercial operations.

This alternative responds to **Issue # 1 – Use Levels** and **#6 Economic and Operational Effects** with a different rationing system than destination quotas. This system provides lowered trailhead quotas in areas where resource concerns have been identified. In conjunction with this use level reduction, the service day allocations are reduced 20% from Wilderness Plan levels. The designation of campsites is expanded to include all sites that are used by commercial operators when servicing clients.

This alternative responds to **Issue #2 – Party Size** by reducing the wilderness-wide party size to 12 persons and 20 stock and by allowing the trailhead quotas to be the limiting factor for party size.

This alternative responds to **Issue # 3 – Trail Suitability** and **Issue #7 Trail Development** with a more restrictive trail system for commercial pack stock. Trail suitability determinations in this alternative also address perceived social and experiential conflicts with other wilderness users in more remote wilderness locations. This alternative proposes a Trail Management Plan that implements the direction in the 2001 Wilderness Plan. The trail inventory and maintenance classes presented emphasize a primitive character by limiting development to the lowest possible

level which could be maintained stably with the anticipated amount and patterns of use as directed in this alternative.

This alternative responds to **Issue # 4 – Grazing Management** by including meadows with severe hydrologic function as not suitable for grazing. It also reduces the maximum utilization levels in areas with functional at risk with no apparent trend.

This alternative responds to **Issue # 5 – Campfires** by not allowing any exceptions to the elevation fire restriction.

1. TRAIL MANAGEMENT PLAN

The concept of trails that are identified as “Not Recommended for Stock” for the purpose of public advisory is the same as Alternative 3. Trails identified as NRFS will be the same as Alternatives 3 and 5, except in cases where any of these trails are no longer designated system trails (see Table 2.26).

The trail system inventory responding to the direction for this alternative is shown in Table 2.26.

2. USE LEVELS AND STOCK NUMBERS

A. Day Rides

Allow 3,350 day rides in 39 analysis units as described in Table 2.33.

B. Overnight Use

Service day allocations would be as follows:

Table 2.21. Alternative 4 service day allocations

Activity	West side entry Allocation (Service Days)	East side entry Allocation (Service Days)
Pack stock supported	2,284	10,640
Non-traditional pack stock	200	500
Day Rides	350	3000

C. Quota

Trailhead Quotas

Overnight commercial pack stock use will be rationed by service day allocations and daily trailhead quotas on people.

Wilderness permits are issued by the Forest Service (or approved contractor) with no split quotas (borrowing).

Single quotas will stay the same. Non commercial quotas would not be modified in this action.

Commercial quotas will be modified as follows:

Table 2.22. Alternative 4 Inyo N.F. trailhead quotas and thresholds

Multiple quota

Trailhead	Quota (People per day)
North Fork Big Pine	15
Bishop Pass	12
Cottonwood lakes	10
Duck Lake	15
Fish Creek	10
High Trail	10
Hilton	10
JMT North	8
Kearsarge	15
Lamarck	0
Little Lakes Valley	8
McGee	15
Minaret	10
Mono Pass	10
Pine Creek	15
Piute Creek	15
River trail	6
Rush Creek	15
Sabrina Lake	15
Shadow	10
Tamarack	6
Treasure	6

Table 2.23. Alternative 4 Sierra N.F. trailhead quotas and thresholds

Multiple trail quotas

Trailhead	Alternative 4 Quota
Devils/Graveyard	10
Fernandez	8
Florence	15
Isberg	8
Jackass	8
Maxson	8
Walton	8

D. Primary Operating Areas

Primary operators will be identified to eliminate all overlap of spot and dunnage operations. The only overlap that will be approved is that between spot and dunnage and all expense traveling trips.

E. Party Size

Party size for commercial pack stock supported parties is 12 persons and 20 head of stock throughout the two wildernesses. If a trailhead quota is lower than the maximum party size, then the quota will limit the allowable party size.

3. GRAZING MANAGEMENT

A. Grazing Strategy

Allow grazing at the utilization, range readiness, inadvertent use/impact critical area 5% standard, and other standards as for Alternative 2. Initial identified stock nights available are the same as for Alternative 2 for areas that are assessed as Fully Functional or Functional at Risk with an upward trend, with the following exceptions:

- A 30% maximum utilization factor will be set on key species in key areas determined to be Functional at Risk with no apparent trend.
- No use will be authorized on key areas determined to be Functional at Risk with a downward trend.
- No use will be authorized on key areas categorized as having severe alteration of hydrological function.

Five meadows that are currently used as pastures will only be used to support client trips, not as pastures. These are Poison, Hell Hole, Jackass, Blayney, and Double Meadows in the Florence/Bear Geographic Unit.

B. Drift Fences

Allow drift fences only where the protection of resources or safety of visitors is of concern; not solely for the convenience of the visitor, outfitter or guide. A list of drift fences in Alternative 4 can be found in Table 2.34.

4. TRAIL SUITABILITY FOR COMMERCIAL PACK STOCK

A. System Trails

In this alternative, trails designated as Not Suitable for Commercial Stock (NSCS) are closed to commercial stock use. In addition to the resource and destination limitations addressed in Alternatives 2 and 3, trail suitability determinations in this alternative also address perceived social and experiential conflicts with other wilderness users in more remote wilderness locations.

There are approximately 165 miles of system trails that will be designated as “Not Suitable for Commercial Stock” based on an analysis of compliance with the Wilderness Plan management direction, resource condition, and consistency with the commercial pack stock direction presented in this alternative (listed in Table 2.26).

B. Use Trails and Routes

The criterion for authorizing use trails is based on the following:

- Must be existing visible trail.
- Trails can accommodate type and level of use.
- Areas to be accessed can accommodate the proposed level of stock and stock have historically used these areas.
- The annual operating plan will document and approve user-created, non-system trails. Pack station operators must provide the Forest Service with their proposed trails by March 1 each year.
- Guided, cross-country travel will not be allowed beyond ¼ mile travel distance from designated trails.
- User-created, non-system trails will not be authorized if an existing system trail provides similar access to a destination.
- Stock travel to designated camps and approved grazing areas is permitted.

The list of user trails approved or prohibited based on these criteria is in Table 2.27.

C. Pass Sanding

No passes will be sanded to facilitate early access over the Sierra crest.

5. CAMPSITES

All campsites that are used by commercial pack stock will be designated sites. Commercial pack stock will be required to use these sites and only these sites in conjunction with their operation. This includes sites used to load and unload for spot and dunnage trips. Stock camps will be designated as well for all expense type trips that hold stock overnight. Trips that hold stock overnight must camp in a designated stock camp. All designated campsites must be 100 feet from water, already established, durable and adequate for loading and unloading stock, and have acceptable access from the system trail.

Locations for all designated sites are found in Table 2.32. Any additional site specific limitations at a site are noted in Table 2.24.

Table 2.24. Alternative 4 site-specific camping limitations

Geographic Unit	Analysis Unit	Camping Limitations
Fish Creek/Convict/McGee	Cascade	Prohibit all spot and dunnage to Iva Belle Hot Springs
Fish Creek/Convict/McGee	Purple Bench	Purple Lake: limit camping when not with clients to no more than 5 nights a year
Fish Creek/Convict/McGee	Silver Divide	One night only on Silver Divide.
Florence/Bear	Sallie Keyes	Prohibit use of site at Old Trail Meadow for overnight holding of stock

Geographic Unit	Analysis Unit	Camping Limitations
John Muir Southeast	Cottonwood	Allow access to Muir Lake west shore campsites on designated system trail only
John Muir Southeast	Shepherd	Anvil Camp: allow overnight camping with pack stock (remove current restriction)
Mono Creek/Rock Creek	Fourth Recess	No camping from Third Recess to below Second Recess in Mono Creek. Close Fish creek camp.
Mono Creek/Rock Creek	Hilton Creek	Close campsites in vicinity of goshawk nests at Davis Lake
Bishop/Humphreys	Sabrina	Prohibit use of campsite at inlet of Blue Lake
Bishop/Humphreys	Sabrina	Set back campsite at Dingleberry Lake from water and contain.
Bishop/Humphreys	Treasure	Close campsite near Treasure Lakes bench

6. CAMPFIRES

Campfires are allowed below 10,000 feet north of the Kings/San Joaquin River divide and below 10,400 feet south of this divide. No change from the Wilderness Management Direction.

No packing in of firewood or charcoal will be allowed into areas closed to campfires.

7. RECREATION CATEGORIES

Recreation categories will be used to manage recreation use as described and mapped in the 2001 Wilderness Plan direction.

ALTERNATIVE 5

SUMMARY

In this alternative there will be no commercial pack stock activities. Standard and guidelines will be the same as in Alternative 1, the No Action alternative, but direction specific for commercial pack stock use will no longer be needed or applicable.

This alternative proposes a Trail Management Plan that implements the direction in the 2001 Wilderness Plan. The trail inventory is based on the same general criteria as Alternative 2. The proposed system of trails and the trail management classes are based on analysis of recreation categories, current and anticipated use, resource impacts, and trail maintenance considerations to ensure that trail management objectives are consistent with area management objectives, with the additional consideration of the removal of all commercial pack stock from the trail system.

1. TRAIL MANAGEMENT PLAN

Implement direction as described in Alternative 3.

The concept of trails that are identified as “Not Recommended for Stock” is the same as Alternatives 3 and 4. Trails identified as NRFS will be the same as Alternative 3, except in cases where any of these trails are no longer designated system trails (see Table 2.26).

Trail classes are designated at levels which would minimally sustain anticipated non-commercial use types and levels.

The trail system inventory appropriate for this alternative is shown in Table 2.26.

2. USE LEVELS AND STOCK NUMBERS

A. Day Rides

Not applicable; no commercial pack stock in wilderness.

B. Overnight Use

No service days would be allocated for commercial pack stock overnight, day rides or non traditional pack stock.

C. Quota

All trailhead quotas would remain the same and commercial quotas would be used to ration remaining outfitter and guide activities. Quotas specific to commercial pack stock operations would be removed.

D. Primary Operating Areas

Not applicable; no commercial pack stock in wilderness.

E. Party Size

No commercial stock permitted in the wilderness.

3. GRAZING MANAGEMENT

A. Grazing Strategy

Not applicable; no commercial pack stock in wilderness.

B. Drift Fences

All drift fences associated with commercial pack stock are removed.

4. TRAIL SUITABILITY FOR COMMERCIAL PACK STOCK

A. System Trails

Does not apply.

B. Use Trails and Routes

With no commercial stock there would be no need to identify any use trails or routes as approved for commercial stock uses.

5. CAMPSITES

Not applicable; no commercial pack stock in wilderness.

6. CAMPFIRES

No change from the Wilderness Management Direction (campfires are allowed below 10,000' north of the Kings/San Joaquin divide and below 10,400' south of this divide).

No packing in of firewood or charcoal will be allowed in closed to campfire areas.

7. RECREATION CATEGORIES

Recreation categories will be used to manage recreation use as described and mapped in the 2001 Wilderness Plan direction.

2.4 ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

Federal agencies are required by the National Environmental Policy Act “to rigorously explore and objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated” (40 CFR 1502.14). Public comments received in response to the original scoping phase and the DEIS were used to develop the alternatives contained in the FEIS.

Many ideas have been suggested and evaluated during the development of the alternatives considered in detail. Various components were considered, such as additional mitigation measures, changes to quotas and allocations, no grazing, and adjustments to commercial use quotas. Addressing all of the possible permutations would create an unmanageably large number of alternatives that would not be helpful to the decision makers or the public. In addition, some components were determined to be outside the scope of the current wilderness plan revision process, were already represented by one or more of the alternatives considered in detail, or were determined to risk unnecessary environmental harm. Therefore, a number of alternatives were considered but dismissed from detailed consideration.

There was a concerted effort by some who commented on the DEIS to forward what might best be described as “Modified Alternative 4.” This proposal suggested reducing quotas, party size and service days further, and identifying more trails as not suitable for stock. This alternative was not analyzed in detail for three reasons. First, it was determined that Modified Alternative 4 did not meet Purpose # 1 (*Provide for needed commercial pack stock services*) for this project. The levels of service that would have been provided in Modified Alternative 4 would have fallen far short of the public need as identified in the Needs Assessment. Modified Alternative 4 would reduce commercial packing services considerably below what is provided today. Secondly, the proposed reductions were rather capricious and lacked rationale beyond a desire to have less packstock in the wilderness. It appeared as though the primary basis for the proposed alternative was social issues rather than environmental considerations. We believe that merely reducing commercial services to arbitrary levels below Alternative 4 does not demonstrate a corresponding improvement to the condition of the wilderness and justify the draconian reduction in public access to these wilderness areas. In addition, Modified Alternative 4 was not analyzed because it is believed that the environmental effects associated with this alternative will ultimately closely resemble the effects described for Alternative 5. The alternative did not provide the decision maker or public with an approach to managing commercial pack stock much different than in Alternative 5.

Table 2.25 Effects Summary

This table summarizes the effects of the six alternatives on the relevant resources in the project area.

Wilderness	
Alternative 1	<p>Overall, impacts to wilderness character with this alternative will be moderate intensity at a number of site specific locations. Less than 50 locations (approximately) of thousands of possible destinations in these wildernesses would have moderate long term impact to some qualities of wilderness character (naturalness). Impacts to some visitor's experience (solitude, unconfined recreation) would be short in duration, while some impacts to wilderness character may be longer term, but not have permanent adverse effects. With the fewest limits on where and how frequently pack stock can go on trails and to locations, this alternative has the greatest risk of increasing the aggregate extent of impact caused by commercial pack stock use and the general public. Campfire closures may be dispersing use to lower elevation campsites and wood depletion may increase at these locations. These locations however will tend to be more abundant with the ability for renewal of downed wood resources. Campsites can expand and new stock camps can be created, though that is not likely since stock camps are well established and the current number and locations of stock camps seem to adequately meet the commercial packers needs. Opportunities for solitude will not be high in first six miles from trailheads and at popular destinations. Beyond this opportunities for solitude and unconfined recreation will be very high. Areas where commercial pack stock are prohibited will have moderate-high opportunities for solitude. There are the most opportunities of unconfined recreation with the primary regulator of use an external control and very few internal controls once inside the wilderness. System trail assignments create a conflict between trail objectives and wilderness character objectives (recreation categories). Wilderness character is moderate-high in popular destinations, and high throughout recreation category 1 and 2 areas with localized impacts at campsites and in primary trail corridors. Uncontrolled growth of day hiking will have a cumulative effect on visitor's seeking solitude in a few areas during a short time of the year.</p>
Alternative 2 – Modified	<p>Generally, the effects of Alternative 2 - Modified are very similar to Alternative 2. The distinguishing feature in both alternatives is the manner of controlling use, the destination quota.</p> <p>Overall, the intensity of impacts to wilderness character with this alternative will be low to moderate and moderate to high at less than 25 site specific locations. These moderate to high impacts will be at fewer locations than in Alternatives 1, 2 and 3. Moderate impacts will occur in locations that can sustain higher levels of use and have been popular for decades by both commercial and non commercial visitors. These locations will be consistent with the recreation category desired conditions. Most locations of moderate impacts to wilderness character are the same in all action alternatives.</p> <p>Impacts to wilderness character are primarily to naturalness and opportunities for solitude and/or primitive and unconfined recreation. Impacts to naturalness are minor in the long term. Impacts to opportunities for solitude occur in high use corridors and occasionally in other areas of the wilderness but tend to be short in duration and are avoidable. Opportunities for unconfined recreation are moderate in this alternative to a portion of the public (clients of commercial pack stock and visitors wanting few to no encounters with pack stock) where travel is either prohibited or limited.</p> <p>Impacts to a visitor's experience would be short in duration, particularly at popular destinations and on primary trails. While some impacts to natural conditions such as locally severe trail impacts may be longer term, they are not likely to have permanent adverse effects. Some long term adverse effects to wilderness character may result site specifically with trail development decisions as affected trails lose their primitive characteristics when improved and developed to facilitate uses. The same action (trail development) that may occur over the long term would enhance ecological and natural qualities of wilderness character.</p> <p>There would be no regional, long term adverse impacts. Beneficial effects in this alternative include improved wilderness character of many destinations where impact sources (pack stock) are removed. However, there will still be sources of impacts from other visitors at these locations. It is likely that the severity of the impact will be reduced over the short and long term. Some visitors that rely upon commercial pack stock support would be permanently affected by closure of these areas.</p> <p>There would be no irretrievable or irreversible adverse effects from this alternative, since a strong element of the alternative is managing for conditions and adapting techniques, controls and regulations to achieve the desired conditions. A monitoring component identifies indicators and thresholds for when to implement adaptive measures. This monitoring strategy is embedded in this alternative to provide the assurance we need to modify and manage actions over time to prevent any irretrievable losses to the wilderness resource.</p>

<p>Alternative 2</p>	<p>Overall, impacts to wilderness character with this alternative will be at a moderate intensity at fewer site specific locations than Alternative 1. Impacts to a visitor’s experience would be short in duration, particularly at popular destinations and on primary trails. While some impacts to natural conditions such as locally severe trail impacts may be longer term, they are not likely to have permanent adverse effects. Some long term adverse effects to wilderness character may result site specifically with trail development decisions as trails lose their primitive characteristics with improvements and development to facilitate uses. The same action (trail development) that may occur over the long term would enhance ecological and natural qualities of wilderness character.</p> <p>There would be no regional, long term adverse impacts. Beneficial effects in this alternative include the improved wilderness character of many destinations where impact sources (pack stock) are removed. However, there will still be sources of impacts. It is likely that the severity of the impact will be reduced over the short and long term. Some visitors that rely upon commercial pack stock support would be permanently affected by closure of these areas.</p>
<p>Alternative 3</p>	<p>Overall, impacts to wilderness character with this alternative will be moderate intensity at fewer site specific locations than Alternative 1 but more locations than Alternative 2. Impacts to a visitor’s experience would be short in duration, particularly at popular destinations and on primary trails. There would be a higher risk of destinations becoming more impacted over the long-term than in Alternative 2 with an external versus internal control. These would likely be long-term minor to moderate local impacts.</p> <p>While some impacts to natural conditions such as locally severe trail impacts, may be longer term, they are not likely to have permanent adverse effects. Some long-term adverse effects to wilderness character may result site specifically with trail development decisions as trails loose their primitive characteristics with improvements and development to facilitate uses. There would more occurrences of this than in Alternative 2. The same action (trail development) that may occur over the long-term would enhance ecological and natural qualities of wilderness character.</p> <p>Beneficial effects in this alternative include improved wilderness character of many destinations where impact sources (pack stock) are removed. There will still be sources of impacts, however, it is likely that the severity of the impact will be reduced over the short and long term.</p>
<p>Alternative 4</p>	<p>Overall, impacts to wilderness character with this alternative will be moderate intensity at fewer site specific locations than Alternative 1, 2, and 3. Impacts to a visitor’s experience would be short in duration, but could be greater at popular destinations and on primary trail compared to Alternatives 1, 2 and 3. While some impacts to natural conditions such as locally severe trail impacts may be longer term, they are not likely to have permanent adverse effects. Beneficial effects in this alternative include improved wilderness character at many destinations where impact sources (pack stock) are removed. There will still be sources of impacts; it is likely that the severity of the impact will be reduced over the short and long-term.</p>
<p>Alternative 5</p>	<p>In this alternative commercial pack stock use would be eliminated. Without commercial pack stock there would be a reduction of encounters and less crowding between parties—especially on the primary trails—leading to an improvement to the experience of hiking visitors.</p> <p>Impacts associated with commercial pack stock use would diminish over time but may persist as sites, trails, and use trails will still receive public use. The majority of visitation would continue but some visitors that choose to use pack stock for their experience will not be able to find that opportunity.</p> <p>In this alternative, minor to moderate impacts would occur locally and wilderness wide with continued visitation. The intensity of these impacts would diminish over the short to long term. Moderate impacts that were associated or partially attributable to pack stock would likely diminish in the long term (10-20 years). There would be beneficial affects to wilderness character with the reduction of site specific impacts and increased opportunities for solitude that would occur by reducing overall wilderness use by 10%. There would be adverse impacts to a large sector of the pubic that desires or depends on pack stock support for their wilderness experience.</p>
<p>Trails</p>	
<p>Alternative 1</p>	<p>The “No Action” Alternative has the fewest control mechanisms on use types and levels and the greatest amount of conflict between trail management levels and the desired condition and management of destinations. Trail levels in this inventory are substantially inconsistent with current on-the-ground conditions. Trail management in this alternative have the greatest potential impacts on physical resources, allowing for the continuation and likely expansion of degraded trail conditions in some areas, and continued negative resource effects.</p> <p>There is substantial conflict with recreation categories and desired area management in this alternative. If implemented, many trails would have an unnecessarily high level of development and management intrusion on the wilderness character and on physical resources (for instance, over 15% of the total system and 28% of the Inyo system is designated at Class 4, a level defined as “rarely present in wilderness”). There are major inconsistencies with on-the-ground conditions and a high probability of physical resource impacts from inadequately developed and maintained trails (for instance, 37% of the Sierra system is designated TC1, and</p>

	<p>nearly 50 miles of managed trail is not on this inventory). Trail management designations for trails with similar characteristics are highly inconsistent between forests in this alternative.</p> <p>This alternative allows commercial stock on any system trail. With no internal controls, there is the lowest predictability of use type and level for each system trail. This will likely cause some continued and potential expansion of resource effects, including some localized severe impacts and inefficient distribution of maintenance funds. Various use trails could be requested, approved or prohibited annually, meaning this alternative would provide very little long-term predictability of use trail approvals, prohibitions or use levels. Currently, 102 use trails (99 miles) are approved for commercial use.</p> <p>Since any trail could potentially be requested for sanding of snow to allow early season passage (though very few would likely be requested in most years), there is a higher potential for expansion of effects from sanding—both beneficial effects in the immediate vicinity of the sanding, and greater potential adverse effects at trails and destinations accessed earlier in the season.</p> <p>Overall, physical trail-related impacts in this alternative will be minor to moderate at the local level, with some isolated moderate to severe effects on certain resources at highly localized sites. Most localized adverse impacts are short term and could be actively mitigated, but without active repair many will likely continue into the long-term (20 years or more). Trail impacts to physical resources at the watershed scale are negligible to minor intensity, while regional impacts resulting from inconsistency with area management are moderate.</p>
<p>Alternative 2 - Modified</p>	<p>In general, the primary consequences from trail-related actions in this alternative would be a net improvement in the trail system and on the associated resources in the trail corridor and improved consistency between trail and area management. These benefits will be primarily evident in the following ways.</p> <p>Trail management and desired area management are most closely aligned, with few anomalies between trail classes and desired conditions. For example, less than 1% of the total system is designated TC4 in this alternative and only 4 miles of TC3 trail is accessing the most primitive (Recreation Category 1) areas. This will result in greatly reduced potential trail conflicts with wilderness character.</p> <p>Trail classes are most closely aligned with current observed trail development levels. This will have beneficial effects by avoiding the need to upgrade many trails, unless there is an overarching benefit to do so. Very few trails are designated at levels below what currently exists, so there will be minimal changes in management that could allow a gradual loss of infrastructure, which in turn would cause resource impacts if use continues at current levels or that would affect the existing users of these trails.</p> <p>This alternative has the highest level of consistency of trail management between the two managing forests.</p> <p>Internal controls using the “destination management” concept ensures a high level of predictability of use types and numbers. Trail development is very consistent with anticipated use and on-the-ground conditions, resulting in greater trail stability and reduced physical resource impacts.</p> <p>Commercial stock is prohibited from approximately 10% of system trails, which were determined unstable with even low levels of recurring stock use, ensuring that the majority of stock use is limited to trails most capable of remaining stable under anticipated use. Reduced maintenance costs on these trails allows for more efficient distribution of trail maintenance and reconstruction funds and more stable conditions on other system trails.</p> <p>This alternative allows for stabilizing nine miles of NSCS trail, then allowing future commercial use. This provides added flexibility for commercial operators to access areas, once resource and trail stability issues are corrected.</p> <p>Commercial stock is limited to use trails which have relatively few risk factors and a high likelihood of continued stability. Highly dispersed undefined routes are approved for very limited use with temporal controls. In this alternative, anticipated use is highly predictable, and these use trails should remain stable or even improve slightly under the prescribed use levels.</p> <p>Limiting commercial stock access over snow-drifted passes until the destination system and use trails are ready for such use will have moderate beneficial effects to these destination trails and resources.</p> <p>Over the short term, this alternative will have negligible to minor localized and regional beneficial impacts, by reducing one of the contributing sources of adverse effects on the most susceptible trails. Physical trail and resource stability will not likely improve substantially during the short term, but will improve over the long term as physical treatments and/or natural recovery occurs. Over the long-term, it is expected that there will be minor beneficial effects at the wilderness scale, with moderate to beneficial effects to resources and trails at the local level. There will likely be some minor reduction in user conflicts at remote destinations.</p>
<p>Alternative 2</p>	<p>In general, the primary consequence from trail-related actions in this alternative would be a net improvement in the trail system and on the associated resources in the trail corridor and improved congruency between trail and area management. These benefits will be primarily evident in the following ways.</p> <p>Trail management and desired area management are more closely aligned than in Alternative 1 and 3, resulting in reduced potential conflicts with wilderness character. For example 9% of the total system is designated TC4 in this alternative.</p> <p>Trail system management shows greater inter-forest consistency. Internal controls allow for greater predictability of use types and numbers, so trail development</p>

	<p>will likely be very consistent with anticipated use and on-the-ground conditions, resulting in greater trail stability and reduced physical resource impacts.</p> <p>Commercial stock is prohibited from 8% of system trails, which were determined unstable with recurring stock use, ensuring that the majority of stock use is limited to trails most capable of remaining stable under anticipated use. Private equestrians will be advised that these trails are not recommended for stock, resulting in improved visitor expectation and safety. Since the NRFS designation does not distinguish between commercial and private, there may be some confusion for private stock about which trails are actually risky versus those that have resource effects. Reduced maintenance costs on these trails allows for more efficient distribution of trail maintenance and reconstruction funds leading to more stable conditions on other system trails over the long-term.</p> <p>One trail would be approved for sanding in this alternative, ensuring relatively localized effects, and ensuring that there would be no expansion of these effects to other trails.</p> <p>Commercial stock are limited to 100 use trails (102 miles), including some undefined (cross-country) routes, and use levels on each trail are limited by destination quotas. In this alternative, anticipated use is highly predictable, and these use trails should remain stable or improve slightly under these use levels.</p> <p>Over the short term, this alternative will have minor localized and regional beneficial impacts, by reducing one of the contributing sources of adverse effects. Physical trail stability conditions will not likely improve substantially until the long-term, as physical treatments and/or natural recovery occurs. Over the long-term, the localized beneficial impacts will be moderate, as funding can be distributed across the system more effectively, and more trails are managed at stable levels. There should be some minor reduction in user conflicts at remote destinations.</p>
<p>Alternative 3</p>	<p>Trail management levels are very consistently aligned with desired destination management levels, with a minimal amount of conflict with recreation categories (for instance, less than 1% of trail system is TC4). This alternative very closely aligns trail management with anticipated use types and levels and on-the-ground conditions. There are fewer internal controls than Alternative 2, so there is less predictability about commercial use levels. This may cause slightly less efficient distribution of maintenance funding. 107 use trails are approved, including undefined or cross-country routes, and fewer destination controls are present, so there is a higher potential for resource impacts and potential for increase of evidence of use trails until monitoring determines that mitigation or closure would be needed. This would likely have a minor to moderate effect at the wilderness scale, and moderate to severe effects at specific use trails with high risk factors.</p> <p>“Not Recommended for Stock” designation is purely a public advisory in this alternative and does not restrict commercial use. Around 140 miles of trail (~15% of system) is designated NRFS due to trail difficulty and awkward conditions for stock. This will likely provide better/safer experience to private equestrians. Alternative 3 has more trails available to commercial stock than Alt 2, with 63 miles (approximately 6%) of system designated as “Not Suitable to Commercial Stock” (NSCS), but little or no noticeable effect likely, since additional trails available are simply awkward for stock, and should remain stable under anticipated use. Reduced costs of maintenance and reconstruction on NRFS and NSCS trails allows for slightly better condition on overall system, resulting in more stable trails and resource condition.</p> <p>Over the short term, this alternative will have negligible to minor localized and regional impacts, by reducing one of the contributing causes of adverse effects, but physical trail stability conditions will not likely improve substantially until the long-term, as physical treatments and/or natural recovery occurs. Some of these beneficial effects are highly dependent upon funding levels.</p> <p>Since any trail could potentially be requested and approved for sanding of snow to allow early season passage (though very few would likely be requested in most years), there is a higher potential for expansion of effects from sanding than in Alternative 2. Sanding will likely occur on between one and five trails annually, depending upon the severity of the winter. Sanding protects immediate trail corridor from widening and multiple trails, but may allow early access to trails and areas still wet and easily damaged.</p> <p>Over the long-term, the beneficial impacts will be moderate, as more trails are managed at stable levels and which do not exceed area needs. At the regional scale, this alternative will have negligible adverse impact for both the long and short terms. Over the long term, the close alignment of trail management and desired area management should have moderate beneficial effects on wilderness resources. desired area management should have moderate beneficial effects on wilderness resources.</p>
<p>Alternative 4</p>	<p>This alternative provides the most restrictive controls to commercial stock use, and limits them to the lowest number of system and use trails. 173 miles (approximately 18% of system) is designated Not Suitable for Commercial Stock (NSCS), effectively confining commercial stock to the 80% of higher development (and generally higher use) trails. 43 use trails (~30 miles) are approved for commercial stock, and no undefined cross-country routes were approved, so this alternative provides the lowest potential for expansion of use trails. However, there is potential for more adverse impacts on the limited number of approved use trails. With no destination controls, there is less predictability of how much use will be present on each system or use trail.</p> <p>The trail system has most primitive character, relative to anticipated use types and levels so will provide least appearance of management intrusion and more primitive character. No trails are designated TC4, and over 25% of system is designated TC1. Lower development levels are likely more susceptible to instability, so there is a higher likelihood of adverse physical resource and trail degradation over the long term. The same trails are designated “Not Recommended for [private] Stock” as in Alternatives 3, and 5, providing a clear expectation and better/safer experience to private equestrians.</p>

	<p>In this alternative, no trails are eligible for sanding to provide early-season access, so there is a likely reduction in impacts on trails and destinations beyond the drifts or passes which would otherwise be sanded. There would likely be an increase in site specific impacts to trail structures and resources in the immediate trail vicinity from non-commercial equestrians and hikers bypassing snowdrifts.</p> <p>In remote locations, there would be minor to moderate benefits through reduced conflicts between different user types, as users choose to segregate. It is likely there will be an increase in localized conflicts between users in high-use trail corridors and destinations. On the regional scale, there will be a minor reduction in conflict overall. Over the long term there will be localized moderate improvements on stability of specific trails and resources with no commercial stock present. At the watershed scale, these improvements would be negligible to minor. In the long-term, the remainder of trails may have minor to moderate adverse localized impacts resulting from inadequate development relative to use levels.</p>
Alternative 5	<p>In this alternative, with the complete elimination of commercial stock from all trails, one of the contributors of trail-related impacts will not be present on any trail, so matching trail management to desired area management is more tied to the anticipated private use and recreation categories.</p> <p>This alternative provides a very high consistency of trail management and desired area management. Reductions in overall stock use will result in some reduction in maintenance needs, reconstruction frequency and scale, and overall costs. This will allow mitigation of local resource problems on all trails, resulting in improved trail and resource stability.</p> <p>The same trails as in Alternative 3 and 4 will be designated “Not Recommended for Stock,” which will provide clear visitor expectations and a better/safer experience for private equestrians. It is likely that private equestrian use will increase slightly, and would be expected to remain mostly on the more developed, comfortable and stable trail system, which would result in very limited effect on trail or resource stability.</p> <p>Use trails will not be used by commercial operators, but most will likely continue to be used at slightly lower levels by private equestrians and hikers. There is a lower likelihood for expansion of use trails, and slightly lower intensity of impacts, so some use trails would likely show minor improvement over the long-term.</p> <p>Overall, this alternative would provide a reduced intensity of adverse impacts on physical resources. Over the short term, there would be negligible to minor beneficial impacts, until physical mitigation is actually implemented. In the long-term, this mitigation and other trail management would be more effective and long-lasting, resulting in a more stable system. User conflicts between equestrians and non-stock users will be reduced almost completely, except in high-use corridors, where minor conflicts between private stock users and non-stock parties may continue.</p>
Socioeconomics and Operations	
Alternative 1	<p>This alternative will continue 2001 Wilderness Plan management and lift the 20% court-ordered reduction in use. This will likely lower some of the costs to commercial pack stock operations and may allow some increase in revenue. The regional economy will experience negligible economic gain from this revenue increase. Under this alternative, there are no known effects to the social environment.</p>
Alternative 2 – Modified	<p>This alternative will provide some modest opportunities for growth in pack station revenue (compared to Alternative 1), but will also implement a number of controls that will likely increase the costs to pack stations providing commercial services in the Ansel Adams and John Muir Wildernesses. These cost increases are likely to be minimal-to-moderate and long-term. This will likely push the costs of commercial pack stock supported trips higher than their current levels. Compared to the No Action, the regional economy will likely experience increased employment and labor income contributions from commercial pack stock operations. When compared to the economy as a whole, however, these increases are likely to be negligible-to-minor. Under this alternative, there are no known effects to the social environment.</p>
Alternative 2	<p>Effects are similar to Alternative 2 – Modified.</p>
Alternative 3	<p>For Alternative 3, the operations and economic effects are expected to be similar to that for Alternative 2. There are no known social effects associated with Alternative 3.</p>
Alternative 4	<p>This alternative will impose restrictions on commercial pack stations that will likely cause the greatest cost increases when Alternatives 1-4 are compared. Compared to Alternatives 2 and 3, Alternative 4 will likely result in decreased commercial pack stock-related employment and labor income contributions. The effects to the regional economy are expected to be negligible and virtually undetectable. There may be some minor social effects as some low income groups find that the price of commercial packs stock trips have rose to unaffordable levels.</p>
Alternative 5	<p>This alternative eliminates commercial pack stock in the Ansel Adams and John Muir Wildernesses. With this alternative, there will be no commercial pack stock-related labor income and employment contributions to the regional economy. The effect of this is likely to be minor and long-term. There may be some social effects associated with this alternative. Groups and individuals that rely upon commercial pack stock to access the wilderness will experience major effects.</p>

	Likewise those that have close ties to the historical and cultural significance of pack stock in the wilderness will experience major effects (although there is no abolishment of private stock under this alternative). Conversely, others will approve of the elimination of commercial pack stock in the wilderness and will likely believe that their wilderness experience will be enhanced.
Hydrology and Soils	
Alternative 1	<p>Water quality is generally good and will remain so except at few very local areas where there may be slight adverse water quality impacts. There will remain areas of local soil erosion, bare soil and sedimentation into surface water from commercial grazing, campsites and trails. Of 60 streams found to be functional at risk, (151 evaluated) an estimated 30% could have improved condition, 15% could have a more degraded condition; 55% will remain in their current condition. Meadow hydrologic function has the greatest potential for increased downward trend and least potential for improvement. Of the 41 meadows found to currently have hydrologic function alteration (237 evaluated), about 24% are projected to have improved condition, 63% should remain in the same condition, and about 12% could have a downward trend.</p> <p>Past and present grazing from production livestock and pack stock is the largest contributor to meadow hydrologic function alteration. Although it is assumed that grazing would continue at the same levels and in the same locations as in recent years, this is the only alternative where grazing would not be limited to certain meadows or limited by number of stock nights. Therefore, grazing could occur in almost any of the 1,500 meadows and grazing numbers could increase or decrease in almost any meadow.</p>
Alternative 2 – Modified	<p>Water quality is thought to be good and will remain so except at few very local areas where there may be slight degradation. There will remain areas of local soil erosion, bare soil and sedimentation into surface water from pack stock grazing, campsites and trails. There would be a very minor reduction of bare, compacted soil and sedimentation into surface water from designating stock holding camps, reducing the number of meadows where grazing is allowed, and limiting grazing stock nights in all meadows where grazing is allowed. Of 60 streams found to be functional at risk, (151 evaluated) it is estimated that 42% could have improved condition, about 1% could have a more degraded condition; about 57% should remain functional at risk. Meadow hydrologic function has some potential for improvement. Of the 41 meadows found to currently have hydrologic function alteration (230 evaluated), about 22% could have improved condition, 65% should remain in the same condition, and about 13% could have a downward trend.</p> <p>Past and present grazing from production livestock and pack stock is thought to be the largest contributor to meadow hydrologic function alteration. Unlike Alternative 1, Alternatives 2-4 limit grazing to those meadows that have been analyzed and designated as suitable for grazing. Under Alternative 2 – Modified, meadows where streams are rated non-functional or functional at-risk with a downward trend are rested for grazing until conditions improve enough to support use. The two exceptions are Jackson Meadow and Purple Meadow. Jackson Meadow has portions where streams were rated functional at-risk, but those sections would be closed to grazing and the segments with streams at PFC would be grazed. Purple Meadow, where the stream was rated functional at-risk with a downward trend in 2001, showed an upward trend in 2004 and 2005. Therefore, it is determined to be resilient and able to support about 1/3 of the grazing that it experienced in the past. This alternative also limits grazing in those suitable meadows to a given number of stock nights. The restriction of grazing to meadows found to be suitable for grazing and not highly vulnerable to impacts should limit future adverse grazing impacts.</p>
Alternative 2	<p>Water quality is thought to be good and will remain so except at few very local areas where there may be slight degradation. There will remain areas of local soil erosion, bare soil and sedimentation into surface water from pack stock grazing, campsites and trails. There would be a very minor reduction of bare, compacted soil and sedimentation into surface water from designating stock holding camps, reducing the number of meadows where grazing is allowed, and limiting grazing stock nights in all meadows where grazing is allowed. Of 60 streams found to be functional at risk, (151 evaluated) it is estimated that 36% could have improved condition, 2% could have a more degraded conditions; 62% will remain functional at risk. Meadow hydrologic function has some potential for improvement. Of the 93 meadows found to currently have hydrologic function alteration (230 evaluated), about 21% could have improved condition, 66% should remain in the same condition, and about 13% could have a downward trend.</p> <p>Past and present grazing from production livestock and pack stock is the largest contributor to meadow hydrologic function alteration. Unlike Alternative 1, Alternatives 2-4 limit grazing to those meadows that have been analyzed and designated as suitable for grazing. They also limit grazing in those suitable meadows to a given number of stock nights. The restriction of grazing to meadows found to be suitable for grazing and not highly vulnerable to impacts should limit future adverse grazing impacts.</p>
Alternative 3	<p>Water quality is generally good and will remain so except at few very local areas where there may be slight degradation. There will remain areas of local soil erosion, bare soil and sedimentation into surface water from pack stock grazing, campsites and trails. Meadow/wetland condition should improve overall relative to Alternative 1. Grazing would be prohibited in meadows that currently contain streams that are functional at-risk with a downward trend. Of 60 streams found to be functional at risk (with any trend), (an estimated 40% could have improved condition, 3% could have a more degraded conditions; roughly 57% will remain functional at risk. There would be a very minor reduction of bare, compacted soil and sedimentation into surface water from designating stock holding camps.</p>

	<p>Meadow hydrologic function has some potential for improvement relative to Alternative 1. Of the 41 meadows found to currently have hydrologic function alteration (237 evaluated), about 29% could have improved condition, 59% should remain in the same condition, and about 12% could have a downward trend.</p> <p>Past and present grazing from production livestock and pack stock is the largest contributor to meadow hydrologic function alteration. Unlike Alternative 1, Alternatives 2-4 limit grazing to those meadows that have been analyzed and designated as suitable for grazing. They also limit grazing in those suitable meadows to a given number of stock nights. Therefore, Alternative 3 limits the future adverse impacts that could occur to hydrologic and soil resources to a lower intensity and smaller extent relative to Alternative 1. Alternative 3 would have similar impacts as Alternative 2, although there could be slightly more widespread adverse effects from trails and campsites and slightly less widespread adverse effects from grazing in meadows.</p>
Alternative 4	<p>Water quality is assumed to be good and will remain so except at few very local areas where there may be slight degradation. There is a greater potential for local improved water quality relative to Alternative 1. There will remain areas of local soil erosion, bare soil and sedimentation into surface water from pack stock grazing, campsites and trails. Of 60 streams found to be functional at risk, (151 evaluated) an estimated 48% could have improved condition, 0% should have a more degraded conditions; 52% should remain functional at risk. Meadow hydrologic function has the second highest potential for improvement of the five alternatives. Of the 41 meadows found to currently have hydrologic function alteration (237 evaluated), about 37% could have improved condition, 61% should remain in the same condition, and about 2% could have a downward trend. There would be a minor reduction of bare, compacted soil and sedimentation into surface water from designating stock holding and spot/dunnage camps.</p> <p>Past and present grazing and activities associated with grazing (trailing, stock movement) from production livestock and pack stock is the largest contributor to meadow hydrologic function alteration. Unlike Alternative 1, Alternatives 2-4 limit grazing to those meadows that have been analyzed and designated as suitable for grazing. They also limit grazing in those suitable meadows to a given number of stock nights. Therefore, Alternative 4 limits the future adverse impacts that could occur to hydrologic and soil resources to a lower intensity and smaller extent relative to Alternative 1. Alternative 4 would have similar impacts as Alternatives 2 – Modified, 2, and 3, although there should be slightly less widespread adverse effects from trails, campsites and meadow grazing.</p>
Alternative 5	<p>Water quality is generally good and will remain so except at few very local areas where there may be slight degradation. This alternative has the greatest potential for local improved water quality of the five alternatives. There will remain areas of local soil erosion, bare soil and sedimentation into surface water from campsites and trails. Of 60 streams found to be functional at risk, (151 evaluated) estimated 58% could have improved condition, 0% could have a more degraded conditions; 42% should remain functional at risk. Meadow hydrologic function has the highest potential for improvement, but still only 41% of the degraded meadows are expected to have improved conditions and 2% could still have a downward hydrologic function trend. There would be a minor reduction of bare, compacted soil and sedimentation into surface water from removal of commercial stock holding sites.</p> <p>With removal of all commercial pack stock grazing, there would be the greatest certainty that meadows would experience beneficial effects to soil and hydrologic resources. Overall, there should be slightly less widespread adverse effects from trails, campsites and meadow grazing.</p>
Wildlife	
Common to all Alternatives	<p>Threatened and Endangered Species: Implementation of any Alternatives would not affect the bald eagle and Paiute cutthroat trout or their habitat found within the analysis area. Implementation of Alternatives 1 through 4 may affect but would not adversely affect the Sierra Nevada bighorn sheep. Alternative 5 would not affect the Sierra Nevada bighorn sheep or its habitat.</p> <p>Forest Service Region 5 Sensitive Species: Implementation of Alternatives 1 through 4 may affect individuals of the following species but would not contribute to a trend toward federal listing of any of these species, or lead to a loss of their viability in the planning (analysis) area: Yosemite toad, mountain yellow-legged frog, willow flycatcher, great gray owl, American marten, Pacific fisher, California wolverine, Sierra Nevada red fox, California spotted owl, Townsends big-eared bat, and the pallid bat. Implementation of Alternative 5 would not affect any of these species.</p> <p>Management Indicator Species or Species Group: Implementation of any Alternative would not result in the loss of viability of any other MIS (i.e., Not on the federal threatened, endangered or proposed species list or Forest Service Region 5 sensitive species list) found within the planning (analysis) area.</p> <p>No other federally listed threatened, endangered, proposed, or Forest Service Region 5 sensitive species or their habitat would be affected by implementation of any of the alternatives.</p>
Alternative 1	<p>The majority of 267 Yosemite toad occupied breeding meadows within the AA/JM Wildernesses would likely be unaffected by commercial pack stock use if grazing patterns continue as reported and observed from 2001 through 2004. Eighty-seven of the 267 occupied breeding meadows would be more likely to have commercial pack stock grazing overlap where impacts to Yosemite toad breeding habitats may occur.</p> <p>Actual grazing use overlap and subsequent impacts would be highly variable based on past use with many meadows likely to receive very light to no use, and therefore a high probability of non-substantive impacts to toad breeding habitat. A small percentage of the 87 occupied breeding meadows (likely < 10%) would</p>

	<p>likely have substantive trampling and chiseling impacts from commercial pack stock grazing in Yosemite toad breeding sites. The 20% ground disturbance standard would be implemented to limit the amount of disturbance in critical breeding areas such as streambanks and lakes and ponds where toads may be found. Impacts in Yosemite toad breeding sites could substantially increase if meadows are grazed at maximum forage utilization levels allowed in the Ansel Adams, John Muir, and Dinkey Lakes Wilderness Plan.</p> <p>Gradual implementation of range unsuitable meadow determinations as reasonably foreseeable action per Wilderness Plan direction may reduce the total number of Yosemite toad occupied breeding meadows where grazing impacts would likely occur.</p> <p>Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be impacted if meadows are grazed to maximum allowable forage utilization levels.</p> <p>The alternative allows for the highest level of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it has the least restrictive management control over campsite use, destination impacts such as access and social trails, grazing impacts, and approved system and use trails. All meadows are open to commercial pack stock grazing. Two hundred forty six meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. Four meadows would be closed to grazing. Sixty one meadows with hydrologic functioning problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates. Habitat structural characteristics could be impacted if meadows are grazed to maximum allowable forage utilization levels</p> <p>Mountain yellow-legged frog stream habitat could be potentially impacted at two meadows approved for commercial pack stock grazing.</p> <p>There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on approximately 7 miles of system trail closed to commercial stock as a result of resource concerns, and 102 miles on 94 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if sections with resource impacts begin to re-vegetate, and narrow in width such as where trails course through meadows, and at stream and spring crossing areas.</p> <p>Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.</p>
<p>Alternative 2 – Modified</p>	<p>Alternative 2 – Modified manages for an increased level of protection for Yosemite toad meadow breeding habitats since grazing would be managed to avoid Yosemite toad occupied breeding habitats. Fifty two meadows approved for commercial packer stock grazing overlap with Yosemite toad breeding areas. Thirty four meadows that are approved for grazing in Alternative 1 are either unsuitable (28) for grazing or rested from grazing (6) in this alternative and would have full protection for the breeding habitats. One hundred ninety seven occupied Yosemite toad breeding meadows outside of grazing zones would be fully protected since grazing would be prohibited. Suitable/unsuitable determinations would be implemented immediately.</p> <p>The alternative allows for some level of control of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it designates overnight stock holding camps, implements destination quotas that would limit destination impacts such as access and social trails, grazing impacts. All meadows outside of grazing zones are closed to commercial pack stock grazing. One hundred forty three meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. A subset of 110 meadows would be closed to grazing as a result of unsuitable for grazing determinations. Thirty four meadows with hydrologic functioning problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates.</p> <p>Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be impacted if meadows are grazed to maximum allowable use levels.</p> <p>Mountain yellow-legged frog stream habitat could be potentially impacted at one meadow approved for commercial pack stock grazing.</p> <p>There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on 73 miles of system trail not suitable for commercial stock, and 80 miles on 82 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if impacted sections narrow in width such as where trails course through meadows, and at stream and spring crossing areas.</p> <p>Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.</p>
<p>Alternative 2</p>	<p>Alternative 2 manages for an increased level of protection for occupied Yosemite toad meadow breeding habitats. Fifty-six meadows approved for commercial packer stock grazing overlap with Yosemite toad breeding areas. Thirty meadows that are approved for grazing in Alternative 1 are unsuitable for grazing in this alternative and would have full protection for the breeding habitats. A 5% critical area maximum allowable disturbance standard would be implemented in all other Yosemite toad breeding habitat areas where commercial pack stock grazing would be approved to minimize trampling and chiseling effects to the breeding habitats.</p>

	<p>and minimize the potential for stock trampling of metamorph toads. Suitable/unsuitable determinations would be implemented immediately.</p> <p>The alternative allows for some level of control of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it designates overnight stock holding camps, implements destination quotas that would limit destination impacts such as access and social trails, grazing impacts. All meadows outside of grazing zones are closed to commercial pack stock grazing. One hundred thirty nine meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. A subset of 108 meadows would be closed to grazing as a result of unsuitable for grazing determinations. Forty one meadows with hydrologic functioning problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates.</p> <p>Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be impacted if meadows are grazed to maximum allowable use levels.</p> <p>Mountain yellow-legged frog stream habitat could be potentially impacted at one meadow approved for commercial pack stock grazing.</p> <p>There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on 73 miles of system trail not suitable for commercial stock, and 80 miles on 82 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if impacted sections narrow in width such as where trails course through meadows, and at stream and spring crossing areas.</p> <p>Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.</p>
<p>Alternative 3</p>	<p>Alternative 3 manages for an increased level of protection for Yosemite toad meadow breeding habitats. Fifty-three meadows approved for commercial packer stock grazing overlap with Yosemite toad breeding areas. Thirty three meadows that are approved for grazing in Alternative 1 are either unsuitable (32) for grazing or rested from grazing (1) in this alternative and would have full protection for the breeding habitats. A 5% critical area maximum allowable disturbance standard would be implemented in all other Yosemite toad breeding habitat areas where commercial pack stock grazing would be approved to minimize trampling and chiseling effects to the breeding habitats, and minimize the potential for stock trampling of metamorph toads. Suitable/unsuitable determinations would be implemented immediately.</p> <p>The alternative allows for some level of control of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it designates overnight stock holding camps, implements destination quotas that would limit destination impacts such as access and social trails, grazing impacts. All meadows outside of grazing zones are closed to commercial pack stock grazing. One hundred forty three meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. A subset of 110 meadows would be closed to grazing as a result of unsuitable for grazing determinations. Thirty four meadows with hydrologic functioning problems that are impacting MIS wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates.</p> <p>Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be impacted if meadows are grazed to maximum allowable use levels.</p> <p>Mountain yellow-legged frog stream habitat could be potentially impacted at one meadow approved for commercial pack stock grazing.</p> <p>There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on 63 miles of system trail not suitable for commercial stock, and 87 miles on 87 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if impacted sections narrow in width such as where trails course through meadows, and at stream and spring crossing areas.</p> <p>Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.</p>
<p>Alternative 4</p>	<p>Alternative 4 manages for an increased level of protection for Yosemite toad meadow breeding habitats. Fifty-six meadows approved for commercial packer stock grazing overlap with Yosemite toad breeding areas. Thirty meadows that are approved for grazing in Alternative 1 are unsuitable for grazing in this alternative and would have full protection for the breeding habitats. A 5% critical area maximum allowable disturbance standard would be implemented in all other Yosemite toad breeding habitat areas where commercial pack stock grazing would be approved to minimize trampling and chiseling effects to the breeding habitats, and minimize the potential for stock trampling of metamorph toads. Suitable/unsuitable determinations would be implemented immediately.</p> <p>The alternative allows for some level of control of potential dispersed impacts to MIS mule deer, yellow warbler, and meadow and meadow edge bird species and their habitats since it designates overnight stock holding camps, implements destination quotas that would limit destination impacts such as access and social trails, grazing impacts. All meadows outside of grazing zones are closed to commercial pack stock grazing. One hundred twenty meadows analyzed are likely to have some level of commercial pack stock grazing use where MIS habitat impacts are most likely to occur. A subset of 138 meadows would be closed to grazing at an unknown future date as a result of unsuitable for grazing determinations. Twenty seven meadows with hydrologic functioning problems that are impacting MIS</p>

	<p>wildlife habitat conditions would continue to be open for grazing where grazing has the potential to exacerbate the problems, or slow restoration rates.</p> <p>Thirteen meadows identified as suitable unoccupied willow flycatcher habitat would be approved for grazing. Habitat structural characteristics could be impacted if meadows are grazed to maximum allowable use levels.</p> <p>Mountain yellow-legged frog stream habitat would not be impacted since all three meadows would be closed to grazing.</p> <p>There would be some potential for a reduced level of human disturbance to MIS wildlife species and habitats on 173 miles of system trail not suitable for commercial stock, and 165 miles on 153 use trails where commercial pack stock would be prohibited. There may be some localized minor level of riparian habitat improvement on these trails, if impacted sections narrow in width such as where trails course through meadows, and at stream and spring crossing areas.</p> <p>Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.</p>
<p>Alternative 5</p>	<p>There would be no commercial pack stock grazing that would overlap with Yosemite toad occupied breeding habitats, or willow Flycatcher and great gray owl meadow suitable unoccupied habitats. Elimination of human and pack stock disturbance on trails, camps, and grazing areas associated with commercial pack stock operations would improve MIS mule deer, yellow warbler, meadow and meadow edge bird guild species habitats, as well as use of these habitats by these species.</p> <p>Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas. Other user groups would likely continue to use campsites, trails, and destinations and possibly hinder rehabilitation of impacted areas of habitat, as well as maintain some level of human disturbance impacts to wildlife species in these areas.</p>
<p>Vegetation</p>	
<p>Alternative 1</p>	<p>Grazing Resources: The area used by commercial pack stock would be a minor portion of the total wilderness area, but not limited to grazing zones. The direct, indirect, and cumulative effects of stock use on vegetation would not be visible and may not be measurable at the wilderness or geographic scale. These effects could be measurable and visible at the analysis unit scale and would be measurable and visible at the site specific scale, and especially in the analysis units and at those sites with substantial vegetation areas still recovering from past chronic and cumulative adverse impacts due to the impacts of historical uses such as production livestock grazing, water diversion, or mining. These include the Glacier Divide, Silver Peak, Cora, Sadler, Triple Divide, Lillian, Rush Creek, Fish Creek, McGee, Hilton, Cascade Valley, Pioneer, Graveyard, Hooper, and Silver Divide Analysis Units. The vegetative resources could trend away from desired conditions, over the long-term, at an estimated 37 of the locations visited during this project with implementation of Alternative 1.</p> <p>There would be increased adverse impacts with Alternative 1 over the other alternatives and opportunities for vegetative recovery in fewer locations. The degradation of these riparian areas would become more noticeable over the long-term and many areas with current patterns of repeated use would eventually have to be closed to grazing.</p> <p>Sensitive and Watch List Plants: Individual sensitive or watch list plants may be affected by commercial and private pack stock activities, hiker use, and trail management activities; however, these impacts would be minor, local, and short-term. There are some long-term moderate to severe impacts to sensitive plant habitat regionally from historic grazing that would be somewhat less likely to recover under this alternative.</p> <p>Under this alternative, the trails would be at the highest trail classes of any alternative, and the trail classes least matched to use, so the impacts to rare plants from trail maintenance and to some extent trail use, although slight, would be greatest of any alternative. There would be less possibility of impacts from avoidance of trail obstacles than in the other alternatives if maintenance actually matches trail class. Any trail impacts would be local, minor, and short-term.</p> <p>More meadows (527) with potential habitat for sensitive riparian species would be open for use under this alternative than any of the others. Sixteen of the meadows with potential habitat were found to have degraded conditions, mostly due to historic cattle and sheep grazing, and would remain degraded more than under Alternatives 4 and 5.</p> <p>Firewood: As in Alternatives 4 and 5, there would be no firewood brought in from outside the wilderness, eliminating risk of introducing pathogens and weed seeds from this source.</p> <p>Fens: A greater number of meadows with fens or fen characteristics (17) would remain in degraded conditions in this alternative than any other and the allowable trampling (20 percent) would be higher than in Alternatives 2, 3, and 4. The trampling would most likely be a local, minor, short-term effect, but degraded hydrologic conditions are likely to be long-term and more serious.</p> <p>Weeds: There would be some risk of weed introduction from pack stock use, hiker use, and trail maintenance since there are populations of weeds at trailheads and pack stations. This risk is about the same as Alternative 2 -Modified, 3, and 4, but higher than Alternative 5. Weed effects are generally long-term, but the severity and extent of negative impacts is site dependent.</p>

<p>Alternative 2 – Modified</p>	<p>Grazing Resources: The areas used by commercial pack stock are a minor portion of the total wilderness area and limited to grazing zones. The direct, indirect, and cumulative effects of stock use would not be visible and may not be measurable at the wilderness or geographic scale. These effects could be measurable and visible at the analysis unit scale and would be measurable and visible at the site-specific scale. The vegetative resources in most locations are expected to be maintained at or toward desired conditions. The vegetative resources could trend away from desired conditions, for the long-term, at an estimated 21 of the locations visited during this project.</p> <p>Sensitive and Watch List Plants: Individual sensitive or watch list plants may be affected by commercial and private pack stock activities, hiker use, and trail management activities; however, the effects of these activities would be minor, local, and short-term. There are some long-term moderate to severe impacts to riparian habitat regionally from historic grazing that would be more likely to recover than under Alternative 1.</p> <p>Under this alternative, the trail classes, and associated use and maintenance impacts to sensitive plants, would be lower than Alternatives 1 and 3, but higher than Alternatives 4 and 5, more consistent with use. The possibility of impacts from avoidance of trail obstacles would be higher than Alternative 1, about the same as Alternative 3, and lower than Alternatives 4 and 5. Any trail impacts would be local, minor, and short-term.</p> <p>Fewer meadows (116) with potential habitat for sensitive riparian species would be open for use under this alternative than Alternative 1, but more than under Alternative 5. Grazing use would be similar to Alternative 1 for the most part, but there may be some shifts in use due to meadow closures. Meadows with severe problems would be rested and those for which range readiness is probably never reached over most of the meadow would be closed, so the riparian potential habitat with the highest risks for degradation would not be available for use until recovered. Sixteen meadows with potential habitat for sensitive riparian plants would remain in degraded conditions. The overall effect would be a long-term beneficial reduction in impacts to potential habitat for sensitive riparian species.</p> <p>Fens: In this alternative, fens would be more protected from inadvertent commercial pack stock use than in Alternative 1 because no grazing would be permitted in fens. Fewer meadows with fens or fen characteristics (13) would remain in degraded condition than in Alternative 1, but more than Alternatives 4 and 5. There would be an overall long-term beneficial effects to fens under this alternative.</p> <p>Firewood: This alternative would have less risk of weed introduction than Alternatives 2 and 3 because of the use of charcoal. Adjustments in elevation closures at specific sites to reflect actual availability of firewood should protect subalpine soils and vegetation better than, or at least as well as, Alternative 1. Case-by-case approval of other campfire use could have a minimal negative impact on subalpine vegetation and careful monitoring would be required.</p> <p>Weeds: There would be some risk of weed introduction from pack stock use, hiker use, and trail maintenance since there are populations of weeds at trailheads and pack stations. This risk is about the same as Alternative 1, 2, 3, and 4, but higher than Alternative 5. If weeds were introduced, the effects would be long-term, moderate to severe, and although beginning locally, could easily become widespread.</p>
<p>Alternative 2</p>	<p>Grazing Resources: The areas used by commercial pack stock are a minor portion of the total wilderness area and limited to grazing zones. The direct, indirect, and cumulative effects of stock use would not be visible and may not be measurable at the wilderness or geographic scale. These effects could be measurable and visible at the analysis unit scale and would be measurable and visible at the site-specific scale. The vegetative resources in most locations are expected to be maintained at or to trend toward desired conditions. With implementation of Alternative 2, the vegetative resources could trend away from desired conditions, for the long-term, at an estimated 21 of the locations visited during this project.</p> <p>Sensitive and Watch List Plants: Individual sensitive or watch list plants may be affected by commercial and private pack stock activities, hiker use, and trail management activities; however, the effects of these activities would be minor, local, and short-term. There are some long-term moderate to severe impacts regionally from historic grazing that would be more likely to recover than under Alternative 1.</p> <p>Under this alternative, the trail classes, and associated use and maintenance impacts to sensitive plants, would be lower than Alternatives 1 and 3, but higher than Alternatives 4 and 5. The possibility of impacts from avoidance of trail obstacles would be higher than Alternative 1, about the same as Alternative 3, and lower than Alternatives 4 and 5. Any trail impacts would be local, minor, and short-term.</p> <p>Fewer meadows (116) with potential habitat for sensitive riparian species would be open for use under this alternative than Alternative 1, but more than under Alternative 5. Grazing use would be similar to Alternative 1 for the most part, but there may be some shifts in use due to meadow closures. Meadows with severe problems (and those for which range readiness is probably never reached over most of the meadow) would be closed, so the riparian potential habitat with the highest risks for degradation would be closed. Sixteen meadows with potential habitat for sensitive riparian plants would remain in degraded conditions. The overall effect would be a long-term beneficial reduction in impacts to potential habitat for sensitive riparian species.</p> <p>Firewood: Under this alternative, there would be the highest risk of the introduction of pathogens and/or weed seeds on firewood brought in from outside the wilderness and increased unauthorized gathering of wood and campfires by non-packer clients. Any campsite used by pack stock clients in the fire closure zone (up to 450 campsites) would be open for campfires with packed-in wood. If pathogens or weeds were introduced, the effects would be long-term, moderate to severe, and although beginning locally, could easily become widespread.</p> <p>Fens: In this alternative and Alternatives 3 and 4, fens would be more protected from inadvertent commercial pack stock use than in Alternative 1 because of the 5</p>

	<p>percent trampling limit. Fewer meadows with fens or fen characteristics (16) would remain in degraded condition than in Alternative 1, but more than Alternatives 4 and 5. There would be overall long-term beneficial effects to fens under this alternative.</p> <p>Weeds: There would be some risk of weed introduction from pack stock use, hiker use, and trail maintenance since there are populations of weeds at trailheads and pack stations. This risk is about the same as Alternative 1, 3, and 4, but higher than Alternative 5. If weeds were introduced, the effects would be long-term, moderate to severe, and although beginning locally, could easily become widespread.</p>
Alternative 3	<p>Grazing Resources: The areas used by commercial pack stock are a minor portion of the total wilderness area and limited to grazing zones. The direct, indirect, and cumulative effects of stock use would not be visible and may not be measurable at the wilderness or geographic scale. These effects could be measurable and visible at the analysis unit scale and would be measurable and visible at the site-specific scale. The vegetative resources in most locations are expected to be maintained at or to trend toward desired conditions. With implementation of Alternative 2, the vegetative resources could trend away from desired conditions, for the long-term, at an estimated 21 of the locations visited during this project.</p> <p>Sensitive and Watch List Plants: Individual sensitive or watch list plants may be affected by commercial and private pack stock activities, hiker use, and trail management activities; however, the effects of these activities would be minor, local, and short-term. There are some long-term moderate to severe impacts regionally from historic grazing that would be more likely to recover than under Alternative 1.</p> <p>Under this alternative, the trail classes, and associated use and maintenance impacts to sensitive plants, would be lower than Alternatives 1 and 3, but higher than Alternatives 4 and 5. The possibility of impacts from avoidance of trail obstacles would be higher than Alternative 1, about the same as Alternative 3, and lower than Alternatives 4 and 5. Any trail impacts would be local, minor, and short-term.</p> <p>Fewer meadows (116) with potential habitat for sensitive riparian species would be open for use under this alternative than Alternative 1, but more than under Alternative 5. Grazing use would be similar to Alternative 1 for the most part, but there may be some shifts in use due to meadow closures. Meadows with severe problems (and those for which range readiness is probably never reached over most of the meadow) would be closed, so the riparian potential habitat with the highest risks for degradation would be closed. Sixteen meadows with potential habitat for sensitive riparian plants would remain in degraded conditions. The overall effect would be a long-term beneficial reduction in impacts to potential habitat for sensitive riparian species.</p> <p>Firewood: Under this alternative, there would be the highest risk of the introduction of pathogens and/or weed seeds on firewood brought in from outside the wilderness and increased unauthorized gathering of wood and campfires by non-packer clients. Any campsite used by pack stock clients in the fire closure zone (up to 450 campsites) would be open for campfires with packed-in wood. If pathogens or weeds were introduced, the effects would be long-term, moderate to severe, and although beginning locally, could easily become widespread.</p> <p>Fens: In this alternative and Alternatives 3 and 4, fens would be more protected from inadvertent commercial pack stock use than in Alternative 1 because of the 5 percent trampling limit. Fewer meadows with fens or fen characteristics (16) would remain in degraded condition than in Alternative 1, but more than Alternatives 4 and 5. There would be overall long-term beneficial effects to fens under this alternative.</p> <p>Weeds: There would be some risk of weed introduction from pack stock use, hiker use, and trail maintenance since there are populations of weeds at trailheads and pack stations. This risk is about the same as Alternative 1, 3, and 4, but higher than Alternative 5. If weeds were introduced, the effects would be long-term, moderate to severe, and although beginning locally, could easily become widespread.</p>
Alternative 4	<p>Grazing Resources: The areas used by commercial pack stock are a minor portion of the total wilderness area and limited to grazing zones. The direct, indirect, and cumulative effects of stock use would not be visible and may not be measurable at the wilderness or geographic scale. These effects could be measurable and visible at the analysis unit scale and would be measurable and visible at the site-specific scale. The vegetative resources in most locations are expected to be maintained at or to trend toward desired conditions. The vegetative resources could trend away from desired conditions, for the long-term, at an estimated 20 of the locations visited during this project.</p> <p>Sensitive and Watch List Plants: Individual sensitive or watch list plants may be affected by commercial and private pack stock activities, hiker use, and trail management activities; however, the impacts of these activities would be minor, local, and short-term for the most part. There would be more restrictions on use in this alternative than Alternatives 1, 2, and 3, so there could be some use displaced to adjacent lands (outside wilderness, National Parks, or other National Forests) where there are populations or potential habitat for these sensitive plants, but most of these populations are either on National Parks or National Forests, so there would be protection. Displacement of use would be less likely than in Alternative 5.</p> <p>Under this alternative, the trail classes, and associated maintenance, would be the lowest of any of the alternatives. However, there would be pack stock use, which there would not be in Alternative 5. There would be more risk from avoidance of trail obstacles than in the other alternatives because of the low maintenance levels. Trail impacts would be minor, local, and most likely short-term.</p> <p>Fewer meadows (116) with potential habitat for sensitive riparian species would be open for use under this alternative than Alternative 1, but more than under Alternative 5. More meadows would be closed to grazing than in Alternatives 2 and 3, so there may be more shifts in use to meadows not currently used. Meadows</p>

	<p>with moderate to severe problems (and those for which range readiness is probably never reached) would be closed, so the riparian potential habitat for sensitive and watch list plants with the highest risks for degradation would be closed to commercial pack stock. Thirteen meadows with potential habitat for sensitive riparian species would remain in degraded conditions. There would be more local long-term beneficial effects of closing meadows than in Alternatives 1, 2, and 3, but there would still be some meadows with negative effects from pack stock use that would remain degraded.</p> <p>Firewood: As in Alternatives 1 and 5, there would be no firewood brought in from outside the wilderness, eliminating risk of introducing pathogens and weed seeds from this source.</p> <p>Fens: Under this alternative, fewer fens would be at risk of degrading and more degraded fens would begin recovery than in Alternatives 1, 2, and 3. Fifteen meadows with fens or fen characteristics would remain in degraded conditions. There would be less protection than in Alternative 5, since most of the risk to fens is from commercial pack stock.</p> <p>Weeds: There would be some risk of weed introduction from pack stock use, hiker use, and trail maintenance since there are populations of weeds at trailheads and pack stations. This risk is about the same as Alternative 1, 2, and 3 but higher than Alternatives 5.</p>
<p>Alternative 5</p>	<p>Grazing Resources: No areas of the wilderness would be used by commercial pack stock. The direct, indirect, and cumulative beneficial effects due to increased vegetative seral status would not be visible and may not be measurable at the wilderness or geographic scale. These beneficial effects could be measurable and visible at the analysis unit scale and would be measurable and visible at the site-specific scale. The vegetative resources in most locations are expected to be maintained at or to trend toward desired conditions. The vegetative resources could trend away from desired conditions, for the long-term, at an estimated 18 of the locations visited during this project.</p> <p>Sensitive and Watch List Plants: There would be no commercial pack stock impacts, but private stock use would continue and could increase. Individual sensitive or watch list plants may be affected by private pack stock, hiker use, and trail management activities; however, these activities would not cause a trend toward listing in this or any other alternative.</p> <p>Under this alternative, the trail classes, and associated maintenance impacts to sensitive plant populations and habitat, would be lower than Alternatives 1, 2, and 3, but slightly higher than Alternative 4, and maintenance needs would be less because of the removal of commercial pack stock. There would be the possibility of impacts from avoidance of obstacles by hikers and private pack stock, but the risk would be less than Alternative 4.</p> <p>There would be no commercial pack stock impacts to sensitive plants or their habitat in meadows in the Ansel Adams and John Muir Wildernesses. There could be some pack stock use displaced to locations outside of these wilderness areas on the Forests, National Parks, or other adjacent lands, where there are populations of these sensitive plants or potential habitat.</p> <p>Firewood: As in Alternatives 1 and 4, there would be no firewood brought in from outside the wilderness, eliminating the risk of introducing pathogens and weed seeds from this source.</p> <p>Fens: Since most of the risk to fens is from commercial pack stock, Alternative 5 would provide the best protection for fens, but there still could be impacts from private stock use. Five meadows with fens or fen characteristics that have degraded conditions would continue to have degraded conditions.</p> <p>Weeds: Commercial pack stock would no longer be a possible vector for weed distribution into the wilderness from the pack stations or other populations in and near the wilderness, so this alternative would have the lowest risk of weed expansion in the wilderness.</p>

Understanding and using the attached Trail Tables (Tables 2.26 and 2.27):

System Trail Tables:

The System Trail tables list all trails which are included in any of the past or potential trail inventories for all five alternatives. These tables are listed separately by forest. If a trail is considered part of the transportation system in an alternative, it is designated with a Trail Class from 1-4. If it is NOT on the system in an alternative, it will have a “0” in the Trail Class column.

Multiple segments of some trails are listed in order to capture changes in potential actions which vary along the length of trail. For instance, in one alternative only a short section of trail may be on the system, whereas in another alternative, an additional length of trail may be included in the system. Other trails may have multiple trail classes at different points along the trail. In some cases, multiple segments are shown where the trail crosses a wilderness or forest boundary.

Trails with an NS behind the Trail Class (for example: 2 NS) indicate that this section of trail is “Not Suitable for Commercial Stock”. An asterisk attached to the NS (for example: 2 NS*), indicates that the trail is “Not Suitable for Commercial Stock” until repaired.

A trail number is shown after the trail name. This is the designated trail system number, and in most cases is the same or similar to numbers assigned to each trail in past inventories. Some trail numbers or names may have changed as the trail networks have been reviewed.

A reference number is used to distinguish segments of a trail.

Use Trail Table

All use trails or routes which have been addressed in any of the alternatives are listed in this table. Trails are generally listed as either “A” as approved or “P” as prohibited. When there is an asterisk in the approval column, it refers to a clarifier in the far right column. Some of these stipulations apply to just some of the alternatives. Additionally, some of these trails were not addressed as use trails in this alternative, but instead were listed as system trails in the system trail table under this alternative. Trails listed as N/A had not been addressed in the proposed action, either because they were overlooked, or criteria regarding which trails were being addressed have slightly changed.

Numerical Discrepancies:

Slight discrepancies in trail mileages or other numbers may occasionally occur within this document for a variety of reasons. Some variance occurs simply as a result of rounding numbers. Trail mileages – especially on trails that have not been recently surveyed – may be estimated, derived from old inventories, or measured from GIS information that has not been verified on the ground. Certain trails were split into segments based on changes in proposed actions, leading to further estimating and potential errors. During the multi-year analysis process and while writing this document, various updates and corrections have been made to some mileages of specific trails, and these changes may not have been carried through the document.

Where discrepancies have been detected, they have been of an inconsequential scale, and do not affect the actions on described segments of trail or geographic features. As more trails are accurately inventoried during future survey efforts, corrected mileages will be entered into inventory databases. Over time, these corrections will likely change mileages and other numbers listed in the various tables in this document.

Table 2.27 Use Trails

Ref #	Use Trail Name	UT ID#	Est. Miles	Alt 1	Alt 2 Mod	Alt 2	Alt 3	Alt 4	Stipulation/Clarifier
Ansel Adams East									
UT 1	Lower Rainbow Falls (bench south of Rainbow Falls,	CCD02	1.75	A	P	P	P	P	
UT 2	Lion Point Trail to creek 3/4 mile east (Old French Trail)	CCD04	0.66	A	A	A	A	P	For hunting season only
UT 3	Deer Lake Camp spur	CCD08	0.23	A	A	A	A	A	Inherent Camp Trail
UT 4	Holcomb Lake - from outlet Holcomb to grazing area west of Holcomb	KNG01	0.30	SYS	P	P*	P*	P	* until use trail is stabilized or rerouted
UT 5	Deadhorse Lake	MIN01	0.61	SYS	P	P	P	P	
UT 6	San Joaquin Peak	RIH01	2.83	A	A	A*	SYS	P	For hunting season only
UT 7	Badger Lake Meadow	RIH02	0.25	A	A	A	A	A	Grazing Access
UT 8	Crest Creek	RUS01	1.89	A	A	A	A	P	For hunting season only
UT 9	Lost Lake	RUS02	1.69	A	A	A	A	P	For hunting season only
UT 10	Weber to Sullivan Lake	RUS03	0.34	P	P	P	P	P	
UT 11	Crest Creek bypass	RUS08	1.45	P	P	P	P	P	
UT 12	Clarice Lake (from the John Muir Trail)	SHE01	0.19	A	A*	A	P	P	*Approved for limited use.
UT 13	Upper Ediza Use Trail - to meadows west of lake	SHE05	0.37	P	P	P	P	P	
UT 14	Garnet campsite to Emerald Lake (former John Muir trail)	THI01	1.22	A	SYS*	P	SYS	P	*NSCS
UT 15	Trail to grazing at inlet of Garnet Lake	THI02	0.69	A	P	P	P	P	
UT 16	Marie Lakes meadow (grazing access, Donohue camp to Marie Mdw)	URU02	0.38	A	P	P	P	P	
UT 17	Upper Davis Lake	URU04	0.82	P	P	P	P	P	
UT 18	Davis Lake to Rodgers Lake (grazing access)	URU05	0.62	A	A*	A	A*	P	*Identify best route to grazing.
Ansel Adams West									
UT 19	Rock Creek Trail to Rube Meadow Trail along Rock Creek	ARC01	0.96	P	A	A	A	P	
UT 20	"No name"/"Tule" Lake	ARC02	0.55	P	A	A	A	A	
UT 21	Rockbound Lake	BEC01	1.68	A	P	P	P	P	

Ref #	Use Trail Name	UT ID#	Est. Miles	Alt 1	Alt 2 Mod	Alt 2	Alt 3	Alt 4	Stipulation/Clarifier
UT 22	Straube/Spano Meadow to Iron Lake trail	CAR01	1.89	A	A	A	A	P	
UT 23	East Fork Cargyle Creek	CAR02	1.71	P	P	P	P	P	
UT 24	Lost Lake (Stevenson Tr. To Lost Lake)	COR01	0.84	P	A	NA	A	P	
UT 25	Pine Flat	JUN01	1.28	A	A	A	A	A	
UT 26	Dike Creek	LAC01	0.51	A	A	A	A	A	
UT 27	Fernandez Pass Trail to Fernandez Lake	LIL02	0.53	A	A	A	A	P	
UT 28	Flat to Monument Lakes	LIL04	0.39	P	A	A	A	P	
UT 29	Onion Springs road to John Muir Wilderness boundary east of Saddle Mtn	ONS01	3.56	A	A	A	A	P	For hunting season only
UT 30	Devil's Bathtub Cutoff	ONS02	1.81	P	A	A	A	A	(1 hour trail ride)
UT 31	Saddle Mountain Cutoff (shortcut from packstation to approved use trail)	ONS03	1.96	P	P	NA	P	P	
UT 32	High Sierra Pack Station to Twin Meadow	ONS04	1.37	P	A	A	A	P	Onion Springs Road to Devil's bathtub trail
UT 33	Trail to Staniford Lake over saddle from Lillian Trail near Vandenberg.	STA01	0.27	A	P	P	P	P	Allow access via Lillian Lake Loop system trail.
UT 34	Anne Lake Grazing (north of lake)	TRD01	0.18	P	A	A	A	A	
UT 35	Post Creek to Timber Creek Trail.	TRD02	1.37	P	A	A	A	P	Low use to avoid well-defined trail forming.
UT 36	Post Creek (Post Creek Trail 24E17 to campsite #31 elev. 9045)	TRD04	0.32	P	A	NA	A	P	
Bishop/Humphreys									
UT 37	Hurd Lake	BIS02	0.42	A	A	A	A	A	
UT 38	Ledge Lake (past Saddlerock)	BIS03	0.27	P	P	P	P	P	
UT 39	Long Lake camp spur	BIS04	0.27	A	A	A	A	A	
UT 40	Margaret Lakes	BIS06	0.38	P	P	P	P	P	
UT 41	Ruwau Lake (from Bishop Pass trail to upper/south side of lake)	BIS07	0.17	P	P	P	P	P	
UT 42	Timberline Tarn	BIS08	0.07	A	P	P	P	P	
UT 43	Saddlerock Lake campsites	BIS09	0.18	A	A	A	A	P	Only to camps, not to Ledge Lake
UT 44	Bishop Pass trail bypass (old Bishop Pass Trail at lower canyon)	BIS10	0.41	P	P	P	P	P	
UT 45	Eastern/Northern trail paralleling Merriam Creek	FRE02	1.02	P	P	P	P	P	West/Southern of two routes is system trail.

Ref #	Use Trail Name	UT ID#	Est. Miles	Alt 1	Alt 2 Mod	Alt 2	Alt 3	Alt 4	Stipulation/Clarifier
UT 46	Upper Merriam (from meadow to lake)	FRE03	0.59	A	P	P	P	P	
UT 47	Shepherd Lake (Lower French Cyn)	FRE07	1.58	A	P	NA	P	P	
UT 48	Merriam Lake to La Salle Lake	FRE08	1.28	P	P	P	P	P	
UT 49	Royce Lake	FRE11	2.48	A	A	A	A	P	
UT 50	L Lake to Steelhead Lake (from Moon Lake Trail on east side of L Lake)	FRE16	1.19	P	P	NA	P	P	
UT 51	Steelhead Lake to junction in French Canyon	FRE18	1.25	P	P	P	P	P

Table 2.28 Trail Management Strategy by Trail Class – Ansel Adams and John Muir Wildernesses

Trail Attributes	Trail Class 1 ¹ Minimal/Undeveloped Trail	Trail Class 2 Simple/Minor Development Trail	Trail Class 3 Developed/Improved Trail	Trail Class 4 Highly Developed Trail	Trail Class 5 – Not Appropriate in Wilderness
Tread, Traffic Flow, Character	<ul style="list-style-type: none"> ♦ Tread generally followable, but may have sections that are intermittent, awkward or hard to follow. ♦ Minimal excavated tread – typically only to define managed route or to allow passage in steep terrain. ♦ Commonly steep for long sections**. ² ♦ Short segments may require route finding between defined sections Native materials	<ul style="list-style-type: none"> ♦ Tread readily discernible, graded, and continuous, but occasionally narrow and rough. ♦ In severe terrain may be wider and more developed to accommodate traffic. ♦ Some steep sections**, usually for short to moderate distances. ♦ Few or no constructed passing sections. ♦ Native materials 	<ul style="list-style-type: none"> ♦ Tread obvious and continuous. ♦ In severe terrain may be wider and more developed to accommodate traffic. ♦ Width accommodates unhindered one-lane travel with occasional constructed passing sections. ♦ Some steep sections**, typically for short segments. ♦ Native materials 	<ul style="list-style-type: none"> ♦ Tread wide and relatively smooth with few irregularities. ♦ Trailbed width may frequently accommodate two-lane travel to allow for frequent passing. ♦ Very few steep sections – typically well-graded. Native materials	
Constructed Features & Trail Elements	<ul style="list-style-type: none"> ♦ Minimal to non-existent ♦ Drainage is functional ♦ In-tread structures minimal, but as needed to protect resources and maintain drainage. ♦ Few or no constructed bridges or foot crossings, except minimum needed to protect resources. 	<ul style="list-style-type: none"> ♦ Structures are of limited size, scale, and number ♦ Drainage is functional ♦ Structures as needed to protect trail infrastructure and resources and maintain drainage. ♦ Primitive or simple constructed foot crossings and fords. 	<ul style="list-style-type: none"> ♦ Trail structures (walls, steps, drainage, raised trail) may be common and substantial ♦ Native trail bridges as needed for resource protection and to provide access appropriate to destination. Generally native materials used in wilderness, but engineered bridges may be appropriate as determined by further analysis ³	<ul style="list-style-type: none"> ♦ Trail structures frequent and substantial ♦ Trail bridges appropriate at water crossings. Generally native materials used in wilderness, but engineered bridges may be appropriate as determined by further analysis ⁴	

¹ Trail Class 1 Trails typically receive very low use by highly skilled wilderness travelers. TC-1 trails are the most primitive designed and managed trails, and may have features which are awkward or impractical for some users. Both stock and hikers may be present and managed on Class 1 trails.

² Grade variances are typically based upon consideration of soil type, hydrologic conditions, anticipated use levels, and other factors contributing to surface instability and erosion potential. Due to increased potential for rapid degradation of trail and connected resources, trails are not intentionally aligned at steeper trail grades in areas with high levels or numbers of risk factors.

³ Designed, non-native trail bridges would only be appropriate under exceedingly rare instances in wilderness, and would require further analysis to determine their appropriateness within wilderness. Native materials or those most in keeping with the natural environment will be preferred.

⁴ Designed, non-native trail bridges would only be appropriate under exceedingly rare instances in wilderness, and would require further analysis to determine their appropriateness within wilderness. Native materials or those most in keeping with the natural environment will be preferred.

Trail Attributes	Trail Class 1 Minimal/Undeveloped Trail	Trail Class 2 Simple/Minor Development Trail	Trail Class 3 Developed/Improved Trail	Trail Class 4 Highly Developed Trail
Obstacles	<ul style="list-style-type: none"> Awkward sections common Obstacles, such as logs, rocks, narrow passages may be present, in some cases requiring occasional dismount and/or high skill levels. Physical barriers, such as downed logs or rocks, when cleared, should allow passage for packs or saddles if either pack or saddle use may be present, to ensure that allowed use stays on trail alignment. Light vegetation likely encroaches into trailway – cleared primarily to define trail. 	<ul style="list-style-type: none"> Awkward sections occasionally present. Blockages cleared to define route and protect resources Physical barriers, such as downed logs or rocks, when cleared, allows for ready passage for packs or saddles if either pack or saddle use may be present. Light vegetation may encroach into trailway, 	<ul style="list-style-type: none"> Obstacles and awkward surfaces infrequent Trail is maintained to allow relatively easy travel by allowed use types. Vegetation removed to allow clear and open passage by all user types. 	<ul style="list-style-type: none"> Few or no notable obstacles exist Vegetation removed to allow clear and open passage by all user types.
Signs	<ul style="list-style-type: none"> Minimum required for basic direction at junctions. Generally limited to regulation and resource protection No destination signs present 	<ul style="list-style-type: none"> Minimum required for basic direction at junctions. Generally limited to regulation and resource protection Typically no destination signs present Basic informational signing at trailheads. 	<ul style="list-style-type: none"> Regulation, resource protection, user reassurance.⁵ Directional signs at junctions, or when confusion is likely. Destination signs rarely present Informational and interpretive signs may be present (outside of wilderness) 	<ul style="list-style-type: none"> Wide variety of signs likely present to manage large number of users. Informational and interpretive signs likely (outside of wilderness) Destination signs rarely present
Typical Recreation Setting & Environs	<ul style="list-style-type: none"> Natural, unmodified Could occur in any recreation category, but most commonly accesses more primitive recreation areas. 	<ul style="list-style-type: none"> Natural, essentially unmodified Potentially occurs in any recreation category, but typically accesses destinations with moderate use and management. 	<ul style="list-style-type: none"> Natural, slightly modified Most common in higher use travel corridors or leading to high use destinations with higher management. 	<ul style="list-style-type: none"> Relatively modified setting Only present in areas with very high use and intensive management. Rarely present in wilderness.

⁵ User reassurance markers will generally not be used on trails in the AA/JM Wildernesses unless exceptional confusion may exist. The PCT requires a high-level of user-consideration, and tends to have slightly more signs than other trails, including the use of “reassurance markers” where there is potential confusion about the desired route. In wilderness, these will be kept to a minimum. A PCT marker may be placed along the PCT on either side of a junction within the first 200 yards, then no more than 3 per mile if confusion with other trails or disturbed areas exists.

Trail Operation and Maintenance Considerations

These considerations are general guidelines to assist in developing trail prescriptions and subsequent program management, operations and maintenance. Trail O&M Considerations offer a general starting point and will likely be adapted to reflect financial or local considerations. The guidance outlined below reflects “typical” considerations for trails in different Trail Classes, recognizing that each trail may have a range of characteristics, variability, and unique management considerations.

Trail Attributes	Trail Class 1 Minimal/Undeveloped Trail	Trail Class 2 Simple/Minor Development Trail	Trail Class 3 Developed/Improved Trail	Trail Class 4 Highly Developed Trail
Trail Management	Typically managed to accommodate: Low use levels Highly skilled users, capable of travel off-trail, and following intermittent trails. In rugged terrain, conditions may be challenging and impractical for some trail users.	Typically managed to accommodate: Moderate use levels Mid-to-highly skilled users, capable of traveling over awkward condition/obstacles Users with some orienteering skill (trail may occasionally have confusing alignment). Trail suitable for both equestrians and hikers, but challenging and requiring good trail skills.	Typically managed to accommodate: Moderate to heavy use Users with intermediate skill level and experience Users with minimal orienteering skills (trail easy to follow). Moderately easy travel for managed use types Random potential for accessible use	Typically managed to accommodate: Very heavy use Users with minimal skills and experience Users with minimal or no orienteering skills (trail easy to follow). Relatively easy travel by managed use types
Maintenance Indicators	Resource protection Route definition Safety commensurate with targeted recreational experience	Resource protection Protection of trail infrastructure Safety commensurate with targeted recreational experience	Resource protection Protection of trail infrastructure and travelability of trail. Safety commensurate with targeted recreational experience	Resource Protection Protection of trail infrastructure and travelability of trail. Safety commensurate with targeted recreational experience
Maintenance Frequency & Intensity	Infrequent recurring maintenance – generally exceeds annual interval. Maintenance may not be scheduled except in response to reports of unusual resource problems or obstacles which effectively close the trail to intended use.	Maintenance scheduled to preserve the trail facility and route location. Maintenance interval may exceed one year, or in response to reports of unusual resource or trail problems.	Trail cleared to make available for use early in use season, and to preserve trail integrity. Maintenance interval typically annual or more frequently, or in response to reports of trail or resource damage or problem affecting managed use type and experience level.	Trail cleared to make available for use at earliest opportunity in use season. Typically, maintenance performed at least annually.

Table 2.29 Ansel Adams and John Muir Wilderness Typical Trail Design Targets

Typical Specifications:		Trail Class 1 ⁶	Trail Class 2	Trail Class 3	Trail Class 4	TC 5
Designed Typical Tread Width	Target width	Excavated only to define route or to allow passage on steep terrain. Typically < 12"	12" – 18"	24"	24"	Not Appropriate in Wilderness
	Exceptions	May have sections where trail is intermittent or lightly defined.	May be to 36" at switchbacks, turnpikes, fords and along precipices.	May be to 48" at switchbacks, turnpikes, fords, steep side slopes and precipices.	May be to 48" at switchbacks, turnpikes, fords, steep side slopes and precipices.	
Design Surface	Tread Type	Native, minimal excavation. May have originally been user-created.	Native, w/ moderate excavation and fill.	Native with some native on-site borrow as fill or tread materials.	Native with some native borrow as fill or tread materials.	
	Surface Obstacles	Roots, rocks, embedded logs <18", natural steps or jump-offs <30".	Embedded roots, rocks, logs <12". Occasional natural steps or jump-offs <24".	Generally clear. Occasional tread protrusions to 6", natural steps or jump-offs <18".	Smooth, few obstacles. Occasional protrusions <6". Natural steps < 12".	
	Steps - Target Rise : Run	<12"	<12" rise : 36" run	9" rise : 36" run	9" rise : 36" run	
Design Grade⁷	Target Range	< 35% (less in areas with high erosion potential)	< 20%	< 15%	< 12%	
	Short Pitch Max (Up to 200' lengths)	45% (less in areas with high erosion potential)	35%	25% (may exceed 25% for short distances if intensive tread structures installed.)	20% (may exceed 20% for short distances if intensive tread structures installed.)	
	Max Pitch Density⁸	< 30% of trail (less in areas with high erosion potential.)	< 10% of trail	<5% of trail	<5% of trail	
Design Cross-Slope	Target Range	No excavation unless natural side slope exceeds 30%.	5 – 10%	5%	5%	
	Maximum	Up to Natural side-slope unless exceeds 30%	15%	10%	10%	

⁶ TC-1 trails are the most primitive designed and managed trails, and may have features which are awkward or impractical for some users. Both stock and hikers may be present and managed at low levels on Class 1 trails.

⁷ Grade variances should be based upon consideration of soil type, hydrologic conditions, anticipated use levels, and other factors contributing to surface stability and erosion potential. Due to potential for rapid degradation of trail and connected resources, generally avoid designing trails at the upper ranges of trail grade in areas with high level of risk factors and erosion potential.

⁸ Maximum pitch density refers to the percentage of the trail that is within 3% of the Short Pitch Maximum Grade.

Typical Specifications:		Trail Class 1 ⁶	Trail Class 2	Trail Class 3	Trail Class 4	TC 5
Design Clearing⁹	Width	4 – 5', with some intrusion of light vegetation into clearing area likely.	5' – 6' with some slight intrusion of light vegetation into clearing area likely.	Stock Trails = 6' – 7' Hiker Only = 5' – 6'	Stock Trails = 6' – 8' Hiker Only = 5' – 7'	
	Height	7-8', with some intrusion of light vegetation into clearing area likely.	8' with some slight intrusion of light vegetation into clearing area likely.	Stock trails = 8-10' Hiker only Trails = 8'	Stock trails = 10' Hiker Only = 8'	
Design Turns	Minimum Radius	If designed, typically 3'	4' – 5'	5' – 6'	6' – 8'	

⁹ Physical barriers, such as downed logs or rocks, when cleared, should allow passage for packs or saddles if either pack or saddle use may be present.

Table 2.34 Drift Fences by Alternative

Location	ALTERNATIVE						Reasoning for Alternative 2 - Modified
	1	2	2 Modified	3	4	5	
Shadow Lake/Ediza Trail	no	no	no	no	no	no	Fence no longer exists.
Trinity Lakes Trail	no	no	no	no	no	no	Fence no longer exists.
John Muir Trail	no	no	no	no	no	no	Fence no longer exists.
Hemlock Crossing	yes	yes	yes	yes	no	no	Fence provides resource protection.
Horse Heaven	yes	yes	yes	yes	no	no	Fence prevents stock from entering areas closed to grazing. Without the fence stock could return to the pack station via PCT which travels through the area closed to grazing at Purple Lake and Duck Lake outlet.
Purple Lake	no	no	no	yes	no	no	Fence could be relocated for resource protection if Purple Lake Meadow is opened to grazing after the required rest period.
Fish Valley	yes	yes	yes	yes	yes	no	Fence will prevent stock from entering an area closed to grazing at Second Crossing and Fish Creek Hot Springs.
Cascade Valley	yes	yes	yes	yes	yes	no	Fence will prevent stock from entering the two meadows located at the junction of the Purple Lake and Fish Creek trails which are closed to grazing.
String Meadow/Coyote	yes	yes	yes	yes	yes	no	Fence is located at the top of several switchbacks and should be relocated at the section entering the meadow. Trail is being short cut by stock moving up and down the hill to the fence causing severe resource damage to the trail.
Island Crossing	yes	yes	yes	yes	yes	no	Fence provides safety to visitors and resource protection. Fence prevents stock from traveling back to the pack station via the Fish Creek Hill Trail. Trail does not provide turnouts, safety zones or passing areas should pack stock or private stock users meet on the trail. Loose stock on the trail would create safety issues with hikers as well. (There are very few areas to get off trail and out of the way in certain situations.) Loose stock would cut trails on route to pack station causing resource damage to trail system.
Fish Creek Springs	no	no	no	no	no	no	Fence no longer exists.
Lee Lake	no	no	no	no	no	no	Fence no longer exists.
Quail Meadow	no	no	no	no	no	no	Fence no longer exists.
Second Recess	no	no	no	no	no	no	Fence no longer exists.

Location	ALTERNATIVE						Reasoning for Alternative 2 - Modified
	1	2	2 Modified	3	4	5	
Lower Pine Lake	no	no	no	no	no	no	Fence will be removed
Hilgard Creek	yes	yes	yes	yes	yes	no	Fence provides safety to visitor and resource protection by stopping stock travel down canyon to the junction of the PCT and traveling north or south. Interaction with loose stock can create a safety issue for hikers and other stock users.
Pinnacle Creek	no	no	yes	yes	no	no	Fence prevents stock from traveling down trail, cutting switchbacks and traveling outside of trail corridor. Fence also prevents stock from traveling upstream and gathering with other stock users at Hutchinson Meadow.
Blayney Meadow	yes	yes	yes	yes	yes	no	Fence prevents stock from entering private land.
Minaret/Johnston Meadow	yes	yes	yes	yes	yes	no	Fence prevents loose stock from traveling on and off trails and entering National Park lands (Devil Postpile) in route back to the pack station at Reds Meadow.
French Canyon	yes	yes	yes	yes	yes	no	Approval for a temporary fence to prevent resource damage to areas around Waterfall Camp.
Glacier Divide	yes	yes	yes	yes	yes	no	Fence will prevent stock from entering an area closed to grazing above the camp and in the general area around Golden Lake. Prevent loose stock from traveling back to pack station and cutting trails causing additional trail damage.
Upper Fish Creek	no	no	no	no	no	no	Remove fence at Tully Hole. Fence serves no purpose since grazing does not occur by pack stock at Tully Hole.
Hilton Creek	yes	yes	yes	yes	no	no	Fence provides safety to visitors and resource protection (fence at Turk Meadow) prevents stock from traveling back to trailhead and onto highway.
Morgan Lake	no	no	no	no	no	no	Remove drift fence.
Spooky Meadow Upper/Lower	yes/ yes	yes/ yes	yes/no	yes	yes/ no	no	Remove fence between the two meadows to prevent additional resource damage/stock gazing in a confined area.

Chapter 3 Affected Environment

Chapter 3 – Affected Environment

Introduction

This chapter describes the relevant wilderness resources that would be affected by the alternatives if they were implemented. Under the National Environmental Policy Act (NEPA), the analysis of environmental conditions is directly related to the expected environmental consequences of the proposed alternatives. NEPA requires that the analysis address those areas and the components of the environment with the potential to be affected by the proposed action; locations and resources with no potential to be affected need not be analyzed. The environment includes all areas and lands that might be affected, as well as the natural, cultural, and socioeconomic resources they contain or support.

In conjunction with the description of the activities of Alternative 1: Current Direction (No-Action) in Chapter 2 and with the predicted effects of the alternatives in Chapter 4, this chapter helps establish the scientific baselines against which the decision-maker and the public can compare the effects of all action alternatives.

Data Collection and Analysis Process

In the environmental analysis process, analysts first identify the resources to be analyzed and the level of analysis, both in spatial extent and in intensity. For this proposal, an interdisciplinary team conducted an extensive assessment of the primary areas where commercial pack stock operations occur. The assessment was structured to respond to the elements identified by the 9th District Court's January 10, 2002, decision (*High Sierra Hikers Association et al. v. Jack Blackwell*) and assess compliance with wilderness management standards and guidelines as specified by the Ansel Adams/John Muir and Dinkey Lakes Wilderness Management Direction (2001). Throughout the data collection process, consideration was given to the effectiveness of standards and guidelines to protect wilderness character.

A study plan was developed and refined over the course of the data collection process and is available in the project record.

Focusing on the features of pack stock operations, and the data needed to answer key questions for decision making, survey tools were identified, designed, and modified and refined over the course of the study. To begin, pack stock operators were asked to map their areas of operation, including campsites, trails and grazing areas. These maps were combined into a geographical information system (GIS) coverage to assist in prioritizing and planning field visits. Data on the intensity or frequency of pack stock use was gathered from commercial use reports known as tally sheets. Areas of overlap and high commercial use were a high priority for site visits. In addition to the high priority areas, some areas not recently used by stock were visited to help establish a baseline for comparison of alternatives.

The interdisciplinary team conducted an extensive, broad condition assessment in approximately 75% of the areas identified by pack stock operators. Areas where field assessments were not

conducted were due to costs or time constraints, and these areas were typically areas of low use, or low concerns. Information was gathered from other sources including past reports, rangers, and district resource managers for these areas.

It is important to highlight that it was neither an objective nor a goal of this assessment process to determine cause of impact. These wildernesses have many users and have been popular recreation areas for many years. It is very difficult to distinguish a specific cause of the impact. The goal of the process was to assess and disclose wilderness resource conditions consistently across the landscape to determine the consequences of continued commercial pack stock use. The following information is the baseline from which environmental consequences are analyzed in Chapter 4.

3.1 Human Environment

3.1.1 Commercial Pack Station Operations

Wilderness Scale

Commercial Packing —Historical Perspective

Mule pack trains were the primary carriers in Alta California during the Spanish and Mexican administrations until the pressure of American emigration beginning in 1846 brought an increase in settlements and construction of wagon roads. There was a resurgence of the pack stock uses in the early days of the Gold Rush in the Sierra Nevada foothills. Most of the pack trains were run by Mexicans, who brought them from Baja California and Sonora. The Mexican packers were also expert at breaking wild mules. Packing operations were slowly taken over by Euro-Americans, although Hispanics and Native Americans continued as wranglers (Jackson, 2004).

When the gold boom ended there was a hiatus in packing activity and travel in the wilderness was infrequent except for shepherds and cattlemen. According to Livermore (1947) “I have had old-timers tell me that during this period they traveled as long as sixty days in the back country and would scarcely see a soul.” Packing had a resurgence in the latter part of the nineteenth century with increasing attention given to the Sierra Nevada by the United States government, scientists, commercial enterprises, and recreationists.

Some of the largest pack trains belonged to the US Army, which used them on expeditions and in the construction and supplying of forts and outposts into the 1890s. Duties of Army units included patrolling the parks and the Sierra Nevada backcountry for poachers and illegal stock grazers and surveying, mapping, and building roads and trails. Private packers were hired for military projects, such as the 1881 scientific expedition to Mt. Whitney under Samuel Langley of the then director of the Allegheny Observatory, later Secretary of the Smithsonian Institution, and the United States Army Signal Service to install astronomical instruments on the summit for recording solar radiation (Farquhar, 1925).

Commercial packers also serviced non-military scientific expeditions. Beginning in April of 1863, pack trains were used during the geological survey of the Sierra Nevada conducted by the California State Geological Survey between 1860 and 1874 (Farquhar, 1925).

Work for government surveying teams continued from the late nineteenth into the twentieth century (Farquhar, 1925; Jackson, 2004). The United States Geological Survey carried on with their reconnaissance of the southern Sierra Nevada from 1893 until the final section of the High Sierra was completely surveyed in 1909. Geological survey teams were packed into the Sierra Nevada in 1947 by the Glacier Pack Train, U.S. Coast and Geodetic Survey teams were packed into Kings Canyon in 1950 by the Rock Creek Pack Station, and, beginning in the 1940s, several packers hauled supplies for the construction of cabins for winter snow pack measurements by the California State Snow Survey, among other projects (Jackson, 2004 and London, 2005).

During the post-World War I depression, a reliable source of income for packers came from Forest Service and Park Service contracts for supplying cow camps, backcountry resorts, backcountry rangers, insect control teams, logging and fire crews, and for hauling building materials for ranger stations, fire look-outs, trails, bridges, dams, and camps. The Great Depression of the 1930s created work for packers to haul tools, materials, and equipment to Civilian Conservation Corps camps. The Works Project Administration (WPA) and Emergency Conservation Work also created work, but both the depression and drought created hard times for packers, especially since fewer private parties made trips into the wilderness (Jackson, 2004).

The abundant snow pack and runoff of the Sierra Nevada lured water and power companies to survey watersheds and construct access roads, dams, reservoirs, power stations, and flow gauging stations for the increased demand for water and electrical power to satisfy a growing population in California. Packers assisted these enterprises from the 1880s into the 1920s.

Fishing was another enterprise engaging packers. The fish-barren streams of the Sierra Nevada started to be planted with trout in the latter part of the nineteenth century to supplement the diet of miners, sheepmen, and cattlemen. “Coffee can plantings” were soon replaced by large scale commercial fish stocking encouraged by the Fish Commission of California (later designated the State Fish and Game Commission) to encourage recreation. Stocking was done by private individuals, the Sierra Club, and by the U.S. Cavalry in the national parks during earlier years. Most of the fish stocking occurred on the west side. In the eastern Sierra Nevada, the Mt. Whitney fish hatchery was established in 1925 and the Olivas family volunteered to pack the fish from the hatchery (Jackson, 2004).

Development of Recreational Packing

Recreational packing began in Yosemite Valley in 1855. In the next decades, families and other groups from communities on both sides of the crest explored and camped in the high country with horses and mules (Farquhar, 1925, 1965). Frank Dusy, a stockman and farmer living south of Fresno who appreciated the beauty of the mountains, may be one of the first professional recreational packers since he took parties in the backcountry of the Kings and Kaweah Rivers by 1868 (Farquhar, 1925). As mountain recreation became popular other ranchers followed suit and hired out their horses and mules and acted as guides. Dan Clodfelder and Bert Smith, who ran pack trains out of Three Rivers, and Thomas Reid and F. A. Brightman, who packed tourists into Yosemite Valley from Hodgdon’s Ranch and Tamarack Flat, followed him in the 1870s (Jackson, 2004).

In 1871, Tom Agnew, who built a cabin in what is now called Agnew Meadows, guided visitors with pack stock in the San Joaquin drainage for the Yosemite Park Rangers. Allie Robinson in 1872 packed commercially from Onion Valley. E.H. Edwards Mercantile in Lone Pine

advertised “Outfitting store for camping expeditions to Mt. Whitney and Cottonwood Lakes” in 1874. The Pine City Feed and Livery Stable (later known as the Lake Mary Pack Station) transported people and supplies in 1878 across the Sierra to and from Mammoth City and Fresno Flats. Helen McKnight Doyle, in her book *A Child Went Forth*, describes pack trips into the Mammoth and June Lakes area for fishing vacations. The Pioneer Stables, located in Bishop Creek, advertised in the *Inyo Register* in 1887 (Eastern Sierra Packers Association, 2000.).

The towns of Visalia in the San Joaquin Valley and Lone Pine in the Owens Valley were the west and east trailheads for mountaineers, hunters, fishermen, explorers, and recreationists taking pack trains into the high Sierra via the Dennison, Jordan and Hockett trails and Cottonwood and Kearsarge Passes, respectively. By the 1880s, the Robinson and Olivas families included summer pack trips into the Kern Plateau of the Sierra Nevada along with their commercial mining operations from their bases in the southern Owens Valley (Farquhar, 1965; Dilsaver and Tweed, 1990; Jackson, 2004).

The founding of the Sierra Club by John Muir in 1892 focused widespread public interest on visiting the Sierra Nevada and preserving Yosemite Valley, the giant sequoia groves, and other natural landmarks. In order to develop a constituency for the Sierra Club’s preservation agenda William Colby started a tradition of conducting trips into the Sierra Nevada in 1901. For the next 50 years the large Sierra Club High Trips kept packers busy and led the way for thousands of wilderness adventurers. They were elaborate affairs, lasting two to four and sometimes up to eight weeks involving an average of 150 people, around 50 packers and long pack trains of up to 250 mules carrying 100 pound stoves and full-time cook crews (Farquhar, 1965; Dilsaver and Tweed, 1990; Jackson, 2004). These types of outings helped to promote the wilderness concept and contributed to building the necessary support and for passage of the 1964 Wilderness Act (Eastern Sierra Packers Association, 2000).

The unrestricted use of forest reserves by packing operations ended in 1906 with the creation of the Forest Service (the Inyo and Sierra National Forests were created in 1907). Regulations were instituted to control the degradation of public lands. The included the number of animals used in each forest, the allowed period of time for grazing, a requirement for grazing permits, a grazing fee, and the approval for structures such as out-buildings, tent sites, drift fences, and corrals. Other concerns such as fire suppression, camp sanitation, trail maintenance, and adherence to Fish and Game laws were addressed. By 1920, both the Park Service and Forest Service required a concessionaire’s permit for packing operations (Jackson, 2004).

Packing continued through this period. Advertisements in the *Inyo Register* in 1912 included: The Nevada Stables, Bishop “Tourists and Campers’ Outfits”; Pioneer Livery Stable, Bishop “All kinds of outfits for tourists’ mountain trips”; Ben Ransome, the Guide of the Sierras, Big Pine “Outing in the Sierras 10 days, 15 days, and 30 day trips into the headwaters of the San Joaquin and Yosemite Valley”; Mt. Whitney Hotel and Anton’s Resort, Lone Pine “We outfit parties at Lone Pine for Sierra trips-horses and pack horses for hire” (Eastern Sierra Packers Association, 2000).

By 1920 packing was a profitable business, with 36 large pack outfits operating in the southern Sierra Nevada and, of those, 15 (42%) were on the east side (Jackson, 2004). Many of the currently operating pack stations can trace their history back to the 1920’s and 30’s (Eastern Sierra Packers Association, 2000). The earliest pack station on the Inyo National Forest that is still functioning is Rock Creek Pack Station, established around 1920 (M. Roeser, 2005).

Most of the early recreation use in the back country, almost all of which was supported by pack trains, was fishing and hunting. After the hoof and mouth epidemic in 1924, reduced visitor use for several years, pack outfits increased in the southern Sierra Nevada to 71 in 1935 with 22 (31%) in the eastern Sierra Nevada (Livermore, 1935).

Packers depended on large parties of wealthy individuals, corporations, agencies, and clubs to generate adequate income. The Sierra Club High Trips were some of the largest trips, often with over 200 people. From the 1920's to the beginning of World War II, Charles Robinson and his son Allie, who ran a pack outfit out of Independence, and later joined by Ike Livermore, became the packers for the Sierra Club (Morgan, n.d.). After about 40 years of large pack trips, from the turn of the century to the 1940s, the wilderness began to be degraded by the overgrazing of meadows, over fishing of the lakes and streams, construction of a dense trail network, and the deterioration of major campsites (Jackson, 2004). The poor condition of the meadows called for continued conservation management. Some meadows were closed to grazing and special allotments with limits to animal units were assigned to packers. The close relationships between packers and federal land management agencies, however, were apparently not affected by the increasing rules and regulations.

Besides the Great Depression, World War II also brought problems. Gasoline rationing restricted travel to pack stations and lack of personnel due to the military draft brought near disaster to the pack outfitters. Even the profitable Sierra Club High Trips were suspended until the end of the war (Jackson, 2004). The Inyo National Forest, which administered all FS land in the eastern Sierra Nevada, listed nine pack operations in 1942. This was 14 less from the war's beginning in 1941.

The post-World War II era brought an improved economy, longer vacations, better access to the mountains by automobiles, and light weight materials recreational packing boomed and the number of pack stations again increased to about 60 on both sides of the crest between Sonora and Walker Passes in 1947 (Livermore, 1947). Two thirds of those outfits and stock were based on the east side. The growing numbers of operations created intense competition and customers demanded better service. With it came an increase in more stringent business practices such as liability insurance, performance bonds, financial reports, schedules of personnel and stock, and logs to track the numbers of animals grazed, number of customers, service days, destinations, and day trip rentals. Along with bookkeeping was added pack station maintenance and increasing costs of doing business such as feed, salaries, stock, equipment, supplies, maintenance, and insurance. Pack outfits either lost money or barely met expenses (Jackson, 2004).

Beginning before the war and continuing into the 1950s, packing operations began to feel changes that made the business less profitable (Jackson, 2004). Government contracts became scarcer and the automobile and airplanes began to replace mules as a means of transportation. Much of the back country was closed to hunting when Kings Canyon National Park was established in 1940 (Livermore, 1947). Boats were restricted to non-motorized ones and permits were required to pack them in. Loose herding of stock was prohibited on non-hazardous trails by 1950. Overused camps and meadows for grazing were placed off-limits and even permitted meadows could no longer support the demands of pack trains. In 1946 the number of animals permitted on any single trip into the national parks was limited to 75.

Compliance with rules and regulations, however, was erratic and lax, primarily because enforcement was difficult (Jackson, 2004). During the 1930s and 1940s most packers did not apply for permits to operate inside the national parks. In the 1950s and 1960s, some packers accepted the inevitable restrictions on both the national parks and national forests but complained that they were being put out of business because of them. One regulation that may have harmed business is the 1966 restriction of the total number of pack and saddle stock allowed for pack stations operating on the Inyo National Forest to fifty head. Prior to that time, 175 to more than 200 head were kept at the larger pack stations in the 1930s to 1950s. Not accounting for fluctuations, the decline in the intensity of pack operations in the southern Sierra Nevada (from Yosemite National Park south) can be partly measured by the estimated number of stock owned, which ranged from 2764 head in 1935 to 1420 in 1986, a 51% decrease. There was also a consolidation of pack stations between 1935 and 1964 although the total number of pack stations in 1964 implies a secondary peak of 66 in a downward trend, of which only 17 (25%) were on the east side, the lowest percentage since 1920 (Jackson, 2004; Livermore, 1935; Sierra Club, 1952; High Sierra Packers Association, 2000).

The number of pack outfits decreased to less than 50 in 1990. Major pack stations from the Kern Plateau to Silver Lake numbered 71 at a historical maximum and only 13 by 2004, an 82% reduction. There has also been a recent slippage in pack trips (Tanner, 2005). In order to maintain a viable business a few of the more prosperous pack stations in the northern study area, Frontier, Agnew Meadows and Reds Meadows have been supplementing their income by offering saddle day trips to tourists and for many years Bob Tanner has organized horse drives in the Long Valley and Mono Basin areas. This is in addition to the earlier variety of trips offered outside the fully outfitted traveling trips such as spot trips, trail rides, base camps, and dunnage packs and caches.

Cooperation, Conservation, and Conflict

Federal regulations and the difficulties of packing itself required packer operations to work together in order to maintain a viable business. This included cooperation between pack outfits and the Park and Forest Services. Some packers, for example, combined their stock for large parties and contributed to trail maintenance among other things. To encourage cooperation the High Sierra Packer's Association, established in 1934 at the instigation of Ike Livermore, created guidelines for better business practices (Jackson, 2005).

Before World War II, the National Park Service began to study the deleterious effect of pack stock on meadows (Jackson, 2005). Besides the deterioration of meadows, stream channels were also damaged, soil moisture decreased, exotic plants were introduced, the behavior of wildlife was disturbed, and unauthorized trails were built or pioneered. The latter was important to packers for gaining access to favorite lakes and hunting areas that could bring in extra business and so the practice continued. After the war the Sierra Club and private riding clubs added their own conservation methods, limiting the number of participants, bypassing vulnerable meadows, packing feed for stock, maintaining trails, cleaning up the back country and designing pack trip strategies to avoid over-concentration of animals and people. In the summer of 1946, packers and the Sierra Club got together to remove garbage from campgrounds in some areas (Livermore, 1947). Other large private parties, such as the Contra Costa Hills Club, the California Alpine Club and the Trail Riders of the Wilderness continued destructive practices (Jackson, 2005).

The integrity of the wilderness environment was a vital issue to both government agencies and the packers who depended on that integrity to attract customers (Jackson, 2005). To avert the trend toward harmful use of the wilderness, and the loss of interest and business thereby, the High Sierra Packer's Association adopted its own "packer's code" in 1948 that advocated ecologically sound practices. Many of the recommendations were incorporated in Forest Service regulations.

Livermore (1947) identified several concerns of packers, including possible new road construction in the wilderness, the difficulty in obtaining sufficient feed for stock in the winter and summer pastures, dirty camps and increasing numbers of backpackers. The latter concern was soon to give packers the most problems. The concern that Livermore expressed was that backpackers could access the wilderness on their own two feet without need for horses and mules and this would diminish the business of packers. Stock had been the primary means of backcountry travel for a century until the end of the war and before then only a few hardy men such as John Muir and Norman Clyde did without animals. What Joseph Le Conte wrote in 1907 held true for decades, "On account of the very considerable distance to be covered and the total absence of any kind of habitation or supply stations, a pack train is almost a necessity, though some times a most troublesome one."

During World War II, however, thousands of soldiers experienced foot travel with heavy packs, and camping out in bivouacs made of shelter halves and sleeping in mummy bags. Also, many Sierra Club members served with the U.S. Mountain Troops and experienced mountaineers designed equipment, trained troops and wrote training manuals. The infantry equipment that the United States Army and Marine Corps developed soon found its way into war surplus stores after the end of the war. Some of the former soldiers learned that they could apply their backpacking skills and available equipment for travel in the mountains and civilians found out that they could do likewise. War surplus stores became their outfitters. Rucksacks associated with the hiking tradition of Europeans living in the mountains of Germany, France, Italy, and Switzerland also found their way into American markets. The slow stream of backpackers in the Sierra Nevada after the war and throughout the 1950s became a popular sport in the 1960s when lightweight equipment such as nylon tents, down filled sleeping bags and external backpack frames made of aluminum were manufactured. Besides mountain warfare designs, much was borrowed from manufacturers of outdoor products to lumbermen, surveyors, prospectors, and Arctic and Antarctic expeditions in the early twentieth century (Sierra Club, 2005). With the availability of lightweight back packing equipment and supplies in the 1960s and 1970s, hiking and backpacking significantly outpaced the use of pack stock by nearly eight to one.

As the high country was opened to more people, concern grew over overgrazing and trampling of meadows, and with federal management of the wilderness. Of all the problems of wilderness use the condition of meadows relative to the use of stock seems to have been the primary issue, particularly the smaller, more fragile meadows (Jackson, 2005). The potential cumulative harm of the sheer numbers of hikers and backpackers over a long period of time was an issue that did not appear until much later. Ike Livermore, who was a director of the Sierra Club as well as a professional packer, proposed that the Club hold a conference of federal and state land managers, leaders of other outing clubs and packers (Sierra Club, 2005). The success of the first High Sierra Wilderness Conference in 1949, which discussed the topic, "The High Country of the

Sierra Nevada” led to the biennial Wilderness Conferences over the next 26 years.¹ It is important to highlight the dominant role of Ike Livermore who spanned both the professional packers and the wilderness protection movement and epitomized the historic tradition of cooperation and the sharing of values that were soon to change.

Relations between packers and the Forest Service were good through the 1970s and early 1980s after which a turn was taken for the worse, according to Marye and Lou Roeser (2005). The surge of backpacking in the 1970s resulted in restrictions on wilderness use, which carried over into packing and conflicts have arisen between the two user groups that continues to the present day. It is unfortunate since both groups have an intense regard for the integrity of the natural state of mountain wilderness. Packers have insisted that they have taken care of the wilderness because the natural state of the mountain environment is necessary to running a successful business besides being an intrinsic personal value. Hikers complain about environmental damage to the wilderness from stock use and are irritated by feces, urine and attracted flies along stock trails while packers and others complain of the damage to the environment by the thousands of backpackers who take to the trails every year.

Commercial Packing—Current Perspective

History and Background

Nineteen pack stations with physical facilities on Forest (outside the Wilderness) or on private inholdings within the wilderness operate transportation services in the Ansel Adams and John Muir Wildernesses (see Table 3.1). The extent of the collective operating area of these pack stations is 9% of the total wilderness acreage. This is based on operators identifying the trails, routes, meadows and campsites they have used historically as service providers.

Table 3.1 List of pack stations operating in the Ansel Adams and John Muir Wildernesses

Pack Station Name	Location	Satellite stations
Frontier Pack Train	Silver Lake	n/a
Reds Meadow Resort and Pack Station/Mt. Whitney Pack Trains	Reds Meadow	Agnew Meadow
Mammoth Lakes Pack Outfit	Lakes Basin	n/a
McGee Creek Pack Station	McGee Creek	n/a
Pine Creek Pack Station / Sequoia Kings Pack Trains	Pine Creek	Onion Valley
Rock Creek Pack Station/Mt. Whitney Pack Trains	Rock Creek	Lower Rock Creek Corral
Bishop Pack Outfitters	North Lake	Cardinal Meadow
Rainbow Pack Outfitters	South Lake	n/a
Glacier Pack Train	North Fork Big Pine	n/a
Cottonwood Pack Station	Cottonwood Creek	n/a

¹ The conferences were held mostly in San Francisco and Berkeley until the 14th and final Wilderness Conference in 1975 in New York City expanded the scope to the entire earth, as its topic indicates, “Earthcare, Global Protection of Natural Areas.”

Pack Station Name	Location	Satellite stations
Minarets Pack Station	Clover Meadow (Miller Meadow)	n/a
Yosemite Trails Pack Station	Fish Camp	n/a
High Sierra Pack Station	Edison Lake	Florence lake
Muir Trail Ranch	Blayney Meadow	n/a
Lost Valley Pack Station	Double Meadow	Florence Lake
D&F Pack Station	Huntington Lake	Edison Lake
Clyde Pack Outfit	Tule Meadow	Maxson Trailhead, Wishon, Courtright Reservoir

In addition to the pack stations, there is one proposal for a llama operation with no base facilities proposing to use up to 500 service days and one proposal for burro supported wilderness use. This operation is small, offering one burro supported trip a year. The itinerary varies from year to year with use occurring to varying degrees in Sequoia Kings Canyon NP and front country areas on the Inyo National Forest.

There are four categories of stock related service: spot, dunnage, full service trips, and day trips. (These services are described in more detail below in the Description of Operations section.) Any one of these types of trips could travel through the project area destined for either Yosemite or Sequoia/Kings Canyon National Parks.

These types of stock supported services require skilled stock handling and care. The public generally does not have access to personal stock and equipment, nor to the specialized skills necessary to travel with stock in the wilderness.

Most of the pack station use is on the primary trails and popular destinations in these two wildernesses. The most popular type of trips are dunnage and spot trips followed by full service trips and day rides.

Since the 2002 operating season², pack station operations have been under a District Court injunctive relief. The relief reduced their service day use levels by 20%, required authorizations of non system use trails, reduced the party size to 12 persons and 20 stock (from 15 persons and 25 head of stock), and required a two year phase-in of the quota system from the 2001 Wilderness Plan (the plan identified a five year phase-in). The court's relief changed pack stock operations and hindered the ability to determine what effect the wilderness plan implementation—on its own—would have made to commercial pack stock operations. When appropriate, distinctions between pre-2001 Wilderness Plan and post 2001 Wilderness Plan are made to describe the changing affected environment over the past 5 years.

There are 75 analysis units where pack station operations overlap in their identified operating areas. In 52% of these areas only two pack stations are overlapping operations, while in 45% of the areas 3-5 operators overlap. Although 75 units were identified as overlap only 17 site specific locations overlap for spot and dunnage services. Most overlap exists as the result of traveling trips going through an operator's primary area for providing spot and dunnage services.

² Two pack stations, D&F and High Sierra Pack Stations were exempt from the reduction in service days and party size because the Forest Service had already conducted environmental analyses for these pack stations.

For the past six years commercial pack stock use is consistently estimated to be around 8%³ of total overnight use on the Inyo National Forest and 10% of use on the Sierra National Forest (wilderness permit and reported pack station use data 1999-2003). On trailheads where pack stations are located the ratio is considerably higher. On these trailheads, overnight commercial pack stock use varies from 4% (Lamarck) to 45% (Hilton). Mono Pass (25%), High Trail (30%), Rush Creek (34%), and Pine Creek (36%) are all trailheads with high percentage of commercial pack stock use. Trailheads on the Sierra National Forest that receive a higher percentage of commercial pack station use include Cassidy (32%), Bear Ridge/Diversion (32%), Margaret (24%), and Isberg (21%) (2002 wilderness permit data).

Description of Operations

The following describes the typical services and daily operations of a commercial pack station operator providing service to clients.

Spot and Dunnage trips

Spot trips are trips in which clients ride stock to a destination with a guide, supported with pack stock for equipment and gear. The riding stock, pack stock and guide do not stay with the party. Dunnage trips are trips in which packers using pack stock carry equipment and supplies for clients who are hiking to a pre-arranged destination, and/or pre-arranged re-supplies for clients on long duration trips. The packer does not stay with clients.

For spot and dunnage trips, the packers will spend an average of one to two hours in the morning saddling pack and saddle stock, and packing loads. Loading 8 to 12 mules will take on average up to 2 hours. Trip planning, animal care, equipment repair, fitting clients to the saddle, and safety briefings would also be accomplished before leaving. The packer or packers will lead the strings to the agreed upon camp. The clients will be dropped off at a designated site and the packer will return home at the end of the day. Work hours for spot and dunnage trips are often from dawn to dusk with up to 12 hours in the saddle, and 2-4 hours packing and saddling stock. These trips do not involve hauling feed, grazing, highline or camp setup.

Spot trips may require the packers to return to the camp to pack the clients and their gear back out. For these trips, packers start in the morning from the base facility, arrive at the campsite and pack the gear and sometimes clients out to their vehicles. Some clients desire to return to their vehicles earlier in the day, so packers spend the previous night in the wilderness either at the campsite with the clients or close by so they can pack them out earlier on their last day. Any overnight trip would involve hauling feed, grazing, highline, or camp setup.

Destinations for spot and dunnage trips could include Yosemite or Kings Canyon National Parks.

Full service trips

Full service trips involve a guide, cook, or other paid employees of the operator that accompany the clients for the duration of the trip. The full time packer or packers that stay with the party during the duration of the trip handle stock for the riders including saddling, packing the mules,

³ The 8% figure includes Mt. Whitney use, without Mt. Whitney use included the level is between 11 and 13%. There is no stock use allowed on Mt. Whitney and this trail, by itself, accounts for 33% of total use on the Inyo NF portion of the JM/AA.

trip planning, animal care, equipment repairs, safety briefings, and possibly trail work to clear trails of debris or obstacles. Most full service trips are booked at the maximum number of clients permitted due to the high volume of work involved. The packers will spend an average of one to two hours in the morning saddling both pack stock and saddle stock for the trip. After saddling, the packers will begin loading mules for the day to travel to the selected campsite. Loading 8 to 12 mules will take on average up to 2 hours. The packer or packers (which sometime include the camp cook) will lead the strings to the next location; travel time can be as long as 6 to 8 hours with only a break for lunch for the guests.

Once in camp the packer will need to identify an existing stock holding area for the night which will accommodate the total number of stock. The area will need a highline put up (placing a rope between trees head high to tie stock on). Any rocks or debris that could injure the animal must be removed. Protective devices for the trees, such as tree savers should be used (cotton, rubber or nylon straps wrapped around the tree to protect the bark). Generally, the process take up to an hour or more and includes unloading the mules, unsaddling, setting up the highline, hauling or watering stock (leading stock down to a water source or bringing water to the stock in a bucket) before placing stock on the highline and protecting the gear from the weather (stacking or covering).

After setting up, if the packer decides to graze the stock (turning stock loose to feed in an adjacent meadow), the animals will be turned loose and monitored as to their location. If the packer is turning out for the night, the stock will be left to roam the area and gathered in the morning at first light. The stock are not always easily found and this task can take up most of the morning. Some packers will keep certain animals tied up for the night to assist in finding the other stock in the morning. Grazing requires hours of work for the packer, but is important for the health of the stock as each animal needs a certain amount of roughage each day to maintain optimum health.

One alternative to grazing is hauling feed (most often pelletized alfalfa and grain, though some packers use a compacted hay product) and feeding the stock on the highline using nosebags. Most packers will feed only pellets/grain for no more than two days in a row as this practice can jeopardize the health of their stock, unless a period of time can be set aside to graze for needed roughage. Packing feed involves additional stock to haul feed. When additional animals are needed to pack in feed, fewer animals are available to provide client service. Hauling feed requires the packers to be conservative with other needs and gear for the trip. Hauling feed allows the packer to begin working with the stock saddling, loading and preparing for the day at first light. Feeding stock on the highline adds about an hour to the daily duties but there is a satisfaction to waking up and having your stock still in camp.

Day Rides

Day rides involve clients riding stock, accompanied by a guide, for periods of a day or less. No overnight equipment is involved.

Day rides require saddling and fitting the client to the tack and the riding animal, safety briefings and guiding. Most day rides fall into the categories of 1 hour, 2 hour, ½ day and full day rides. Packer and stock preparation for these trips is similar to above without the pack stock duties.

Other Operational Duties

The packer’s day generally starts early in the morning and ends late at night. Shoeing, veterinary care, facility maintenance, transportation of stock via truck to trailheads, taking reservations and accounting are a few of the additional business activities packers accomplish on a day-to-day basis.

Rest days are critical to the health of working animals, consequently they cannot be used every day.

Recent Commercial Pack Stock Use in the Ansel Adams and John Muir Wildernesses

Stock/Client Numbers

With the reduction in service days that took place in the 2002 operating season it appears that stock numbers increased. It appears from the use data that from 2001-2003 there was a trend towards using more stock per person and more trips with more stock into Sequoia Kings Canyon National Park. Records from both Inyo and Sierra National Forests show that there was a 2% increase in the number of stock per client for spot and dunnage trips, a 16% increase in number of stock per client for full service trips and a 5% increase in spot and dunnage trips accessing Sequoia/Kings Canyon National Park.

In 2003, 92% of all trips were spot or dunnage and 8% full service trips. Full service trips utilize more stock per person 4:10 as compared to 6:10 ratio of people to stock for spot and dunnage. Dunnage trips typically use the least number of stock per client.

In 1998, 923 clients were serviced with 5,567 head of stock on the Inyo National Forest. In 2003 3,606 clients were serviced with 5,664 stock On the Inyo. Fewer clients are being serviced with more stock. Figures 3.1-3.3 display commercial pack stock trends by geographic unit. Figure 3.1 displays commercial pack stock trends in people served and stock used between 1996 and 2003. Figure 3.2 shows the commercial stock numbers by geographic unit in 2003. Figure 3.3 shows the commercial pack stock clients by geographic unit. Table 3.2 provides a breakdown by analysis unit of commercial stock and client numbers from 2001 to 2004.

Figure 3.1 Commercial pack stock trends in people serviced and stock used 1996-2003

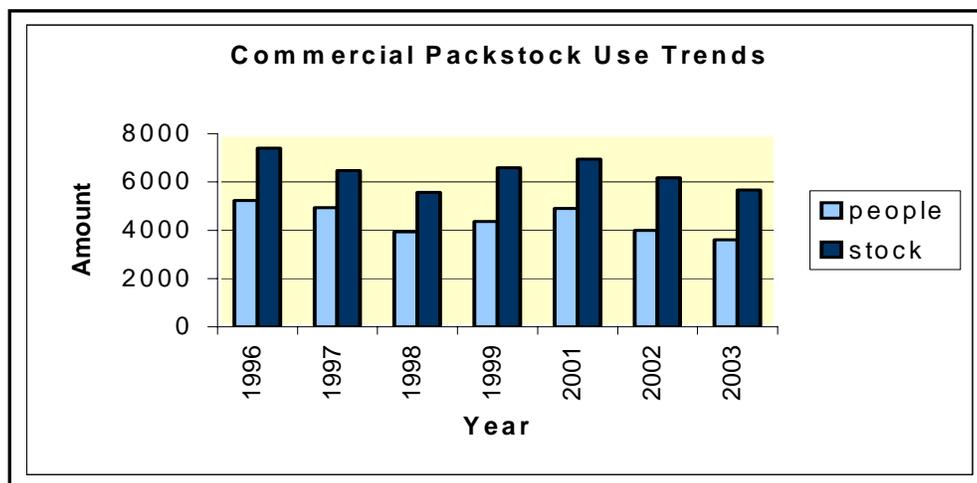

Figure 3.2 Commercial stock numbers by Geographic Unit 2003

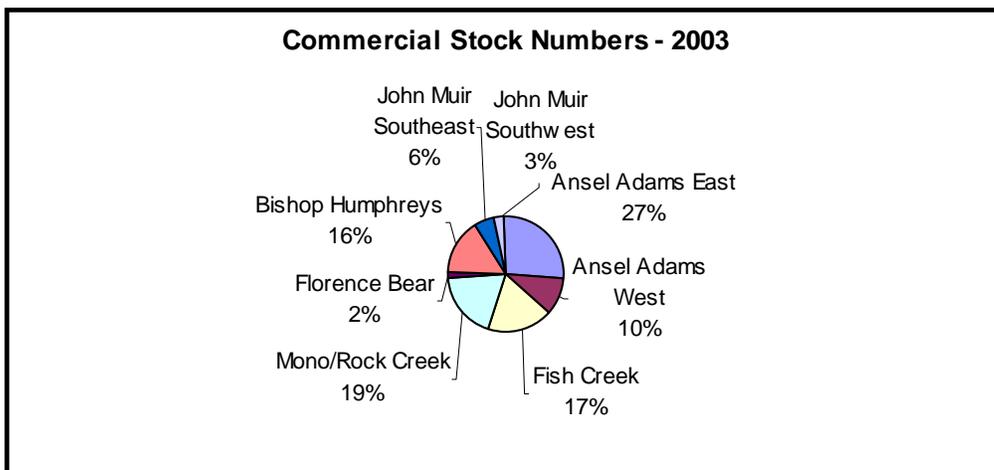

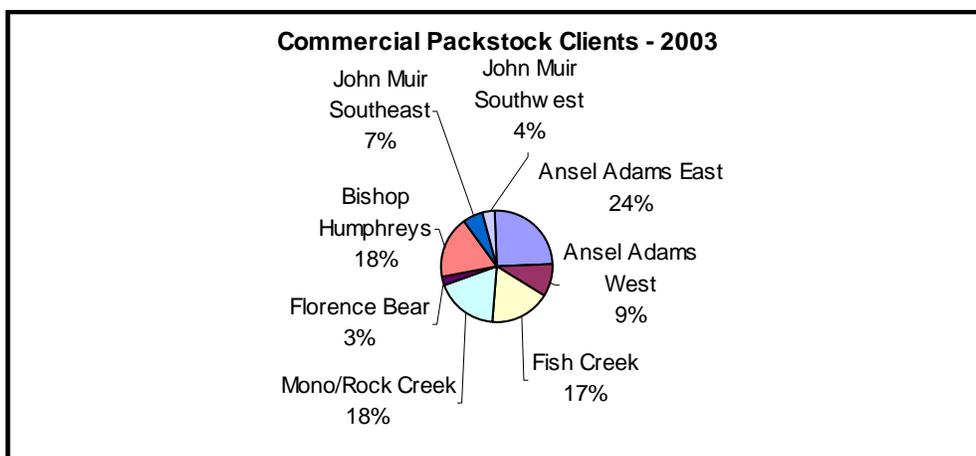

Figure 3.3 Commercial pack stock clients by Geographic Unit 2003

Grazing Operations

Historical pack stock use in support of sheep and cattle grazing, mining operations, logging operations, and for recreation purposes likely greatly exceeded the numbers and geographic extent of today’s use. Recent reported pack stock grazing use is approximately 8,500 stock nights at approximately 172 meadows in the Ansel Adams and John Muir Wilderness areas, based on the highest numbers of stock nights of grazing use reported in either 2001-2002. Commercial pack stock operators are required to fill out “Stock Use Reporting Cards” that include forage area used, numbers of stock, and estimated duration of grazing time. Using the best available information the table below summarizes the reported pack station grazing by analysis unit for 2001-2003.

Of the 125 locations where grazing was reported during 2001-2003, only 22 (17.6%) had grazing all three years. That is, if the reports of use are complete, about 82% of the meadows have at least one year rest after being grazed.

Table 3.2 Summary of reported commercial pack stock use by geographic unit

Geographic Units	# Pack-stations Reported Grazing Use	Total Reported Use 2001-2003 (in stock nights)		
		2001	2002	2003
Ansel Adams East	4	1616	1154	1040
Ansel Adams West	3	142	114	197
Fish Creek/Convict/McGee	7	2292	2047	717
Mono Creek/Rock Creek	5	42	897	480
Bishop/Humphreys	5	133	176	493
Florence/Bear	6	214	80	178
John Muir SW	1	251	155	125
John Muir SE	1	9	0	0
TOTALS		4598	4670	3147

Day Rides

Four pack stations on the Sierra National Forest have traditionally conducted day rides in these wildernesses. In the last couple of years the overall use has averaged 275 service days. In all cases use has been below the permitted number of service days allowed, and is not a significant use in these wildernesses.

Eleven pack stations on the Inyo National Forest have traditionally conducted day rides in the Ansel Adams and John Muir Wildernesses. Using the high reported number from the last couple of years, day rides have averaged 3876 service days. Similar to above, this use has been below the permitted number of service days allowed.

Party Size

The current party size is 15 persons and 25 head of stock wilderness wide. This party size was determined through a federal rulemaking process with other units in the Central Sierra to gain consistency in the contiguous wilderness in this region. In 2002, the injunctive relief imposed by the District Court lowered the party size for commercial operators affected by the relief to 12 persons and 20 head of stock. Since 2002, use reports reflect that change.

Data from reported pack station use shows very few trips use the maximum party size. In six years of data from 1995⁴, parties exceeding both the 12 persons and 20 head of stock occurred in 2% of total pack station trips. The highest year was 1995 at 2.5 % of total trips. Trips that exceeded 12 persons occurred 7% of the time. Trips that exceeded 20 stock occurred 6% of the time. Two operators, Reds Meadow and Rock Creek Pack Stations have a disproportionate percentage with both using greater than 20 stock 10-15% of their trips, prior to the District Court's injunctive relief.

⁴ The years since 2001 when the court ordered party size reduction was put into place were not used in this calculation.

Campsites

Across the wilderness, most campsites that are used for holding pack stock by commercial operators are well-established. Generally speaking, the packers are not creating new campsites, they utilize the existing sites. Some expansion of the sites occurs over time particularly as stock holding areas change.

Geographic Scale

Ansel Adams East

Two pack stations, Frontier and Reds Meadow, base their operation in this area. Four additional operators identify use in the region. Rock Creek Pack Station travels thru the area to Yosemite National Park, where they operate under an Incidental Business Permit with the Park. Rock Creek has substantial use in this area, with 33 trips reported in 2001. Mammoth Lakes Pack Outfit (MLPO) identifies some use in the Ansel Adams East. This use includes very low use into Deer Creek (Crater Creek Analysis Unit) via either Red Cones Trailhead or Duck Pass. Four operators identify use in the Crater Creek area, with MLPO, Rock Creek and McGee all identifying grazing in this area.

There is heavy commercial pack stock grazing in this area, particularly in the Rush Creek drainage and the Thousand Island AU. There were reported stock nights of 1616, 1154, and 1040 in 2001, 2002, and 2003 respectively, in 26 locations by four pack stations. Eight meadows were only used one of those years, nine in two years, and nine were used all three years. Reds Meadow has pasture permits for Johnston Meadow and Minaret Falls.

Ansel Adams West

Two pack stations base their operations in this area: Minarets and Yosemite Trails. Minaret's operation is concentrated in the Staniford, Lillian, Cora, Sadler, and Triple Divide Analysis Units (AU) with low use reported in the other AUs in the region. Yosemite Trails Pack Station operates only on the ¼ mile of trail from the Chiquito trailhead to access Yosemite National Park where they operate under an Incidental Business Permit. This use is regulated by Yosemite National Park and the Sierra National Forest's trailhead quota. With respect to service days, travel across the short distance of the Sierra National Forest at Chiquito Pass has been counted as day use for both pack stations for the past four years. This use will be described as, and allocated as, overnight use for this analysis.

Two east side pack stations, Rock Creek and Reds Meadow, identify use in this area. These operators pass through, typically from Yosemite National Park over Isberg Pass (Sadler AU) and on to Summit Pass (Cargyle AU). Here, trails, grazing areas, and campsites are identified as overlapping the operations of Minarets Pack Station.

There is light grazing use in this area, with reported stock nights of 142, 114, and 197 in 2001, 2002, and 2003 respectively, at 12 locations by three pack stations. None of the locations were used all three years, seven were used in two of the years, and five in only one year.

Fish Creek/Convict/McGee

Overall, the Fish Creek/Convict/McGee Geographic Unit receives low to moderate levels of use by six different pack stations. Of all the areas in the project, however, the Silver Divide has the

highest concentration of overlapping operators. This area is identified for use by six operators: McGee, High Sierra, D&F, Mammoth Lakes, Reds, and Rock Creek. It is the primary area of operation for Mammoth Lakes Pack Outfit with their base facilities located in the Mammoth Lakes Basin adjacent to the Duck Pass trailhead. They are the only operator that relies upon this area as their primary area.

Both High Sierra and D&F with their west side base operations access the area from the south of Silver Divide (primarily over Goodale Pass). Goodale Pass is nine miles from Lake Edison. Loops from the west side over Goodale and Silver Pass, with days spent in the Grassy Lake and Peter Pande area are typical of the few full service trips that are conducted from these west side operations.

Rock Creek Pack Station accesses Fish Creek primarily over Silver Pass on extended full service traveling trips from Rock Creek over Mono Pass and exiting at either Duck Pass, Reds Meadow or on through to Yosemite National Park. These trips, numbering up to 30 a year, intensively use the grazing resources in the area. In the late 1980s the Forest limited the number of trips by Rock Creek Pack Station over Silver Divide to 13 trips due to increasing concerns over the resource conditions in the area and the heavy use and impacts associated with these traveling trips.

Reds Meadow accesses the area primarily from Reds Meadow down into Lower Fish Creek. They can loop up through Cascade Valley and back out to Reds for the occasional full service trips but the majority of their use in this area is spot or dunnage trips to Lower Fish and Iva Belle hot springs.

McGee Creek Pack Station accesses the area primarily over McGee Pass. Their use is predominantly spot and dunnage trips into the Upper Fish Creek vicinity, including Tully Lake. With a 12 mile ride from the pack station to just the pass, spot and dunnage trips into Upper Fish generally require that the wrangler either spend the night (and graze the stock or pack in feed) or travel back over the pass often arriving back after dark. Until 2001, McGee had been utilizing the grazing resource at Lee and Cecil for layovers associated with the long spot and dunnage trips over the pass. In 2001, when conditions of the access trail were determined to be of high concern, the pack station was asked not to use the area for grazing (although the trail could be used for spot /dunnage trips).

In Convict Basin, the commercial pack station located at Convict Lake ran trips into the basin up until the mid 1980s. At this time floods washed away a bridge that was required to make the trail passable to pack stock. A decision was made to no longer authorize use into the wilderness from Convict Lake. Use began accessing the upper basin sometime after this by other pack stations (Mammoth Lakes Pack Outfit and McGee) by way of Laurel Trailhead. Up to 30 trips and 200 stock have been reported a year in this basin recently.

This area receives the heaviest commercial pack stock grazing, with 2292, 2047, and 717 stock nights reported in 2001, 2002, and 2003 respectively, mostly in Silver Divide and Cascade AUs. The grazing took place in 32 reported locations by seven pack stations, all three years in ten of the locations, in two of the three years at five locations, and once in three years at 17 locations. There were some closures in effect for Yosemite toad, particularly in McGee Canyon.

Mono Creek/Rock Creek

Although eight operators identified that they use portions of the Mono Creek region, five of these have no recorded use in the past ten years. At one time these operators may have passed through the area on extended traveling trips, but today these trips rarely occur. The primary operator is Rock Creek Pack Station, accessing the area from the east over Mono Pass. Rock Creek has a high proportion of the full service traveling trips that spend one to three days per trip in the Mono Creek corridor. There is a heavy use of the grazing resources associated with these trips. They also offer spot and dunnage trips to various locations in the Mono Creek corridor, including Pioneer Basin, Fourth Recess, and Hopkins.

High Sierra Pack Station accesses the area from the west side at Lake Edison. Their use has been limited beyond Second Recess for the past ten years, but in the past had done more trips to Pioneer Basin. Conflicts with Rock Creek, and possibly the grazing restriction in Pioneer Basin contributed to a choice to reduce their use to this area.

D&F has incidental use to the lower Mono Creek area, while Bishop Creek and Pine Creek have incidental use associated with traveling trips through Mono Creek. Lost Valley has identified use but has not been in the Mono Creek area for over ten years.

Reported grazing use in this area has been quite variable, with 42, 897, and 480 stock nights reported in 2001, 2002, and 2003 respectively. Five pack stations reported grazing in 22 general locations. Thirteen locations were used only once and eight were used two of the three years, with the very general “Mono Creek” used all three years. The Pioneer Basin has been closed to grazing since 1988 due to resource problems.

Bishop/Humphreys

In the central section of the John Muir Wilderness, three pack stations provide direct access into this area: Pine Creek Pack Station accessing from Pine Creek and primarily traveling into Pine Creek and French Canyon; Bishop Pack Outfitters accessing Piute Creek and Sabrina Basin with heavy use into the Golden Trout Lakes areas west of Piute Pass; and Rainbow Pack Station accessing Bishop Pass with high use over the pass into Sequoia Kings Canyon National Park. High Sierra Pack Station accesses the area from the west and identifies operating areas in this region, but the most recent use reports has very little use beyond Hutchinson Meadow. Rock Creek, Lost Valley, and Reds identify use in the area but these operators have reported no use in the recent past with the exception of some traveling trips by Rock Creek

This area has relatively light grazing, all reported in Glacier Divide and French AUs. Five operators reported use of 133, 176, and 493 stock nights in 2001, 2002, and 2003 respectively, in six locations. Hutchinson Meadow received use all three years, Upper French Canyon was used in two years, and grazing was only reported in one of the three years in the other four locations.

Florence/Bear

This area is bisected by the Pacific Crest trail and John Muir Trail corridor. Most of the seven operators that identified use here only pass through the area on longer traveling trips. Two operators, High Sierra and D&F, utilize this area on a regular basis. High Sierra’s Pack Stations are located at Edison and Florence Lakes, while D&F hauls their stock into Edison from their base facility near Huntington Lake.

Muir Trail Ranch conducts packing operations from their base camp located on private property at Blayney Meadow, which is an in-holding within the John Muir Wilderness. The stock related activity is a small but important part of their guest ranch resort that is located on the private property. The guest ranch has been in operation since 1940. They hold a Special Use Permit, which was originally issued in 1948 (reissued in 1956), for primitive four wheel drive access from Florence Lake to the private property.

Lost Valley operates from its base headquarters on private property located at Double Meadow adjacent to the Muir Trail Ranch. In addition they maintain facilities and a corral at Florence Lake under a Special Use Permit. In past years Lost Valley has operated a burro rental service as well as traditional horse and mule outfitter and guiding. They have primarily operated from the private land but also to some extent from the facilities at Florence. They may also use the jeep road for primitive motorized access to their private property.

Moderate pack station use occurs at the Hilgard branch of Bear Creek, Sallie Keyes, Senger Creek, with low use dispersed onto many other destinations in the area.

Six operators reported grazing at fourteen locations in this area. The reported stock nights were 214, 80, and 178 in 2001, 2002, and 2003 respectively. Lou Beverly was the only meadow where grazing was reported all three years, three meadows were used in two of the years, and ten were only used once in three years. Hilgard and Rosemarie meadows are closed to grazing in alternating years.

In addition, several meadows are used as pastures: Jackass, Poison, and Hellhole by High Sierra and Double Meadow and Blayney in the East Florence AU by Lost Valley Pack Station and Muir Trail Ranch. Jackass is only partly in the Wilderness, part of the meadow is a Forest Service administrative pasture, and there are two exclosures.

John Muir Southeast

This area is characterized by the access it provides to Sequoia-Kings Canyon National Park. Five operators identified use in this area: Cottonwood Pack Station, Glacier Pack Trains, Mt. Whitney Pack Trains, Rock Creek, and Sequoia Kings Pack Station. Cottonwood operates at Cottonwood Creek and accesses Cottonwood Lakes Basin as well as provides access to Yosemite National Park both via the John Muir Wilderness and via Golden Trout Wilderness over Cottonwood Pass. They have low use into Cottonwood Lakes by recent use reports. Glacier Pack Trains operates primarily into North Fork of Big Pine with some hunting trips into Baker. Their use into North Fork of Big Pine is moderate, primarily supporting hikers and climbers in the form of spot and dunnage trips into the drainage. Sequoia Kings Pack Trains operates from Onion Valley primarily accessing Sequoia Kings Canyon National Park. Mt. Whitney Pack Trains has use authorizations for the Golden Trout and for this region of the John Muir Wilderness to access Sequoia Kings Canyon National Park. Rock Creek is part owner of the Mt. Whitney Pack Trains and has identified this area as a part of that operation, but also could be operating as Rock Creek and exiting any one of the trails from a trip through the National Park.

Pine Creek Pack Station was the only operator to report grazing in this area. The only reported grazing use was at Sawmill Meadow, with nine stock nights in 2001. Cottonwood Pack Station has a pasture permit for Windy Gap Meadow.

John Muir Southwest

This region has four operators that identify use: Lost Valley, Clyde, D&F, and High Sierra. One operator, Clyde Pack Outfit, is the primary user of this area and disperses a light to moderate level of use over many destinations. High Sierra and D&F operate at the north end of this region.

Clyde Pack Station is the only operator to report grazing in this area, with 251, 155, and 125 stock nights reported in 2001, 2002, and 2003 respectively in 20 locations. None of the locations was used all three years, six locations were used two of the three years, and fourteen locations were only used once in three years.

3.1.2 Wilderness

Wilderness Scale

The Ansel Adams and John Muir are adjoining wildernesses. They compose the central portion of a larger wilderness landscape that extends from Walker Pass to Tioga Pass and are one of the nation's largest contiguous wilderness landscapes in the lower 48 states. To the north the Ansel Adams is contiguous with Yosemite National Park. To the south, the John Muir wraps around the northern portion of Sequoia-Kings Canyon National Park.

The Ansel Adams Wilderness, originally named the Minarets Wilderness, was established by the 1964 Wilderness Act (78 Stat. 890; 16 U.S.C. 1131-1136). An additional 119,000 acres were added and the wilderness was renamed in the 1984 California Wilderness Act. There are 78,775 acres administered by the Inyo National Forest and 151,483 acres administered by the Sierra National Forest.

The John Muir Wilderness was originally established by the 1964 Wilderness Act (Public Law 88-577). 81,000 acres were added in the 1984 California Wilderness Act (Public Law 98-425). There are 351,957 acres administered by the Sierra National Forest and 228,366 acres administered by the Inyo National Forest; this area is in the northern portion of the Fish Creek watershed. There are also 240 acres of private land within the wilderness boundary. This includes private in-holdings at Blayney Meadow that are used for commercial pack stock operations by Muir Trail Ranch and Lost Valley Pack Station.

Wilderness Character and the Wilderness Act

The Wilderness Act (Public Law 88-577) provides the definition of what a wilderness area is intended to be and what unique values these areas should be providing. The Act in Section 2(a) states the designated wilderness areas shall be administered “for the use and enjoyment of the American people in such a manner as will leave them unimpaired for future use and enjoyment as wilderness and so as to provide for the protection of those areas, the preservation of their wilderness character.”

In this defining statement, two potentially competing objectives are put forward: use and enjoyment and the unimpaired, preservation of wilderness character. Wilderness character is a complex notion to define. There is no definition of wilderness character in the Wilderness Act and no legislative history on the meaning of the phrase (Landres et al., 2005). The Wilderness Act in Section 2 (c) refers to both environmental and social qualities of wilderness character:

an area of undeveloped Federal land retaining its primeval character and influence, without permanent improvements of human habitation, which is protected and managed so as to preserve its natural conditions and which (1) generally appears to have been affected primarily by the forces of nature, with the imprint of man's work substantially unnoticeable; (2) has outstanding opportunities for solitude or a primitive and unconfined type of recreation; (3) has at least five thousand acres of land or is of sufficient size as to make practicable its preservation and use in an unimpaired condition; and (4) may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value.

Policy development in the early years following passage of the Wilderness Act involved review committee reports and focused on the specific language of the Wilderness Act to define the concept of wilderness character. Section 2c in the Act been used to define and describe wilderness character (USDA Forest Service, 1972 and Landres et al., 2005).

Forest Service policy for wilderness management states that the agency is to:

Manage wilderness toward attaining the highest level of purity in wilderness within legal constraints. Each designated wilderness is affected by a variety of human influences that vary in intensity. In one area, human influence may be very limited; in another area, major disturbances occur. The number and intensity of these influences cause a gap between attainable legislative wilderness and the conditions that exist on a wilderness. The goal of wilderness management is to identify these influences, define their causes, remedy them, and close the gap between attainable level of purity and the level that exists on each wilderness. (FSM 2320.6)

In addition, the agency direction states that “Each wilderness should be at least as wild in the future as at the time of classification. Resource impacts shall be decreased or held constant. Conditions shall always be improved in situations where degradation exceeds wilderness resource criteria as defined by the designating legislation.” (FSH 2309.19 21.1)

The agency is responsible for insuring that the overall condition of the wilderness at the time of designation does not deteriorate or degrade; and that the conditions improve over time by managing the changing influences affecting wilderness character.

The Sierra and Inyo National Forests have a thirty year history of actively managing for an excessive demand for human use and enjoyment while taking actions to protect resource values. This history demonstrates successful attempts to reduce overall use levels, reduce party size, remove structures, improvements, trash, reduce campsite density, improve campsite conditions, close areas to improve conditions and reduce crowding, close areas to grazing, improve trails, and generally manage impacts. These actions have moved these wildernesses towards more purity, while at the same time allowing a sustainable level of use and enjoyment by the public.

Current interagency efforts to monitor wilderness character (Landres et al., 2005) define wilderness character as the combination of biophysical, experiential, and symbolic qualities that distinguish wilderness from all other lands. Wilderness character is protected or diminished and sometimes both, by management decisions and actions. According to Landes et al. (2004):

Because wilderness character is multidimensional, composed of both biophysical and social aspects, actions taken to protect one aspect of wilderness character may diminish another aspect. For example, a bridge built to protect a stream bank from erosion caused by people or horses crossing the stream may also diminish the opportunity for people to experience the challenge of crossing a stream, and it may diminish the feeling or experience of a natural setting. Similarly, the required use of hardened or designated campsites to protect the soil and vegetation in an area may diminish the opportunity for unconfined recreation and the sense of freedom from the constraints of society.

It is the responsibility of the agency to insure that wilderness character is protected and that the values of wilderness, including the local place-based and culturally significant components of wilderness are protected.

For purposes of analyzing the effects and existing conditions on wilderness character the following identified qualities of wilderness from the Wilderness Act are used:

Untrammeled – wilderness ecosystems are essentially unhindered and free from human control or manipulation.

Undeveloped – wilderness is essentially without permanent improvements or modern human occupation.

Natural – wilderness ecological systems are substantially free from the effects of modern civilization.

Outstanding opportunities for solitude or a primitive and unconfined type of recreation – wilderness provides outstanding opportunities for people to experience solitude or primitive and unconfined recreation, including the values of inspiration and physical and mental challenge.

These four qualities are used in discussing the conditions of the wilderness resource in both Chapter 3 and 4.

Desired Conditions for the Ansel Adams and John Muir Wildernesses

These two wildernesses are managed to achieve desired conditions that are set forth in the 2001 Wilderness Plan. Three “recreation categories” describe the physical, resource, managerial and social setting for managing visitor recreation use. Most of the wildernesses is managed for low use and very pristine conditions (Recreation Category 1). A very small portion (3%) is managed for concentrated use at popular destinations (Recreation Category 3); these destinations have been popular for decades and continue to draw a large portion of the overall wilderness use. These areas are to be managed intensively to insure a non degradation standard is met, therefore more management presence may be experienced. The third category (Recreation Category 2) is to be managed for higher levels of use in the primary trail corridors but low levels of use dispersed off the primary trail corridor. This category will generally see low to moderate amounts of use and where use does concentrate it will require more management, but not intense management as needed in the Recreation Category 3 areas.

This management strategy allows for use and enjoyment while preserving the four components of wilderness character. These recreation categories guided use level determinations made in the 2001 Wilderness Plan, specifically trailhead quota determinations. It follows research and agency direction for managing wilderness and protecting values. Though solitude or natural conditions are not found to the same degree in all parts of the wilderness, there are outstanding opportunities for solitude and the land remains substantially unaffected by civilization, offering an extraordinary contrast to civilization in the modern world. The challenge of management is to maintain wildness, provide experiences of wildness and preserve wilderness character conditions in an ever changing world.

Visitor Use

Recreational hiker, pack stock and riding stock use have been popular in these wildernesses since the early 1900s. Little more than anecdotal evidence regarding use levels exist prior to 1965. No consistent units of measures exist to draw firm conclusions about use trends over the past fifty to one hundred years. However, observations that were documented in some noteworthy historical

reports trace the type and levels of use in a very coarse way and from these it is reasonable to make some general estimation on how use has changed over time.

In a 1935 report on the High Sierra packing business, pack outfits estimated that they served 75-1500 persons a year per outfit. Cumulatively across the Sierra this was extrapolated to 32,000 people (Livermore, 1935). Today, pack outfit numbers range from 55 persons to 1100 persons serviced per outfit, for overnight use in the two wildernesses on the Inyo NF (USDA Forest Service, Inyo National Forest, 2003a).

In a USDA study of a proposal to add the north and middle forks of the San Joaquin drainage to Yosemite National Park in 1955, use levels in this area were portrayed as very low: In the North Fork of the San Joaquin (Ansel Adams West): “Recreational use in the headwaters of this drainage is limited primarily to fishermen and hunters. Several hundred people visit this limited area each year. Access is mainly from Clover Meadow or Granite Creek” (USDA Forest Service, 1955).

Observations from the Middle Fork of the San Joaquin and Rush Creek state:

Wilderness use, over the trails from the end of the roads totaled about 11,300 visitor days in 1955. These people go in by horse and on foot. Many of them are “Backpackers” and often includes the entire family. ...Use of the John Muir trail in and out of the park through Donahue Pass, is very light. It is calculated that not more than 200 people and 90 head of horses and mules use this trail each summer (USDA Forest Service, 1955).

Today roughly 1,000 people a year are recorded traveling over Donahue Pass from various starting points in the Ansel Adams and John Muir Wilderness. This includes hikers traveling the north to south route of the increasingly popular John Muir Trail.

A report of the High Sierra Wilderness District by wilderness manager Arn Snyder in 1960 indicates that recreation use had steadily increased for many decades (Snyder, 1960). Snyder estimated that 10,000 to 13,000 people visit that portion of what would become the John Muir Wilderness each year. Use figures for roughly the same area today are about 6,000 to 7,000 people per year (USDA Forest Service, Sierra National Forest, 2003).

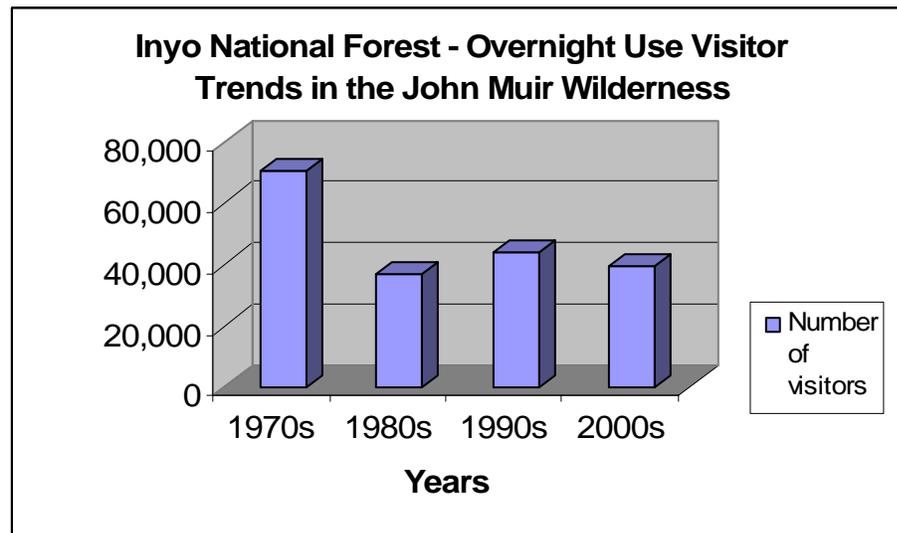

In summary, use has clearly increased on the east side of the Sierra, particularly with the increases in day use. On the Westside use appears to have decreased from the highs reported by Snyder and those of the 1970s, but appears to have leveled off in the last decade.

The number of people visiting these wildernesses is two to three times higher presently than when the Wilderness Act designated these areas. Today, there are more parties taking shorter trips into these wildernesses than in the 1960s. Visitor days may be equal to or only slightly more in 2003 than in 1964 (National Forest Recreation Visitor Days Data). This is the result of the average length of stay decreasing from an estimated 6.7 days (Snyder, 1960) to 3.4 (USDA Forest Service, Inyo National Forest, 2003a).

Although it is difficult to determine trends with great precision, data indicates that overall use levels have dropped since the increase of backpacking use in the 1970s (see Figure 3.4). Backpacking and day use has increased more than riding and pack stock use. Backpacking increased steadily until the 1960s and then sharply in the 1960s and 1970s (USDA Forest Service, Inyo National Forest, 1974). With limitations put into place in the late 1970s and early 1980s, overall use may have dropped off. However, visitation has shown a predictable pattern of

high and low use years, usually depending on snowpack, for the past fifteen years (USDA Forest Service, Inyo National Forest, 2003a), maintaining a similar overall use level.

Figure 3.4: Inyo National Forest - overnight use visitor trends in the John Muir Wilderness. This demonstrates some coarse trends of use over the past 30 years. Prior to the 1970s visitor use data was not estimated with any recording tool, such as at trailhead register or permit, so data is not comparable prior to the early 1970s.

While backpacking use has steadily increased in popularity, commercial pack stock use shows a gradual decline. The type of trips, the locations of trips and the season of use has changed more than the overall use, and these are as significant factors as overall use. The type of commercial pack stock use has changed from a business of renting stock to visitors and primarily all expense and spot trips to an increase in the dunnage type trips. More importantly, locations where commercial stock use occurs has changed more than overall numbers. This will be discussed further in the geographic scale.

The historical use by the Sierra Club has also contributed to the past and present impacts of these wildernesses. The Sierra Club outings began in 1900. They traveled on long multi-week trips with large numbers of stock (horses, mules and burros) and people. The Club itself recognized the impacts associated with their use and conducted a study on these impacts in the mid 1970s. The study investigated effects of trampling by humans and pack stock, firewood production and availability, human waste disposal, and impacts of pack stock on meadows (Stanley et al., 1977). The effects detailed in this document indicate that the same issues found in 2001-2004 existed in the 1970s. This helps confirm that these impacts do go back in time and have not gotten particularly worse in the past twenty years, and that other use groups, namely the Sierra Club, have contributed to the effects that exist on the ground today.

Use Data Sources

Tally Sheets – used for stock numbers, clients, service days actually used, type of trip, location of service provided.

Wilderness Permits – used for party size, managing quota, total public use by trailhead (including commercial uses).

Day use study – estimates of day hiking by trailhead (INF only).

Current Use

Visitor use data is most accurate in recent years⁵. Use data for overnight visitation is collected from two primary sources, wilderness permits and “tally sheets.” In analyzing use data, some data sets are more accurate than others. Commercial stock numbers and people served (clients), for example, are more accurate and precise on tally sheets since data on wilderness permits estimates the stock to be used while the tally sheets record what was actually used.

Service days⁶ are a less reliable or precise indicator of use trends. Service days count the number of people and days serviced by the pack station. For operators that do a lot of all expense trips, the service days used are higher than the operators running primarily spot and dunnage. An operator who runs spot and dunnage may actually serve more people and the people may spend more time in the wilderness. An operator may change their operations one year to running only spot and dunnage trips and use less service days than the previous year when they used more service days with all expense trips. It does not necessarily mean that they have less use that year, even though they used less service days.

Yet, it has also been noted by the interdisciplinary team that all expense trips have a higher impact than spot and dunnage trips. All expense trips require larger campsites. The holding and grazing of stock causes more disturbance than a string that travels in and out in a day, dropping the party. For these reasons, service days are not a good indication of use levels, or use-impact relationships. For the purpose of analyzing the effects of commercial packstock operations, the data sources listed in the inset box above provide the best understanding of the context and intensity of use levels. Typically, the number of people is a more reliable indicator of use levels and trends.

Wilderness Permit data on the Inyo National Forest has some irregularities that need to be accounted for. During the wilderness reservation contract (1996-1999) increased quotas were used to account for lack of no shows⁷. This resulted in elevated overall use levels. The 1980s and early 1990s data lacks precision with unreported use (data gaps) by commercial operators and/or ranger districts. With the advent of computers the quality of data has improved.

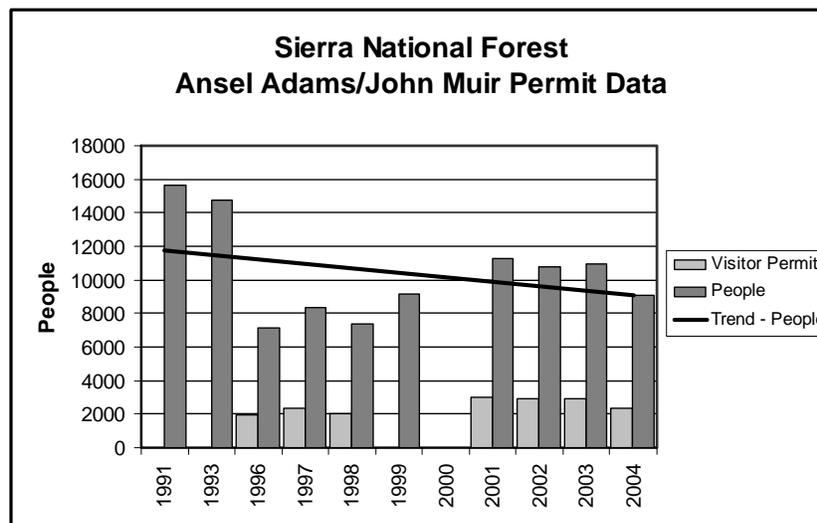

Overall visitor use (commercial and non commercial) has been mostly stable in the last ten years with approximately 18,000 permits and 50,000 to 60,000 visitors per year accessing from the Inyo National Forest. Entry from the Sierra National Forest use is less than the eastside, with an average of approximately 2500 permits and 9000 visitors per year (see Figure 3.5).

⁵ Use reports (wilderness permits and tally sheets) vary in accuracy over the years. 2001-2004 have been the most accurate on the Inyo, due to improved database capabilities and improved reporting by commercial operators. In the 1980s and 1990s there are reports of use but the data lacks precision or completeness. The Sierra National Forest data is most accurate for 2002-2003 with incomplete data for the 1980s and 1990s.

⁶ A service day is a day or any part of a day on National Forest System land for which an outfitter or guide provides goods or services, including transportation to a client. (FSM 2709.11-95-9,37.05)

⁷ The wilderness permits were sent out upon reservation during these years. Since there was no need to pick up the permit, no shows were not accounted for and the Forest estimated a no show rate that was added to each trailhead quota.

Figure 3.5: Visitor use trends on the Sierra National Forest

Notes:

- 1) 1991, 1993 - Data from 2001 wilderness permit + visitor days data from Minarets RD (conversion @ 6.54 VD/P)
- 2) 1996-2000 - Data recalculated from many original source records
- 3) 2001-2004 - Data from SNF Visitor Permit Database
- 4) 99-00 Data for HSRD lost on DG computer system

The timing of this use is concentrated into an eight week period. Most visitation takes place from the end of July to early September, with the highest peak of use within the first two weeks of August. July 4th is also a peak of use that is typically followed by a lower period before it peaks again in August.

The percentage of commercial pack stock use on primary access trails are listed in Table 3.3. While the overall percentage of commercial pack stock clients is at 6-10% of total use, this use is concentrated at the trailheads where the pack stations are located. At these trailheads the percentage of use is higher⁸.

Commercial Packstock Use

As stated above, use reports prior to 2001 are incomplete and cannot reliably show accurately the trends of all pack stations over time. What we can assess, based on limited information from the 1970s compared to the same data today, is whether overall levels of use have significantly changed. Data indicates that commercial pack stock client use has shown an overall decrease by approximately 22% from 1970s to 2004, when measured in percent of use. Table 3.2 and Figure 3.6 shows the decrease in commercial pack stock client numbers in these wilderness areas (in terms of both overall numbers and as a percentage of overall use).

⁸ Percentage of use is a very coarse and unreliable indicator of use levels. A severe spike or drop off in overall use can affect the percentage of commercial use even if the level of commercial use remains stable. On the Inyo, the Mt. Whitney area, which receives a very intense amount of use can greatly skew the percentage figures. Estimates over the years may show wide variations in estimations of percentage of commercial use because of this factor. For this reason using the number of people is a more reliable indicator of use trends. This will be discussed in more detail at the geographic scale.

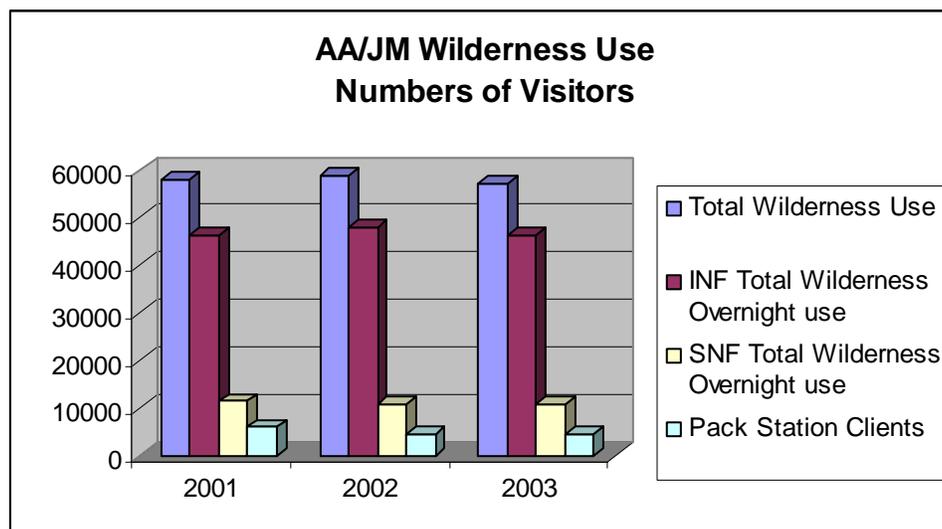

More currently, from the most accurate data sets, data shows commercial pack stations are servicing fewer people. 2001 was the last year that the pack stations operated without the new constraints from the 2001 Wilderness Plan. It was also a high use year for pack stations compared to the previous five years of recorded use. For these reasons, it becomes a good baseline from which to measure changes in use and effects of the 2001 Wilderness Plan on the pack stations.

Table 3.3: Current overnight use in the Ansel Adams and John Muir Wildernesses. Inyo and Sierra total overnight use figures come from Wilderness permit data. Pack station clients come from tally sheets for all pack stations.

Year	INF Total Wilderness Overnight use	SNF Total Wilderness Overnight use	Total Wilderness Use	Pack Station Clients	Percent of Use that is Commercial Pack Stations
2001	46,451	11,427	57,878	5991	10.4%
2002	48,048	10,804	58,852	4640	7.9%
2003	46,204	10,920	57,124	4479	7.8%
2004	44,155	9,011	53,166	4015	7.6%

Note: 2001 estimates

Figure 3.6: Ansel Adams and John Muir Wildernesses: number of visitors. This figure displays the percentage of overnight visitor use entering from each Forest compared to pack station clients in the Ansel Adams and John Muir Wildernesses. Sources of data are described in the Use data Sources box above.

The extent of pack station use in the wilderness can be described in overall numbers, in location specific numbers (expressed at the geographic unit scale below) as well as overall spatial distribution of use. The results of a spatial analysis that buffered all trails, campsites and grazing areas that packers identified as having used (even when they have not used some of these

locations for years or decades) indicates that the total area that pack stations use is 9% of the land base for these two wildernesses.

Although total amount of use and extent of the operation provides an understanding of the overall magnitude of use that occurs over the 800,000 acre planning area, the timing and type of use may have more of a bearing on resources impacts. For instance, in looking at the above information, one cannot tell if a destination or trail is receiving more use even if overall use is decreasing. For this reason, the discussion at the geographic scale becomes particularly relevant to the effects of pack station use in these wildernesses.

Quota Availability

Trailhead quotas were implemented for pack station use in 2002 at the direction of the 2001 Wilderness Plan. Prior to this pack stations wrote their own wilderness permits and were not subject to trailhead quota limits. In implementing the Wilderness Plan direction any new or reduced quota was phased in over a three year period. (The Record of Decision had identified five years, but the District Court injunctive relief directed three years). The target quota level was implemented in 2004.

An analysis of the commercial and non-commercial quotas reveals that the quotas for both of these uses are fairly equitable.

On the Inyo National Forest, there are a total of 81 trailheads managed with specific quotas. Twenty-two trailheads are identified as “commercial” trailheads, where the packers compete with outfitter and guides for this quota space. For 18 trailheads, commercial operations must compete with the general public for quota space. A full analysis of quotas being filled can be found in the project record.

On the Sierra National Forest, the 2001 Wilderness Plan listed 23 trailheads with specific quotas. In addition, eleven additional trailheads were inadvertently omitted from the 2001 Wilderness Plan, for a total of 34 trailheads managed with a quota. Of these, seven have separate quotas for commercial and public use, and three of those further separate commercial use into quotas for packers and non-stock outfitter/guides.

For Sierra National Forest trailhead entries, Table 3.5 shows that for 2004, the first year when the new Wilderness Plan quotas were fully implemented, the public did not have a disadvantage when attempting to acquire quota space. In 2004, public quotas only filled to capacity a few days during the peak season.

In summary, wilderness wide, trailheads fill at approximately the same frequency in a season for commercial trailheads as for the general public trailheads. The most significant example of a potential equity issue in commercial and non commercial access occurs on a non pack station used trail, the North Fork of Lone Pine Creek. On this trail, the general public quota was filled 50 days in 2004 while the commercial quota (mountaineering guides) was filled 3 days. Tables 3.4 and 3.5 show some of the comparisons between commercial and non commercial quota accessibility indicating that quotas are having an affect on pack stations, and on some trails more than the general public, in other cases less than the general public.

Table 3.4: Quota availability on the Inyo National Forest, 2004. This indicates that quota availability varies by trailhead and no clear trend is evident.

Trail	Number of Days Commercial Quota Reached 2004	Number of Days General Public Quotas Reached 2004
Shadow Creek	4	2
Hilton Lakes/Creek	8	3
North Fork Big Pine	5	17
Piute Pass	4	5
Rush Creek	7	0
Mono Pass	8	2
Bishop Pass	2	8
Lamarck	1	8

Table 3.5: Quota availability on the Sierra National Forest, 2004. This indicates that the commercial operators are experiencing more difficulty getting quota than the general public.

Trailhead	Number of Days Packer Quota Reached 2004	Number of Days O/G Quota Reached 2004	Number of Days General Public Quotas Reached 2004

Day Rides and Day Use

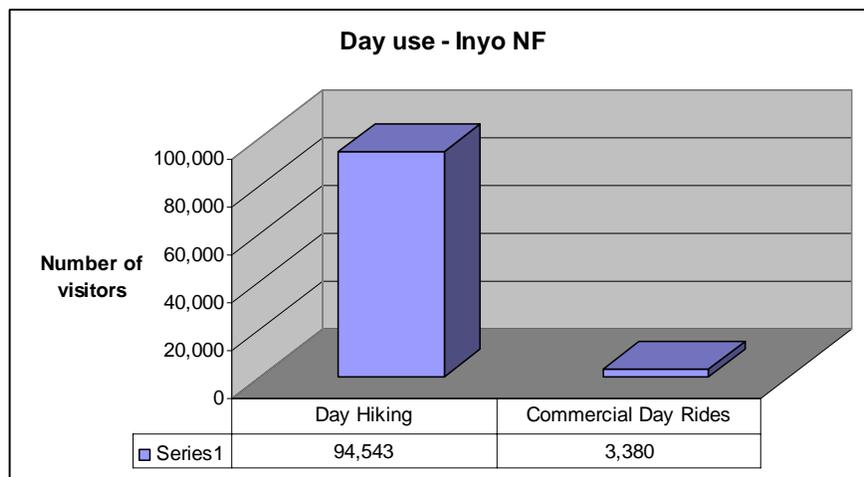

On the Inyo National Forest, day use activities in the wilderness are popular. Many people desire to hike, fish and lightly explore the wilderness environment. On these excursions, visitors rarely travel more than six to ten miles into the wilderness. Many trailheads are not at the wilderness boundary, and there are up to three miles that must be traveled to reach the actual designated boundary. Most day use only occurs at the very perimeter of the wilderness.

The level of commercial day ride activities occurring varies by operator. On the Inyo N.F., 11 of the 12 pack stations have an allocation and provide day ride services. Of these 11, 5 operators operate at low use levels, offering less than 100 service days (one person for either 1 hour ride, 2 hour ride, half day ride or a very rare all day ride) a season (the equivalent of 8 maximum party sizes over the course of 3 months). Three pack stations use between 100-200 service days. Two

pack stations have moderate to high levels of day rides (McGee Canyon and Mammoth Lakes Basin) and one operator has a very high level of day rides (at Reds Meadow) for which most of these rides go less than ¼ mile into the wilderness. Most all of these day rides go a very short distance into the wilderness.

Conversely, non commercial day hiking amounts to a very large volume of use in these two wildernesses. Findings from a study done on the Inyo National Forest between 2001-2003 estimates 94,543 day hikers in the Ansel Adams and John Muir, not counting Mt. Whitney day hikers (recorded by required wilderness permits at between 9,000 and 10,000 people).

Figure 3.7: Day use comparison between hikers and commercial day rides on the Inyo National Forest.

Commercial day rides and day use on the Sierra National Forest is not a significant use. Day rides amount to 242 to 310 commercial day rides a year in the Ansel Adams and John Muir Wildernesses. The locations of day rides vary. No data exists for day hiking visitors on the Sierra N.F. portion of these wildernesses.

Party Size

There have been few empirical studies of group size influences on either the extent or intensity of ecological impacts (Monz et al., 2000). Consumption of firewood and disturbance to wildlife are two areas where group size may have some quantifiable differences in impact (the former showing that large groups consume more wood resources leading to increased impacts, and the latter showing that one large group may be less of an impact than many smaller groups on wildlife). Generally, “where use and pre-existing impact levels are high, even large differences in amount of use have little effect on amount of impact” (Monz et al., 2000). Large groups of hikers and stock users can, if they do not use minimum impact techniques, cause observable impact in trail-less areas and while camping. Management of group size can be accomplished through limits on group size, as well as through other means.

The experiential impacts of large groups may be more of an issue than the ecological impacts of large groups. According to Monz et al. (2000):

From the standpoint of impact on experiences, we believe that the current groups size limits in place in most areas do have some benefits for protecting wilderness experiences. Seeing very large groups, for example, more than 20 people in a group, does bother many wilderness visitors. Such groups once

existed in wilderness, although they were always a minority. Now, in part because of group size limits they are very rare. But research also shows that encountering many other use, user and impact variables in wilderness is more bothersome than group size issues.

Whether the group size “problem” is widely experienced is clearly debatable. Repeatedly, studies find that the effect of large groups on a visitor’s experience ranks low, though this varied by wilderness (Monz et al., 2000). When ranked against other perceived problems it is consistently amongst the lowest ranked problem. In the John Muir Wilderness it ranked as 13th in the list of problem identified by hikers (Watson et al., 1993).

The current condition of the wilderness resource cannot be attributed to any one user group or type of use. However it is documented that the impacts associated with stock do tend to be greater than hikers (DeLuca et al., 1998; McClaran and Cole, 1993; Cole and Spildie, 1998). McClaren and Cole (1993) state that: “Even low levels of pack stock use can cause substantial impacts. Compared to impacts caused by backpackers, pack stock impacts to trails and campsites are more severe, and pack stock impacts to grazing areas have no corollary for backpackers’ impacts” (McClaren and Cole, 1993). They also state that party size is not the most effective means of reducing physical impacts and again, responds to social rather than biophysical impacts:

Of these behaviors [limiting party size, requiring feed to be packed in, encouraging riders to stay on trails, restricting loose herding of stock, restricting the practice of tying stock to trees or picketing stock and encouraging hobbling of stock] limits on party size may have the least effect of physical impacts. Party size limits are likely to be the most effective where physical impacts are likely to occur quickly (Cole and others 1987). Because most impacts occur with the initial use in such areas, subsequent use isn’t as important. Party size limits may be more important to avoid conflict with backpacking groups. Such groups particularly dislike encountering large parties with stock (Stankey 1979) (McClaren and Cole, 1993)

An analysis of party size in the Ansel Adams and John Muir Wildernesses, based on reported pack station use, indicates that amongst all pack stations over the course of eight years of data, 18% of trips had a party size greater than eight persons and 11% of trips greater than ten persons. There was a shift in 2002 when the court ordered a reduction in wilderness wide party size of 12 persons and 20 stock. For 6 years, up to 2001, the average trips with parties greater than eight persons was 17% and dropped to an average of 13% for 2002 and 2003. Even more dramatic a shift occurred with party size greater than ten persons, with the 6 years up to 2001 averaging 14% and dropping to 6% for 2002 and 2003.

Even though the party size limit was 12 persons, the reduction in parties between 8-10 may have resulted from total number of allowed stock per party being reduced from 25 to 20. This may have eliminated commercial pack stock services for groups greater than eight. Operators reported being effected by this change in 2002, stating that it restricted the size of spot parties as it limited the number of pack animals that could accompany a “full” party of 12 persons.

User Conflicts

A 1990 study was conducted in the John Muir Wilderness to understand the nature of conflict between stock and hikers. Findings from this study, combined with two other wildernesses, one being the adjacent Sequoia-Kings Canyon National Park, provide some insight into the conflict and potential management options for reducing the conflict (Watson et al., 1993). Findings point

out that conflict between these two user groups has increased with an increase in use of the wilderness, in particular with an increase in hiker use. It also showed that hikers who disliked horses were in the minority. The source of most of the reported conflict in the John Muir and Sequoia Kings Wildernesses were related to horse manure in places where hikers have to walk and noisy or rude stock groups. According to Watson et al. (1993), “Strong, consistent predictors of conflict between hikers and horse users were general feelings of inappropriateness of horse use in wilderness, differences in perceptions of visitors’ status related to horse use, differences in the strength of attachment to the wilderness, and the value placed on opportunities for solitude.”

Watson found that in the John Muir Wilderness less than 10% of stock users disliked their encounters with hikers, while 53 % of hikers disliked encounters with horseback riders. Hikers indicated that the behavior of others had interfered with their enjoyment of the wilderness. The main behavior of stock users that hikers complained about was stock defecation in places (primarily along trails) where hikers would have to walk. The next most frequently disliked behavior was stock groups making noise, being rude to hiker groups and littering. Hikers were found to place more importance on solitude than stock users.

Watson et al. (1993) also summarizes his findings with:

Stated as simply as possible, hikers who dislike meeting horses in wilderness believe the horse should not be in wilderness; they believe they are an inappropriate use of the resources. These hikers also are not as likely to accord high status to horse users, have stronger relationships with the wilderness, and place more value on the opportunities for solitude than those who do not dislike horses. Translating this knowledge into management strategies requires acknowledging first of all that hikers who dislike horses are in the minority.

Visitor Impacts

Use/Impact Relationship

For forty years, research on ecological impacts in wilderness has pointed to a curvilinear relationship between use and impact. In particular, research on soils and vegetation show that damage can occur at low levels of use, and these impacts do not always become greater as use increases (Frissell and Duncan, 1965; Dotzenko et al., 1967; LaPage, 1962; Merriam and Smith., 1974; Young 1978; Cole 1982). Research has gone so far as to conclude that amount of use alone may not be the most relevant factor to control (Washburne, 1982).

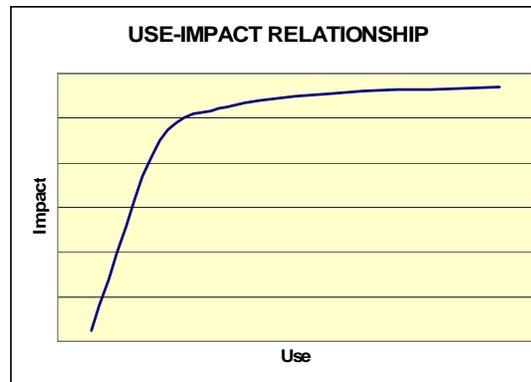

Figure 3.8
Use/Impact
Relationship

Many ecological impacts are often influenced by factors other than the amount of use including situational factors such as the type of use, the timing of the use, the behavior of the visitor and the bio-physical character of the resource being affected.

Research on the influence of various use types on trails has repeatedly shown that stock use has more erosion potential than either hikers or llamas. (Cole and Spildie 1998; Dale and Weaver, 1978). However trail location may be an important factor in causing deterioration of a trail (Helgath,1975). Kuss (1987) found that the greatest change in trail depth, cross-sectional area and soil penetration resistance was found to occur with low levels of use. Burdee and Renfro

(1985) found that trail depth was related to visitor use amongst other factors, while trail width was related to soil type of vegetation type on the Appalachian Trail. The timing and frequency of maintenance is also a factor in trail deterioration. Amount of use is merely one variable for impacts on trails.

Noticeable impacts exist at popular and easily accessed destinations. Any primary trail that accesses a subalpine lake or stream within 6-10 miles of a trailhead can expect camping impacts, trailing impacts and less solitude. These are areas where backpackers, day hikers and commercial pack stock users all converge. Once off the main trail corridors, these two wildernesses offer exceptional opportunities for cross country travel and more primitive experiences abound. In these areas off the main trail, which dominate the landscape, impacts are mostly unnoticeable, especially to the average visitor. In fact, the average visitor probably does not notice many of the impacts that managers record in a high use area.

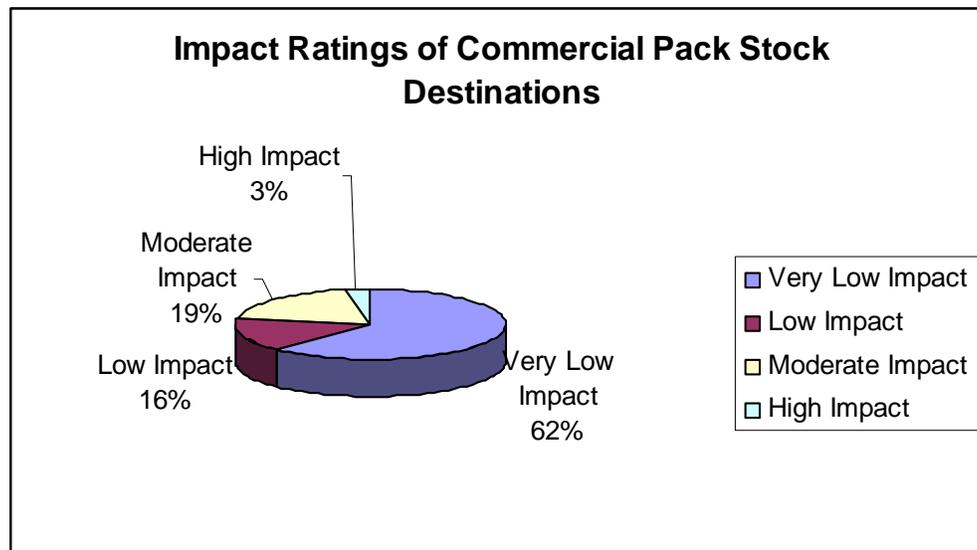

The most noticeable impact for visitors is likely the experiential effects of perceived crowding on the trail and at camping locations and use conflicts.

Goethe Lake, Glacier Divide. Use and impacts are light in trail-less destinations. Such areas are prevalent once inside the wilderness more than six miles from a trailhead. Access to these locations are relatively easy for hikers, yet commercial pack stock do not frequent these locations.

Data that was collected on the general conditions of destinations reveals few destinations with high levels of impact (Figure 3.9). Of 167 destinations that were identified for use by commercial pack stations, 4 rated as high impact sites (2%). The factors used for this rating include access issues (trail and use trail effects), riparian concerns, recreation impacts, camping potential and identified risk factors. Forty destinations rated out with moderate impacts (24%) while the rest (74%) rated out with low impacts. This indicates that while there are some locations of intensive impacts associated with use and are used by commercial pack stock, the vast majority of the destinations do not show significant signs of deterioration. These conditions will be more detailed in the geographic unit discussion.

Figure 3.9. Impact Ratings of Commercial Pack Stock Destinations. This figure shows the proportion of destinations identified by commercial pack stations for use under four categories of impact: high impact (4 destinations); moderate impact (24 destinations); low impact (20 destinations) and very low impact (79 destinations).

Trails

Trails have a high localized impact on the wilderness character. There is a high percentage of both highly developed and highly degraded trails, with little middle ground of primitive well maintained trails. This may have the single most effect on the wilderness character of these wildernesses. Highly developed trails, with substantial structures show the noticeable influence of humans, while highly degraded trails diminish the primitive, unconfined, and pristine qualities that wilderness represents. Though most of the wilderness is trail-less, and many visitors seek the trail-less experience, the majority of visitor's wilderness experience is associated with trails. As cross country travel increases, discernable use trails are increasing. Continued foot and stock travel on these developing use trails tends to facilitate more use to the more pristine destinations. (Gimblett, 1999)

The condition of the wilderness resource varies greatly across the 800,000 acres. There is a vast majority of the landscape that gets very light to no visitor use at all and therefore no impact or influence of recreational use is visible. However, where use concentrates, impacts are noticeable. Campsite density and occupied campsites is higher in popular locations (Gimblett, 1999; Inyo National Forest, undated). These destinations comprise less than 30% of the wilderness, but probably closer to 90% of the average visitor's experience. So, although the majority of the wilderness offers high opportunities for solitude, undisturbed qualities and primitive, unconfined experiences, the majority of visitors experience the impacts of heavily used and highly developed trails, moderate and severely degraded trails, sometimes crowded corridors and destinations, and noticeable recreational impacts associated with camping and traveling in the wilderness.

The 2001 Wilderness Plan provided direction for trails management. No new trails will be constructed and no trails will be upgraded solely to provide access for stock. Trails will be managed consistent with the recreation categories to prevent inconstant trail objectives with the desired

conditions and qualities of destinations. Use trails guidance is provided to help manage these trails consistently over time.

Campsites

As described above, campsite impacts reach a peak with light to moderate use and beyond this point decreases significantly. (Frissell and Duncan, 1965; Dotzenko et al., 1967; Young, 1978; Cole, 1982). Soil compaction leads to increased runoff and erosion potential. Often the core area of activity of a campsite receives intense compaction.

Expansion of a campsite is an impact that occurs over time. Expansion of a campsite can occur when an existing site is too small to accommodate the size of the party. Change occurring at the periphery of the site may increase the area of impact and cause more significant impact than amount of soil compaction or vegetation loss at the core of the site. Wood fires can also profoundly change the ecology of an area. The removal of woody resources may deplete surrounding area of nutrient recycling in the ecosystem. The fire itself can change soil properties, loss of nitrogen, organic matter, changes in pH and concentration of minerals (Shreiner, 1978) in the localized area of the site. Ash and charcoal concentration may cause changes that repeated use exacerbates (Cole and Dalle-Molle, 1982).

The proliferation of campsites and their associated impacts (described above) can lead to a larger area of impact. When campsite choice is left to the visitor, as it is in these two wilderness, with few areas closed to camping other than the 50 foot buffer from water, more management is often required to reduce the number of sites, remove newly created sites, and reduce the expansion of a site, known as containment. Each year wilderness rangers and volunteers remove hundreds of campsites that have been created by visitors. Most new campsites result from the non commercial visitor, as commercial pack stock destinations tend to be to the same location, and overnight holding of stock occurs at existing sites. Very few new stock camps have been created in the past twenty to thirty years.

Impacts that affect the functionality of a site may lessen its desirability. Campsites used by stock parties do tend to be larger and have more impact than sites used by hikers. Stock camps typically have areas where stock is held, areas where “high-lines” are placed between trees to hold stock. If trees are impacted to a point where they lose their functionality for high-lining, or increased impact would be considered unacceptable, the site either expands or can be abandoned for a new site. Campsite expansion at stock sites has been observed over the years and it has been up to permit administrators to work with the packers on campsite management.

The ecological impacts of pack stock use are similar but more severe than hikers (Cole and Spildie, 1998; DeLuca et al., 1998). A case study in the Selway-Bitterroot Wilderness in Idaho demonstrated the value of a containment strategy on stock campsites at heavily used destination areas. The number of campsites as well as the intensity of the site impacts changed as a result of an intensive management strategy. Designated stock holding areas, containment of the size of the site combined with restoration efforts in closed areas all contributed to a reduced area of disturbance, less bare soil and tree scarring. Root exposure and bare mineral soil exposure increased as a result of concentrated and repeated stock use in the same area. But improvement in the former stock holding area compensated for the deterioration in other parts of the campsite.

Campsite inventory has been conducted in the last ten years over the majority (70%) of Inyo National Forest’s portion of the Ansel Adams and John Muir Wilderness. Similar inventory work was done in the late 1970s and 1980s in some locations.

The condition of campsites can change with annual maintenance of campsites and containment and restoration work accomplished by wilderness rangers. In preliminary analysis the density of campsites appears to be within standards throughout the wilderness, with a few pockets where on-going ranger work can target elimination of some sites in locations where density appears to be approaching standards. Similarly, considerable work has been done since 2001 to remove campsites that are within 50 feet of water. Project work in Humphreys Basin, (specifically Golden Trout Lakes), French Canyon (Moon, L Lake, Elba) and other locations have accomplished implementation of the 2001 Wilderness Plan standards for distance from water and density of sites.

Specific effects of campsite, including stock holding campsites used by commercial pack stations can be found in the geographic unit discussions.

Geographic Unit Scale

In the discussion below, commercial use—people and stock—is categorized as very low, low, moderate, and high. The client and stock use recorded on tally sheets by pack stations was divided into these categories to provide a consistent method of characterizing use levels in these wildernesses. In the methodology used to analyze tally sheet data, a two way spot or dunnage trip with 10 people and 10 stock in and 10 stock to return and bring the party out, would be counted as 2 trips, with 10 people and 20 stock total. Not all spot and dunnage trips are two way. It is believed that this most accurately analyzes the amount of stock used to service a party.

People and Stock Use Categories

Very Low	= 1-10
Low	= 11-50
Moderate	= 51-200
High	= 201-350
Very High	= 351-800

Ansel Adams East

The northern portion of this Geographic Unit receives no commercial pack stock use. From Parker south to Crater Creek, however, there is moderate to high commercial pack stock use. This unit is very desirable for many types of recreational activities. Popular trips include those starting or ending from the Reds Meadow vicinity. The John Muir Trail and Pacific Crest Trail traverse this unit and it is a popular trip to start at Reds Meadow area and travel to Tuolumne Meadows or Yosemite Valley. In 2004, 1007 people reported exiting to Yosemite, via Donahue Pass, from various trailheads entering the Ansel Adams and John Muir Wildernesses on the Inyo National Forest. Most of this unit is Recreation Category 2⁹ with the Thousand Island, Garnet, Rush Creek and Shadow/Ediza Analysis Units being managed as Recreation Category 3.

Very high commercial stock numbers are recorded in the Rush Creek Analysis Unit (AU). Rush Creek and tributaries of Middle Fork of the San Joaquin drainage have a high percentage of commercial pack stock use. Up to 34% of the use in Rush Creek is commercial pack stock, with

⁹ “Recreation Category” is the desired setting for areas in the Ansel Adams and John Muir Wildernesses. Three categories were established for social and ecological conditions and are defined and mapped in the 2001 Wilderness Plan.

up to 100 wilderness permits issued to Frontier Pack Trains in a season. The primary destinations are Clark, Alger, Davis, Waugh and Weber Lakes. Commercial pack stock use is distributed amongst these primary destinations, with Clark Lake receiving a slightly higher proportion of the use.

The areas where pack stock use occurs show light to moderate wilderness impacts. Frontier Pack Trains is required to use specific campsites for their overnight holding of stock. This generally protects the destination from the expansion of impacts by the pack stock use, but the sites are large and heavily impacted.

Waugh Lake has a low level of wilderness character due to the presence of the constructed dam for water storage. Generally the wilderness character of this area is diminished by the presence of the structures and, to a lesser extent, the heavy stock use.

High to very high commercial stock numbers are recorded in the Upper Rush Creek AU. Pack station destinations in this area include Marie Meadows, Davis Lake and Donahue Meadows. Davis and Marie Meadows have established campsites with stock holding areas and/or grazing associated with them. These camps concentrate impacts associated with stock and people into fairly contained areas. These locations, just off the John Muir Trail, have moderate opportunities for solitude.

In the Thousand Island AU, Thousand Island and Garnet Lakes receive a high amount of overall use. Very high commercial stock numbers are recorded in this area. This high use, which has been occurring for at least 40 years, has contributed to visible impacts to wilderness character. The area is being managed as a Recreation Category 3, and requires considerable management to maintain the qualities of wilderness character. There are low opportunities for solitude at Thousand Island and Garnet Lake due to the popularity and draw of these destinations.

Day use is high in this area, with the combined use on the High Trail, River Trail and John Muir Trail. Highly impacted campsites (large total area, proximity to water, social trails, vegetation loss, barren core), combined with grazing impacts at the inlet and trailing to grazing, leads to a perception of a disturbed landscape at Garnet Lake. These conditions are, to some extent overshadowed by the high scenic qualities of the area.

The Shadow/Ediza AU also has high to very high recorded commercial stock numbers. Specifically, the Shadow Creek corridor and Ediza Lake receive high use. A moderate percentage of the use is commercial pack stock. Rosalie Lake receives moderate pack stock use with some associated grazing. The area has low opportunities for solitude as it draws over 1,500 overnight visitors and up to 50 day hikers a day (USDA Forest Service, Inyo N.F., 2003b). Primarily due to the proximity of a holding area near water, campsites for Reds Meadow's full service trips in the Shadow corridor show signs of moderate impacts. A camping site used at the inlet of Ediza Lake is also showing impacts. The highest concern at this site involves access that bisects a riparian area.

Moderate commercial stock numbers are recorded in the Minaret AU. Less than ten permits a year are issued to commercial pack stock parties. Total use ranges from 140-200 permits a year. Emily Lake shows considerable impact, due to camping conditions and trail deterioration. This human disturbance affects the wilderness character at this destination.

The King Creek AU, managed as Recreation Category 2, has a low level of overall use and subsequently has higher opportunities for solitude than the remainder of the Ansel Adams East

region. A few destinations used by commercial pack stock, including Holcomb, Superior, and Anona Lakes, show signs of diminished wilderness character due to human disturbance caused primarily by stock campsites and trails impacts. Although no one destination in this analysis unit receives high stock numbers, cumulatively this area has high to very high stock numbers, equivalent to Thousand Island, Rush Creek and in some years Shadow/Ediza. Reported stock numbers are higher at Superior Lake than the other destinations.

Ansel Adams West

This area receives a moderate level of overall recreation use. Commercial pack stock use is distributed fairly evenly throughout this region, with light to moderate levels of use throughout the area. Higher use (moderate) occurs in the Lillian, Staniford, Lake Catherine, and Cora Analysis Units. Throughout the region the wilderness resource shows evidence of light to moderate impacts with a few exceptions of areas that show evidence of heavy use.

High use in the 1970s led to the establishment of camping closures at all or part of four lakes: Lillian, Cora, Rainbow and Sadler. One effect of these closures was the dispersion of use and impacts elsewhere. A ¼ mile circumference around Rainbow Lake, which has limited capacity for campsites, was closed entirely to camping. After this closure, pack stock use drifted over to Flat Lake where two large established stock camps became the destination for this area.

Relative to other Recreation Category 3 areas, the Staniford AU receives moderate use and shows only moderate impact. There are access issues with Staniford, as the system trail does not go to the actual lake and use trails have developed to access the camping. The lake has some good camping opportunities. Lady Lake has moderate opportunities for solitude and a high capacity for camping.

Moderate commercial stock numbers are recorded in the Lillian Analysis Unit. Fernandez Creek junction has multiple large stock camps that are large in total area, with extensive vegetation loss, barren core and soil compaction. The sites also have campsite development, including benches, hitching rails and shelves.

Low commercial stock numbers are recorded in the Triple Divide AU. Anne Lake has some impacts associated with pack stock use. The trails, use trail, and campsite around this lake all show signs of moderate impact and disturbance. Rutherford Lake offers very limited camping opportunities and the existing sites are close to water. The area is below the elevational fire closures but has very sparse firewood resources.

Moderate commercial stock numbers are recorded in the Sadler AU. Sadler Lake has a higher density of highly impacted campsites, including two large pack stock camps and associated grazing impacts. Opportunities for solitude are moderate. Isberg and Joe Crane Lakes show moderate recreational impacts and moderate opportunities for solitude.

Low to moderate commercial stock numbers are recorded in the Cora AU. Cora Lake has moderate opportunities for solitude. Moderate to severe impacts at many large campsites affect wilderness character. Low to moderate commercial stock numbers are recorded in the Lake Catherine AU

Fish Creek/Convict/McGee

While this region shows overall low to moderate use levels of use by six pack stations (relative to other geographic units), this use makes up a high percentage of non-John Muir Trail use. Despite this overall moderate use, three AUs—McGee, Purple Bench, and Silver Divide— have high commercial numbers. The commercial pack stock use of the area shows a high proportion of full service traveling trips. This area is accessible from the east side over Duck Pass, Reds Meadow, and McGee Pass trailheads. From the west side, Goodale Pass is nine miles from Lake Edison. Impacts to the wilderness character are moderate at a number of the destinations used by commercial pack stock. Impacts are high relative to the use levels occurring.

Moderate commercial stock numbers are recorded in the Convict AU and commercial stock access is via the Laurel Lakes trailhead only. Convict shows impacts from past heavy use, including noticeable tree mutilations from firewood gathering and campsite development. Current overall use is low but commercial pack stock use is moderate to high. In 2001, commercial use was high but dropped off in 2002 and 2003. Genevieve shows impacts at a large campsite and the condition of the site diminishes the wilderness quality at that location. Opportunities for solitude are likely high, but if more than one party is in the vicinity the opportunities would be compromised. Cloverleaf Lake has high opportunities for solitude and generally very high wilderness character.

High commercial stock numbers are recorded in the McGee AU. This very scenic drainage accesses Upper Fish Creek. Overall use in this drainage is moderate—typically 200-300 parties a year enter at the trailhead. Since 1995, the highest number of people served was in 2003, with 215 clients. Stock numbers have been less than 200/year except for in 2003 when the stock number reached over 200. The pack station destinations in this area are light to moderate and spread between Grass, Round, Steelhead, and Big McGee Lakes. A campsite used near Round Lake shows moderate impacts mostly associated with site access. Big McGee Lake has a cluster of campsites where the pack station drops parties off in the only area appropriate for camping. The opportunities for solitude are moderate to low. These are the last sites before McGee Pass. This, combined with topography, has caused a concentration of sites around McGee Lake.

Very high commercial stock numbers are recorded in the Purple Bench AU. Purple Lake has a high concentration of pack stock use and impacts. Most of the impacts are contained to three primary campsites in the vicinity of Purple Lake. However, use trails between camps and the general condition of these trails add to the overall level of recreation impact. Although the area is of high scenic quality, the wilderness character is diminished by the disturbance and human influence. Opportunities for solitude are low. The solitude of the area is further compromised by its popularity with John Muir Trail (JMT) through-hikers. At Duck Lake (where overnight camping has been closed) some of the historical impacts that exist are in a recovery stage. There is high day use to Duck Lake. Also in the Purple Bench AU, Lake Virginia has moderate levels of impact with low opportunities for solitude (mostly due to its location on the JMT). It has a high capacity for durable camping.

Moderate commercial stock numbers are recorded in the Upper Fish Creek AU. Three pack station destinations, Tully Lake, Horse Heaven, and Tully Hole, show moderate impacts to wilderness character. Tully Hole has low opportunities for solitude due to its location on the John Muir trail and very little opportunities for camping away from the influence of the trail. It has some moderate impacts from camping with one stock camp at the east end of the meadow. Horse

Heaven has a high concentration of campsites that are moderately impacted and one large and highly disturbed stock camp with a wire drift fence that extends across the trail. Tully Lake (Recreation Category 1) has some access issues, a small capacity for camping right at the lake, but most of the year likely experiences high opportunities for solitude. One relatively small and contained stock camp, suitable for moderately sized parties (6-8 people), is located in a saddle at the north east end of the lake. This location is currently not accessed by the system trail, requiring a use trail to be used to access the camp.

Very high commercial stock numbers are recorded in the Cascade Valley AU. This unit has high scenic qualities where the trail follows Fish Creek as it cascades down the valley. It has relatively light use throughout the unit, except for one location, Iva Belle Hot Springs, which draws a concentration of use. Pack stations transport parties to the area but are prohibited from camping closer than ½ mile from the hot springs. The destination has low opportunities for solitude and is severely impacted with a high density of heavily impacted campsites. The unique qualities of the area, however, may offset the disturbance and high human influence that diminishes the wilderness character. Cascade Valley (proper), Second Crossing, and Third Crossing show moderate impacts to wilderness quality, with large stock camps noticeable at both Second and Third Crossing. The Fish Creek Trail bisects the Third Crossing stock camp. This site is an expansive area of disturbed soils and vegetation/tree mutilations with evidence of stock holding throughout the area.

High commercial stock numbers are recorded in the Silver Divide AU. Moderate to high impacts are evident throughout this analysis unit. Squaw Lake, located on the JMT, has low opportunities for solitude. Peter Pande has moderate opportunities for solitude, with severe impacts along the trail accessing the lake. The human influence and disturbed environment of the access trail have contributed to a diminished wilderness character. It is a large lake but has relatively few good campsite options, with limited capacity for holding stock. Olive Lake is a moderately small lake with very little capacity and a well-established stock camp. Due to the size of the lake, opportunities for solitude would be greatly affected if more than one party were camped at the lake at the same time. Due to its proximity off the main trail, it appears as though the lake gets little use, and with the exception of the one large stock camp, the impacts are minimal. Lost Keys Lakes appear to have sustained impacts in the past but gets very little use currently, either by the public or by the pack stations. Lake of the Lone Indian has low opportunities for solitude due to its location adjacent to the trail and limited camping opportunities. Like Olive Lake, more than one party camped at Lake of the Lone Indian would diminish the solitude. Jackson and Grassy Lake receive a high concentration of use. Grassy Lake exhibits more impact than Jackson Meadow, perhaps due to its smaller size and concentration of intense impacts of stock camps and grazing. The stock camps contribute to a sense of a disturbed area and diminish the qualities of wilderness character.

Mono Creek/Rock Creek

This region covers a large area of high visitor use, much of which has a high proportion of commercial stock use. A large percentage of very degraded trails characterize the area.

In this geographic area, Hilton, Fourth Recess, and Graveyard AUs have high-recorded commercial stock numbers. Pioneer and Silver Peak AUs have moderate to high-recorded stock numbers, while the Bear AU has moderate commercial stock numbers. Little Lakes, Tamarack,

Morgan Lakes, Hopkins, and Volcanic AUs have low-recorded stock numbers. There is no recent recorded commercial stock use in Laurel, Second Recess, and Devils AUs.

In the Hilton AU, Hilton Lakes were historically the location of a resort and recreation residence structures and there is a noticeable human presence on the land. The area has been improved greatly since its designation as wilderness, when these structures were removed. Some remnants of this era are the logjam of structure materials at the outlet of Davis Lake, and a garbage dump in the vicinity of one of the campsites. Presently, the area receives a moderate level of overall visitation, but very high commercial stock numbers are recorded in this area. The Hilton AU has the highest proportion of commercial pack stock use to overall use (45%) of all areas on the Inyo N.F. The area shows evidence of this heavy stock use with large impacted sites, holding areas, and the extensive use trails that have resulted from stock travel between camps. Some rehabilitation occurred in 1999 to reduce the impacts at the peninsula of Second Lake. At many times in July, the opportunities for solitude are low. The presence of human disturbance is noticeable throughout Second and Davis Lake and on up to 3rd and 4th Lake. Beyond 4th Lake the area retains a more primitive quality with no record or evidence of use.

Little Lakes Valley receives the highest level of day use in the Ansel Adams/John Muir on the Inyo National Forest. An average of 100 -150 day hikers per day visit this area annually (USDA Forest Service, Inyo N.F., 2003b). It has high scenic qualities, easy hiking, and access to popular mountaineering. Commercial pack stock use is very low, both relative to hiker use and in general. In 2001, seven parties with commercial stock support entered into this area: in 2003; one party. Gem Lake, the farthest trailed destination, has high recreational impacts with the campsites and trails, and shows very little potential and capacity for good durable campsites. Chickenfoot Lake has capacity for durable camping and is suitable for larger groups. Long Lake is also impacted with campsites at the inlet; suitable camps are located in this vicinity but access is not hardened and crosses some riparian areas. The entire unit is a Recreation Category 3.

Up to five trips a year has been recorded by Rock Creek Pack Station into the Tamarack AU. This is a quiet area that receives very light use (40 total parties in 2003). There are high opportunities for solitude. The wilderness character is high as it offers a very quality primitive and unconfined type of recreation experience as the areas is generally low in development of trails. Some historic manipulation of the water below Dorothy is noticeable, most likely for grazing purposes.

Morgan Lakes AU is commonly accessed from Little Lakes Valley. Historic impacts from mining are noticeable and remains of this use along with old camping impacts are noticeable. It receives very light overnight use currently. Commercial pack stock use is low to moderate.

In the Fourth Recess AU, the condition of the Mono Creek trail is very poor. The highly degraded Mono trail corridor with unsigned spurs that often lead to large packer camps diminishes the wilderness qualities of the area. Three large packer camps, two in the vicinity of the confluence of Third Recess and one below the junction to Hopkins are extensive in size and received a high condition class rating for barren core, extensiveness of social trails, vegetation loss, and total size. The presence of humans and particularly stock use are substantially noticeable in this corridor. Opportunities for solitude are moderate. Fourth Recess itself has limited camping, but is very popular due to it being the first major destination over Mono Pass (Gimblett, 1999). It has the potential to be crowded with parties. This crowding is probably

exacerbated by the camping potential limited to a relatively small area around the outlet. One very suitable site for large parties exists at the west side of the outlet.

The Pioneer Basin AU receives a moderate level of overall use but shows unmanaged recreation impacts—moderate in severity. Although grazing was prohibited in the 1980s, the trail system has deteriorated and use trails are proliferating as a result of a trail system that does not meet the needs of the use demands. Campsite impacts are moderate at Mudd Lake with a high density of Class 3, 4, and 5 sites. The upper basin receives use by hikers camped lower in the basin. Very few good camping opportunities exist above Lake 10,880. Severe trail degradation to Lake 10,900 and up to Lake 10,880 from the east side of the basin has visual as well as resource impacts. Opportunities for solitude can be high at times but in mid-season are most likely moderate, even low. Multiple stock camps exist in the lower basin, including one primary camp at Mudd Lake, but two or three other large sites at the northeast side of Mudd show vegetation loss, barren core, soil compaction, and some severe tree mutilations from firewood gathering. There are many use trails that serve to connect these large camps, including a trail from Mudd Lake stock camp to the Third Recess stock camp. One very suitable stock camp exists at the stream crossing ½ mile above Mudd Lake.

Use in the Hopkins drainage is concentrated at lower Hopkins Lake. An old trail over Hopkins Pass to Big McGee Lake in the McGee drainage has not been maintained and there has been no recorded commercial pack stock use for years. Commercial pack stock operations utilize lower Hopkins Lake where campsite impacts are noticeable from stockholding and a large site shows vegetations loss, a large barren core, soil compaction, and is within 50 feet of water. This is the most logical site for the camp, but is poorly located and expansive. There is a use trail from the inlet of Hopkins Lake that travels through springheads and then reaches the ridge and descends down to the main Hopkins Valley and is noticeably degraded in a few locations. It appears to be used for stock to access upper Hopkins area and provides a loop trip opportunity back to the lower lake.

Laurel AU has no recorded commercial pack stock use and appears to have received only very light use for a long period of time. Very light impact is noticeable at camp locations lower down in the valley. There are few sites at Laurel Lake and virtually no noticeable sites at Grinnell Lake. The area has high opportunities for solitude and is substantially undisturbed with only historic impacts at an old stock campsite lower in the valley. It provides a primitive experience.

Similar to Laurel Lake, Second Recess has no evidence of stock use in many years. The trail is overgrown and has not been cleared making stock travel very difficult. Camping impacts are old, and as such, show little evidence of the presence of humans. The opportunities for solitude are high.

The PCT/JMT is the primary travel route through the Silver Peak AU. It is a moderately high use corridor for thru-hikers, Rock Creek's full service trips from Mono Creek to Mammoth and Yosemite, as well as High Sierra's spot and dunnage trips. Use appears to be concentrated in the vicinity of Quail Meadow for thru-hikers and Rock Creek Pack Station. Mott Lake is receiving a very high level of use as well and has some moderate camping impacts with a moderate capacity for camping. The area appears to be quite popular and can become crowded. High Sierra has recorded up to ten trips a year into Mott and D&F was observed servicing clients in this area in 2004, although there is no recorded use in the past three years by this outfit. Recreation impacts

are moderate to high mostly due to the condition of the trail, specifically the last ½ mile to the lake.

With the presence of a snow survey cabin and snow sensor structure, the Volcanic AU shows a high degree of human presence. Other than this site and its associated impacts on wilderness character, the area has high opportunities for solitude and is otherwise untrammled and undisturbed. Light commercial pack stock use is recorded.

In the Graveyard AU, Graveyard Lakes is a very popular primary destination and high commercial stock numbers are recorded in this area. High Sierra and D&F Pack Station combined have about 40 trips a year in the area and bring over 100 people a season. The camping is concentrated around the outlet, as the camping potential is rather limited to this area. It is a mid-sized lake and with more than one or two parties the area can feel crowded. It is likely that many nights a summer there are more than three parties camped at a time. The upper lakes in this basin receive lighter use. Some impacts at the campsites exist at the second and third lakes. Above these lakes, the imprint of humans is substantially less noticeable, other than the trail, which becomes non-existent after the third upper lake. Opportunities for solitude are low at the lower lake and moderate at the upper lakes.

Two other destinations, Feather and Arrowhead Lake, receive some pack stock use. Arrowhead Lake has no recorded use in the past three years, but the narrow trail offers primitive and unconfined recreation that accentuates the wilderness character of the area. Light impacts are noticeable at Feather Lake, but there are high opportunities for solitude. The trail to Feather Lake is not entirely visible and difficult to follow. This combined with the high scenic qualities at the lake makes the setting high in wilderness character. Only one reported trip to this destination was recorded in the past three years.

The Devils AU receives very light commercial stock use with moderate camping impacts at the inlet of the lake. Four trips were reported in this area in 2003, with no recorded trips for 2001 and 2002. Opportunities for solitude are moderate, particularly near the outlet of Devil's Bathtub where there is a high concentration of campsites. Devil's Bathtub, the primary recreation attraction within this analysis unit, is primarily a day use destination.

The Bear AU has moderate commercial stock numbers. This area is used primarily as a corridor for traveling into the Bear Creek and John Muir Trail (JMT) corridor. The presence of humans is mostly limited to parties accessing the JMT, although one very lightly used site below the JMT junction offers a suitable campsite location for larger parties and stock parties. The opportunities for solitude are moderate on this corridor. Given that this is a primary access to the region from Lake Edison, the area probably has a high proportion of commercial stock use.

Bishop/Humphreys

This area receives moderate to high visitor use and moderate commercial stock use throughout the area. Two analysis units have no reported commercial stock use, Granite Park and Gable.

There is low commercial stock numbers recorded in the Horton AU. This area is a Recreation Category 2 and receives low use, less than 75 permits a year. Commercial pack stock use has mostly been day trips associated with spring horse drives. Although there are past indications of human use in the area (mining cabins), there are high opportunities for solitude. There is a moderate level of day use (average of eight people a day).

Very high commercial stock numbers are recorded in the Piute AU. Piute Pass Trail is a high use trail with 700-800 permits a year. Up to 15% of this use is commercial stock use. Visitors on this trail experience a high level of stock use (Gimblett, 1999) most of which continues over the pass. Very low levels of day rides occur (only 2-3 trips a year) and most go to Loch Leven Lake. Piute Lake has good campsite potential and shows moderate impacts from sustained high use that occurs by the general public. Commercial packers have applied material (sand, manure) to the Piute Pass Trail (referred to as “sanding”) to harden the snow pack and make it easier for stock to pass and melt the snow. The area is a Recreation Category 3.

In the Lamarck AU, the trail to Lamarck Col accesses Sequoia Kings Canyon National Park. Use is moderate on this trail and pack stock use is low with 4-6 trips a year to either Lower Lamarck or to the Col area. Day use is moderate with an estimated 12 parties a day. Lower Lamarck has limited camping opportunities at the outlet, and opportunities for solitude are low and easily diminished if more than one party is camped there. The area has evidence of recreation impacts—moderate trail development and concentration of campsites—but is otherwise scenic and mostly undisturbed with limited human influence.

Sabrina AU receives a moderate level of overnight use (over 500 permits a year) with about 11% of this use serviced by commercial pack stock. The area is a Recreation Category 3. High commercial stock numbers are recorded in this area. Popular destinations for pack stock service are Emerald Lakes, Dingleberry Lake, Moonlight Falls and Midnight Lake. Blue Lake, the first destination, has low opportunities for solitude, moderate recreation impacts and limited good camping. Emerald Lakes is currently accessed by a primitive use trail, and has some large campsites that are of moderate impact. The campsite identified for pack stock use at Dingleberry Lake is close to water and exhibits moderate impact. All these locations have low opportunities for solitude and show slight disturbance. The upper basin, Hungry Packer, Midnight Lake, and Moonlight Falls, all have better opportunities for solitude.

Tyee receives low overnight use (40-60 permits a year) and moderate day use (11 persons a day). Rainbow Pack Outfitters reported two trips in 2002, one trip in 2004 and none in other years. Very low commercial stock numbers are recorded in this area. Day use occurred in 2004, but had not been authorized into the area prior to that. The trail is primitive and opportunities for solitude are mostly low during the daylight hours. Solitude likely improves after daylight hours.

Low commercial stock numbers are recorded in the Treasure AU. Treasure Lakes receives moderate overall visitor use and low commercial stock use. Day use is moderate at an estimated 12 people per day. The area has moderate opportunities for solitude despite its proximity to very popular developed recreation area. There is a moderate capacity for camping at the lower lake and the impacts to campsites are moderate. Use trails are not extensive. The area is in a Recreation Category 2.

Bishop Creek is one of the highest use areas in the two wildernesses. Moderate commercial stock numbers are recorded in this area, with just fewer than 1,000 wilderness permits (parties) issued annually. One of the primary draws is the access to Sequoia-Kings Canyon National Park; particularly the very popular “North to South loop” between North Lake and South Lake through the Park, with start and end points in the Bishop Creek drainage. Both Bishop Pack Outfitters and Rainbow Pack Outfitters offer North-South loop full service trips. With this high visitor use, commercial pack stock use is proportionately low. Stock use overall in this area is moderate. The majority of the pack stock use goes into the Park. In 2001, 20 trips went into the park, and in

2003 41 trips went into the park; those same years 16 trips and 12 trips were serving clients just on the Inyo N.F. side of the pass. The area has a highly developed trail to the pass, with more primitive trails accessing Chocolate, Ruwau, and Marie Louise Lakes. Long Lake is the primary destination for day rides into the area. Most of the use on the Inyo N.F. side of the pass is spot or dunnage to this location. Very light pack stock use is currently reported at Marie Louise, and the destination has low camping potential with campsites that are not suitable for more than six persons. The trail is primitive and with current light use maintains a primitive character. Ruwau, Chocolate, and Bull Lakes are similar to Marie Louise in access and camping potential at the destination. The area is a Recreation Category 3. No grazing was reported in this analysis unit.

Very high commercial stock numbers are recorded in the Glacier Divide AU. Between 2001 and 2003, commercial stock numbers have averaged about 650 per year. The primary destinations for commercial pack stock use are Golden Trout Lakes, Muriel Lake, and Hutchinson Meadow, with light or occasional use to Packsaddle Lake. Golden Trout Lakes shows severe impacts on trails and use trails and at campsites. The location and scenic qualities of the area draw a high concentration of visitors. Two large stock camps in the vicinity are contained but are close to water. In the mid-summer, opportunities for solitude are low. Muriel also shows a high concentration of use and pack stock service up to fourteen trips a year. There is a high density of campsites around the outlet of Muriel; some that show severe impacts with vegetation loss, barren core, soil compaction, and overall high impact ratings. There was some restoration work done in the summer of 2003 that may have improved conditions at both Golden Trout Lakes and Muriel Lake. Hutchinson Meadow receives a high concentration of use. Campsite density is high in this area with very high impacts. An extensive drift fence along with the campsite impacts causes the presence of humans to be substantially noticeable.

Florence/Bear

This area is heavily used by thru-hikers on the John Muir Trail. Very light use occurs off this main corridor. Stock use is relatively light and mostly dispersed throughout this area, with the highest of this use occurring in the Sallie Keyes and Seldon AUs. Very light use occurs in Italy, Bear Lakes, Apollo, Hooper, and Dutch Analysis Units.

Light commercial stock numbers are reported in the Apollo AU. Overall, visitor use here is also low. Much of the light use that does occur is by pack stations during hunting season. No more than light impacts are known to be occurring in this area. There is no visible trail to Orchid Lake.

Moderate commercial stock numbers are recorded in the Italy AU. Commercial stock trips rarely travel beyond Hilgard Meadow, but this meadow is currently and historically a popular destination for stock parties. Based on reports and current conditions, use is most likely considerably lower than levels in the past. There are multiple pack stock camps that show moderate impacts to vegetation and total area of use. There is a primitive trail from Hilgard Meadow to Lake Italy. The area around Hilgard Branch and up to Italy Lake has moderate levels of solitude, with occasional quite low levels of solitude in mid-summer, due to the popularity of trips that loop through this area.

Low to moderate commercial stock numbers are recorded in the Seldon AU. Most destinations used by pack stock in this unit do not show specific stock related impacts, with the exception of Rosemarie Meadow. Rosemarie Meadow has a large stock camp but the impacts have a moderate impact rating as the site is relatively well contained. Noticeable impacts of use trails,

stock camps, and grazing are low to moderate. It is a pass-thru area for most hikers and a suitable location for stock parties. Rose Lake receives a low level of use but shows evidence of higher use in the past, with a moderate density of impacted campsites. There is limited camping due to the topography and access limitations around the lake. The opportunities for solitude at Rose Lake and unconfined recreation are very high. Lou Beverly Lake also appears to have received more use in the past than it does currently. It has moderate camping potential with some evidence of moderate impacts, but these impacts are not readily noticeable. It is a quiet, pleasant setting with high opportunities for solitude, though this may not have been the case in the past. The chain of lakes above Lou Beverly Lake has minimal evidence of use and impacts from the light levels of use. Overall, this upper area exhibits high wilderness character and has high opportunities for solitude and unconfined recreation.

Moderate to high commercial stock numbers are recorded in the Sallie Keyes AU. Moderate use occurs by High Sierra Pack Station offering spot and dunnage services into their primary area. With the added use of traveling trips (recently by Mammoth Lakes Pack Station and occasionally by Rock Creek, Pine Creek, and Bishop Pack Outfits) use impacts concentrate at Sallie Keyes Lakes and vicinity. Commercial stock numbers are moderate (51-200 per year) in this unit. There is a high density of pack stock camps in this vicinity, with camps that show high vegetation loss, large barren core, and a large total area. Combined with associated grazing, stock use and the impacts associated with stock use are quite noticeable. A snow survey cabin detracts from the naturalness and adds to the overall sense of human presence in this area.

John Muir Southeast

Most of this region is characterized by the access it provides to Sequoia-Kings Canyon National Park. Commercial pack stock operators all use Shepherd, Taboose, Kearsarge, and Sawmill Trailheads and range from 3% (Sawmill) of the use on those trailheads to 11% (Taboose). Pack stock facilitates the ability of parties to exit one of these trailheads from Bishop Pass or farther north. North Fork of Big Pine, Onion Valley (Kearsarge Pass) and Cottonwood Lakes have pack stations adjacent to the trailhead and most of their use is contained in those basins.

Very low commercial stock numbers are recorded in the Coyote AU. Most of this AU is in Recreation Category 2. Overall, the area receives low use, 40-50 permits a year. Occasional hunting trips occur in the fall. The area has high opportunities for solitude.

Very high commercial stock numbers are recorded in the North Fork of Big Pine AU. Most of the lower portion of this basin is in Recreation Category 3. Total overall use is very high; up to 900 permits and 2600 people have been recorded in a season. Approximately 12% of the use is commercial. Total numbers of people and stock are high in this drainage, with almost all the use being spot and dunnage trips with no overnight holding of stock. There are moderate to low opportunities for solitude in this confined canyon where most of the use is concentrated at lakes and climbing areas. Day rides offered by the pack station accompany the pack stock going up the trail for the day.

Low commercial stock numbers are recorded in the Birch AU. This area is Recreation Category 1. Less than 20 permits are issued annually on this trailhead. Commercial use is limited to the occasional commercial pack stock supporting fall hunting trips. There are high opportunities for solitude and primitive and unconfined recreation opportunities.

The Taboose AU receives light to moderate use: 112 permits and 259 people total overall use. This trail is also primarily used to access Sequoia-Kings Canyon National Park. Commercial pack stock use comprised 11% of use in 2003. Moderate commercial stock numbers are recorded in this area. The trail offers moderate to high opportunities for solitude and is mostly in Recreation Category 2. Recreation impacts are light to moderate as most camping occurs over the pass.

Low commercial stock numbers are recorded in the Sawmill AU. Much of this area is Recreation Category 1 and current use levels (57 permits and 142 people) are consistent with that category. There are high opportunities for solitude and high wilderness character, with a strong sense of remoteness and primitive recreation opportunities. Commercial use is 3% of total use in this drainage. The trail enters Sequoia-Kings Canyon National Park providing access to the Woods Creek area of the Park.

The Baxter AU area receives very light total use. Commercial stock numbers are occasionally recorded in this area. On occasion, a commercial serviced party that entered by way of another trailhead may exit over Baxter Pass. The opportunities for solitude are outstanding with a primitive trail and sense of remoteness that enhances the wilderness character of the area.

The Kearsarge AU has one of the highest used trails by the general public on the Inyo N.F. (996 permits, 3064 people). The area is in Recreation Category 3. Low commercial stock numbers are recorded in this area and comprise 4% of the total use that enters at Onion Valley. Both commercial pack stock and the general public use Kearsarge as an exit on trips that may have entered on other trailheads. Opportunities for solitude are moderate to low in this area. A highly developed trail and long standing impacted campsites exist in this area.

Moderate commercial stock numbers are recorded in the Shepherd AU. Most of this drainage is a Recreation Category 2. Commercial pack stock use is 5% of total overall use, approximately 25 trips a year. Overall, 269 permits are issued to 691 people a year. This trail is a popular access to Sequoia-Kings Canyon National Park. There has been a prohibition on camping and grazing by pack stock at the primary camping location, Anvil Camp. There is a high density of campsites at this location and moderate opportunities for solitude.

In the Whitney AU, the main Mt. Whitney Trail is closed to all stock. Parties are, however, dropped off on the Sequoia-Kings Canyon side of Mt. Whitney and come over via Trail Crest, unassisted (no stock support after party separates from packer). Up to eight trips are authorized per year for this type of use.

Moderate commercial stock numbers are recorded in the Cottonwood AU. Most of this area is a Recreation Category 3. Cirque Lake and South Fork Lake are Recreation Category 2. In 2002, 1,200 permits (parties) and up to 4,000 people were recorded in this area as overnight visitors. Commercial pack stock use is light, with 18 permits issued in 2002 and 20 permits in 2003. The use is mostly spot and dunnage trips and no overnight holding of stock occurs in the basin. There are low opportunities for solitude. A California Fish and Game cabin near Lake 2 and associated fish rearing activities provides a presence of human influence in the area, though most of the activity surrounding the fish rearing occurs in spring.

John Muir Southwest

This area has light overall use and light-to-moderate commercial pack stock use.

In the Fleming AU, very low-to-low commercial stock numbers are recorded. Rae Lake and Fleming Lake receive a moderate to high level of use. Other destinations in the area show signs of light use and impact. Dale Lake has a signed use trail with the lower section noticeably degraded.

Low commercial stock numbers are recorded in the Red Mountain AU. This area receives low use and light-to-moderate impact. There is a stronger sense of remoteness in this area and high opportunities for solitude.

Very low-to-low commercial stock numbers are recorded in the Bench AU. Access to McGuire and Guest Lake are limited by the degraded condition of the trail. Both destinations show moderate impact from recreational use and have moderate opportunities for solitude. Horsehead Lake has high opportunities for solitude but remnants of past use (including a picnic table) indicate that use levels were higher than they are currently here.

3.1.3 Trails

Wilderness Scale

Introduction

Originally, trails in what are now the Ansel Adams and John Muir Wildernesses were undeveloped routes used by various Native American tribes. The first developed trails for equestrian travel in this area occurred in the mid-1800s to provide transportation for mining activities, and by the military to access remote forts and camps in the Owens Valley during western Indian wars. Most of these new trails likely followed the same general routes as the earlier Native American routes, except where terrain or other conditions forced them to follow more stock-friendly alignments. Recreational trail use in these areas began in the late 1800s, and continued to grow into the early 1900s. As greater numbers and less-experienced riders were taken into remote areas, rugged trails were gradually improved by stockmen and government agencies to provide safer and more comfortable passage.

System Trails

System trails serve as the primary transportation routes for both private and commercial visitors to destinations in these wilderness areas. Trail inventories have been maintained on the forests during the past 5-60 years, with varying levels of accuracy. System trails are defined as “forest development trails wholly or partially within or adjacent to and serving the National Forests and other areas administered by the Forest Service that have been included in the Forest development transportation plan.” Nearly 1,000 miles of system trail lie within the Ansel Adams and John Muir wilderness boundaries. Approximately 340 miles of these are within the Ansel Adams; and 635 miles are within the John Muir. Just over half these trails (approximately 55%) are managed by the Sierra National Forest. Additionally, approximately 200 miles of trail just outside of the wilderness boundary provide access to wilderness from trailheads and pack stations. All trails in these wildernesses (except trails in the Mt Whitney area) are open to both hiking and equestrian uses. Some trails are rough or impractical for equestrian use and may rarely or never be used by pack and saddle stock.

With less than 1,000 miles of trail in these combined wildernesses, the actual density of the trail system is exceedingly low. There is an average of one mile of system trail for every 830 acres of wilderness; or roughly $\frac{3}{4}$ linear mile of trail per square mile of wilderness. Due to terrain limitations, it would be impractical to build and maintain trails that would be suitable for normal hiking and equestrian use in much of the wilderness. Most trails lie near the bottoms of canyons, generally paralleling stream or river channels.

Commercial pack stock operations use roughly 80% of the trail system on at least an occasional basis, and have regular recurring use on about 50-60% of the wilderness trail system. Private equestrians are allowed to travel off of system trails—either on user-created trails or cross-country in areas with no trails. Commercial stock is limited to system trails unless otherwise approved (2001 Wilderness Plan).

In general, most trails show characteristics of development that are consistent with the recreation categories that they access, though the trail may be unstable or inadequately maintained. Since

the recreation categories were heavily developed around existing conditions and use levels, and (to the extent that trails have been managed) these trails have been managed in response to use types and levels. In areas of high intensity use, which often were designated as Recreation Category 3 in the 2001 Wilderness Plan, historically a more developed and maintained trail was necessary to handle the use. As repair or maintenance was performed, the trails were intuitively designed to be responsive to the high levels of use. Very remote areas with limited use (Recreation Category 1) have very few trails, and these tend to be lower development trails.

System Trails – Funding and maintenance

Trails on the forest trail inventory are funded for maintenance and reconstruction through a variety of funds. Recurring (or “annual”) maintenance funds are allocated to the forests on an annual basis, based upon various criteria—primarily miles of trail, with some slight added weighting for wilderness miles, trail class, etc. Maintenance funds allocated to the forests are also used for trail planning, Worker’s Compensation, Unemployment payments, overhead/support and general trail program management. Substantial changes in budget direction and for calculating the distribution of funds makes an accurate linear comparison of Forest level funding during the past decade difficult and inaccurate. Funding estimates discussed below are approximate, and reflect maintenance funds available to field level planning and maintenance.

Recurring maintenance funds are used for basic maintenance of all system trails and bridges. This includes removing fallen logs and rocks from the trailway; cleaning, repairing, and installing waterbars or other drainage structures; performing various incidental repairs on trail structures; and replacement of signs.

In general, trails with higher use have received higher levels and frequency of maintenance than those with more limited use. Determining maintenance work assignments is commonly driven by seasonal (usually winter) damage, such as trails with many downed logs in the trailway, damage caused by flooding or avalanches, etc. As reports of damage or obstacles are received, the urgency is determined in part by the extent of damage, whether health and safety is a factor, resource impacts, and the level of use, which may compound the other factors. Any one trail could have substantial maintenance needs one year, and very low needs in other years. The ability to respond in a timely manner to annual maintenance needs is directly related to available funds. Maintenance needs that are considered less urgent—commonly on trails with relatively low use—may be deferred into future years.

In addition to recurring maintenance funds, the forests receive construction (or reconstruction) funds that are specifically earmarked for larger scale projects—usually focused on deferred maintenance work. These funds vary widely year to year, and are very unpredictable. These may be used for replacing bridges, repairing trails, constructing new trails, and obliterating abandoned trails. Other trail funding sources are available on occasional and unpredictable cycles. These are generally targeting specific types of work or emphasis items, such as trail/resource stabilization, “Burned Area Emergency Rehabilitation” after fires, or other enhancement work.

In addition to pure infrastructure maintenance and structural repair, other work is performed on resources within the trail corridor which are affected by the existing trail or by trails which have been abandoned through realignments. In some cases, performing such resource stabilization—

such as repair of headcuts in meadows, damage to stream banks, placement of soil retention structures in abandoned trails, and naturalization of hydrological function—can be as or more costly than trail repairs.

The total non-motorized trail mileage of the Inyo National Forest is approximately 1200 miles, of which only about 1/3 are in the Ansel Adams and John Muir Wildernesses. Nearly half of the total trail funds for the forest are spent on these trails, however, due to the relatively high use, relatively rugged terrain, remoteness and wilderness designation (which increase mobilization and work costs).

Funding for trails was relatively high during the late eighties and early nineties, peaking on the Inyo N.F. in 1992 at approximately \$400,000 (equivalent to \$550,000 in 2005 dollars, due to inflation) for maintenance, and then gradually declined over the next decade, with some fluctuation.

Table 3.6. Inyo National Forest trail funding (entire forest - 1200 miles) and Sierra National Forest Trail funding (entire forest - 1100 miles)

Fiscal Year	Maintenance	Construction or earmarks
Inyo National Forest

2005	\$130m	\$60m

Of the maintenance funds, approximately \$80,000 per year is spent on the roughly 420 miles of Inyo N.F. trail in the AA/JM Wildernesses, including inventory and support. This averages to approximately 190 maintenance dollars per mile of trail. Trail construction funds include some construction and reconstruction of trails outside of these wilderness areas, as well as replacement of trail bridges inside and outside of these wildernesses. The majority (approximately 75%) of trail reconstruction funds on the Inyo N.F. are expended within the AA/JM Wildernesses. This is highly variable from year to year, however, since such funding is project-specific.

The Sierra National Forest has approximately 1100 miles of system trail, of which roughly half is in the AA/JM wilderness. It is estimated that approximately 75% of the system budget is spent on trails in the Ansel Adams and John Muir Wildernesses.

In 2005, approximately \$90,000 was spent by the Sierra National Forest on trails in the AA/JM Wilderness, including inventory, planning and support. This averages to about 160 dollars per mile of trail. Less reconstruction funding has been available on Sierra NF wilderness trails as compared to Inyo NF trails. This has made it difficult to reduce or offset maintenance backlogs, where funding is lower than maintenance need.

In the Affected Environment section (below), certain trails in the planning area are described as degraded, unstable, or substandard. These terms are used as general descriptions, though the implications of poor condition or substandard development are further described in the Environmental Consequences section (Chapter 4).

The estimated costs to maintain the trail system to standard and to reconstruct trails to standard are dependent in part upon the development level (Trail Class) of each trail, so this varies by the alternatives described in Chapter 4. Current funding for trail maintenance is not sufficient to perform all maintenance activities on every trail in order to meet standard. Additionally, certain trails are currently in need of reconstruction before they can be stably maintained. This accumulated backlog is also addressed by alternative in Chapter 4.

In addition to accomplishing work through Forest Service funded staff, other opportunities exist for repairing or maintaining trails. These include various volunteer groups or individuals, permittees providing stock support or labor, grant-funded work, etc. Such resources help extend limited maintenance funds, and provide a more stable trail system. Whether work is funded by the Forest Service, or provided from other sources, the same guidance governing NEPA, design, and implementation applies.

Use Trails

“Use trails” are trails or routes that are not on the Forest inventory. These trails have generally formed from repeated use, accessing campsites, remote lakes or other locations not served by system trails. Certain “use trails” may have been constructed at one time for a purpose which has changed, so the trail or former road has not been managed as a system trail. Occasionally use trails provide alternate access to an area also provided by system trails. Some of these have developed primarily by and for non-commercial users, such as angler trails along creeks and lakes, mountaineering routes, or paths over high un-trailed passes. Others are primarily used by commercial stock to access campsites away from system trails or to access lesser-used destinations where no trail has been constructed. Some of these use trails are nearly undetectable, because the use levels may be so low—in some cases less than one trip annually.

Since use trails are not on the forest trail inventory, trail maintenance funding is not provided to maintain the trails. Where resource conditions on use trails require stabilization, funds other than trail maintenance are occasionally used. This has traditionally been rare and at relatively low levels.

System and Use Trail Assessments

Trails were evaluated for trail infrastructure stability and associated resource stability, as well as potential for impacts on both. Assessments were made of current conditions, effects of trails on resources, and on risk factors (natural factors and human-caused) such as terrain steepness, connectivity to hydrology, proximity to riparian, steepness of trail alignment, and others. These were combined into a numerical rating that summarized the level of impacts and potential

concern of that segment of trail. The primary focus of the assessments was on trails in the lower development levels, which were generally assumed to have the greatest risks and the lowest chance of mitigation through purely physical treatments. Certain higher development primary trails were also assessed when they were clearly out of character or showed substantial resource effect and trail deterioration.

Approximately one third (330 miles) of the total system trail network was both field-assessed and assigned a rating. These trails were lower development trails that also appeared to have the highest commercial pack stock visitation and potential concerns. The overall rating was on a scale of zero to five (0-5). The project record contains the assessment protocols and rating definitions for system and use trails. A rating of “0” represents a trail with no discernible effect or instability. Only about 10 of the system trails assessed had this rating, and these were generally lightly defined routes that received little use. The remaining designations from “1” to “5” assigned a ranking that ranged from generally stable with few notable effects or risk factors to increasingly severe instability and higher risks. Trails with a rating of “5” reflected severe current effects, combined with substantial risk factors leading to further instability. Two system trails in the analysis area received a rating of “5”.

Approximately 90 use trails, totaling roughly 80 miles, were field-assessed and assigned a rating. Since these trails tended to have less use and minimal active management or development than system trails, many of these show minimal impact and, in some cases, were undefined for parts of their length. Approximately 1/3 of the use trails evaluated are currently rated “0”, which implies that the trails were very lightly defined (or undefined) and stable. Almost 60% of the assessed use trails had a resource rating of “1” or less. Of the 90 use trails assessed, 12 (or 13%) had ratings of 3 or 4, which implies that these trails had measurable impacts and/or risk factors likely leading to high instability.

Most trails, even those with higher (more severe) resource ratings, are generally stable for most of their lengths. It is uncommon to find more than 10% of a trail with high levels of instability or resource concern, and many were less than 5%. Five system trails had problems of high concern over the majority of their lengths, and one was considered unstable for its entirety.

The following table summarizes the assessed system and use trails for the entire AA/JM wilderness.

Table 3.7 Wilderness scale trail resource ratings in the Ansel Adams/John Muir Wildernesses

Overall Rating	# Trails Assessed	Approx System Trail Length (Mi)	# Use Trails Assessed	Approx Use Trail Length
0	10	25	29	35
1	56	78	24	20
1.5	3	16	1	0.4

Overall Rating	# Trails Assessed	Approx System Trail Length (Mi)	# Use Trails Assessed	Approx Use Trail Length
3.5	3	20	1	1
4	13	16	4	3
5	2	2	0	0

Geographic Unit Scale

Ansel Adams East

There are approximately 135 miles of trail in the Ansel Adams East Geographic Area (AAEA). All trails in this area are managed by the Inyo National Forest, though a few miles of trail on southernmost edge of the area are on Sierra National Forest lands and managed by the Inyo NF through formal agreement. The northern 1/3 of the AAEA area (north of Rush Creek) lies immediately east of the Yosemite Park boundary, and is very lightly used, with a low density of trails—most of which are rarely, if ever, used by commercial pack stock. Conversely, the southern 2/3 of the AAEA area—mainly lying west of the Mammoth Lakes area—is used intensively by commercial pack stock operators, as well as by many hikers and some private equestrians.

The Ansel Adams East Geographic Unit has a relatively high density of system trails, roughly one mile of trail in every 640 acres (or one mile of trail per square mile).

In general, the trails in this area receive a large amount of stock and hiker use, and are developed at fairly high levels. Most high development trails were not assessed for resource condition, but were generally stable with incidental localized exceptions. As shown in the table below, of the system and use trails which were specifically assessed and rated, approximately 2/3 were generally stable (rated at “2” or less). However, where trails were damaged, they appeared to be particularly damaging to the resource. This area had the most assessed trails with severe conditions (rating of 4 or 5).

Table 3.8 Summary of system and use trails assessed in Ansel Adams East

Overall Rating	# Trails Assessed in GEO UNIT	Approx System Trail Length (Mi)	# Use Trails Assessed	Approx Use Trail Length
0	3	6	5	7.5

2	10	10	1	2
2.5	2	2	1	0.6
3	8	13	1	0.3
3.5	n/a	n/a	n/a	n/a

Overall Rating	# Trails Assessed in GEO UNIT	Approx System Trail Length (Mi)	# Use Trails Assessed	Approx Use Trail Length
4	3	4	3	2.3
5	1	1	n/a	n/a

The most intensively used areas and trails accessing these areas are in the northern Minarets. These are the trails into the Shadow and Ediza Lakes area and the Garnet and Thousand Island Lakes area (Thousand Island and Shadow/Ediza Analysis Units). The primary corridor trails here are the Pacific Crest Trail and John Muir Trail, running north/south on either side of the San Joaquin River drainage. The River Trail parallels these trails along the course of the San Joaquin River, leading to Thousand Island Lake, where all three trails converge. The Shadow Creek Trail provides access to Ediza Lake at the base of Mounts Banner and Ritter. All of these primary trails are highly developed and maintained (Trail Class 3) and are used heavily by commercial pack stock.

Use Trails in the AAEA are primarily used to access grazing. Some of these trails are currently highly degraded and travel thru areas with high risk factors. In particular, use trails accessing grazing on the west side and north of Thousand Island Lake, and to the west side of Garnet Lake are impacting meadows and the lake shores—including one area where commercial stock are actually traveling in Garnet Lake for 200-300 feet to bypass a rocky outcrop.

In the Rush Creek AU, commercial stock and private backpackers heavily use trails. The primary trails are well developed and generally stable. Most secondary system trails accessing the outlying lakes and camps are less developed, but appear to be maintained consistent with use levels.

Spooky Meadow is accessed via two trails. The most direct trail climbs from Gem Lake on the north and the longer route is via the Clark Lakes trail on the south. The northern/direct trail is highly degraded with severe access issues and high risk factors, primarily steepness, rocky terrain, and inadequate design.

Three use trails in the Rush Creek AU that are mostly undefined—the Crest Creek Use Trail, the Lost Lake Use Trail, and the Weber Lake to Sullivan Lake Use Trail—access areas rarely visited by commercial pack stock. The route between Weber and Sullivan is in close proximity to the lakes and descends awkward rock slabs between the lakes. The other two routes are basically undetectable and in relatively open slopes with minimal risk factors present.

In the Upper Rush Creek AU, the Marie Lakes trail provides good access to camps at meadows below the lakes, but beyond the camps it is extremely difficult and undeveloped. Commercial stock is not currently using this trail.

A use trail accesses grazing near Rodgers Lake from Davis Lake. The trail winds through small meadows and rock benches, and crosses two small streams, causing some bank damage, and meadow trampling. The use trail between Lower and Upper Davis Lake is barely discernible and rugged, and appears very awkward for stock travel. There are slight impacts with moderate risk factors on this trail. Two undefined routes have been identified as use trails in the Upper Rush AU including one that leaves the PCT about one mile below Donohue Pass, travels across an

open alpine basin with few risk factors, and has little or no evidence of past use. A possible shortcut route between Marie Meadows and the PCT, (duplicating the Marie Lake Trail) was identified by a pack station, but no discernible trail is present.

In this AU, the Garnet Lake to Emerald Lake Trail (this is the old John Muir Trail, relocated in the 1960s, but continues to receive use) shows severe impacts over much of its length. The Garnet Lake to River Trail, which also provides access to Altha Lake from the north, is very steep and undeveloped with risk factors present and a high potential for worsening. The Garnet Lake Spur Trail (along the north shore) travels in close proximity to the lake and through small meadows, has few trail structures, and is being used to access camps by commercial stock.

The Shadow Ediza AU has a high density of social and user trails, mostly related to campsites. Of the seven analyzed trails, two are causing severe alteration of soil and hydrologic processes. The Ediza-Iceberg System Trail is one of the trails in the project area with the most severe soil and hydrology impacts, with deep incision, multi-trailing, and hydrologic function alteration of the adjacent meadow.

In the Shadow/Ediza and Thousand Island Analysis Units, some of the less-developed trails currently have degraded conditions, including deep incision and riparian impacts. The trail leading between Ediza, Iceberg, and Cecile Lakes has some of the most consistent and severe impacts of any trail surveyed (rated “5” on a scale of 5), even though few, if any, commercial stock have recently used it. Almost the entire section of trail from Ediza to Iceberg Lake has severe risk factors, primarily because of its steep alignment almost entirely within riparian for its entire distance. The Laura Lake Trail from the JMT above Shadow Creek travels through a steep and confined route through meadows and along a stream and shows severe impacts. Though past maps and inventories showed a trail connecting Laura and Altha Lakes, none was apparent, and the terrain does not appear conducive to stock access.

The Cabin Lake Trail is lightly used, but climbs a steep slope, has isolated impacts to small meadows in the lower sections, and is in very close proximity to (and may be affecting) a stream channel for a short distance near the lake. Nydiver Lake Trail climbs the opposite side of the Shadow Creek drainage and disperses above a small camp half way to the lakes.

A use trail accessing Clarice Lake from the John Muir Trail is lightly used and lightly defined with few resource issues. This route was used as a camp access for administrative purposes, but any places where a trail had become evident were restored to a natural appearance. A use trail leading around the south and west sides of Ediza Lake is well defined, and used by the public and commercial operators as the only route available to access good camps on the west/north sides of the lake. There are short sections with moderate incision and some impacts at two stream crossings, as well as some short steep sections with some erosion.

The PCT traverses River-High unit, is highly developed and receives heavy use, but goes through many areas with risk factors. It requires frequent maintenance to keep it stable.

A use trail accesses grazing near Badger Lakes, and has some erosion on a dry slope between the lakes and the grazing area. A faint trail climbs from the PCT to San Joaquin Peak along its northern slopes. It appears to receive very little use and is generally on open dry slopes, with minimal risk factors. An easily followed spur leads from the PCT to Badger Lake, with no resource problems or risks.

In the Minarets AU, Emily Lake Trail travels steeply along a small stream and through a very wet spring-fed meadow before reaching the lake and currently shows substantial impacts to the trail and resources in the corridor. Attempts to stabilize the trail in the worst sections appear to have failed. Deadhorse Lake Trail is completely indistinct, and appears to have little or no use. Terrain below the lake makes stock passage impossible. Access from Minaret Lake to Cecile is via an undeveloped trail that stops in cliffs before reaching Cecile Lake.

In the King Creek AU, the trail to Superior Lake is generally stable until just before the lake, where impacts to meadows and streams are moderate to severe for short distances, just before reaching the camps. Likewise, the Holcomb Lake Trail is generally rough and stable thanks to rocky soils, but has severe resource effects going around the south side of the Lake, just past the primary packer camp.

The Anona Lake user trail is faint immediately above Fern Lake, but becomes more defined as it continues to Anona. There are slight problems with incision on riparian, which appear to be worsening without even simple trail drainage structures in place.

In the Crater Creek AU, the Deer Creek trail from the PCT to the Mammoth Crest Trail is faint in the canyon below the lakes, with few resource impacts or risks. At the head of this canyon, the Mammoth Crest Trail continues north to George Lake, and southeast to Duck Pass. This southern section of trail is sporadically defined, and rocky with some erosion above the lake.

Ansel Adams West

There are approximately 185 miles of system trails in the Ansel Adams West (AAWE) geographic unit. The Sierra National Forest manages all trails in this geographic area. The density of system trails in this Geographic Unit falls in the same range as the average for the entire wilderness, roughly 0.8 miles of trail per square mile (or one mile of trail per 807 acres of land).

Partially due to the remoteness of trailheads from population centers on the west side, most areas and trails in the AAWE receive light to moderate use. Trails in these areas are generally stable, but are lacking adequate drainage structures and general maintenance. Since trails in the area have received minimal maintenance and repairs, trails in areas with even moderate use show some signs of instability, especially where risk factors, such as steepness or meadow environs are present.

Overall, the majority of trails assessed for resource stability were generally stable in this unit. Use trails receive low enough levels of stock and hiker use that they were generally stable, and none received more than a rating of “2”. No system or use trail was rated higher than a “3”, indicating moderate impacts with some potential increase of instability.

Table 3.9 Summary of system and use trails assessed in Ansel Adams West

Overall Rating	# Trails Assessed	Approx System Trail Length (Mi)	# Use Trails Assessed	Approx Use Trail Length
0	n/a	n/a	1	1.4
1	7	4	1	0.4

Overall Rating	# Trails Assessed	Approx System Trail Length (Mi)	# Use Trails Assessed	Approx Use Trail Length
1.5	1	8	n/a	n/a
2	3	2	2	0.5
2.5	1	10	n/a	n/a
3	3	7	n/a	n/a
3.5	n/a	n/a	n/a	n/a
4	n/a	n/a	n/a	n/a
5	n/a	n/a	n/a	n/a

There is a relatively low density of use trails in the AAWE. Since use levels are low to moderate, the use trails are generally lightly defined, with some exceptions. Various routes exist to some less-visited locations, or to traverse between the north-south system trails. The most intensively used trails in the AAWE are those in the Fernandez and Lillian Lake Loop areas, leading toward Fernandez, Post-Peak and Isberg Passes into Yosemite National Park. The “California Riding and Hiking Trail” is a compilation of other existing trails in this area, and traverses this Geographic Area north to south.

In the Staniford Lakes AU, commercial operators are using an alternative access route to Staniford Lake, to bypass a short, rough, degraded section of the Lillian Lake Loop Trail. This trail leaves the system trail from near Vandenberg Lake and traverses a short steep pass to the east of the main trail on an alignment that would not be practical to maintain. Risk factors include steepness and loose soils, as well as a creek crossing with incision and bank damage, which would not sustain increased use. Chittenden Lake Trail is mostly a cairned route across gentle rock slabs, until about ½ way to the lake, where the trail crosses extremely steep slabs and travels through a small hanging meadow with some incision.

A spur trail leading to and through camps at Vandenberg Lake, is also the shortest way to continue on the main trail, so stock and hikers are walking through the camps and creating a parallel trail with an unnecessary creek crossing with moderate impacts. The main trail is in better shape with few or no impacts and risk factors.

In the Lillian Lake AU, the Fernandez Trail (one section of the California Riding and Hiking Trail) is one of the primary trails through this area and has short, isolated resource problems—a few rated at severe—due to poor trail location across meadows and at stream crossings. A lightly defined use trail accesses camps near Fernandez Meadow from the Fernandez Pass Trail. The trail appears to have very limited current use, so resource effects are minimal, but many risk factors, mainly meadows and stream crossings, are present along the route. A similarly undefined trail accesses Monument Lake from Flat Lake through bedrock slabs and ledges, where route finding would be difficult for most equestrians, but very few resource risk factors exist.

In the Triple Divide AU, the Anne Lake system trail is receiving moderate to high use, and is located in areas with high risk factors, including stringer meadows and steep slopes, with short, isolated sections with severe impacts. A use trail leading from Anne Lake north to a grazing area

(Avalanche Meadow) follows a poor alignment, but the use appears low enough that the use trail is not overly degraded. Risk factors such as steepness and alignment could be a problem if use increases. The Post Creek - Timber Creek Use Trail (mostly undefined route) traverses between the Post Creek Trail and the Timber Creek Trail across about 1.5 miles of dry, moderately sloped, lightly timbered hillside with very few risk factors. This “use-trail” is ill defined, and is difficult to find, except by experienced riders.

In the Sadler AU, the McClure Lake Trail, which leads to grazing and camps south of and above Sadler Lake, is badly incised and affecting hydrology with many severe impacts in meadows on the south shore of Sadler Lake and where it climbs between the two lakes. The trail becomes vague just below McClure Lake. The Isberg Trail has short, isolated resource problems due to poor trail location across meadows and at stream crossings. The Timber Creek System Trail is degraded and rough, with some resource problems (mostly moderate) and appears to receive very limited use and maintenance.

In the Cora AU, the Cora Lake Use Trail accesses camps on both the West and North sides of the Lake. The trail is well defined, and mostly travels across low angle slopes around the lake. Slight incision and impacts at small stream crossing and crossing are present through a meadow on the north side of the lake.

In the Arch AU, the Margaret Lakes Trail and the California Riding and Hiking Trail are the primary travel routes. The Margaret Lakes Trail receives the moderate traffic, with all other trails in this analysis unit receiving very light use. In general, the trails in this analysis unit are fairly stable, though they have received minimal maintenance in recent years. Because of low use and minimal maintenance, many of the trails in this analysis unit may be difficult to follow, with sections of intermittent tread and many downed trees. There is one notable use trail in this analysis unit. This use trail links the String Meadow Trail with the Rock Creek Trail. The use trail leaves the String Meadow Trail, contours around a forested side slope, where it crosses an unnamed boggy stream, and later crosses Rock Creek proper just before the junction with the Rock Creek Trail.

Trails in the Bench Canyon AU receive light use. Rockbound Lake is accessed by an undefined use trail with no visible tread.

The Lake Catherine AU is the northern-most analysis unit on the Sierra National Forest, and contains the western slope of the Minarets. The Stevenson Trail is the primary travel route in this analysis unit. The trail receives light to moderate use and shows some incisions and rutting due to lack of maintenance. The Dike Creek Use Trail, used to access Lake Catherine, is visible and continuous, with few notable resource effects.

In the Cargyle AU, the primary system trail passing through this unit is the Mammoth Trail, which receives light to moderate use and is used to travel between the Sierra National Forest and Inyo National Forest. The trail is well-developed but shows signs of degradation, with major incisions and other erosion problems, especially in areas with high risk factors. There are sections of the trail in Cargyle Meadow that contain puncheon in need of repair. There are two notable use trails in this analysis unit. The East Fork Cargyle Creek Use Trail is difficult to follow due to low and discontinuous tread. There is also a use trail between the Iron Lake Trail and Straub/Spano meadows which is visible and continuous.

The Onion Springs AU contains one system trail, the Devil's Bathtub Trail. This trail receives moderate use, and is a popular day use trail from Edison Lake. It follows parts of an old jeep road, which makes the trail wider than wilderness standard widths in some areas. Two use trails fall in this analysis unit, and both receive low use. The Devil's Bathtub Cutoff use trail is generally stable and in areas of low risk factors. The Saddle Mountain Use Trail leaves the end of Onion Springs Road and is generally stable to the northern edge of this analysis unit. It is primarily used during hunting season by commercial stock operations.

The Fuller Buttes AU contains part of the French Trail, a historic trail that receives low use. Currently, this trail is maintained by a volunteer group on an annual basis. Two other system trails in this analysis unit, the South Fork Trail and the Hell's Half Acre Trail, are steep and in need maintenance. These trails are generally used to access the San Joaquin River by hikers.

In the Lower Mono Creek AU, trails generally see low visitor traffic and may be hard to follow, with several notable exceptions. The Tule Lake Trail, Doris Lake Trail, and Mono Meadow Trail all receive moderate use due to their proximity to Mono Hot Springs. Generally, all three trails are stable with isolated resource problems. An old cable suspension bridge on the Mono Meadow Trail is in need of maintenance, and the Doris Lake Trail shows incisions through meadows on the way to Doris Lake.

The main trail through the Cold Creek AU is the Goodale Pass Trail. This trail receives heavy use from both hikers and stock users, including commercial stock. The trail is used to access Graveyard Meadows, Graveyard Lakes, and the Silver Divide (in the Fish Creek Geographic Unit). The trail is generally stable and does not show any significant resource damage south of the Pass. The Graveyard Cutoff system trail follows the old Graveyard jeep road and receives light use.

The Jackass AU contains two main trails. The Norris Lake Trail receives moderate to heavy use from day hikers and some commercial stock use. The trail is generally stable. The Jackass Lakes Trail is a popular day hiking trail and is used by climbers to access the Balls. The trail receives moderate to heavy use and is generally in stable condition.

The Chiquito AU contains three system trails that are used to access Chiquito Lake and Yosemite National Park. Commercial stock use trails in this analysis unit to access Yosemite National Park.

The Cassidy AU, Junction AU and South Fork AU all share the California Riding and Hiking Trail as their primary travel corridor. Use on these sections of the California Riding and Hiking Trail varies from low to very low, and the trail is difficult to follow in certain sections. In the Cassidy AU, the trail has severe risk factors due to steep grades as it drops into the Middle Fork San Joaquin. All secondary system trails in these three analysis units receive low to very low use. The Miller's Crossing Trail in the Cassidy AU and Junction AU displays severe risk factors due to steep terrain and lack of maintenance and trail structures. The section of this trail in the Junction AU is difficult to find.

In the Iron Creek AU, there are two system trails. The Iron Creek Trail is the primary trail between the Mammoth Trail and the Stevenson Trail, and receives low to moderate use. The trail has narrow rocky sections that present difficult travel for stock. A short section of the Iron Lake Trail in this section is fairly stable and receives low use.

In the Bridge Crossing AU, there are three primary system trails and a secondary system trail. The Mammoth Trail, Iron Creek Trail and Snake Meadow Trail are generally steep with multiple trailing and rutting and lack of trail structures. These trails receive low to moderate use. The section of the Mammoth Trail in this analysis unit has area of severe incising of two to three feet east of Sheep Crossing. The Junction Butte trail, a secondary trail, drops steeply into the Middle Fork San Joaquin and receives very low use from both commercial and private parties.

The Hot Springs AU contains two main trails: the Mono Crossing Trail and the Rattlesnake Creek Trail. Both trails receive low to moderate use. These trails are fairly stable but do have sections that show moderate risk factors, including rocky steep sections. At times, both trails are used as a stock driveway. These trails receive very low commercial stock use.

Fish Creek/Convict/McGee

There are approximately 170 miles of trail in the Fish Creek/Convict/McGee Geographic Area. The Inyo NF manages just over 100 miles of trail in this area, the majority of which are Sierra NF trails managed by the Inyo under formal agreement. This Geographic Unit has the highest density of system trails in the planning area, nearly twice the wilderness average. There are roughly 1.3 miles of system trail per square mile (or 1 mile of trail per every 490 acres). This can be attributed to relatively moderate terrain and a long history of mining, sheep grazing, and recreation.

Table 3.10 Summary of system and use trails assessed in Fish Creek/Convict/McGee

Overall Rating	# Trails Assessed	Approx System Trail Length (Mi)	# Use Trails Assessed	Approx Use Trail Length
0	3	6.5	2	1.5
1	10	11	1	0.3
1.5	1	5	n/a	n/a
2	11	19	4	3.6
2.5	2	4	n/a	n/a
3	8	12	2	1.1
3.5	n/a	n/a	1	0.5
4	3	6	n/a	n/a
5	1	1.5	n/a	n/a

The most intensively used and primary corridor trails are the Duck Pass Trail, the Pacific Crest Trail (PCT) between Duck Lake and Silver Pass, McGee Pass Trail (both east and west of the Pass), Goodale Pass Trail (north side of Silver Divide), Minnow Creek Trail and the Fish Creek (Cascade Valley) Trail. Although there are isolated resource problems, these trails are fairly stable and seem to be maintained at close to their standard. The trails do travel through areas with risk factors—especially at the many creek crossings and across some meadows—but have generally been well located and fairly well developed in these higher-risk areas.

In the Convict AU, the drainage above Convict Lake is accessed by the Laurel Lake Trail, because the Convict Creek trail, which would be more direct, has been impassable to stock since the early 1980s when much of the trail and two trail bridges were destroyed by cataclysmic natural events. The trail is impractical to maintain for stock, and is difficult for hikers. Trails in the vicinity of Dorothy Lake, Genevieve, Edith, and Cloverleaf Lakes are generally under-maintained and poorly located, often forced into meadows or riparian areas to access the primary destinations and campsites. These trails have moderate resource effects, and have some risk factors present if stock use were to increase.

In some cases, non-system trails have developed to bypass problem sections of system trail. In the case of a use trail accessing Cloverleaf Lake on the north side of the creek, this use trail is currently in better condition and more stable than the system trail. Access to Bighorn Lake is via a steep undeveloped trail from Dorothy Lake. This route has moderate effects and high risk factors. The use trail to Bright Dot Lake is undefined, shows little or no evidence of recent use, travels through areas that would be difficult for equestrians, and has high resource risks. In addition, the Edith Lake and Genevieve use trails have caused moderate soil and water resource degradation.

The McGee Analysis Unit has trails with severe soil and hydrology effects. Major trail erosion occurred in 2003 resulting from heavy summer rain. The Baldwin Canyon Trail above Baldwin/Scheelore meadow eroded and deposited sediment covering about 15% of the meadow. The trail is incised with headcutting above and below the meadow. Other trails in the AU, including the primary McGee Pass (eastside) Trail, are generally stable, although the secondary trails leading up steep draws on either side pass through areas with many risk factors, primarily wet meadows and steep side hills. The Steelhead Lake Trail and Grass Lake spur have some resource problems, mostly caused by poor design considerations. One section of the Steelhead Trail was rerouted in the early 1980s, but, due to poor design, was never adopted for use by commercial packers. The old trail, which had problems prior to the rerouting, continues to be used as the primary route. A primary destination at Big McGee Lake is accessed via the first part of the old Hopkins Pass Trail, with some slight resource problems where the trail crosses meadows.

In McGee Canyon, two use trails have particular concerns and risk factors. The Baldwin Cutoff cuts between the Baldwin Canyon Trail and the McGee Pass Trail, accessing a campsite along the route, which could be accessed directly from the McGee Trail. Problems with the primary McGee Pass Trail at the Steelhead Lake junction have increased the desirability of the Baldwin Cutoff for equestrian travel. The trail has moderate resource problems and is affecting hydrology at a creek crossing. Golden Lake Use Trail travels across a meadow/bench past “Meadow Lake” before climbing steeply along streams, meadows, and rough terrain toward Golden Lake. Other camp access trails, such as the routes accessing the Round Lake camp and “CCC Camp” have slight resource problems, which could be readily addressed.

In the Coldwater AU, Duck Pass trail is the primary route through this unit, and is heavily used by commercial stock and private hikers to access the PCT and a very large backcountry area south of Mammoth and west of McGee Pass. Despite and due to the heavy use, the trail is highly maintained and generally stable with isolated resource problems. Certain secondary trails in the Coldwater/Duck Pass area, such as the Sky Meadow trail from Emerald Lake, the Emerald to Skelton Lake Trail, and the Woods Lake Trail, are located in areas with many risk factors, including climbing along stream channels and within riparian corridors. The trails have very few

features, and despite relatively low use-levels, appear degraded, with potential to degrade further. Commercial stock has used these trails lightly in past years. The Sky Meadows Trail has some severe resource impacts with very high risk factors, climbing steeply in the immediate vicinity of a stream and wet meadows.

In the Purple Bench AU, the Ram Lake (Purple Lake) Trail from the PCT is heavily used by commercial operators to access camps immediately above Purple Lake. It becomes increasingly degraded with severe resource impacts, despite relatively low stock use, due to proximity to streams, riparian, and meadows, eventually dispersing in very difficult terrain. Pika Lake Trail has some moderate resource problems over much of its length, with steep grades and some incision on dry slopes leading to incision in meadows on the south side of Duck Lake.

Routes between Virginia Lake and Ram Lake and Ram Lake to Franklin Lake are undefined and rarely used, accessing some of the remote areas away from the primary trails and destinations. Meadows and steep slopes between granite benches and talus slopes would be especially susceptible to increased use in these areas. Other use trails access dispersed campsites along the PCT. Some of these are in high-risk areas or shortcut system trails.

In the Upper Fish Creek AU, the trail to Lee and Cecil Lake above “Sheep Camp” was one of the most severely degraded trails in both of the wilderness areas, with severe impacts to meadows and springs along almost its entire length. The trail is incised and acts as a channel that diverts surface flow and spring flow, lowering the water table in meadows adjacent to the trail. Climbing straight up along streams and steep stringer meadows, with few or no structures, this trail is susceptible to future degradation under even very limited use. Use trails continue beyond Lee Lake outlet to Cecil Lake area. Tully Lake is accessed by a slightly developed system trail and by use trails accessing camps. All have resource problems and high risk factors, mainly proximity to streams and meadows. Other use trails access grazing at the south side of the Lake.

Other than incision at some stream crossings, trails in the Cascade Valley Analysis Unit have only minor impacts to soil and water resources. System trails provide stable access to most destinations, so very few use trails are present or needed other than to access campsites or grazing areas. Such trails exist at Pond Lily Lake and the Second Crossing Campsites. A use trail accessing a wet grazing area at Second Crossing has severe impacts with severe risk factors where it climbs to the meadow. This trail is subject to rapid degradation if use continues.

In the Silver Divide AU, the Goodale Pass Trail and the Minnow Creek Trail are the two primary travel corridors. The Goodale Pass Trail crosses between the Mono and Fish Creek drainages. It receives relatively low commercial stock use and, primarily due to steep alignment and erosion, it is in degraded condition on the north side. A “bypass” trail (original system trail over pass) drops down to Lake of the Lone Indian Trail, and is equally awkward with jump-offs and erosion. This trail appears to be used for bypassing late-melting snowdrifts for a short period in spring. In the same area, a steep use trail shortcuts the system trail and parallels the creek between Lake of the Lone Indian and Papoose Lake, causing moderate to severe impacts to streamside vegetation. The Minnow Creek Trail serves as the primary access route for lakes on the north side of the Silver Divide. The trail is generally stable, with the exception of high stairs and multiple trailing near the junction with the Goodale Pass Trail. The Peter Pande Trail climbs steeply above Grassy Lake, and is severely degraded with severe resource effects. The trail is incised and affecting surrounding resources, capturing surface flows, and transporting massive amounts of sediment. The trail is in a poor location and would be impractical to fix in place. The

Long Canyon Trail to Beetlebug Lake is lightly used, with slight to moderate impacts, and deteriorates to a steep, rough trail with moderate erosion and soil loss before reaching the lake.

Use trails access the basins and benches above the system trails in the Olive Lake and Peter Pande area and are undefined and go through areas with high risk factors. Use trails accessing Pick and Shovel Mine and Brave Lake are generally stable and in areas with relatively few risk factors.

In the Margaret AU, trails in the Margaret Lakes area receive light to moderate use by commercial pack stock. The main trail has some moderate resource effects, but is generally stable until it goes past Rainbow Lake. Here there are some moderate resource impacts associated with the trail including one very high-risk section of incision in a meadow above the lake, before becoming faint and dispersed. The trail beyond Baby Lake becomes extremely steep and hazardous for foot and equestrians through bedrock slabs and cliffs descending to Silver Creek. The Silver Creek trail climbs from Fish Creek into the Margaret Lakes area via a steep, brushy trail, which shows minimal evidence of use during the past twenty years or so. It is highly degraded and has not been maintained for many years. The upper mile of the trail is used to access grazing areas between Coyote Lake and the Silver Creek-Baby Lake junction. Stock is turned out between the grazing and a drift fence near Coyote Lake, leading to severe multi-trailing, widening, and soil loss in the upper ½ mile. The trail is decimated, but not directly affecting stream courses.

Saddle Mountain Use Trail from Onion Springs to Fern Lake near Margaret Lakes is nearly undetectable on the Fern Lake (John Muir Wilderness) side of the saddle and appears very awkward and is practically unused by stock for decades. It has to traverse at least two meadows with high risk factors, including one near Fern Lake, which shows some incision near a stream. South of the John Muir boundary, this use trail is more evident and generally on dry, timbered slopes.

Mono Creek/Rock Creek

There are approximately 92 miles of system trails in the Mono Creek/Rock Creek Geographic Unit. The Sierra NF maintains 63 miles of these on the west side of the crest, and the Inyo NF manages the remaining 29 miles east of the crest. The density of system trails is under the average for the wilderness area, with roughly one mile of trail per 950 acres of wilderness land, or about 0.7 miles of trail per square mile. The analysis units on the east side of the crest (Inyo NF) have a much higher density of trails, than on the west side (Sierra NF). Generally, the terrain is more moderate and access to the trailheads is considerably easier on the east side of this geographic unit than the west side.

System trails assessed in this unit had a relatively large number of trails with moderate to high levels of resource effect and instability. No trails were designated at the most severe level, but nearly half were rated higher than “2”, indicating moderate current impacts with potential for further instability. In, general, assessed use trails were relatively stable, with the exception of two particularly impacted trails, rating higher than “3” for much of their lengths.

Table 3.11 Summary of system and use trails assessed in Mono and Rock Creek

Overall Rating	# Trails Assessed	Approx System Trail Length (Mi)	# Use Trails Assessed	Approx Use Trail Length
0	n/a	n/a	2	1.6
1	9	11	5	6.2
1.5	n/a	n/a	n/a	n/a
2	6	12	3	2
2.5	1	0.2	2	2.5
3	8	11	n/a	n/a
3.5	2	15	1	1.1
4	2	2	1	.5
5	n/a	n/a	n/a	n/a

The primary access trail through this area is the Mono Pass (Mono Creek) Trail, which traverses the Sierra Crest from Rock Creek (Little Lakes Valley) to Thomas Edison Lake. The Pacific Crest Trail crosses this area just above Lake Thomas A. Edison. West of Mono Pass, the Mono Creek Trail is heavily used by stock and is highly degraded for a primary system trail.

Generally, the trail appears to have been adequately designed with a few locations where poor alignment is the primary problem; rather, it is evident that maintenance performed is not consistent with the very high levels of use. The Pacific Crest Trail south of Mono Creek is lightly used by commercial stock and is adequately maintained, but is used heavily north of Mono Creek, and is substandard in some sections heading north toward Silver Pass.

East of the crest, the most intensive use occurs in the Hilton Lakes area, where multiple pack operations use the trail system. The trails in this AU are causing moderate hydrologic and soil impacts. A high concentration of user trails has reduced soil productivity and increased erosion beyond normal trail impacts. The system trail accessing Lake #3 and #4 climbs a steep slope and has become badly eroded. Between the two lakes, the trail crosses a stream where multiple stream ford locations have affected the stream morphology. The Pine Grove to Hilton Lakes Trail is a steep trail that was moderately developed with switchbacks and some simple structures, but has not been used regularly by stock since the main Hilton Trail to the upper pack station was developed. It now serves as access for hikers from the Pine Grove camps.

Due to moderate terrain, a myriad of use trails access different destinations and campsites in the canyon. Most of the use trails have only low to moderate resource impacts, but there is a high density of trails near Lake #2 and Davis Lake. Use trails on Hilton Ridge and the Hilton Cutoff trail are simply shortcuts from the system trail. A use trail to Lake #5 has received very little use in decades, but is in a location with high risk factors, following the outlet stream and riparian corridor. Lower in the canyon, old mining roads access the Hilton Mines, which have long been out of operation. These are mostly located on an open rocky slope, and are mostly passable but have not received maintenance since operations ended.

In the Little Lakes AU, Little Lakes Valley trails are used heavily by hikers—especially day hikers—but have very limited commercial pack stock use. The main Little Lakes Valley Trail is

an old road that has been maintained as a high level trail. Spur trails to side destinations include a system trail with moderate resource impacts and a less-used use trail with lower impacts to Gem Lakes. Chickenfoot Lake also has both a system and a use trail accessing the lake and camps, though there are few risk factors along these routes, until reaching the lakeshore. A spur trail traveling along the southern shore of Long Lake leads to camps south of the lake, and has some impacts on wet meadows and Yosemite toad habitat before reaching the camps. This trail continues across meadows, and eventually to Treasure Lakes, but cliffs and talus make this impassable to pack stock. Snow bypasses have formed during early-season use at multiple locations in the canyon.

The system trails in the Tamarack area are generally stable, with the exception of some isolated problems on the Dorothy Lake loop at creek crossings and at the inlet to Dorothy Lake. Tamarack Lake Bench has a myriad of use trails with generally low to moderate impacts, crossing the wide-open benches and meadows between the various lakes. Some of these travel through areas with high risk factors.

The system trail through northern portion of the Morgan Lakes Analysis Unit is an old mining road that has not been maintained. The trail has a minor amount of rilling that is eroding the trail, but it is not contributing sediment to surface water. In this AU, one lightly defined use trail climbs from below Morgan Lakes to Bear Lake. This route is steep, but has relatively few risk factors.

In the Fourth Recess AU, the Mono Creek Trail has severe impacts in a variety of locations and is especially degraded for a primary corridor trail. These impacts are especially prevalent in the Fourth Recess AU. Obstacles, including seasonal downed logs, which are common in this avalanche-prone zone, often force both stock and hiker traffic into sensitive meadows, springs, and archaeological sites, creating multiple bypass trails.

Golden Lake in the upper headwaters of Mono Creek is accessed by a system trail with minimal development that parallels Golden Creek and stays in the riparian corridor for almost its entire length. This trail has severe resource impacts, primarily incision, spring and stream impacts, and headcuts, with severe risk factors.

Third Recess Trail shows signs of inadequate design and alignment, including very steep grades through bedrock and riparian habitat and very few structures, mostly old waterbars. Moderate to severe effects are present on the majority of trail length. These effects include effects to springs, tread widening, incision, and water diversions. Sphagnum is present in meadows in trail corridor.

The Fourth Recess area is accessed by a use trail that is generally stable with few risk factors, except at a stream crossing near the outlet of lake, where there are moderate problems with incision, multiple trailing, and bank damage. Stock and hiker parties currently and historically use the area.

The Pioneer Basin AU has extensive widespread moderate soil and hydrology impacts from trails, and a few areas with severe impacts. Of the six trails analyzed for overall resource impacts, half are causing severe impacts. The system trail is moderately incised and multi-trailed along most of its length, and at many stream crossings, the incision is severe and has the potential to divert a portion of streams during high flow. Trails are capturing water from some small channels and therefore leading to alteration of flow and increased trail erosion in local

areas. Therefore, some trails are locally out of compliance with Riparian Conservation Objective #2, Standard and Guideline #100 (see project record for a list and explanation of RCOs).

In the Fourth Recess AU, the area with the heaviest trail effects and resource impacts is Pioneer Basin on the bench north of Mono Creek, just west of Golden Lake. This basin is dominated by large alpine meadows, springs, and myriad streams. Trails and use trails are in areas with many risk factors, creating a network with many access and resource issues. Due to changed use patterns and confusing trail maps/inventories, it is unclear which routes in this basin have historically been maintained as system trails and which are just well worn use trails. Trails with the worst resource impacts include access to Lake 4 (10,900'), a system trail between Mudd Lake and Lake 2 (10,840') and 3 (10,862'), and a use trail to the same destination. All of these have severe resource impacts, most with moderate to severe incision, water diversion, stream impacts, headcuts, and multiple trailing. Above Lake 3 and 4, there are some very lightly used routes with little to no trail definition.

A shortcut use trail descends a steep, grassy slope below Mudd Lake directly to a camp on Mono Creek, duplicating access provided by the Pioneer Basin system trail and Mono Creek Trail.

Hopkins Basin immediately west of Pioneer Basin has a system trail and user trail with conditions, geography, and risk factors very similar to those in Pioneer, though the use is lower. Both are incised, with moderate to severe resource effects present. The use trail provides a shortcut route from Hopkins Lake to the upper reaches of the system trail. The system trail ends about a mile below Hopkins Pass, and becomes an undefined route through the upper basin to the pass. The north (east) side of pass has not been maintained for decades and is not passable to stock. The portions of the trail through the Hopkins Creek meadow complex are moderately incised and multi-trailed. While this diverts some overland flow and has the potential to alter the meadows' hydrologic function, there is no evidence that the overall meadow hydrologic function has been altered. A trail at Lower Hopkins Lake is also incised and multi-trailed, and continues to erode through overland flow capture. However, the trail is in a dry area and is not degrading water quality or causing erosion off-trail.

A rough system trail accesses Laurel Lake in the Laurel AU. A system trail is shown accessing Grinnell Lake, but is not evident on the ground. There appears to be no likely route, and risk factors are present between the lakes.

Second Recess trail appears to be receiving very little, if any, commercial stock use. The trail is rough, with major overgrowth, avalanche debris, and very awkward conditions. The Mono Creek crossing is nearly impassable during even moderate flows. Resource impacts are low to moderate with the very low use levels, but risk factors exist if use patterns changed. An undefined use trail continues beyond the system trail to Mills Lake.

In the Silver Peak AU, the PCT climbs from Mono Creek to Silver Pass. Parts of the PCT are degraded and awkward, and some resource effects are present at stream crossings and where it crosses meadows below the pass. Some resource effects continue from abandoned sections of the PCT trail, which were rerouted decades ago. Mott Lake Trail in the Silver Pass corridor has moderate to severe resource impacts in a few areas along its length, including heavy incisions. The trail is at times degraded and awkward to travel, with slickrock in the tread, and awkward jump-offs and obstacles—especially just below the lower lake.

In the Volcanic AU, a use trail accesses the Volcanic Knob area from the PCT on the southern edge of the Mono Creek drainage and follows a moderately defined trail past a snow-survey cabin, then continues east to some small lakes at the base of Recess Peak. The trail is generally stable and follows moderate grades through areas with few risk factors, with the exception of a short section where it crosses the southern lobe of Volcano Meadow accessing the snow-survey cabin. The trail to Volcano Meadow is not causing soil or hydrologic degradation outside of the trail tread.

In the Graveyard AU, the Goodale Pass trail serves as the primary travel route, providing access to Graveyard Meadows, Graveyard Lakes and the Silver Divide. The Goodale Pass Trail is generally stable in this analysis unit. The Graveyard Lakes system trail climbs steeply from the Goodale Pass trail on a mostly dry timbered slope. There are very few trail structures on this trail relative to the evident high level of use. Erosion and soil loss and very awkward conditions are present. The trail becomes much less developed and undefined after reaching camps at the lowest lake. Access to these upper lakes is provided by a use trail with moderate to high resource effects, and severe risk factors (primarily proximity to streams and meadows between the lakes, as well as steepness of alignment). The uppermost lakes have no evidence of a defined use trail.

A well-defined use trail that shows signs of past maintenance leaves lower Graveyard Meadows at an unmarked junction, and climbs mostly on a dry brushy ridge with few risk factors to Arrowhead Lake, then becomes very faint and sporadically defined to Feather Lake. Some risk factors exist if stock use increased in the section above Arrowhead.

Bishop/Humphreys

There are approximately 81 miles of trail in the Bishop Creek and Humphreys Geographic Area. The Inyo NF manages roughly 54 miles of trail. This Geographic Unit has a relatively low density of system trails, approximately 0.6 miles of trail per square mile (or one mile of trail to 1,060 acres).

Table 3.12 Summary of system and use trails assessed in Bishop/Humphreys

Overall Rating	# Trails Assessed	Approx System Trail Length (Mi)	# Use Trails Assessed	Approx Use Trail Length
0	n/a	n/a	13	15
1	7	15	14	10
1.5	n/a	n/a	1	0.4
2	11	11	6	4.6
2.5	3	3	n/a	n/a
3	5	18	2	1.1
3.5	1	5	1	0.5
4	2	4	n/a	n/a
5	n/a	n/a	n/a	n/a

There are three main high-use corridors over the Crest of the Sierra: the Piute Pass corridor (Piute Pass Trail and Piute Canyon Trail), the Pine Creek Pass corridor (Pine Creek Pass Trail and French Canyon Trail), and Bishop Pass, which accesses destinations in Kings Canyon National Park. Another high-use area with a well-developed trail system is the basin above Sabrina Lake on the east side of the crest, but there is no trail access across the crest.

The Gable AU contains the Gable Lake trail that climbs from Pine Creek on a steep, poorly designed trail that originally provided access to various mining claims in the area, which have long-since stopped operations. The trail is awkward and collapsing at the start, and then becomes less developed as it approaches the lakes. About one mile below the lakes, the trail enters a meadow and stream system, where it has captured water flows. The main trail ends at a mining cabin and shaft just east and below Gable Lake, but a less-developed trail climbs through benches to the lake.

Most of the trails in the Pine Creek AU area have only localized hydrologic and soil impacts, with some erosion at stream crossings and some incision in meadow areas. The main Pine Creek system trail, leading almost to the wilderness boundary was an old mining road, and is therefore wider than a hiking trail. The area is rocky, however, and relatively little soil is disturbed. This trail is highly developed and travels through very rugged, rocky terrain, with some awkward conditions. In early season, some sections of trail are under snowdrifts, and lightly used bypass trails have formed below Honeymoon Lake area and just below the pass. A route was identified to Birchim Lake, but was not found on the ground. The most likely access to this lake would have to cross-springs and steep slopes between granite benches, where moderate risk factors exist and degradation is likely if use patterns change.

In the Granite Park AU, the Italy Pass system trail leaves Pine Creek Trail near Honeymoon Lake, and becomes extremely awkward as it passes the southwest shore of the lake. The trail splits, with the only stock-passable access going through a mudflat at the inlet of the lake. The trail is mostly undeveloped and very, awkward, steep, sporadic, and frequently in areas with high risk factors, crossing streams and alpine meadows with Yosemite Toads present and steep slopes. No defined use trail is present to Chalfant Lakes (which are just north of the Italy Pass trail) and no stock-practical approach was identified with the lakes entirely closed in by rocky ridges and slabs.

The Horton Lakes system trail ends at an old mining cabin at the lowest Horton Lake. An old mining road—not used for mining for over a half century—continues on to Hanging Valley on the west side of Mt Tom, and is used by hikers/climbers to approach the summit of Mt Tom. Other old mining roads exist on the slopes of Mt Tom and have not been maintained since mining use stopped. These are all on steep rocky slopes, with little or no riparian, streams, or other risk factors. A poorly defined use trail follows Horton Creek toward the upper lakes and is almost entirely in riparian zones and in immediate proximity to the stream.

In the Piute AU, the primary Piute Pass Trail is highly developed, though it climbs through a steep granite canyon, and there are many steep and awkward sections with steps, jump-offs, and slick rock slabs. The trail runs along the North Fork of Bishop Creek over most of its length, and in a few places is directly on lakeshores or the streambank. However, the small amount of sediment eroding from the trails does not appear to be altering water quality. The trail has 3-4 culverts along its length, which alter surface flow patterns, and there is rilling below at least two of the culverts, bringing fine sediment into small ponds. This could alter the ponds' habitat value.

A snow bank persists just to the east of Piute Pass longer than snow on trails either side of the pass. Commercial packers have applied material (sand, manure) to the trail (referred to as “sanding”) to harden the snow pack and make it easier for stock to pass and melt the snow. The resulting runoff has a higher concentration of sediment than would occur without the sanding. The sanded area is far from the nearest surface water body and therefore does not likely directly degrade water quality. However, sanding can allow access to other snowy or wet trails that might be more vulnerable to soil loss and stream diversion than later in the season.

A faint and mostly stable use trail (mostly on bedrock slabs) accesses a snow-survey cabin south and east of Piute Lake. Another accesses camps on the north side of the lake and is generally low-angle and stable, though it crosses some meadows with slight incision present.

Lamarck Lake Trail is well developed up to Grass Lake, where most day use occurs. From here to Lamarck Lake, the trail is steep and not well designed, but generally stable to just below Upper Lamarck Lake. Here the trail is forced into the outlet creek of the lake and is causing impacts to the stream. The Lamarck Col trail is a partially constructed, low-development trail leading from the Lamarck Lake Trail (between the two lakes), up a steep slope with constructed switchbacks to a small alpine lake/tarn just east of the Col. Overall, the trail is generally stable, though moderate to severe impacts are present at a stream crossing and incision is affecting small meadows along short sections of the trail. A trail leading up the Grass Lake outlet stream directly to Grass Lake from the North Lake parking area was abandoned when the newer Lamarck Lake Trail and a spur trail to Grass Lake was constructed at least 30 years ago. Periodically, this trail was maintained, primarily for former access to grazing in past decades. The trail is steep, deeply eroded, has very few structures and much harder to stabilize for heavy use than the new trail.

Some trails in the Sabrina Analysis Unit have slight to moderate incision and incised stream crossings, but the effects are local and not causing overall water or soil quality concerns. The Sabrina Basin trail is a highly developed trail climbing steeply into a large granite basin. Most of the trail is stable, though some sections are awkward for stock, including short sections over 40% grade, with many steps and rip-rap tread surface.

Above Blue Lake, a low-development system trail contours up to Baboon Lake. Some sections of this trail are steep, with some risk factors, but currently show only slight resource impacts. A use trail also accesses Baboon Lake along the creek, but is steep, has moderate resource impacts, and becomes impassable to stock before reaching the lake. The system trail accessing Donkey Lake has some moderate impacts at creek crossings, and becomes faint and confusing before reaching the lake, but is generally stable with the current level of use. An alternative non-system route following the Donkey Lake outlet is undefined and impassable to stock.

Despite maps and inventory suggesting a system trail from the Sabrina Trail to Topsy-Turvy and PeeWee Lakes, no trail exists within about ¼ mile of the lakes, blocked by cliffs and a waterfall. Alternative access across granite slabs from the Hungry Packer trail, however, was found and it is stable with few or no risk factors and relatively easy for equestrian travel. Some evidence of past stock use was found. The Moonlight Lake system trail was also shown going all the way to the lake, but was not found above the “Moonlight Falls” camp.

Emerald Lakes are accessed by a well-defined use trail that generally follows a stable alignment with few risk factors, with the exception of short sections in close proximity to the creek. No use

trail was found accessing Fishgut Lakes from Dingleberry Lake. Any route in this vicinity would be steep, climbing between granite ledge systems, with high potential for risk factors.

In the Tyee AU, a moderately developed trail climbs from the South Lake Road to Tyee Lakes, and then becomes less developed as it climbs over the shoulder of Table Mountain and descends steeply to George Lake. It is more developed and easy to follow to Sabrina Lake trail, though the grades are consistently steep, with some soil loss.

Much of the Treasure Lakes system trail is severely eroded. The trail is incised deeply enough that overland flow is captured in the trail and cannot be improved using water bars. The trail continues to incise and widen. The Treasure Lakes system trail ends at the inlet to the lowest Treasure Lake. Some use trails, which appear to be used by hikers and climbers accessing the alpine basins above, continue steeply directly alongside the creek channel and through small alpine meadows above the lower two lakes.

In the Bishop Creek AU, the Bishop Pass Trail was recently reconstructed, and is generally stable and readily used by stock. Due to rugged, steep, rocky terrain, some sections of trail are awkward for equestrians, especially above Bishop Lake. The Chocolate/Ruwau Lake Loop leaves the Bishop Pass trail, and climbs steeply up a dry gully to Bull Lake, then enters a riparian zone, stream channels, and meadows with many moderate to high resource effects for much of its length. The trail deteriorates into multiple ruts and a scramble trail as it climbs over a steep saddle then down to Ruwau Lake. The section between Ruwau and Bishop Pass trail at Long Lake is steep, awkward and eroded, but not directly affecting riparian for most of its length. The Marie Lakes trail is only lightly developed and somewhat rough with some erosion problems, but is generally on dry slopes, with minimal resource problems. One creek crossing has slight resource impacts and risk factors with potential to worsen if use levels increased substantially.

Many short, lightly developed use trails access many camps and small lakes and tarns in the corridor on either side of the main trail. Some of these, such as the trails to Hurd Lake, Long Lake Campsites and campsites at Saddlerock Lake, are fairly stable with few risk factors. Others, such as Timberline Tarns, Margaret Lakes, and Ledge Lake trail must cross meadows or streams, and/or have other risk factors.

In the Glacier Divide AU, the Piute Canyon Trail is the primary corridor trail accessing Piute Pass from the west. It is highly degraded in sections, with some resource impacts, mainly capturing overland and stream flows. A section of the Piute Canyon trail was rerouted away from Golden Trout Lakes (just west of the pass), but the abandoned section of trail is still the primary route to Golden Trout Lake, so heavy use has continued, leading to severe resource impacts to meadows and stream channels. Near Golden Trout Lakes, there is a high density of trails, and many of those trails are incised and diverting surface flow and in one case, diverting an entire intermittent stream. The area is therefore not in compliance with Riparian Conservation Objective #2, Standard and Guideline #100 because trails are disrupting hydrologic connectivity of aquatic features.

A well-defined and heavily used use trail traverses at a moderate grade from near Piute Pass to Muriel Lake. The route is poorly located in some sections, traveling through some wet meadows with some moderate impacts, and descending a short, steep slope near the lake. Undefined and dispersed routes access Wahoo Lakes across moderate terrain with few risk factors. A use trail to Goethe Lake appears to be primarily used by hikers, and is mostly located on dry rocky slopes, except at a few short sections where the trail crosses small streams and sloping meadows.

Packsaddle Lake is accessed via a poorly defined trail with cairns. Yosemite toads are present in the trail vicinity. Other risk factors are present such as steepness and proximity to streams and meadows. Lower Honeymoon Lake is accessed via a similarly undefined trail, which appears lightly used, with some limited effects, and risk factors present.

In the Humphreys Basin AU, two low-development system trails exist, one leading to Humphreys Lake and another to Desolation Lake. Both have low to moderate resource impacts, which could be corrected with relatively minor repairs. Cross-country travel by hikers or stock is relatively easy throughout the basin, and multiple possible routes between destinations would be relatively easy to find. A mostly undefined use trail between Mesa, Tomohawk and Square Lakes is occasionally used, and not causing notable resource impact at current levels of use.

The French Canyon Analysis Unit has extensive trail incision and multi-trailing that is diverting overland flow, springs, and streams. Many of these trails continue to erode and new multi-trails are being created due to poor trail condition that encourages users to walk off-trail. Some of the deepest incision observed in the project area is along the L-Lake to French Canyon trail. The most visibly degraded areas along the trail are within 500 ft of the junction with the Elba Lake Trail. Here, the old trail is incised up to 3 feet, and is acting as an ephemeral stream channel. There is evidence that the trail completely diverted an intermittent stream for some time, and the stream cut its downhill bank to follow the incised trail. There is a check dam to keep water from flowing into the incised trail. It seems to be working, because the current creek bottom is lower than check dam. Therefore, the stream's flow will only go into the trail if it overtops its banks. The currently used trail is also incised about 1.5 feet.

The L Lake/Moon Lake Trail climbs onto the bench south of French Canyon. It has severe resource effects along much of its length, and is affecting springs, stream flows, and meadows. The Moon Lake Cutoff trail shortcuts some of the Elle Lake trail and follows a slightly better alignment, though it also has moderate to severe resource effects.

Both a system and use trail access Merriam Lake on either side of Merriam Creek. Both are low-development, but the system location west of the creek seems to have the least resource effect and lowest intensity of risk factors for continued use. The use trail on the east appears to have lower use but higher resource effect. A use trail continues past Merriam Meadow camp, and on to LaSalle Lake, but it is ill defined and upper part is not passable to stock.

A use trail from Pine Creek Pass to Royce Lake appears to receive very little use and is hard to distinguish. Current resource effects are low and other risk factors are few, though there are some potential problems with steepness of alignment near the pass.

A use trail between Elba and Alsace Lakes has moderate to severe impacts to meadows and incision on steep slopes. Risk factors include saturated meadows. Many other routes and very faint use trails connect the various lakes in the benches above/south of French Canyon, including French, Steelhead, Alsace, Chevaux, Puppet, Star, Paris, and Blanc. These are all either indistinct or only intermittent trails with minimal definition.

The North Piute AU contains a section of the Piute Canyon Trail that is steep and poorly located in sections. The trail is difficult for stock to use because of high steps and rocky chutes. A bridge that once spanned Pinnacles Creek was removed several years ago, and the current creek crossing can be treacherous or impassable during winter runoff or following a rainstorm.

Florence/Bear

There are approximately 73 miles of trail in the Florence Lake – Bear Lake Geographic Unit. All trails in the area are managed by the Sierra National Forest. This Geographic Unit has the lowest density of trails in the AA/JM wildernesses. On average there is only about ½ mile of trail per square mile, or approximately one mile of trail in 1200 acres.

Table 3.13 Summary of system and use trails assessed in Florence/Bear

Overall Rating	# Trails Assessed	Approx System Trail Length (Mi)	# Use Trails Assessed	Approx Use Trail Length
0	n/a	n/a	4	5.7

4	n/a	n/a	n/a	n/a
5	n/a	n/a	n/a	n/a

In the Bolsillo AU, there is one system trail (Corbett Lake Trail) and several use trails. The Corbett Lake Trail accesses Corbett Lake from the Kaiser Pass Road, is in generally stable condition and receives low to moderate use from visitors to the Bolsillo campground and High Sierra Ranger Station. Few commercial stock use this trail. The Corbett Lake Trail to Cunningham Lake use trail receives low commercial stock use and has few risk factors for trail degradation. This trail is barely discernable. The Kings Castle use trail is primarily used by commercial stock during hunting season. It receives low commercial stock use and shows few risk factors for trail degradation.

The few trails that are in the Ershim AU receive low use. The Ershim Lake use trail accesses both lower and upper Ershim Lakes from the Dusy-Ershim OHV trail, and receives low use from commercial stock.

The Dutch/Boulder AU and the Dutch AU are linked together by several system trails. The Florence Lake Trail receives much higher use than any other trail in these two analysis units. This trail provides access to the PCT, Kings Canyon National Park (Evolution Valley) and the Piute Canyon Trail, though many visitors choose to bypass the section of the Florence Lake Trail in the Dutch/Boulder AU by taking the Florence Lake ferry to the south end of Florence Lake. The Boulder Creek crossing on the Florence Lake Trail can be impassable during winter runoff or heavy rainstorms. The Florence Lake Trail also provides access to the Thompson Lake Trail and Hot Springs Pass Trail in these Dutch/Boulder and Dutch AUs. Both trails receive low use and see infrequent maintenance. They may be difficult to follow and may have moderate risk factors due to steep grades. The Crater Lake Trail, at the west end of Florence Lake, receives moderate day use from both stock and hikers. The trail is steep and rocky with moderate risk

factors including several creek crossings. The beginning of the trail is severely eroded. The Crater Lake Trail provides access to the Dutch Oven Trail in the Dutch AU. The Dutch Oven Trail receives low use and can be difficult to follow because of many cattle trails in the area.

In the Dutch AU, there are several use trails. The Lost Lake use trail is a bypass trail that starts and ends at the Thompson Lake Trail and is used to access Lost Lake. The Dutch Oven to Summit Lake use trail is difficult to follow, and has numerous trees across the trail. The trail is fairly level with minimal change in terrain.

In the Dutch/Boulder AU, the Slip Rock use trail follows a historic shepherd's route through numerous beaver ponds and wet meadow areas, and is obstructed by downed trees and vegetation. This use trail also travels through the Ward Mountain AU and Sallie Keyes AU after leaving the Hot Springs Pass Trail in the Dutch/Boulder AU. The Slip Rock use trail currently receives very little use.

Trails in the Hooper AU generally receive low use, though the Hooper Diversion Trail receives low to moderate use. All of the system trails in this analysis unit are poorly located and have moderate to high risk factors in some areas, including steep grades. The Hooper Diversion Trail receives low to moderate levels of hiker and commercial stock use for access to lakes in the Hooper Basin. The Hell Hole Trail is a commercial stock route used to access to grazing areas in Hell Hole Meadow. The Poison Meadow Trail and Cirque Lake Trail also pass through this analysis unit and receive very low use. The Infant Buttes use trail is a hunting trail that leaves the Hooper Diversion Trail east of Infant Buttes. The use trail contours along some steep side slopes before achieving a lower grade, where it crosses both intermittent and perennial streams and wet meadows.

In the Ward Mountain AU, the Ward Mountain use trail traverses a bench below Mount Shinn from the Thompson Lake Trail to Ward Mountain Lake. The final leg of this use trail is a steep climb to Ward Mountain Lake along a creek. The use trail is currently not passable by stock due to downed trees. The Heather Lake use trail departs from Blayne Hot Springs (in the Sallie Keyes AU) and traverses east along the south side of the San Joaquin River. This use trail then switchbacks up rocky, steep slopes and avalanche chutes to Heather Lake, just below Mosquito Pass. In its current condition, numerous downed trees and thick vegetation along this use trail make passage very difficult for stock.

The trails and use trails in the Apollo AU are very lightly used and tend to be sporadic and hard to find. The Cirque Lake Trail is the primary system trail from which these use trails depart. This trail is lightly defined but can be followed where it leaves the Bear Creek trail. The trail becomes less obvious as it nears Cirque Lake. At current levels of use, the trail is causing no notable resource effects.

There are several use trails in the Apollo AU. The Cirque Lake Trail to Depressed Lake use trail contours on easy grade through fairly stable rocky soil on the north side of a meadow to Gold Pan Lake. From Gold Pan Lake to Depressed Lake, the trail winds through rock and short stretches of meadow. The Marcella Lake use trail also leaves the Cirque Lake Trail and travels less than ¼ mile cross country to Marcella Lake. The Apollo/Orchid use trail does not connect with the Cirque Lake Trail, but rather leaves the PCT/JMT near the Seven Gables junction and climbs through slopes before reaching Orchid Lake followed by Apollo Lake.

In the Italy AU, the Lake Italy trail is used by commercial stock primarily to access camps at “Hilgard Bench,” about 1.5 miles from the PCT. Above this, the trail is poorly developed, confusing, and located in meadows, springs, along streams, and other extremely high risk factor areas. Even incidental stock use has created moderate to severe impacts, although the erosion is not severe and was not observed to be degrading water quality. Below Italy Lake, the trail becomes hard to follow, and goes through rock slabs, steep slopes and talus fields that are impractical to stock.

In the Bear Lakes AU, the Seven Gables Trail climbs steeply from the PCT into a narrow canyon, and is confined to very near the stream channel on both sides of the creek, with multiple creek crossings. The trail is hard to find and travels over granite slabs, eventually dispersing into extremely difficult terrain about 1.5 miles from the PCT.

In the Seldon AU, trails have very few structures and drainage improvements, with the exception of the PCT, so where trails are receiving moderate levels of use, erosion and potential resource effects are common. The Sandpiper Lake Trail leaves the PCT, and climbs at moderate grades to Lou Beverly Lake, with only moderate effects, but climbs steeply through bedrock slabs and short, steep chutes with erosion and very awkward conditions leading to Sandpiper Lake. This trail is causing moderate to high resource impacts on springs and meadows near the lake, and fades into a use trail that climbs directly up a stream course toward Three Island Lake. This use trail becomes undefined as it crosses meadows and streams in terrain with very high risk factors before reaching Three Island Lake.

In the Marie Lake area, no use trails are evident accessing the Medley or Sandpiper area or Seldon Pass, and would only be used for shortcutting system trails to the same destinations. An undefined route with no notable effects and, if use levels do not increase, few risk factors accesses Marshall Lake.

In the Sallie Keyes AU, the PCT has moderate to severe resource effects on meadows and streams south of Seldon Pass. This includes incision, stream diversions and multiple trailing. Trail condition is substandard for a high-development primary trail. Trails in the Sallie Keyes AU are generally not contributing to water or soil resource degradation, although there are a few instances where a trail is disrupting surface flow. Along one section of the PCT, in a meadow between Sallie Keyes Lakes and Senger Creek, the trail captures overland flow from the very wet meadow and transports it down the trail, acting as an intermittent stream. However, this diversion does not appear to be altering the meadow hydrologic function or vegetation composition. The Sallie Keyes Cutoff Trail between the PCT and Florence Lake Trail is severely incised in places due to steep grades and lack of water diversion structures, and receives moderate use. The Florence Lake Trail in this analysis unit (and in the East Florence AU) is one of the most heavily used system trails in the JM/AA on the Sierra National Forest. The trail has severe multiple trailing in places, but is generally flat and stable.

There are several use trails in the Sallie Keyes AU. A faint use trail climbs gradually along Senger Creek to a camp about one mile from the PCT. Most of this trail is on dry, low angle slopes with few risk factors. The Sallie Keyes to Muir Trail Ranch use trail follows Senger Creek down steep slopes. This use trail has been abandoned. The Tombstone use trail climbs steep slopes from Double Meadow to The Tombstone, and is not well defined. This use trail receives little use, and the use that occurs is primarily during hunting season.

The East Florence AU contains two of the most heavily used system trails in the JM/AA on the Sierra National Forest: the Florence Lake Trail and the Florence Ferry Trail. The Florence Ferry Trail connects the ferry landing on Florence Lake to the Florence Lake Trail. The trail parallels the private inholding access road, crossing rocky slabs and small sandy benches. The trail is generally stable with few risk factors. The section of the Florence Lake Trail in this analysis connects the South Fork San Joaquin River with Double Meadow. The section parallels the private inholding access road between the junction with the Florence Ferry Trail and Double Meadow (the trail continues to parallel the road to Muir Trail Ranch in the Sallie Keyes AU). There is severe multiple trailing along this section, but the trail otherwise is stable and has few risk factors.

John Muir Southeast

There are approximately 100 miles of trail in the John Muir Southeast (JMSE) Geographic Area. All trails in the area are managed by the Inyo National Forest. Due to the steep terrain with few practical routes through the area, this unit has a very low density of trails, the second lowest in the JM/AA wildernesses. There is roughly one mile of trail for every 1100 acres of land, or just over one half mile of trail per square mile. JMSE is a narrow north-south band of Wilderness, so trails cross into national parks on the west side of the crest in relatively short travel distance. Along much of this area, it is possible to travel from a trailhead on the Inyo National Forest into the National Park in 6-10 trail miles.

Table 3.14 Summary of system and use trails assessed in John Muir Southeast

Overall Rating	# Trails Assessed	Approx System Trail Length (Mi)
0	3	11
1	4	11
1.5	1	3
2	2	6
2.5	1	4
3	n/a	n/a
3.5	n/a	n/a
4	n/a	n/a
5	n/a	n/a

There are four intensively used primary trails in the JMSE. All of these trails are maintained at a high level and are generally stable. North Fork of Big Pine Creek accesses the northern Palisade glacier area and does not provide trailed access across the crest into the National Park. The Kearsarge Pass Trail provides the shortest access (approximately four miles) across the crest into Kings Canyon NP. The Mt. Whitney Trail crosses into Sequoia NP just below the summit of Mt Whitney, and—aside from summiteers that are briefly in the park—it is used by more overnight hikers exiting the park than entering from the east. New Army Pass Trail provides access

between Cottonwood Lakes and Sequoia NP, but is used less by commercial stock than Cottonwood Pass to access the same areas.

The primary system trail in the North Fork of Big Pine is heavily used and highly developed until 4th Lake, and then gradually becomes less developed until it ends at 6th Lake. From this trail, a steep low-development trail climbs toward Sam Mack Meadow and the Palisade Glacier. This rough trail was used most heavily when a guiding school had a semi-permanent camp on the east end of the glacier, and sometimes to assist in rescues when helicopters could not be used. Use, especially stock use of this trail, has dropped off dramatically during the past 30 years, and is now more of a scramble route. A very steep trail to 6th Lake was abandoned many years ago, when the current system trail was built, but is still being used by hikers. It has some moderate erosion problems and many risk factors if stock use were present, but is mostly stable with the current level of hiker use.

A variety of lightly used use trails are used by commercial stock to access seasonal hunting or to provide seasonal stock support for snow survey needs. The use trails are generally stable and are mostly on dry open slopes with few risk factors, with only occasional stream crossings or riparian effects. These include a trail from Black Lake to Coyote Ridge, a use trail between campsites at 4th and 5th Lake, a trail accessing the Snow Survey Cabin at 2nd Lake, and accessing a snow survey site, and a trail to the “Heidi Cabin.”

In the North Fork of Lone Pine, the “Mountaineers Route” has never been used by stock, due to the steep, scrambling character of the trail. Sections of the trail go through talus fields and up cliffs, requiring basic climbing techniques. Since this trail is accessed by the Mt Whitney Trail, it is also closed to all stock use.

In the Birch AU, a rough trail on mostly steep, dry slopes provides access to just below Birch Lake, where the trail disperses into dense willows and rocky terrain. Most commercial use in the area provides access for hunting parties, and stock must be trucked to the trailhead, so trail use by stock is sporadic and low. From this trail, an ill-defined use trail leads north to a camp near springs east of Kid Mountain. Other short use trails lead to camps used by hikers. The trails are very lightly used, and generally do not have high risk factors or current resource effects.

In the Taboose AU, the Taboose Pass Trail is steep, rough, and rocky, especially near the top of the pass, and receives very low commercial or private stock use. There are some low to moderate effects, mainly some erosion of tread and capture of seasonal surface flows. Due to poor trail location a snowdrift forces use off the trail into an obvious bypass during heavy snow years. This bypass is in a rocky area and is not causing notable effects.

At the lower end of the canyon, a use trail leads to Shingle Mill Bench. The trail is generally faint but can be followed and appears to be used occasionally for hunting trips by private and commercial stock.

In the Sawmill AU, the Sawmill Pass Trail is a moderately developed trail leading into Kings Canyon NP. The trail leading to Sawmill Meadow and Sawmill Lake had been built for heavy use at the turn of the century for providing access for oxen and stock to a sawmill and flume, and to a rudimentary dam at Sawmill Lake. Above Sawmill Lake the trail is less developed and generally stable due to rocky soils, with the exception of some alpine meadows near the summit. On heavy snow years, the trail is often buried and some use trails have formed around the drifts.

In the Baxter AU, the Baxter Pass Trail is a very low development trail that has suffered from multiple catastrophic events during the past two decades, including a flood that changed the course of the lower stream channel and creek, and a landslide which buried large sections of the trail about 2/3 of the distance to the pass. The trail is steep and has few structures. The trail is in a Sierra Nevada Bighorn Zoological area with use restrictions. This trail provides access to the Kings Canyon NP, but the trail on the west side is even less developed and in rougher shape than the east side.

In the Kearsarge AU, the Kearsarge Pass Trail was recently reconstructed, is in very stable condition, and is currently maintained to standard. Since the trail on the Inyo NF side of the pass is very short, and since most good overnight camping is west of the Pass, most trail use is by backpackers and commercial stock traveling through the forest into the Park or accessing the PCT.

A very low-development trail heads north from Onion Valley and splits into two trails accessing Golden Trout Lakes, which are in two sub-drainages. The main trail climbs a loose, rocky slope with multiple trailing and soil movement alongside a cliff band, and then follows the creek drainage up a rocky gully with sporadic trail tread. The northern spur of the trail is less defined and goes through rougher terrain.

Both hikers and commercial stock use two faint use trails to access Bench Lake (above Matlock Lake). One trail climbs a dry sandy slope above Matlock Lake, while the other climbs and contours over from Flower Lake. Both are of minimal profile, though the trail from Matlock is shorter and appears to have fewer risk factors. A faint trail provides access from the Sardine Canyon trail into the Little Onion Valley but becomes impassable and undetectable before reaching Parker Lake.

In the Shepherd AU, the Shepherd Pass Trail climbs steeply from Symmes Creek for about 10 miles to the pass and into Sequoia NP. The trail is moderately developed and mostly stable, except on some steep sidehills in the lower canyon and at the final 1/3 mile of trail ascending the headwall and chute of loose scree and talus east of the pass. This slope is constantly moving, making a quality trail nearly impossible to maintain. Resource effects are low and risk factors few, with little or no riparian effect from the trail.

The Junction Pass trail accesses the same area as the PCT over Forester Pass, but climbs through a steep talus slope and over the 13,200' shoulder of Mt Keith. It is subject to large boulders rolling into the trail. The trail is hard to find in many places. Resource effects and risk factors are low, but costs to improve and maintain this trail would be extremely high relative to the use. The George Creek Trail leading to the west side of Mt Williamson has never been constructed, and has gradually deteriorated to the point that it cannot be followed. Most of the trail in the lower canyon followed the riparian zone alongside George Creek, and is overgrown by willows.

In the Whitney AU, the Mt Whitney Trail has been closed to all stock, commercial and private, except for administrative purposes, since the 1960s.

In the Cottonwood AU, the Cottonwood Lakes area is accessed by highly developed trails that go through the Golden Trout Wilderness prior to reaching the John Muir Wilderness and the Cottonwood Lakes Basin. The New Army Pass Trail climbs out of the basin into Sequoia NP, but is used by very few commercial stock. In the Cottonwood Basin, a low-development trail travels between the inlet of 3rd Lake and the New Army Pass Trail, traversing just above 2nd

Lake. This trail is on the immediate eastern banks of 3rd Lake, and crosses a wet meadow and stream. It has very high and consistent risk factors, primarily the location of trail on the lakeshore and in wet, hummocky meadow and at the stream crossing.

A short use trail between the DFG cabin and the “Frog Pond” provides access for DFG administering the fisheries in the basin. It is mostly on dry slopes, except as it nears the outlet stream from 3rd Lake. Another poorly located and undeveloped trail connects South Fork Meadow and the Cirque Lake Trail. This provides access to the same destinations accessed by the well-developed trail system from Cottonwood Lakes Basin. Camps at Southfork Meadow are also accessed from the lightly developed Southfork Creek Trail. The upper segment of this trail climbs a moderate-angled rocky slope, and is dispersed and hard to follow.

A number of undeveloped use trails access dispersed and lightly used destinations such as Hidden Lake and Windy Gap. These trails are generally stable and have few risk factors unless use increased dramatically. Use trails have formed around 4th and 5th Lakes, primarily due to anglers. These are on the immediate shore of the lakes, and must cross a creek from the system trail at an awkward location.

In the South Fork Big Pine AU, primarily mountaineers accessing the southern Palisade Glacier and the peaks above use South Fork Big Pine Trail. The trail is moderately developed, but with some awkward, rocky sections as far as the first lake, with slight resource impacts at small stream crossings near Willow Lake. Above this lake, the trail climbs very steeply with few drainage or stabilization structures up to Brainard Lake. Some erosion and slight resource effects are present.

In the Meysan AU, the Meysan Lake Trail leaves from the Whitney Portal Trailhead, and has been closed to commercial stock use since the 1960s, as were the other trails in the Whitney Portal area. This trail is generally stable with the current level of use, but has risk factors in some steep sections, and is in close proximity to riparian for short sections.

John Muir Southwest

There is an estimated 131 miles of trail in the JMSW Geographic Area. The Sierra NF manages all trails in the area. This area has a moderate density of system trails, roughly—the same as the overall wilderness—at around 0.7 miles of trail per square mile, or 1 mile of trail per 880 acres. The primary trail corridors in the John Muir Southwest Geographic Area are the Blackcap Trail, the Woodchuck Trail, and the Crown Valley Trail.

Table 3.15 Summary of system and use trails assessed in John Muir Southwest

Overall Rating	# Trails Assessed	Approx System Trail Length (Mi)	# Use Trails Assessed	Approx Use Trail Length
0	n/a	n/a	2	2.4
1	n/a	n/a	n/a	n/a
1.5	n/a	n/a	n/a	n/a
2	2	3	n/a	n/a

Overall Rating	# Trails Assessed	Approx System Trail Length (Mi)	# Use Trails Assessed	Approx Use Trail Length
2.5	2	2	n/a	n/a
3	2	11	n/a	n/a
3.5	n/a	n/a	n/a	n/a
4	n/a	n/a	n/a	n/a
5	n/a	n/a	n/a	n/a

In the Hobler AU, the Blackcap Trail and the Hobler Lake Trail receive moderate use, while all other trails receive low to very low use. The Blackcap Trail is the primary access trail for the high altitude lake basins in the John Muir Southwest Geographic Unit. The trail is generally stable through this analysis unit but shows incision on the west end of Post Corral Meadow. The Hobler Lake Trail is generally stable and shows few risk factors. The Burnt Corral Trail receives low use, primarily from commercial and private stock use, and currently is obstructed by many downed trees. The Reddy's Hole Trail is nearly impossible to find in some areas, and receives very low use.

The Hobler AU also contains two use trails. The Burnt Corral to Reddys Hole use trail, which leaves the Burnt Corral Trail at 9200 feet where the Burnt Corral Trail crosses Burnt Corral Creek. The use trail traverses rocky timbered side slopes and crosses several ridges before dropping into Reddys Hole where it joins the Reddys Hole system trail. This use trail is currently very difficult to follow and receives low use. The beginning of the China Hole use trail is easy to follow through this analysis unit, before it becomes faint as it drops into the North Fork Kings River canyon.

In the Post Corral AU, the Blackcap Trail is the primary trail corridor. This section of the Blackcap trail receives moderate use and is in generally stable condition, though there is multiple trailing and incision in sections of Post Corral Meadow. The Hell For Sure Trail is a secondary trail that receives moderate use as an access route to Rae and Fleming Lakes area. This section of the Hell For Sure Trail is in poor condition as it climbs slopes. The trail is steep and lacking trail structures, allowing water capture and channeling and leading to erosion. A section of the Reddy's Hole Trail also passes through this analysis unit and receives very low use. The Post Corral AU also contains the Post Corral to Fleming Creek use trail. This trail is primarily used by commercial stock. The China Hole use trail travels through this analysis unit as well, and is used to access the North Fork Kings River. This section of the use trail is hard to follow and presents moderate risk factors as it steeply descends to the North Fork Kings River.

In the Fleming Mountain AU, there are several system trails, all of which are generally stable and receive low to moderate use. The Hell For Sure Trail in this analysis unit does show widening at the Fleming Creek crossing below Fleming Lake. The Dale Lake user trail is well defined and rocky in some areas. The tread shows some erosion and gullies. The Rae Lake user trail shows some erosion that is occurring on lower section of this trail.

In the Red Mountain AU, the Hell For Sure Trail shows some sections of erosions due to lack of trail structures. The section of this trail between Hell For Sure Lake and the Kings Canyon

National Park boundary is difficult for stock to navigate due to steep rocky sections. Also in the Red Mountain AU, the Blackrock Lakes use trail is difficult to follow between Devil's Punchbowl and Blackrock Lakes outlet.

In the Bench AU, there are several use trails and only one small section of the Bench Valley system trail. This short section of the Bench Valley system trail is generally stable with few risk factors. The Crabtree to Horsehead user trail is not visible for most of its length, though there are sections of clear tread near Roman Four Lakes. The Fall Creek to Crabtree user trail is generally not continuous, though it is marked with blazes from historic routes.

In the Big Maxson AU, there are many secondary system trails that spur off of the primary trail corridors of the Blackcap Trail and the Woodchuck Trail. Generally, the primary and secondary system trails in the analysis unit are in need of maintenance and lacking trail structures. The Bench Valley Trail in particular is in very poor condition along certain sections of the trail. The trail leaves the Blackcap trail at the North Fork of the Kings River and climbs a steep ridge. The trail is in very poor condition along this section. It is rocky and difficult for stock. It is stable as it contours and climbs around a ridge to Fall Creek. It continues up the drainage, crossing creeks, wet sections, meadows and rocky areas before switchbacking up a very steep ridge to McGuire Lakes. This section of switchbacks is severely eroded, with gullies greater than three feet deep in sections. In some flat dry meadows above Guest Lake, the trail shows multiple trailing and incision. Failed trail features are causing erosion problems and trail reroutes are common on this trail. A small section of the Blackcap Trail between the Potholes (PG&E cabin) and Big Maxson Meadow is in very poor condition where it climbs a steep rocky ridge. The trail here has become loose, rocky, and eroded.

There are two user trails in the Big Maxson AU. The Bench Valley user trail connects the Meadow Brook system trail to the upper Bench Valley system trail and is currently used by commercial stock as an alternative to the lower section of the Bench Valley system trail, which is currently difficult for stock to travel on. The Fleming Creek to Meadow Brook user trail climbs steeply out of Fleming Creek and is generally not suitable for stock travel.

In the Basin AU, the Blackcap Trail is generally stable, but has areas where it crosses wet meadows and is incised. This section of the Blackcap Trail has moderate risk factors. The Crown Basin Trail is fairly stable with low to moderate risk factors. The use trails in this analysis unit are faint, hard to follow, and display general characteristics of low use trails.

In the South Woodchuck AU, the primary trail corridor is the Woodchuck Trail. The trail is generally in stable condition with low risk factors. All other system trails in this unit receive low to moderate use, are generally easy to follow and show low to moderate risk factors in some areas. The use trails in this analysis unit are faint and difficult to follow.

The North Woodchuck AU contains no system or use trails.

The Crown Valley Trail is the primary trail corridor in the Crown Lake AU. The trail sees moderate use, is easy to follow and travels across generally low grades. There are few risk factors. All other system and use trails in this analysis unit receive low use.

In the Crown Basin AU, there are two system trails and one use trail. The Coyote Pass Trail is primarily used to access a private inholding near Mountain Meadow, and receives low use. The analysis unit also contains a low use, low grade section of the Crown Basin Trail. The

Hummingbird Lake use trail received low use as it connects the end of the Crown Basin Trail to Hummingbird Lake. The use trail travels across a wet meadow, presenting moderate risk factors.

In the Finger AU, there are several system trails that receive low use and infrequent maintenance. The Hoffman Mountain Trail in particular is severely eroded in certain sections due to intermittent stream capture and lack of trail structures. The Cabin Trail is impassable to stock in certain areas due to downed trees. A short section of the Woodchuck Trail passes through this analysis unit. This section is stable and receives moderate use.

In the Spanish AU, the Crown Valley Trail is the primary trail corridor. Two secondary trails, the Statham Trail and the Spanish Loop Trail receive low to moderate use. All system trails in this analysis unit show a lack of maintenance and trail structures.

In the Rodgers AU, there are several system trails and no use trails. Generally, the system trails in this unit are steep and have sections of incision and erosion. All system trails in this are generally in need of maintenance. The Crown Valley Trail is the primary trail corridor and sees moderate use. It passes through a private inholding in this analysis unit. Several secondary system trails access various destinations from the Crown Valley Trail. The Tehipite Trail receives moderate use and is primarily used to access Kings Canyon National Park. The Blue Canyon Trail, which receives light use, also accesses Kings Canyon National Park and passes through a private inholding.

3.1.4 Heritage Resources and American Indian Concerns

Heritage Resources

Wilderness Scale

Heritage resources include archaeological sites, historic buildings, cultural landscapes, objects, and environmental features that inform us about human activities. In the Ansel Adams and John Muir Wildernesses treatment of Heritage Resources is done under the provisions of the Programmatic Agreement: Controlling Impacts on Historic Properties; Management of Ansel Adams, John Muir, and Dinkey Lakes Wildernesses, Sierra and Inyo National Forests.

Human history takes place within an environmental context. When the first evidence of human activity in the High Sierra appears, the passes had long been deglaciated and the region supported big game. The climate continued to change and between 5000-3000 years ago, forests and meadow systems developed (Wood, 1975), opening up new niches for human occupation. During this time eruptions from the Inyo-Mono Craters periodically blanketed the Sierran crest from Yosemite to Sequoia-Kings National Parks, causing localized disruptions in use (Jackson and Morgan, 1999). Information about past environments may be found in fens, meadow soils, and tephra deposits.

Scientific evidence first puts people in the Sierran alpine and sub alpine zones at about 7500 years ago. The High Sierra was used by both east and west side peoples and reflects the prehistoric culture history of both California and the Western Great Basin. The earliest uses reflect big game hunting and procurement of obsidian for tool making from the volcanic landscape of the eastern Sierra. Use was probably by individuals, or hunting and trading parties. As meadow systems developed, archaeological evidence shows that whole groups of people traversed and even summered in the high country, continuing the all important obsidian procurement and tool production. In the latest prehistoric period, obsidian procurement had dropped off while trade in other goods was maintained through to the 19th century AD. In both the High Sierra and the White Mountains to the east an intensive summer high altitude occupation pattern developed around 1300 years ago. In the Sierra, these sites are located along the major trails. There is ample evidence of continual east-west relationships from sites in the Sierra and from the ethnographic literature. (Bouey and Basgall, 1984; Davis, 1965; Essene and Hulse, 1935; Fowler and Liljeblad, 1986, Gayton, 1948; Gifford, 1932; Hall, 1982; Hinds, 1959, 1962a, 1962b; Jackson and Jackson, 1997; Jackson and Morgan, 1999; Kroeber, 1925; Latta, 1936; Liljeblad and Fowler; 1986, McCarthy, 1993, 1996; Merriam, 1967; Polanich, 1996; Steward, 1933; Stevens, 2002; Theodoratus et al., 1984; Wickstrom, 1992; Woolfenden, 1996.). The “Summary of Regional Prehistoric Changes” table summarizes these relationships and provides the context for regional research and interpretation and is in the project record.

With the discovery of gold, “The World Rushed In” (Holliday, 1981) to the Sierra Nevada, drastically disrupting indigenous lifeways. Historic era activities that occurred in the High Sierra include mining, grazing, hydroelectric development, recreation, film making, academic research, and land management activities (Cook, 1943; Hull, 2004; Reid, 1983, Theodoratus et al., 1984). Much of this activity was supported by pack stock operations (e.g. Jackson, 2004). With wilderness designation, certain activities have been reduced or eliminated.

Each of these eras and activities has helped shape the modern landscape of the wilderness and has left distinctive remains. The most enduring are the trail corridors used throughout human history (Jackson, 2004; Snyder, 2001; USDA Forest Service, Inyo and Sierra National Forests, 2001). Site condition monitoring in the project area (Jackson et al., 2005; Kerwin, 2005; Morgan et al., 2005, Planas and Parrish 2004; Reynolds 2002; Reynolds and Kerwin 2003, 2005) has found that some pack stock operations have adverse effects on some heritage resources and not on others. For instance, shod hooves trampling flaked stone tools may be an adverse effect while trailing past Basque aspen carvings is not. Activities that cause erosion of tephra deposits are. The monitoring results will be used to compare alternatives.

Approximately 60% of the project area has been inventoried for heritage resources. The areas inventoried to date are those most intensively used areas by commercial pack stock. The numbers of sites and site types given under the Geographic Scale discussion are based on both formally recorded sites, sites noted but not formally recorded and reported sites.

Geographic Unit Scale

Ansel Adams East

Sixty four percent of the Ansel Adams East geographic unit has been inventoried for heritage resources. Additional inventory in high impact areas may be needed. There 107 known sites; 86 prehistoric and 21 historic.

Of note are the Rush Meadows Archaeological District; the Mammoth Trail (2601, 26E01) was an important transportation corridor in prehistoric and historic times. The latter runs through both Ansel Adams East and West Geographic Units. The Bloody Canyon Trail (2516), a prehistoric trail goes through the Bloody Canyon AU.

Known resources by analysis unit:

- Bloody Canyon AU: three prehistoric and one historic site.
- Parker AU: one prehistoric site
- Rush Creek AU: 8 historic and 18 prehistoric sites.
- Upper Rush Creek AU: 3 historic and 34 prehistoric sites.
- Thousand Island AU: nine prehistoric sites.
- Shadow Ediza AU: two historic sites.
- River Corridor AU: four prehistoric sites.
- River High AU: four prehistoric and two historic sites.
- Minaret AU: an historic mining complex.
- King Creek AU: two prehistoric and two historic sites.
- Crater Creek AU: one prehistoric site on the Inyo portion; nine prehistoric sites and two historic sites on the Sierra NF portion managed by the Inyo.

Ansel Adams West

Inventory of all the trails, campsites, and grazing areas proposed for in the Strategy has been completed. This work includes ten historic Native American travel routes that have been inventoried, including the French (26E16), Mammoth (26E01), Isberg (24E01) and Mono Trails (27E46), major aboriginal travel and trade corridors. A total of 116 heritage sites are recorded in

the Ansel Adams West Geographic Unit of which 109 are prehistoric, six are historic, and one has both historic and prehistoric components.

The Mono Trail, a prehistoric and ethnographically known travel corridor, passes through the Lower Mono, Onion Springs, Hot Springs, and Cold Creek Analysis Units. The Mammoth Trail (26E01) is currently recorded as a historic trail as is the French Trail (26E16).

Known resources by analysis unit:

- Lillian AU: one prehistoric site.
- Triple Divide AU: three prehistoric sites and one historic site.
- Sadler AU: three prehistoric sites.
- Cora AU: 11 prehistoric sites and 2 historic sites.
- Bridge AU: 12 prehistoric sites.
- Cassidy AU: one historic site.
- Junction AU: three prehistoric sites.
- Arch AU: seven prehistoric sites and one historic sites.
- Lake Catherine AU: four prehistoric sites.
- Cargyle AU: 16 prehistoric sites and 1 historic site.
- Lower Mono AU: 10 prehistoric sites and 1 site with historic and prehistoric components.
- Cold Creek AU: six prehistoric sites.
- Chiquito AU: one prehistoric site.
- Staniford AU: one prehistoric site.
- Onion Springs AU: three prehistoric sites.
- Fuller Buttes AU: six prehistoric sites.
- South Fork AU: 13 prehistoric sites and 1 historic site.
- Hot Springs AU: eight prehistoric sites.

Fish Creek/Convict/McGee

Inventory of this geographic area on the Sierra NF is 100% of the areas identified in the Strategy. On the Inyo NF 25% of the total area has been inventoried. Addition inventory may be needed. There are 60 known sites, 59 prehistoric and one multicomponent.

Known resources by analysis unit:

- McGee AU: four prehistoric and one multicomponent site.
- Purple Bench AU: 18 prehistoric sites.
- Upper Fish Creek AU: one prehistoric site.
- Cascade Valley AU: 12 prehistoric sites.
- Silver Divide AU: 17 prehistoric sites.
- Margaret AU: seven prehistoric sites

Mono Creek/Rock Creek

In this geographic area the Sierra NF surveyed 100% of the area identified in the Strategy and the Inyo has surveyed 17%. Additional inventory may be needed. This geographic area contains most of the Mono Trail (2901 and 29E01). The trail runs through the Fourth Recess, Pioneer, Hopkins, Laurel, Second Recess, Silver Peak, Volcanic, Graveyard, and Bear Analysis Units. There are 83 sites, 80 prehistoric, one multicomponent, and one historic site.

Known resources by analysis unit:

- Hilton Creek AU: six prehistoric sites and three historic sites.
- Little Lakes AU: one prehistoric and one historic site
- Fourth Recess AU: 10 prehistoric sites.
- Pioneer AU: four prehistoric sites.
- Hopkins AU: four prehistoric sites and one historic site.
- Laurel AU: three prehistoric sites.
- Second Recess AU: nine prehistoric sites and one multicomponent site
- Silver Peak AU: seven prehistoric sites
- Volcanic AU: one prehistoric site.
- Graveyard AU: 19 prehistoric sites and one historic site.
- Bear Ridge AU: 10 prehistoric sites.
- Devils AU: one prehistoric site.

Bishop/Humphreys

The Sierra NF has surveyed 100% of the area identified in the Strategy and the Inyo NF has surveyed 22%. Additional inventory may be needed. The Piute Trail (30E01), a prehistoric travel corridor, is in this geographic unit. There are 42 reported sites; 38 prehistoric and 5 historic.

Known resources by analysis unit:

- Gable Creek AU – historic mining remains.
- Pine Creek AU – historic mining remains, one prehistoric site.
- Horton AU – one prehistoric and one historic.
- Piute AU – four prehistoric sites and one historic structure.
- Lamarck AU – two prehistoric sites.
- Sabrina AU – dispersed prehistoric remains reported.
- Bishop Creek AU – some prehistoric and historic remains reported.
- Glacier Divide AU – 20 prehistoric sites.
- Humphreys AU – three prehistoric sites.
- French Canyon AU – five prehistoric sites.
- North Piute AU – one prehistoric site.

Florence/Bear

All of the area identified in the Strategy was inventoried. A portion of the Piute Trail (28E25, 30E01) is in the geographic area and goes thru the East Florence and Sallie Keyes Analysis Units. A grand total of 63 sites with 55 prehistoric, one multicomponent, and seven historic sites formally recorded:

Known resources by analysis unit:

- Dutch AU: 18 prehistoric sites, 5 historic sites, and 1 multicomponent site.
- Bolsillo AU – one prehistoric site.
- Dutch Boulder AU – two prehistoric sites.
- Hooper AU – one prehistoric and two historic sites.
- Italy AU – three prehistoric sites.

- Bear Lakes AU – three prehistoric sites.
- Seldon AU – seven prehistoric sites.
- Sallie Keyes AU – 13 prehistoric sites.
- East Florence Lake AU – one prehistoric site.
- Ershim AU – six prehistoric sites.

John Muir Southeast

With 27% of the project area surveyed, there are six known sites: four historic and two prehistoric. Additional inventory will be needed. Site of note include the Lon Chaney Cabin and the Tuttle Creek Ashram

Known heritage resources by analysis unit:

- Coyote AU: site reported at a trailhead parking/camping area.
- North Fork Big Pine Creek AU: one historic site.
- Taboose AU: one prehistoric site.
- Kearsarge AU: one historic site.
- Cottonwood AU: historic remains reported.
- North Fork Lone Pine Creek AU: one historic site.

John Muir Southwest

Inventory has been conducted on all of the area identified in the Strategy, with 21 formally recorded prehistoric and 7 historic sites.

Known resources by analysis unit:

- Hobler AU: three prehistoric sites.
- Post Corral AU: six prehistoric sites.
- Red Mountain AU: one prehistoric site.
- Big Maxson AU: two historic sites.
- Basin AU: one historic site.
- South Woodchuck AU: one prehistoric and one historic.
- Rodgers AU: four prehistoric and two historic sites.
- Spanish AU: five prehistoric sites.
- Finger AU: one prehistoric site and one historic site.

American Indian Concerns

Wilderness Scale

The project area is part of the traditional territory of indigenous people who today belong to the following tribes, communities, and organizations.

Federally Recognized Tribes: The Bishop Paiute Tribal Council, the Big Pine Indians of Owens Valley, the Utu Utu Gwaitu Paiute, Fort Independence Paiute, the Lone Pine Paiute-Shoshone, Big Sandy Rancheria, North Fork Rancheria, Cold Springs Rancheria, Picayune Rancheria, and Table Mountain Rancheria.

Tribes in the process of seeking federal recognition: Mono Lake Indian Community, North Fork Mono Tribe, Dunlap Band of Mono Indians, and American Indian Council of Mariposa County.

Organizations include American Indian Center of Central California, Haslett Basin Traditional Committee, Mono Nation, Sierra Mono Museum, Central Valley Indian Health, Native Earth Foundation, and Sierra Nevada Native American Coalition.

Many Indian people retain a deep, abiding concern about what occurs within their aboriginal territory. These lands are considered the center of their universe, their homeland; spiritual reverence for the land is often expressed by tribal members. Thus, we are speaking not only of cultural survival, but spiritual survival as well; among many Indian people the concepts are inseparable. It is felt by many that they have a responsibility to manage the land properly; that Creator put them there to do just that.

Archaeological sites and landscapes have a value to Indian people beyond the scientific information they contain. Although the surface material has in some cases disappeared or been greatly diminished, the cultural value of the trail, the prehistoric site, the gathering site, the sacred place, the history of travel and trade, the need to conduct ceremonies, etc. remains. One kind of significance assigned to a site or place is called a Traditional Cultural Property. Thus, access to sites and the protection of places of tribal value is important. (Administrative Record of consultation for the Sierra PA on file at the Sierra National Forest, Clovis; Administrative Record of consultation for the Sierra Nevada Forest Plan Amendments, on file at the Regional Office, Vallejo.)

Geographic Unit Scale

Ansel Adams East

The Bloody Canyon Trail (2516) has tradition cultural significance to the Southern Miwok and Mono Lake Kuzeditkaa , who conduct an annual walk over it. A Traditional Cultural Property (TCP) evaluation has been requested by the participants.

Ansel Adams West

The Mono Trail Corridor is considered a potential Traditional Cultural Property and is currently being evaluated as such. Western Mono peoples conduct an annual walk over it.

Mono Creek/Rock Creek

The Mono Trail is considered a potential Traditional Cultural Property and is presently being evaluated as such. Western Mono peoples conduct an annual walk over it.

A traditional gathering area of *Carex sp.* in Quail Meadow (Graveyard AU) requires protection from grazing impacts.

Bishop/Humphreys

The Piute Trail is considered a potential Traditional Cultural Property. It is the site of an annual traditional walk by the Western Mono peoples. It goes thru the Piute, Glacier Divide, Humphreys, French Canyon, and North Piute AUs. Hutchinson Meadow, along the trail, is an important meeting area and retains traditional cultural values.

Florence/Bear

The Summit Lake area in the Dutch AU is an area of traditional cultural value. Another location, Blaney Hot Springs also has traditional cultural value. Protection and preservation is important.

John Muir Southeast

Taboose Pass Trail and Kearsarge Pass Trail are becoming used for annual traditional walks. These are potential Traditional Cultural Properties.

3.1.5 Socioeconomics

This section examines the economic and social environment of the region affected by the alternatives. The project area consists of four counties divided into two general geographic areas. The eastern Sierra portion of the project area consists of Inyo and Mono Counties, while the western Sierra project area is made up of Madera and Fresno Counties. These counties provide services to visitors and employees and receive tax revenue or benefits through retail and other trade. Consequently, these counties could be affected by changes in the levels of commercial pack stock use in the Ansel Adams and John Muir Wildernesses. The following discussion is an overview of the economic and social affected environment for these four counties.

Population and Demographics

Relative to the west side counties and California in general, the east side counties are sparsely populated and slowly growing. In the 2000 census, the population for Inyo County was 17,945—a decrease of 1.8% from the 1990 census (California average was an increase of 13.6%) with an average of 1.8 persons per square mile (California average was 217.2 persons per square mile). Mono County's population in 2000 was 12,853—an increase of 29.1% from the 1990 census—with an average of 4.2 persons per square mile. Conversely, the west side counties are far more densely populated and are growing at faster rates. In 2000, the population of Madera County was 123,109—an increase of 39.8% from the 1990 census. The county had an average of 57.6 persons per square mile. Fresno County reported a population of 799,407 in 2000—an increase of 19.8% from the 1990 census. The county has an average of 134.1 persons per square mile (U.S. Census Bureau, 2000).

In terms of demographic characteristics, the counties are fairly similar. In 2000, the median age in Inyo County was 42.8, Mono County's was 36, Fresno County's was 29.9, and Madera County's was 32.7 (California's median age was 33.3). For race, counties have similar characteristics with the west side counties having slightly higher percentage of individuals reporting Latino or Hispanic origin. In Inyo County, 80% of the census respondents reported that white was their race and 10% reported American Indian and/or Alaskan Native as their race. In addition, 12.6% of the respondents stated that they were of Hispanic or Latino origin. For Mono County, a large majority of census respondents report white as their race (84.2%), while 9.5% report "some other race," and 2.4% report American Indian and/or Alaska Native. In addition, 17.7% of the respondents stated that they were of Hispanic or Latino origin. In Madera County, 62% of the respondents identified their race as white, 24.4% reported "some other race," and 4.1% reported their race as Black or African American. In addition, 44.3% reported that they were of Hispanic or Latino origin. For the 2000 census in Fresno County, 54.3% of the respondents identified their race as white, while 25.9% responded that their race was "some other race." Also, 44% of the respondents to the 2000 census reported a Latino or Hispanic origin. By comparison, in California as a whole, the 2000 census reported that 59.5% of the respondents reported that their race was white, followed by 16.8 % reporting "some other race," and 10.9% reporting Asian. Statewide, 32.4% of the respondents reported Latino or Hispanic origin (U.S. Census Bureau, 2000)

Economics

In terms of economics, the east side counties are far more reliant upon tourism and recreation for their jobs compared to the west side counties. On the east side, the arts, entertainment, recreation, accommodation, and food services sector of the economy accounts for 30% of all jobs in Mono County and nearly 18% of all jobs in Inyo County (compared to 7.2% in Fresno County and 7.7% in Madera County). West side counties rely heavily on the educational, health, and social services sector for employment. This sector was the top employer for west side counties in the 2000 Census and was responsible for 19.2% of all jobs in Madera County and 22.8% of all jobs in Fresno County (U.S. Census Bureau, 2000). In addition, as shown by the top employers in each county, the west side counties have far more diversified economies.

In Fresno County, the top fifteen employers in the county, include three hospitals (Community Medical Center; St. Agnes Hospital; US Veterans Hospital); two colleges/universities (California State University, Fresno; Fresno City College) and wholesale groceries and related products (Lyons Magnus Manufacturing and Stamoules Produce); and one employer each in poultry and eggs (Foster Farms), department stores (Gottschalks), wholesale machinery, equipment, and supplies (Grundfos Manufacturing), meat products (Harris Ranch Beef Company), groceries and related products (Ito Packing), farm labor and management services (Kreger Inc.), electrical goods (Pelco), and preserved frozen foods (Wawona Frozen Foods). A majority of these employers are in Fresno (eight out of fifteen) (California Employment Development Department, 2004b). It is projected that the services sector will experience the most growth in Fresno County between 1999 and 2006 (17.4% growth with 11,900 new jobs added) (California Employment Development Department, 2004a).

Out of the top fifteen employers in Madera County, two are related to public administration (Central California Women's Facility and Valley State Prison); hospitals (Children's Hospital of Central California and Madera Community Hospital); general farms, primarily crop (Deniz Packing and RJ Sales); and groceries and related products (Lamanuzzi & Pantaleo and Papagni Fruit Company). The remaining top employers in the county are from a wide range of industries including beverages (Canandaigua Wines); personnel supply services (Central Ag Labor); lumber and other building materials (Certainteed); apparel, piece goods and notions (Gottschalks); general farms, primarily livestock and animal specialties (Johnson Morgan); glass and glassware, pressed or blown (Madera Glass); and hotels and motels (Pines Resorts). The majority of these employers (eleven out of fifteen) are in Madera (California Employment Development Department, 2004b). (California Employment Development Department, 2004b). It is projected that the services industry will experience the most growth in Madera County between 1998 and 2006 (17.4% growth with 11,900 new jobs added) (California Employment Development Department, 2004a).

Of the top eleven employers in Inyo County, four are related to public administration (California Department of Transportation, Death Valley National Park, Inyo County Government, and Los Angeles Aqueduct Systems); two are related to hospital/medical clinics (Northern Inyo Hospital and Toiyabe Indian Health Project); two are related to miscellaneous amusement and recreation services (Bishop Paiute Gaming and Paiute Palace Casino); and one each in hotels/motels (Furnace Creek Ranch), water well drilling (Coso Operating Company), and food store (CG Roxane Water). The majority of these businesses are in Bishop, California (five out of eleven). (California Employment Development Department, 2004b). Similar to Fresno and Madera Counties, it is projected that the retail trade sector will experience the most growth in Mono

County between 1996 and 2006. (10.5% growth with 190 new jobs added) (California Employment Development Department, 2004a).

Of the top nine employers in the Mono County, three are categorized as hotel/motel (June Mountain Ski Area, Mammoth Mountain Inn, and Mammoth Mountain Ski Area); two are eating and drinking places (Mountainside Grill, Whiskey Grill at Mammoth); and one each are in public administration (Mono County Government), elementary and secondary schools (Mammoth Elementary School), and miscellaneous business services (Mammoth Lakes Fire Department). The majority of these employers (seven out of nine) are in the Town of Mammoth Lakes. (California Employment Development Department, 2004b). It is projected that the services industry will experience the highest percentage of growth between 1999 and 2006 (17.1% growth with 360 new jobs added) (California Employment Development Department, 2004a).

In terms of unemployment, west side counties generally have had high unemployment rates relative to the averages both statewide and in the east side counties. In 2001, Madera County had an unemployment rate of 12.1%. From 1995 to 2000, the unemployment rate varied from a high 15% in 1995 to a low of 11.6% in 1999. Fresno County's unemployment rate in 2001 was 13.7%. From 1995 to 2000, the unemployment rate varied from a low of 13.1% in 1996 to a high of 14.2% in 2000 and 1998. By contrast, east side counties had a lower unemployment rate over this period. The unemployment rate Inyo County in 2001 was 4.9%. From 1995 to 2000, unemployment in the county has varied from 9.4% (in 1995) to 5.5% (in 2000). The unemployment rate in Mono County in 2001 was 5.6%. From 1995 to 2000, the unemployment rate has varied from a high in 1995 of 10.8% to a low in 2000 of 5.6%. Statewide, the unemployment rate in 2001 was 5.3% (U.S. Department of Labor, 2004).

Median household incomes in the west side counties are slightly lower compared to east side counties and the poverty levels are slightly higher. For the 2000 census, Inyo County had a median household income in 1999 of \$44,970, with 12.6% of the population below the poverty line. Mono County's median household income was \$44,992, with 11.5% of the population below the poverty line. For Madera County, the 2000 census reported median household income of \$36,286, with 21.4% of the population below the poverty line. For Fresno County, the 2000 census reported that the median household income in Fresno County was \$34,725 with 22.9% of the population below the poverty line (U.S. Census Bureau, 2000).

All four counties have added jobs between 1998 and 2002, with Mono County experiencing a higher job growth rate compared to the other counties. In Inyo County, 320 jobs were added during this time, an increase of 4.1%. In Mono County, 1,010 jobs were added to the economy (an increase of 17.6%). The analysis area for the west side counties to measure job increase is the Fresno Metropolitan Statistical Area (MSA) (combination of Fresno and Madera Counties). From 1998 to 2002, 25,800 jobs were added to the Fresno MSA (an increase in 6%) (California Employment Development Department, 2004a).

Economic Analysis of Pack Station Activities

The Impact Analysis for Planning (IMPLAN) model was used to calculate the direct, indirect, and induced labor income generated by commercial pack station operations in the project area. The IMPLAN model is an input/output model. The inputs included the reported gross revenue from pack station operations in the project area and average spending per visitor group that utilizes pack station services on a visit to the project area. Commercial pack station revenue

numbers were generated from reported gross revenue. Much of this information, however, was incomplete and some assumptions were made to determine the gross revenue for all commercial pack stations operating in the project area. Two studies were used to determine visitor spending in local communities when visitors utilize the services of commercial pack station operations. Since spending studies used by the Forest Service typically use a unit known as party days, visitors utilizing commercial pack stations services were converted into parties. According to the National Visitor Use Monitoring Results for the Inyo National Forest, the average party size of forest visitors is two. The total pack station number of visitors was determined from tally sheets and reports from the pack stations. This total number was divided by two to reflect the total number of commercial pack station party days. Again, because of incomplete information, some assumptions of the use were made.

Next, the average amount of money these visitors spend during a visit was determined. The report *Spending Profiles of National Forest Visitors* provides estimates of the spending per party per day for forest visitors. According to this study, for example, an out-of-town overnight visitor spends an average of \$268 per day on goods and services while on a visit to the Inyo National Forest.

Using these inputs (the spending of pack station clients and the gross revenue of the pack stations), the economic impact of pack station use in the Ansel Adams and John Muir Wildernesses was estimated (see table). The table expresses the contribution analysis in terms of labor income generated from pack station activities.

Results

Table 3.16 Regional economic impact of pack station activities in the Ansel Adams/John Muir Wildernesses

Pack Station	Direct Labor Income	Indirect Labor Income	Induced Labor Income
East Side Pack Stations	\$942,639	\$163,598	\$489,662
West Side Pack Stations	\$679,762	\$189,671	\$661,385

Pack Station	Direct Employment	Indirect Employment	Induced Employment
East Side Pack Stations	74.7	7.5	17.0
West Side Pack Stations	39.5	6.7	20.2

Using the IMPLAN model, commercial pack station related activity generates approximately \$1,622,401 in direct labor income in the project area. This is labor income related to the direct spending of visitors on various goods and services such as food and beverage, gasoline, and lodging. This spending is expected to generate another \$353,269 in indirect labor income. This type of labor income is related to indirect industries needed to support the direct industries impacted by the initial round of visitor spending. Lastly, approximately \$1,151,047 in induced labor income is generated by the commercial pack station operations. This labor income is related to household spending resulting from the direct and indirect economic effects of the industry. Given assumptions and spending patterns put into the model, commercial pack station operations are currently generating approximately three million dollars in labor income for the project area.

Approximately 104 direct jobs are supported by current pack station operations, with approximately 14 indirect and 37 induced jobs supported by the activities of this industry.

The direct labor income numbers in this table do not represent the total spending or revenue related to pack station operations, but rather the labor income or economic impact to the local economy generated by the total spending or revenue as determined by the IMPLAN model. As with any system, the economies of Inyo, Mono, Madera, and Fresno Counties are not a closed entity: a substantial portion of spending on goods and services that occurs within the local economy results in revenue that does not stay within the local economy. These effects are accounted for in the IMPLAN model and the calculation of labor income.

Conclusions

When compared to the overall regional economy, the economic contribution of pack stations in terms of direct labor income and direct employment is relatively minor. For east side counties, the direct, indirect, and induced labor income generated by pack station operations is \$1,595,899, approximately 0.2% of the overall personal income in the two-county study area. Likewise, the direct, indirect, and induced jobs generated by pack stations total 99.2 jobs and represent 0.5% of the total jobs in Inyo and Mono Counties.

For west side counties, pack station operations represent an even smaller percentage of personal income and employment. The labor income generated by pack station operations is \$679,762 and this represents .008% of the total personal income in Fresno and Madera Counties and the jobs generated by this activity total 66.4 jobs, approximately .01% of the total number of jobs in the two counties.

It is important to note that this regional economic analysis is at the county scale. Labor income generated by commercial pack stations is compared to labor figures from counties in the project area. This is generally the appropriate scale for a regional economic analysis. Unquestionably, smaller communities within the project area feel the economic effects of an industry such as commercial pack station operations more than the county as a whole. Because of the limited or, in most cases, absence of economic data for smaller communities within the project area, it is not possible to provide a quantification of the economic impact of commercial pack station operations to smaller communities. Additional discussion on the localized economic impacts of pack stations can be found in Chapter 4.

3.2 Physical Environment

3.2.1 Soil

Soils within the project area are predominantly derived from granite. Other sources of parent material include volcanics such as andesite, basalt, rhyolite, tephra and pyroclastic deposits, and metasediments such as hornfels, marble and quartzite (USDA Forest Service, 1995b). Most of the high elevation meadows are rich in volcanic ash. Soils forming in volcanic materials tend to have finer textures, higher water holding capacities, and lower bulk densities than soils forming in other parent materials. Soils formed in tephra and ash tend to be light and fluffy when dry and when exposed can be exceptionally dusty.

Soil conditions were analyzed based on Soil Quality Standards from FSH 2509.18. They were also analyzed in terms of Best Management Practices (BMPs). Applicable BMPs are described in Forest Service's Best Management Practices Handbook (included in the project record), and include BMPs regarding pack stock-related campsites and trails (Practice 4-10), and protection of wetlands (Practice 7-3).

Soil quality and productivity depend on climate, inherent soil type, and current soil condition. Soil productivity is limited by the high elevation and low air and soil temperatures. At warmer lower elevations found in the western portion of the analysis area, soils have higher productivity.

Most soils in the analysis area are highly susceptible to erosion by water. Sheet and rill erosion are common on moderately steep to very steep, granitically derived, immature soils throughout most of the wilderness. These soils do not tend to compact well, making them particularly susceptible to erosion and dust formation on trails and in campsites.

In the Inyo National Forest portion of the AA/JM Wildernesses, it is estimated that disturbances from campsites and trails cover less than 0.5% percent of the land, using recent campsite and trail inventories. It is assumed that there is a similarly low percentage of disturbance on the Sierra portion of the project area. However, this is only an assumption because there is little quantitative data existing for the number and ground disturbance from campsites on the Sierra National Forest. Because the number of overnight users per area in the SNF and INF are roughly similar, it can be reasoned that campsite density and size should be similar. Given the localized nature of impacts, soil quality and long-term soil productivity are being maintained on a wilderness-wide scale. There are specific sites where there is not full compliance with standards. These sites tend to be in sensitive habitats, such as springs, moist soils around lakeshores, meadows, riparian areas, or in areas of concentrated visitor use and some grazing areas. Potential impacts to soil productivity include: 1) trampling and erosion related to grazing; 2) trail erosion, especially from user-created, unmaintained trails, incised and multi-trailing; and 3) campsites with loss of nutrients by removal of duff and litter through trampling and woody debris through firewood collection and direct trampling and vegetation removal. Many of these soil impacts can take decades to recover.

Meadows

Meadow soils are unique, because they are derived from alluvial deposits and glacial debris and tend to be very deep, well stratified, and relatively free of rock fragments. They are rich in decaying organic matter and often are in areas with a high water table, which makes them

relatively fertile. Meadow soils are more easily compacted than other soils. Although soils in some portions of wet meadows may be permanently saturated near the surface, most wet and moist meadows have seasonally high water tables, primarily in spring and early summer. Meadow soils that are moist are usually more susceptible to compaction than drier uplands or very wet soil (Warren et al., 1986, Hagberg, 1994). Compaction reduces water infiltration, concentrates water, and can lead to gully erosion.

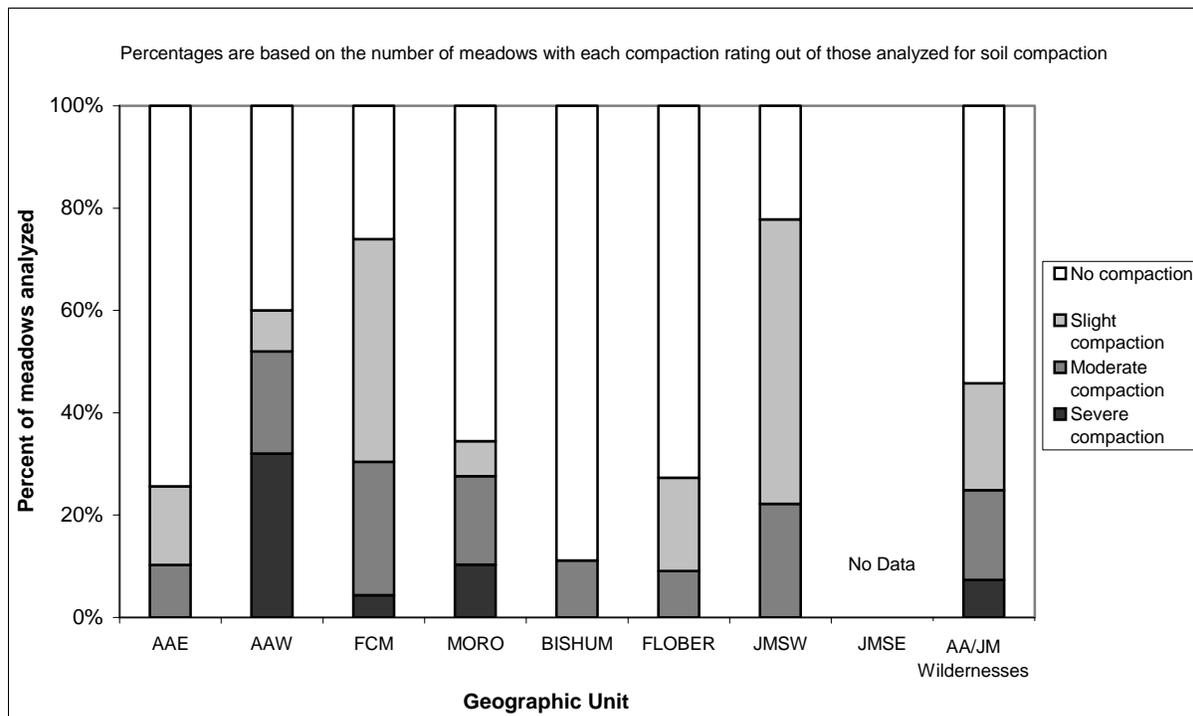

All moist and wet meadows were delineated on air photos to understand their extent in the project area. Although we did not delineate jurisdictional wetlands, we assume that all moist and wet meadows are wetlands, at least over most of their area. About 1,500 meadows/wetlands are known to exist within the project area, covering about 11,700 acres.

Methods for determining the extent and severity of soil and water resource conditions in meadows is explained in the document Meadow Inventory Criteria for Meadow Ratings in the project record. Ratings for each meadows' characteristics is in the *Meadow Table: Raw Data from Field Analysis* in the project record.

Soil compaction in meadows in the Ansel Adams and John Muir Wildernesses was generally found to be greater in severity and extent in areas with a higher density of recent commercial pack stock or cattle grazing. Of all the meadows in the project area, about 1,120 acres, or 14%, are known to have at least slight compaction. Campsites, trails and other use areas contribute to compacted area, and will be discussed in a later section. Of the 177 meadows evaluated for compaction, 54% have little or no soil compaction, 21% have low levels, 18% have moderate levels, and 7% have severe soil compaction. The percent of analyzed meadows with compaction in each Geographic Unit is shown in Figure 3.10.

Compaction was measured qualitatively using standard soil quality methods. Soil pits were dug in meadows in areas where grazers could access, and in areas that are not accessible to grazers, such as under shrubs or trees. The soil properties pertaining to compaction were then observed and rated based on the criteria described in Figure 3.10. For an explanation of the rating system and results for all meadow rapid evaluation criteria for soil, water, vegetation and wildlife current conditions, see the Study Plan in the project record.

Figure 3.10 Soil compaction in meadows, by geographic unit

Note: the following describes the criteria used for no, slight, moderate, and severe compaction:

None: No compaction

Slight Compaction: Weakly restrictive to water movement, root penetration and plant vigor, or more severe compaction over less than 5% of the meadow.

Moderate Compaction: Moderately restricts water movement, and root penetration. May be limited evidence of platy structure and mashed roots, "J" curved roots at the compacted layer may be present. Plant vigor appears to be affected. Compaction is not alleviated over the winter rest period.

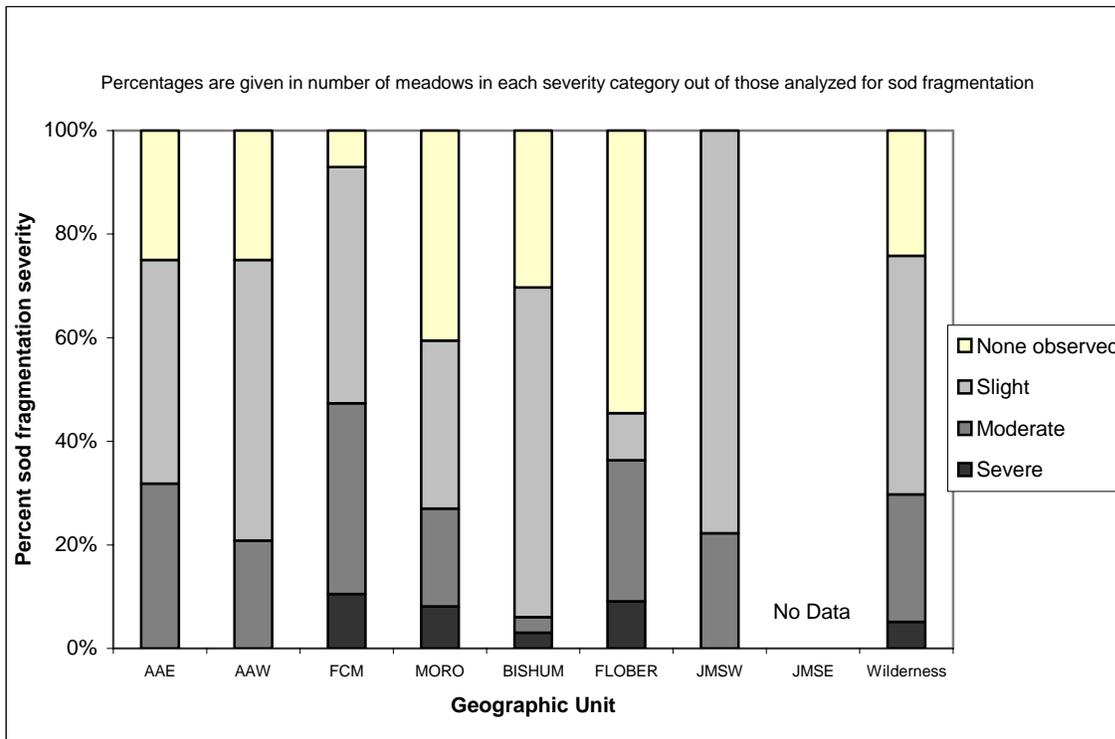

Severe Compaction: Greatly restricts water movement, root penetration. Evidence of platy structure and mashed roots. A "J" curve root at the compacted layer is common. May be evidence of water runoff. Plant vigor and cover is affected.

AAE = Ansel Adams East, AAW = Ansel Adams West, FCM = Fish Creek/Convict/McGee, MORO = Mono/Rock Creek, BISHUM = Bishop/Humphreys, FLOBER = Florence/Bear, JMSW = John Muir Southwest, JMSE = John Muir Southeast, AA/JM = Ansel Adams/John Muir

Sod fragmentation breaks up the continuity of the vegetative cover and increases the potential for erosion and soil loss. Sod fragmentation of meadows has a different spatial pattern than soil compaction. Soils that are easily compacted are not always easily fragmented. Of the 1513 meadows known to exist in the AA/JM Wilderness, 215 were evaluated for sod fragmentation. Over 75% of evaluated meadows in the AA/JM Wildernesses have some sod fragmentation. Slight sod fragmentation occurred in 46% of evaluated meadows, 25% had moderate sod fragmentation, and 5% had severe sod fragmentation (Figure 3.11).

The Fish Creek/Convict/McGee and John Muir Southwest Geographic Units have the highest percentage of meadows with at least slight sod fragmentation, at over 90% of meadows. However, the Florence/Bear, Mono Creek/Rock Creek, and Fish Creek/Convict/McGee Geographic Units have the highest proportion of meadows with severe sod fragmentation.

Figure 3.11 Sod fragmentation severity in meadows, by geographic unit

Note the following describes none, slight, moderate, or severe sod fragmentation:

None: No sod fragmentation observed, or trace amounts of fragmentation

Slight: Fragmentation up to 5% of the sod surface

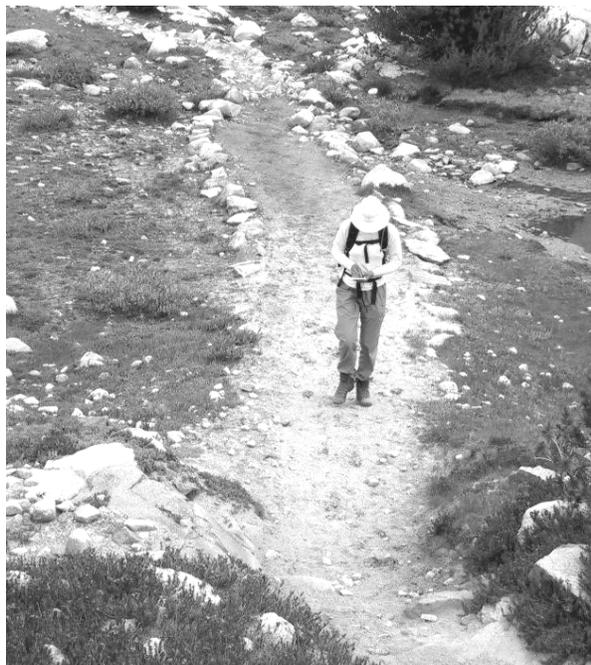

Moderate: Fragmentation from 6-15% of the sod surface

Severe: Fragmentation of over 15% of the sod surface

Trails

All trails compact soil within the trail tread, and most trails are incised below the surrounding landscape by at least a few inches. These impacts are considered to be a normal consequence of any recreational use in the wilderness, and are not considered to be altering soil or hydrologic processes unless effects are beyond minimal effects within the tread.

There are trail segments that have negative impacts on water and soil resources locally throughout the AA/JM Wildernesses, usually in localized areas and having localized effects. Deeply incised trails are diverting overland flow into the trail, causing it to act as a

Piute Pass Trail, near Loch Leven. This portion of the trail has normal trail depth and width for a high use trail, and is not causing soil or water resource degradation.

channel and further incise. In a few locations, trails are lowering the water table adjacent to the trail. Deeply incised and poorly placed trails have diverted water from streams and springs, in some cases dewatering the stream and altering its aquatic and riparian habitat. Almost 60% of trails are in Riparian Conservation Areas and, therefore, have the potential to affect water quality, flow and stream morphology. Trails can also become too wet or incised for comfortable travel, and multi-trailing can result as users walk or ride off-trail to bypass the difficult trail segment.

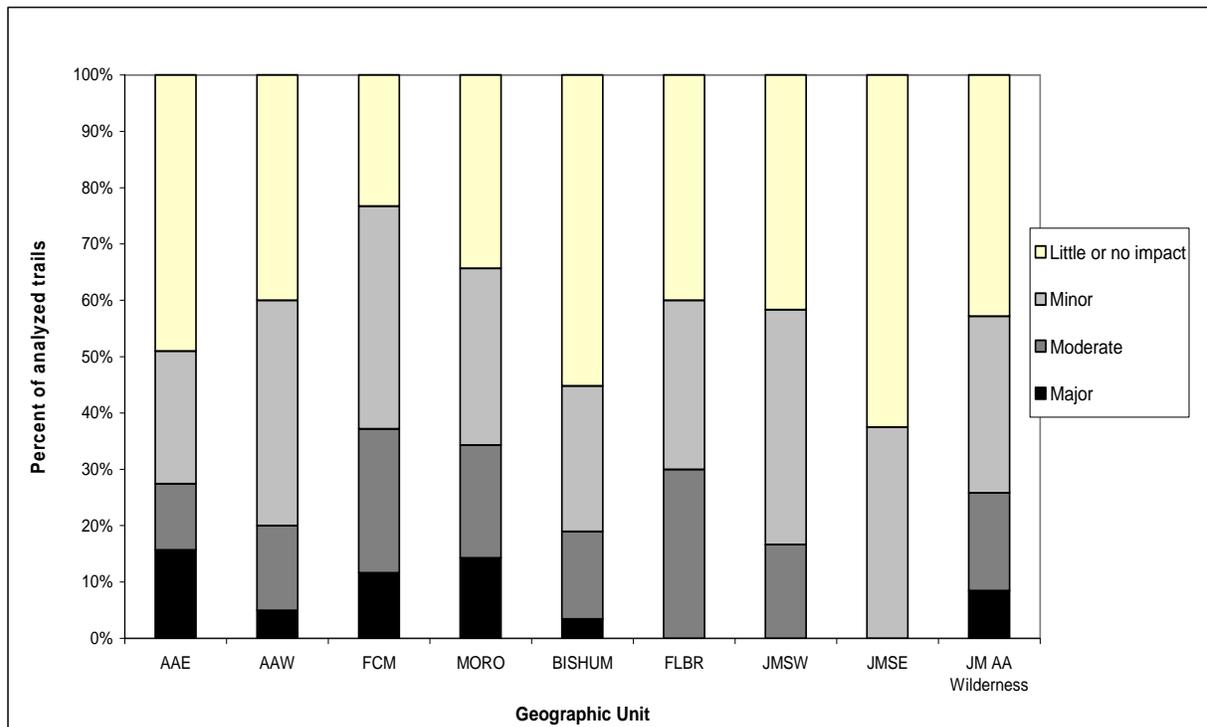

Pacific Crest Trail, south of Seldon Pass. Abandoned, impassable trail and newly developed trail. The old trail on the right captured water from the meadow and uptrail, causing the trail to incise and headcuts to propagate into meadow. The headcuts, shown on the right side of the photo caused loss of productive soil and likely locally lowered the meadow's water table.

Trails are present over a wide variety of geomorphic surfaces, terrains, and soil types. Areas with the greatest soil and hydrologic alteration are generally trail segments through meadows, adjacent to water bodies, on steep slopes or at stream crossings. While steep trails tend to erode and incise more easily, flat, wide open areas show more multi-trailing.

In the project area, 350 trails were evaluated for trail condition and effects on resources and 236 were analyzed for overall resource rating. Generally, resource impacts are site specific and do not include the entire trail. Of the 236 trails analyzed, 43% are causing little or no alteration to soil or hydrologic processes. Another 31% are causing minor alteration, 17% are causing moderate alteration, and 8% are causing major alteration of soil or hydrologic processes. Figure 3.12 shows the percent of analyzed trails in each Geographic Unit with each resource rating severity. The Ansel Adams East, Fish Creek/Convict/McGee, and Mono Creek/Rock Creek Geographic Units had the highest portion of analyzed trails causing severe resource degradation, while the others had few or no trails causing severe soil or water resource degradation.

Figure 3.12 Trails: water and soil resource alteration rating by geographic unit

Percent of analyzed trails with minor, moderate and severe impacts to resources, summarized by Geographic Unit and wilderness-wide. Resource ratings are based mainly on soil and water impacts. In the field, 236 trails were analyzed for their resource rating, and given a rating of 0-5, with 0 representing no resource impacts and 5 representing the most severe impacts. For this analysis, trails rated from 0-1 were considered to have little or no impacts, trails rated 2 were considered to have minor impacts, trails rated 3 were considered to have moderate impacts, and trails rated 4 or 5 were considered to have severe impacts.

The following describes minor, moderate, and major impact:

Minor: Headcuts, stream crossings, and water diversions confined to relatively small footprint. Generally stable with some slight risk of further degradation.

Moderate: Headcuts, incision, stream crossings, and water diversions may be somewhat unstable with some risk factors present, increasing the potential to become more serious, but not currently in a state of dynamic change. Soil or water resource effects occurring outside of the trail tread.

Major: trail incision, stream crossing widening, water diversions, or headcuts that are in a state of advanced instability with high risk to resources if not physically treated. Substantial risk factors exist that increase the instability and likely deterioration rate of the problem.

Campsites

At campsites, trampling causes loss of vegetation, abrasion or displacement of surface soil organic matter layers, and compaction of soils. Vegetation loss and soil compaction decrease water infiltration rate and can result in greater erosion and lower soil productivity. Some sites, especially those used regularly for overnight stock holding, we found to have a layer of loose, easily erodible soil on the surface, with a compacted layer below.

Campsites are expected to create bare soil and soil compaction that may persist from year to year (USDA Forest Service, 2001), and are a normal consequence of any camping. The effects become unacceptable when large volumes of soil are being lost or when eroded soil is entering surface water.

Many factors can affect how much change occurs on an individual campsite including the amount and frequency of use, type and behavior of the users, and the environmental conditions of the site itself. Campsites where pack stock are regularly held generally disturb a larger area than backpacker sites because additional area is used to tether animals (Cole, 1990).

Campfires cause significant changes in soil organic matter and chemistry but are limited in total surface area. Soil productivity is significantly lower in campfire areas and their presence or visibility will persist for many years. Removal of organic material used for firewood results in the removal of downed woody material that would otherwise serve as protective soil cover, recycle nutrients to the soil, and provide habitat for soil organisms and wildlife.

3.2.2 Hydrology

High quality water and aquatic habitat is necessary for ecosystems and human users within the AA/JM Wildernesses, and for developed areas downstream. East of the Sierra crest, water flows into the Mono Lake and Owens River drainages, which together provide over 50% of the water for the city of Los Angeles (Los Angeles Department of Water and Power, 2004). This water is used for domestic and commercial purposes in eastern sierra communities. West of the Sierra crest water flows into the San Joaquin and Kings River Drainages. These rivers are integral to California's Central Valley, with uses including agriculture, drinking water, hydropower and groundwater recharge (Central Valley Regional Water Quality Control Board, 1995).

Hydrologic response to snowmelt and rainfall tends to be rapid due to a large proportion of bedrock. Average total precipitation varies from 15 to 60 inches per year, with greater precipitation on the west side, and generally increases with elevation. The elevational increase in precipitation is more gradual on the west side than the east side of the Sierra Nevada crest. Beyond normal erosion processes associated with snowmelt and rainfall runoff, avalanches and rock slides occur in the steep terrain. These events can have major effects to hydrologic and geomorphic processes, but occur relatively rarely in any one area.

Stream geomorphology ranges from steep, straight bedrock channels in headwaters to meandering rivers in low gradient meadows. Many of the streams are either bedrock or boulder controlled, and are not vulnerable to alteration by human activities. Others, especially those in low gradient meadow areas, have channels dominated by fine sediment, and are susceptible to human alteration. Sediment loads in streams are variable, depending on the sediment source material, small-scale differences between snowmelt and rainfall patterns, and relative position in the watershed.

Most of the project area is underlain by granodiorite, a granitic rock type. Weathering of this bedrock typically creates a mantle of cobble to sand-size material over time. Because most of the project area was glaciated in the past 15,000 years, this weathered material is relatively thin compared to an unglaciated area. Consequently, sediment loading is generally low.

In the headwater streams, channels are normally boulder controlled and retain very little fine sediment. Where the headwaters run through meadow areas, the channel often has boulders along some of the channel length, with fine sediment build-up in other segments.

Fine sediment loads are higher in some areas, such as in the Margaret Lakes Basin, even though the source material is glaciated granodiorite, as it is in most of the project area. The difference is likely due to climate, perhaps with faster snowmelt causing higher velocity flows more capable

of moving sediment. In other areas, such as the Convict and McGee Analysis Units, sediment loads are higher than other areas because the source material is highly erosive metasedimentary rock.

Almost all major streams and rivers originating in the AA/JM wildernesses are impounded and diverted outside the wilderness near the wilderness boundary. Rush Creek, in the Ansel Adams East Geographic Unit, is impounded inside of the wilderness. These dams fundamentally alter the aquatic and riparian habitat, hydrology, water quality, and stream geomorphology downstream of the dams. While mining, recent and historical stock grazing, and recreational use have caused local hydrologic alteration within the wilderness areas, the effects are negligible downstream of the dams because the overriding effects of the dam.

Current Hydrologic Condition

Pack stock use is concentrated in and near riparian areas. Riparian Conservation Areas (RCAs)¹⁰ encompass only about 40% of the project area. However, 75% of requested commercial pack station campsites, 60% of system and user trail lengths, and almost all grazing areas are within RCAs.

Water Quality

There is very little quantitative water quality information available for the Ansel Adams and John Muir Wildernesses. Due to its remoteness and the few studies completed, water quality is assumed to be excellent except in very local areas¹¹ with very high, concentrated recreational use, where fecal matter and sediment may enter lakes and streams.

The little water quality data that exist within the AA/JM Wildernesses indicate that common human pathogens, such as *Giardia*, *Cryptosporidium* and other non-pathogenic indicators of fecal contamination, such as fecal coliform, exist in varying concentrations. However, no studies have collected water quality data at the same place more than twice throughout the year, or in subsequent years, and therefore the results cannot be used to determine general water quality or significant effects of recreational use on water quality.

Suk et al. (1987) found that out of fifteen 100 gallon water samples taken in the John Muir Wilderness in 1984, seven contained at least one *giardia* cyst. The highest concentration of cysts was 14 in 100 gallons of water. Although theoretically only one cyst is needed for human infection, the few studies completed on the topic suggest that about 10 *giardia* cysts at one time are required to be consumed for human contraction of giardiasis (Randtorff, 1954; Atwill, 1995). Because people tend to drink only a few liters of water per day, 14 cysts in 100 gallons of water may not be a large enough concentration to cause human illness. Suk et al. (1987) took two one-time water samples in areas used moderately to heavily by commercial pack stock. One, in North Fork Bishop Creek, adjacent to the heavily used Piute Pass Trail, found no *giardia* cysts. The other, at Long Lake on the South Fork of Bishop Creek, found 14 *giardia* cysts in 100 gallons of water. Gable Creek, which has had little to no pack stock use in the past, was found to have 6 cysts per 100 gallons. Other samples in high and low use areas within the John Muir Wilderness were found to have 0-5 cysts per sample.

¹⁰ Riparian Conservation Areas are areas adjacent to water bodies and wetlands and have specific standards and guidelines established in the Sierra Nevada Forest Plan Amendment.

¹¹ Here, “very local” is on the scale of tens of square feet.

Derlet et al. (2004) determined total coliform levels in 37 water quality samples at 31 sites in Sierra Nevada wilderness areas. Three of those sites were within the John Muir Wilderness. Two sites were in the Cottonwood Lakes area in the John Muir Southeast GU, where there is moderate commercial pack stock use (20 trips in 2003, when the water quality samples were taken) and heavy hiker use. The other site was on Taboose Creek, which receives light commercial pack stock use (one trip in 2003) and light to moderate hiker use. The two samples in the Cottonwood Lakes area had no coliform bacteria found, while the site on Taboose Creek had 150 colony forming units (CU)/100 ml. The water quality objectives in the Lahontan Basin Plan (LRWQCB, 1994) is less than 20 CU/100 ml of fecal coliform for a one-time sample. Derlet et al. did not determine fecal coliform levels, only total coliform, and therefore it is unknown whether the fecal coliform levels met standards. Out of the 37 water quality samples taken in Sierra Nevada Wilderness Areas in Derlet et al. (2004), 15 had levels over 20 CU/100 ml. Derlet et al. (2004) found that all samples taken below meadows used for sheep or cattle grazing contained coliform. However, there was no sampling downstream of meadows known to be grazed exclusively by pack stock (Robert Derlet, personal communication, July 11, 2005). The presence of coliform could be a result of contamination by humans, pack animals, cattle or sheep grazing, or from natural sources.

Studies outside of the AA/JM Wildernesses but in other Sierra Nevada wilderness areas, have found that *giardia* and coliform levels are generally higher in areas heavily used by backpackers, pack stock, or grazing livestock, but are sometimes high in areas with light use and sometimes low in areas with heavy use (Derlet and Carlson, 2004; Suk et al., 1987).

In streams originating in the Wilderness, water quality outside of the wilderness, at the site of use by municipal water districts is known to be good. According to Mammoth Community Water District (MCWD), naturally occurring arsenic is the only pollutant of concern for groundwater and surface water supplies originating on the Inyo N.F. (MCWD, 2002). The Los Angeles Department of Water and Power (LADWP) must treat their water obtained from the Owens Valley to reduce sediment levels, but they assume that most of that sediment originated from dirt canals in their conveyance system, far downstream of wilderness (LADWP, 2004). Total coliform bacteria levels always met standards of less than 5% of monthly samples positive for coliform in 2004.

There have been few studies about nutrients in Sierra Nevada lakes, and no studies were found that discussed terrestrial nutrient inputs. A few studies suggest that algae and phosphorous levels have increased in some Sierra Nevada lakes over a wide area in the past two decades (Sickman et al., 2003; Schindler et al., 2001), but these studies cite introduced fish and atmospheric deposition as causes. Sickman et al. (2003) suggested that the widespread nature of eutrophication suggests that nutrients entering lakes are airborne. Nutrient contributions from recreational activities are unknown, but could occur from human waste, soap used for washing, sunscreen washed off in lakes, or packstock or cattle manure.

Quantitative water quality data was not collected as part of this project, partially because beneficial uses, such as swimming, municipal drinking water, and fish spawning habitat, were not observed to be affected by water quality. Downstream water quality at the areas of municipal use is assumed to be an indication of wilderness water quality, because the water originates in the wilderness. However, municipal water quality is not completely indicative of wilderness water quality. Some wilderness values and beneficial uses within the wilderness, such as wildlife habitat or fish spawning habitat, may be more sensitive to water quality than municipal uses

downstream. Further, any pollutants becomes diluted downstream. Because it is assumed that the water quality currently meets or exceeds water quality standards from the Lahontan Water Quality Control Plan (standards can be found in Water Quality Standards document in the project record), the water is subject to the “nondegradation objective” (LRWQCB, 1994). This object requires, “continued maintenance of existing high quality waters” that exceed quantitative standards, with no degradation. There is no indication that water quality has degraded due to recreational uses, according to the small amount of quantitative data available. There are not enough quantitative data to determine whether that assumption is correct.

Although overall water quality is likely good, according to studies cited above, historical and recent mining, water diversions, livestock grazing and recreational use have altered hydrologic processes in some local areas of the Ansel Adams and John Muir Wildernesses. These activities, focused mainly in meadows, adjacent to lakes, and along trails, have altered surface water flow patterns, stream geomorphology, sediment loads, groundwater hydrologic connectivity, and riparian vegetation composition. Aquatic habitats sensitive to the above impacts include lakes, streams, wet meadows, and fen habitats and their associated plant and animal assemblages.

For this analysis, the affected environment by watershed as well as geographic units and analysis units will be discussed. The scale of watersheds discussed will be at the Hydrologic Unit Code (HUC) 5 scale, which are watersheds ranging in size from 50,000 to 250,000 acres. HUC 5 and HUC 6 watersheds contained within each Analysis Unit are listed in the project record. HUC 6 watersheds are smaller than HUC 5 watersheds, ranging from 10,000 to 50,000 acres.

The following features have the most consistent alterations of soil and water processes, and will be discussed separately:

- Meadows/Grazing: Compaction, bare soil, and stream alterations have an affect on soil hydrologic function, meadow hydrology, and vegetation composition
- Trails: Incised and/or multi-trailed system and user trails run through moist/wet meadow areas, springs, and stream crossings. In these environments, trails have altered surface flow patterns, dewatered small areas of meadows, and increased fine sedimentation into water bodies.
- Campsites: Large and/or multi campsites are often close to water bodies. The campsites are bare of vegetation and heavily compacted. Conditions lead to off-site erosion and sedimentation into adjacent water bodies.

Meadows

Less than 1.4% of the AA/JM Wilderness area is covered by meadows. Meadows are important for wildlife habitat, livestock and pack stock forage, water holding capacity, and for filtering sediments and protecting water quality. Because such a small fraction of the area is meadow, modification of meadows has a relatively greater impact than in other land types in the watershed.

Grazing impact assessments are focused on meadows because they are the areas most sensitive to grazing, with low gradient, alluvial areas that are sod covered and can be readily altered (Berg et al., 1996). Conversely, many of the stream reaches outside of meadows have bedrock or boulder channels that do not easily change, and uplands are often bedrock or sandy soil that cannot be compacted or chiseled.

Documentation suggests that extensive cattle and sheep grazing and pack stock use between the mid 1800s and the early 1900s denuded vegetation, compacted soils, and altered stream morphology within Sierra Nevada Wilderness areas (Muir, 1894; van Wagtendonk and Parsons, 1996). These changes likely contributed to headcuts, stream downcutting and lowering of the water table existing today in some of the meadows within the project area. These conditions are attributable to grazing because grazing animals chisel and compact soil, and remove the protective sod and productive topsoil. Stream incision and gully erosion can result. If gullies are deep enough, they can intercept and divert surface and groundwater. This can lower the water table and alter the meadow's hydrologic function as the meadow is effectively drained by the gully (Hagberg, 1995). Trails through meadows can become incised and have a similar dewatering effect on a meadow. While vegetation can recover relatively quickly on an overgrazed meadow with its water source unaltered, hydrologic function and geomorphic recovery can take decades longer (Kondolf, 1993).

Between 2001 and 2004, 227 meadows or meadow groups covering 3,000 acres were analyzed through a rapid assessment method. The analyzed meadows made up about 15%, by number, of the 1,513 existing meadows in the project area. By area, these 227 meadows cover 26% of the 11,700 meadow acres of the project area.

Meadow Hydrologic Function

The most comprehensive measure of meadow condition evaluated was meadow hydrologic function. This measure is required during range analysis under the Riparian Conservation Objectives (RCOs) from the SNFPA (see RCO Standards and Guidelines in the project record). Hydrologic function is defined as:

- The ability of the soil in a meadow to withstand intake, retain and transmit water (USDA Forest Service, 1995a),
- The ability of the meadow to dissipate energies associated with overland flow from adjacent sites and to improve flood water retention, and
- The ability of the meadow to maintain a water table capable of supporting its Potential Natural Vegetation (PNV). PNV is defined as the plant community that would become established if all successional sequences were completed without human interference under the present environmental and floristic conditions, including those created by man.

The degree of hydrologic function was determined by observation, including observation of soil compaction, vegetation cover and type, spring flow alteration, stream incision and headcutting, stream PFC rating, and evidence of lowered water table.

An example of a meadow with slight alteration of hydrologic function is Lower Spooky Meadow in the Rush Creek Analysis Unit. Here, extensive hoof punches of stream channels have caused headcuts that are advancing into the meadow, dewatering the portion of the meadow just adjacent to the headcut. An example of a meadow with moderate hydrologic function alteration is Hilgard Meadow in the Italy Analysis Unit, where the meadow's stream is incised, streambanks are sloughing, and soil is compacted, but the meadow still receives sufficient water to support its vegetation. An example of severe hydrologic function alteration is at Grassy Meadow in the Silver Divide Analysis Unit, where the stream is no longer able to access its floodplain due to incision and portions of the meadow appear to be drying out. The water table

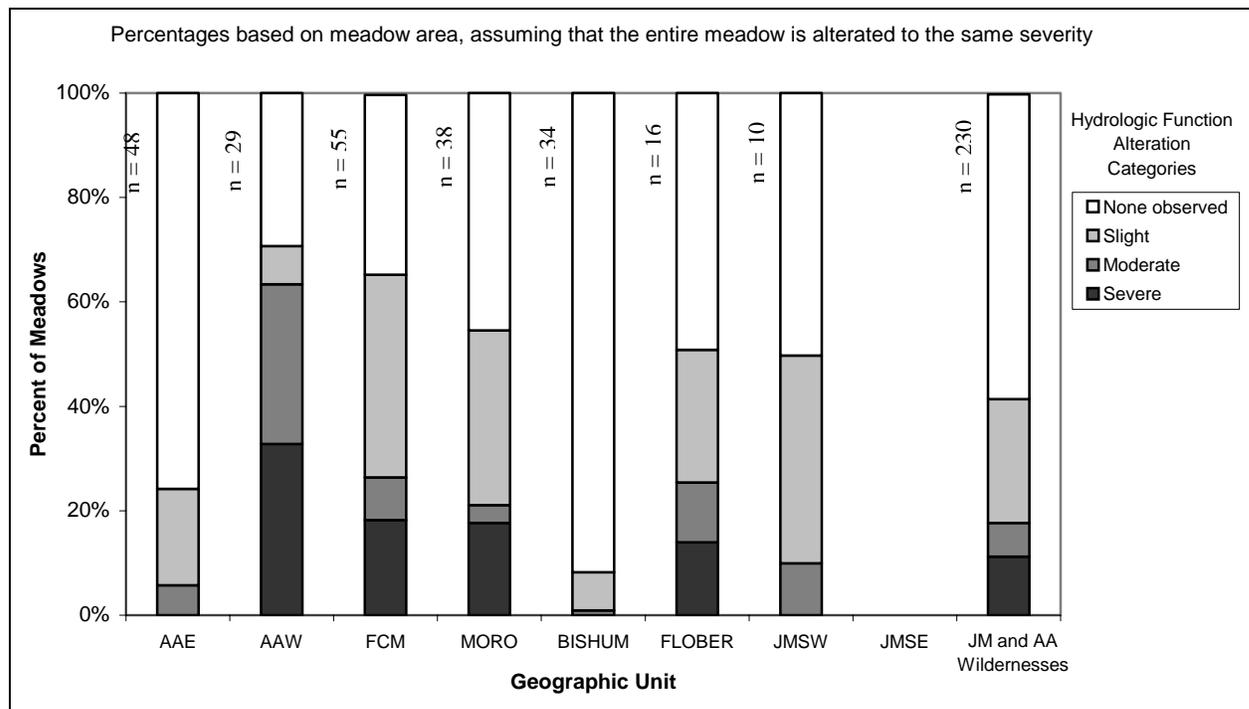

appears to be lowered to the point that the Potential Natural Vegetation of the meadow has been altered.

A headcut in Grassy Meadow. The headcut shows that surface flow is being diverted into this newly created tributary. The vegetation adjacent to the headcut appears to have been altered, suggesting that the headcut has altered vegetation composition and local hydrologic function. Features such as this headcut are also found in other locations in Grassy meadow. The stream in the upper left hand corner of the photo will be captured by the headcut if it continues to advance.

The degree of hydrologic function alteration for all 230 of the field visited meadows was determined. Figure 3.13 shows hydrologic function alteration results by Geographic Unit and wilderness-wide. Out of all the meadow area within the Ansel Adams and John Muir Wildernesses, about 11% (by area) has some known hydrologic function alteration, with 3% severe, 2% moderate, and 6% slight. Out of only the analyzed meadows, about 40% (by area) have some hydrologic function alteration, with 10% severe, 7% moderate, and 23% slight. A list of the individual meadows with hydrologic function alteration and their use, if known, is available in the project record.

Figure 3.13 Hydrologic function alteration of meadows by geographic unit

Note: The percent of meadows in each category is based on the percent out of all meadows visited in the field. It is assumed that if a meadow received a rating, the rating applied to the entire meadow. This was not always the case, but is an estimation for analysis purposes.

The following is a description of none, slight, moderate and severe hydrologic function:

None: No hydrologic function alteration

Slight: Some alteration of the stream channel or surface flow patterns, but water table levels are not altered and there is good recovery potential.

Moderate: Lowered water table, water source alteration, or altered stream functioning condition affecting meadow soil condition and vegetation. Potential to recover and therefore unaltered Potential Natural Vegetation.

Severe: Long-term alteration of Potential Natural Vegetation with a lowered water table or otherwise altered water source.

Meadows with severe and moderate hydrologic function alteration usually have a lowered water table, and do not meet current RCO standards (see project record for RCO standards).

The Ansel Adams West, Fish Creek/Convict/McGee, Mono Creek/Rock Creek, and Florence/Bear Geographic Units contained the highest percentage of meadows with at least slight hydrologic function alteration.

It is assumed that out of the meadows not analyzed in the field, a smaller percentage have altered hydrologic function than those that were visited. The IDT focused on meadows that were used or requested by commercial packers, and were more likely to have impacts from commercial pack stock grazing. The visited meadows were usually the larger meadows, and were more likely to have had production livestock (cattle and sheep) held in them during historical or recent times. The visited meadows were often along main trail corridors where hiker and private and commercial pack stock users normally travel. The visited meadows experience greater impacts from trails and campsites because of their proximity to trail corridors.

Alteration of meadow hydrologic function is not altering beneficial uses. Alteration of meadow hydrologic function has the potential to affect downstream beneficial uses. There is no evidence

that hydrologic function alteration of meadows in the AA and JM Wildernesses is at this time severe or extensive enough to alter beneficial uses outside of the Wilderness areas.

There is some correlation between recent cattle or pack stock grazing in meadows and hydrologic function alteration. Hydrologic function alteration is often a result of processes that take many years to occur and decades to heal. It is assumed that historical cattle, sheep and pack stock grazing occurred on almost all meadows in the project area, and impacts have accumulated over time.

Proper Functioning Condition of Streams

One component of meadow hydrologic function alteration is stream condition. A comprehensive evaluation of stream condition is Proper Functioning Condition (PFC). The USDA Forest Service, Bureau of Land Management and National Resource Conservation Service developed a PFC protocol (USDI, 1999; USDI, 1998) that was used for assessing stream condition in this project. The PFC protocol uses characteristics of streams to categorize the segment into one of five categories: Proper Functioning Condition (PFC); Functional at-risk with an upward trend (FAR upward); Functional at-risk with a non-apparent trend (FAR unknown); Functional at-risk with a downward trend (FAR downward); and Non-functional. Under the Wilderness Plan and the SNFPA RCOs, streams and other aquatic features should be, at a minimum, Proper Functioning Condition.

A stream that is functional at-risk or non-functional likely has at least slight adverse effects to beneficial uses. Beneficial uses that could be affected are cold freshwater habitat, wildlife habitat, spawning, reproduction and development, water quality enhancement, and flood peak attenuation/flood water storage. The effects include altered stream channel sediment loading, reduced riparian vegetation for wildlife use, altered stream geomorphology, and reduced ability for flood storage and groundwater storage.

PFC analyses were usually done on only one segment of a stream within a meadow, and are sometimes only indicative of a small portion of the stream. A PFC rating does not necessarily correlate with the condition of the overall meadow because it focuses only on the condition of the stream and the adjacent riparian area. Stream condition often correlates with meadow hydrologic function, but not always, as can be seen by a comparison between the results of hydrologic function and PFC evaluation in Figures 3.13 and 3.14.

Of the 230 meadows evaluated, PFC analysis was completed on the streams or ponds in 152 of them. Only one stream was found to be Non-functional during the original analysis. Subsequently, some members of the IDT returned to Martin's Meadow in the McGee AU in 2005, and rated the stream in the lower portion of the meadow to be non-functional. Of the streams where PFC analysis was completed, 59% are at PFC, 10% are FAR with an upward trend, 20% are FAR with a non-apparent trend, and 11% are FAR with a downward trend. Figure 3.14 shows the proportion of evaluated streams with each functional condition rating, by Geographic Unit and wilderness-wide.

Figure 3.14 Proper functioning condition analysis results by geographic unit

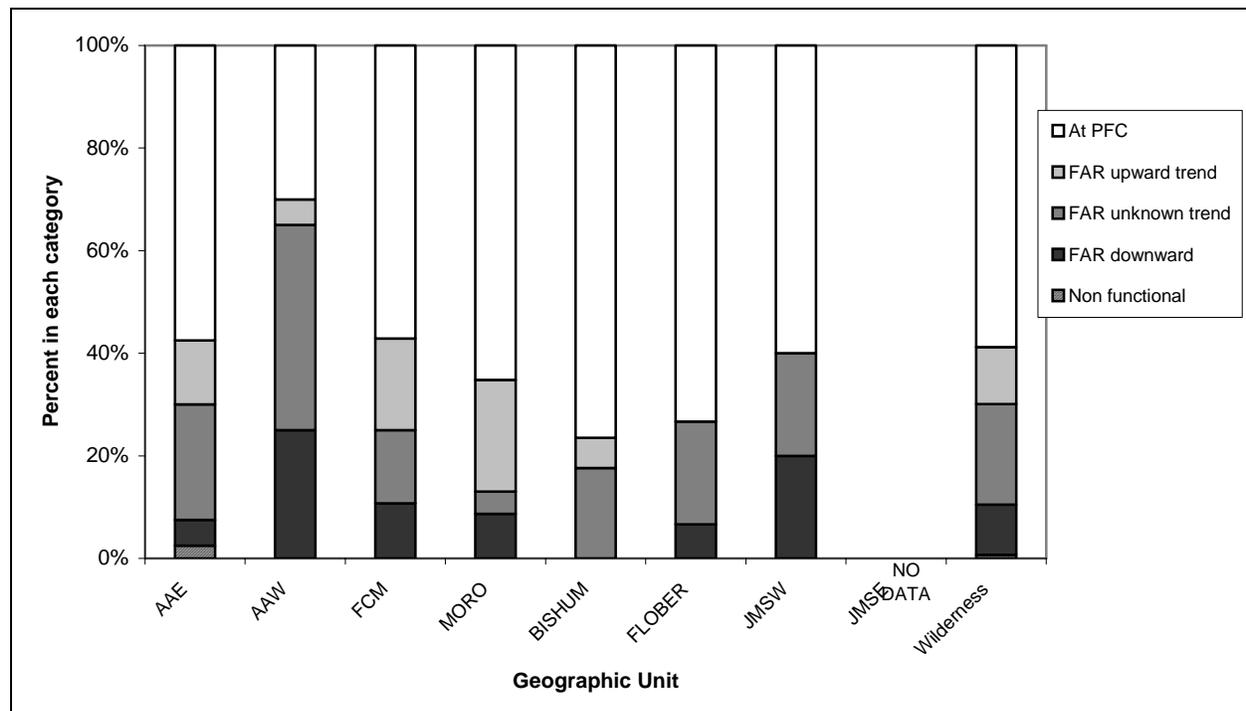

Figure 3.14 shows that the Ansel Adams West (AAWE) Geographic Unit has the highest percentage (75%) of stream reaches not at PFC. It is assumed that most of the stream impacts in Ansel Adams West have resulted from historical and recent cattle grazing and not commercial pack stock use because there is very little commercial pack stock use in the area and there has been recent cattle grazing.

Eric Berlow, PhD, Associate Research Scientist with the UC San Diego White Mountain Research Station in Bishop, California, completed statistical analysis of qualitative data collected by the IDT between 2001 and 2004. He found that there is a correlation between heavy reported commercial pack stock grazing and impacts to stream channels. There were 160 meadows where stream impacts were rated as none, minor, moderate or severe. In these meadows, it was calculated that the average reported commercial pack stock grazing was about 13 in meadows with no to minor stream impacts, and 46 in meadows with moderate to severe impacts. Further, 7 out of the 8 meadows with more than 120 average stock nights reported from 2001 to 2003 had moderate to severe impacts. These statistical analyses do not show causation, as no experiments or research has been done to show that the commercial pack stock grazing caused these stream impacts. However, there is statistically significant correlation between stock nights of commercial pack stock grazing and impacts to stream channels.

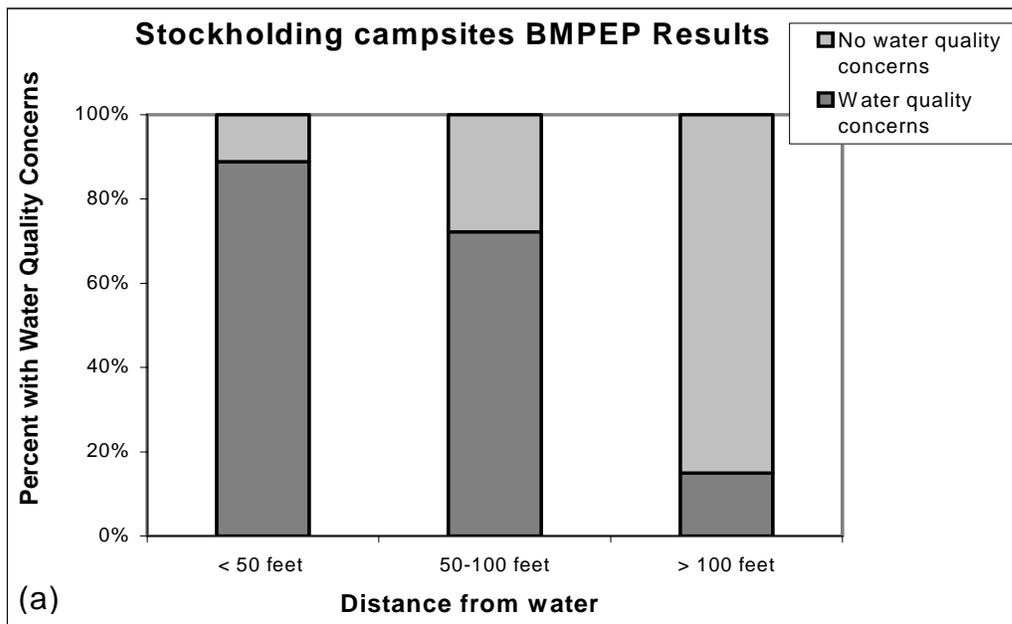

Campsites

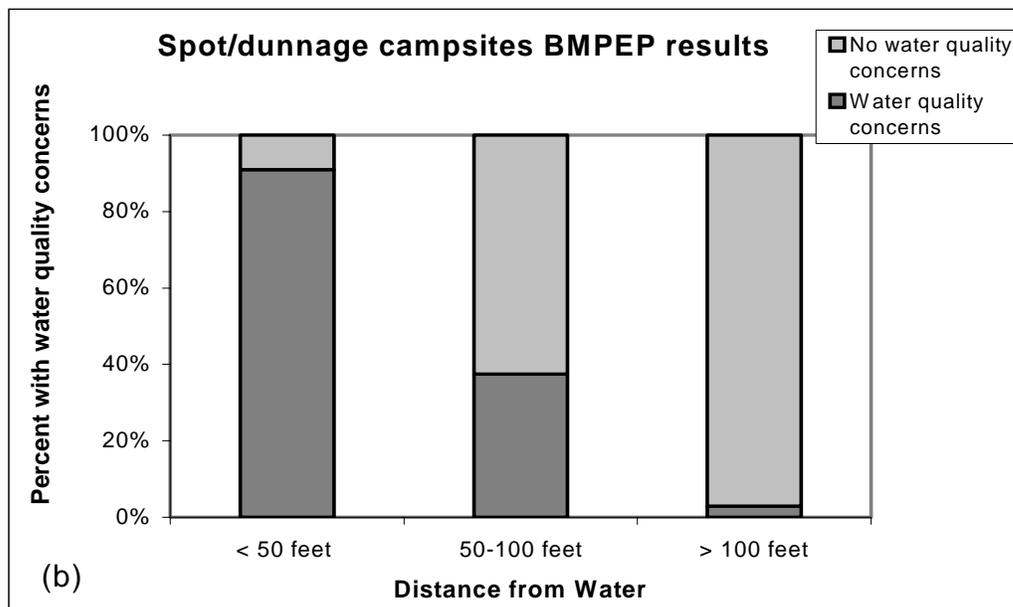

Campsites create an impervious surface of bare and compacted soil that increases runoff from the site. Campsites can erode and result in increased sedimentation into surface waters. Locally, manure and sediment is entering water from campsites, but it is uncertain whether local sedimentation is affecting the overall water quality of any lakes or streams.

Commercial packers identified approximately 1,617 campsites that they have used in the past or would like to use in the future, and of those, 163 sites were evaluated for water quality effects using the BMPEP protocol and other observations. The sites evaluated were all identified by commercial pack stock operators as sites they use or would like to use. However, some of the sites evaluated did not have any evidence of pack stock use. The Best Management Practice Evaluation Program (BMPEP) “Stock Facilities in Wilderness” protocol was used to evaluate the water quality at pack stock-related campsites (the BMPEP protocol is in the project record located in the Supervisor’s Office in Bishop, CA). BMPEPs document the distance from water and whether the site is contributing substances to water. Under the Wilderness Plan guidelines, all campsites should be located at least 100 feet from water if topography allows, and in no case should they be less than 50 feet from water. A summary of BMPEP campsite results by analysis units is available in the project record. For locations of all sites where BMPs were evaluated, see Maps of commercial pack-stock related campsites and results of BMP evaluations are in the project record.

Figure 3.15 displays the percent of sites with water quality concerns for stock holding and spot and dunnage campsites by the distance the site is from water. BMPEPs were not completed for non-stock related campsites as part of this project.

Figure 3.15 Percent of spot/dunnage and stock holding campsites with water quality concerns at different distances from water.

The four sites where stock use type is unknown are not shown in Figure 3.15. Of these sites that are less than 50 feet from water, 75% are contributing substances to water. Of the unknown type of sites 50-100 feet from water, roughly 60% are contributing substances to water, and of those over 100 feet from water, about 10% are contributing substances to water.

Most of the analyzed campsites within 50 feet of water, regardless of the site type, are contributing sediment and/or manure to surface water. Conversely, most of the analyzed sites over 100 feet from water are not contributing substances to surface water, regardless of site type. The few sites over 100 feet from water with water quality concerns usually were not contributing sediment to water themselves, but the sediment source was social trails associated with the sites. The difference between the water quality concerns of stock holding and spot/dunnage sites is in those sites 50-100 feet from water. In the stockholding sites, the majority (~70%) of sites 50-100 feet from water are causing substances to enter water, while in the spot/dunnage sites, the minority of sites (~35%) are causing substances to enter water. The difference is likely in the size of sites and the activities that occur at the sites. Stock holding campsites are usually larger than spot/dunnage sites because there are associated stock holding areas where pack strings are highlined. The larger sites have a larger area of easily erodible bare soil and therefore sediment is more available for transportation toward water. There is also more manure present at stock holding sites.

Although about 40% of all campsites in the wilderness are contributing sediment and/or manure into surface water, very few sites have enough volume of sediment or manure entering water to cause observable water quality degradation. Exceptions are large sites such as at Waterfall Camp in French Canyon, which comprises four acres of bare, loose soil, and Fish Camp in Mono Creek, where the large stockholding site is within 10 feet of water. There are no quantitative water quality data to determine the local or downstream water quality effects. Observations for sediment plumes leaving the site during rain, sediment deltas in lakes, and rills or other signs of erosion at the campsites suggest that sediment and manure volumes entering water are usually small.

There is little difference between the proportion of campsites causing sediment or manure to enter water in the different Geographic Units.

3.2.3 Air Quality

Air resources management in the Sierra Nevada is highly complex because the major sources of degradation are far from the summits of the Sierra ridgeline. The 1977 Clean Air Act amendments designated three air shed protection classes: I, II, and III. The AA/JM Wildernesses are Class I air sheds requiring the most stringent degree of protection. The majority of air quality degradation in these wildernesses is thought to occur from pollution and fires in the San Joaquin Valley and on the Western slope of the Sierra Nevada Mountains as the prevailing winds are from the west (University of California et al., 1996). However, there is very little information available about wilderness air quality.

Air quality impacts from recreational activities in the project area were not directly measured, but are estimated to be highly local and short in duration. It was observed that trails and campsites developed in volcanic ash were extremely dusty when dry, with both pack stock and hikers causing dust to enter the air. This affect is highly localized and of short duration as the dust quickly dissipates. Dust is a problem generally from late June through October. Although ash is present in most of the project area, soils are especially ashy in the Ansel Adams East Geographic area.

Geographic Unit Scale

Ansel Adams East

The northern portion of this geographic unit drains to the east of the Sierra Crest into Rush Creek and Mono Lake (Mono Lake West Shore and Mono Lake South Shore HUC 5 watersheds). The southern portion drains to the west into the Middle Fork of the San Joaquin River. A list of all analysis units in the project area and the corresponding watershed are available in the project record.

The Ansel Adams East Geographic Unit is the only unit within the AA and JM Wildernesses containing major dams within wilderness boundaries. Rush Creek is fundamentally altered at and below Waugh Lake Reservoir. Upstream from the dams, however, the eastern portion of the Ansel Adams East Geographic Unit is generally in good hydrologic condition.

The portion of the Ansel Adams East Geographic Unit that drains into the San Joaquin River is in poorer hydrologic condition than the north portion of the unit, although effects are localized. It contains some of the most severe and widespread trail impacts. Trails and campsites are locally altering flow patterns, causing sedimentation into water bodies, and altering riparian habitat. There is a high density of social and user trails in many stream corridors, causing loss of riparian vegetation and diversion of surface flow.

Ansel Adams East is the geographic unit with the highest proportion of analyzed trails causing severe soil or hydrologic process alteration. Generally, only portions of the trail are in degraded conditions.

Meadows

The Ansel Adams East Geographic Unit has about 140 meadows covering about 1,100 acres. These are almost all moist to wet meadows that are likely also wetlands. Of these meadows, 50 (630 acres) were analyzed in the field. There are a low proportion of meadows with severe soil compaction, sod fragmentation, or hydrologic function alteration. However, a high percentage of meadow streams were found to be functional at-risk.

Of the 44 meadows analyzed for sod fragmentation, about 25% have little to none, 45% have slight, 30% have moderate, and 0% have severe sod fragmentation. About 75% of meadows evaluated for compaction were found to have little to no compaction, while 15%, 10%, and 0% were found to have slight, moderate, and severe compaction, respectively. Of the 50 meadows evaluated for hydrologic function, 4 have moderate hydrologic function alteration and 12 have slight alteration (see the Table 3.37, the *Geographic Unit Meadow Table*)

The results of PFC evaluations show that this unit has the second highest incidence of streams that are functional-at-risk, and one of two streams that were rated non-functional in the project area (Figure 3.13). Therefore, it is assumed that while streams in this area have been impacted, the meadows adjacent to those streams are more resistant to hydrologic function alteration.

Trails

Ansel Adams East is the geographic unit with the highest proportion of analyzed trails causing severe soil or hydrologic process alteration. Of the 51 trails surveyed, 16% have severe resource impacts, 12% have moderate resource impacts, and 24% have slight resource impacts (see Table 3.17. for a list of trails known to have resource impacts). This geographic unit has soils with a layer of pumice or volcanic ash, which are highly susceptible to sheet, rill and gully erosion because of their low cohesive strength. This is especially problematic on moderately sloping to steep slopes. Generally, only portions of the trail are in degraded conditions. Many trails in this geographic unit have risk factors such as steep (>25%) slopes, highly erosive soils and have proximity and connectivity to riparian vegetation and water bodies.

A user trail crossing a stream at Superior Lake, in the King Creek Analysis Unit. There are three different headcut trails shown in the photo, each a slightly different path for campsite access.

Table 3.17 Trails within Ansel Adams East GU causing moderate to severe overall impacts to soil and water resources. A total of 51 trails were surveyed in the field, and these 13 caused at least moderate impacts.

Trail Name ST = system trail UT = user trail	Analysis Unit	Resource Rating	Specific soil/water concern (n/a indicates unknown values)						Risk Factors

Campsites

The Ansel Adams East geographic area has a similar percentage of stock holding or spot/dunnage campsites causing water quality concerns as other geographic units (about 40%). A table showing summarized BMPEP results for all analysis units in each Geographic Unit is available in the project record.

Many pack stock related and non-packstock related campsites in Ansel Adams East are too close to water, and there is an especially high density of sites at Ediza Lake. Of the 18 stock holding or spot/dunnage sites surveyed for BMP compliance, 12 are within 100 feet of water and 3 are within 50 feet of water. One stockholding campsite, near the junction of Shadow Creek and Nydiver Creek (Shadow-Ediza AU), is notable for the degree of erosion and subsequent sedimentation from the site. The site has a stockholding area 30 feet from a stream and does not meet Best Management Practices (USDA Forest Service, 2001).

In the King Creek AU, three packstock-related campsites were evaluated for BMP compliance and all three are contributing sediment into water bodies, and are less than 100 feet from water.

At Superior Lake, a campsite on the northwest side of the lake is accessed by a trail with an incised and widened stream crossing that has the potential to capture stream flow. The site itself is not contributing to water quality or soil degradation.

Ansel Adams West

The entire Ansel Adams West Geographic Unit is within the San Joaquin River Watershed, with about 90% of the unit within two HUC 5 watersheds: the northern portion is in the San Joaquin River/Granite Creek Watershed and the southern portion is in the Lower South Fork San Joaquin River Watershed. These two watersheds are the only watersheds with a substantial area covered by the Ansel Adams West Geographic Unit. The rest of the unit is within the Mono Creek, Upper South Fork San Joaquin River, Mammoth Pool Reservoir, and Chiquito Creek HUC 5 watersheds. These watersheds contain such a small segment of the geographic unit that the overall watershed conditions cannot be attributed to geographic unit data.

This analysis unit has the most severe and widespread meadow soil and hydrology impacts of all geographic units, but has relatively few observed severe trail or campsite impacts.

Meadows/Wetlands

Ansel Adams West contains about 280 meadows covering about 1,600 acres. All of these are moist to wet meadows that are assumed to be at least partly wetland. Of those meadows, 25 (230 acres) were visited in the field to determine condition and suitability.

This geographic unit is distinguished by its extent of meadow compaction and hydrologic function alteration (Figure 3.13). About 30% of the analyzed meadows show severe hydrologic function alteration and about 30% show moderate hydrologic function alteration. Ansel Adams West also has the highest proportion of analyzed stream segments found to be functional at-risk and the highest proportion of meadows with severe soil compaction (see Figures 3.10 and 3.14 and Table 3.37, the *Geographic Unit Meadow Table*).

While most of the meadows visited in the northwestern portion had hydrologic function alteration, those meadows in the northeastern portion of the unit (Cargyle and Lake Catherine AUs) had very few impacts observed.

Moderate and severe hydrologic function alteration assumed to have some contribution from commercial pack stock was only found at meadows surrounding Sadler Lake and the meadow above Sadler Lake, between Sadler and McClure. The other 10 evaluated meadows with moderate or severe hydrologic function alteration did not show recent pack stock impacts, and it is assumed that most of the impacts are due to cattle grazing that continued in this area until the mid 1990s. The meadows near and above Sadler Lake also likely experienced cattle grazing until the mid-1990s, but continued pack stock use is likely prolonging recovery and causing new streambank trampling and chiseling impacts.

Although this unit has the highest proportion of hydrologic function alteration, the degree of current cumulative watershed impacts in the watersheds appear to be small. The meadows are spread over many streams, and those with severe hydrologic function alteration are generally not all lined up on one stream segment. Therefore, the impacts of meadow hydrologic function alteration may be buffered by areas between the meadows, and there is little evidence that meadow impacts have caused cumulative impacts to lower portions of the watershed.

In the Lillian and Cora AUs, three out of the four meadows analyzed have severe hydrologic function alteration, and the other has slight alteration. These AUs have the highest percent of meadows with severe hydrologic function alteration in the Ansel Adams West Geographic Unit.

Trails

Of the 19 trails analyzed for resource rating in Ansel Adams West, none were observed to be causing severe soil or hydrologic alteration. However, 16% were observed to have moderate impacts and 42% were observed to have minor impacts. Table 3.18 shows trails (system/user) that have a resource rating of moderate or severe and their specific soil/water concerns.

Table 3.18. Trails within Ansel Adams West GU causing moderate to severe overall impacts to soil and water resources. A total of 19 trails were surveyed in the field, and these 3 caused at least moderate impacts.

Trail Name ST = system trail UT = user trail	Analysis Unit	Resource Rating	Specific soil/water concern (n/a indicates unknown values)						Risk Factors	
		1-5 (5 = Most severe impact)	Trail incision/headcuts	Off-trail erosion	Multi-trailing	Sedimentation into water	Stream flow interception	Trail incision/headcuts	Steep Slopes	Proximity to water
Anne Lake ST	Triple Divide	3	Mod	n/a	n/a	n/a	n/a	Slight	Yes	No
McClure Lake ST	Sadler	3+	Mod	n/a	Mod	n/a	n/a	Slight	Yes	No
Timber Creek ST	Sadler	3+	Mod	n/a	Mod	n/a	Slight	n/a	Yes	Yes

Campsites

The Ansel Adams West geographic area has a similar but slightly lower proportion of analyzed stock campsites with water quality concerns than the other geographic units. About 30% of the analyzed sites were contributing substances to water (see summaries of BMPEP Protocol Campsite Results Table, available in the project record.). Three campsites are known to be out of compliance with wilderness plan requirements and RCOs, two in the Sadler and one in the Triple Divide AU.

In the Triple Divide AU, two stock related campsites were evaluated for BMP compliance and both were contributing sediment to surface water. A spot/dunnage site on the southeast shore of Rutherford Lake in the Triple Divide AU is within 25 feet of the lake and slanted toward the lake, with increased sedimentation observed in the lake below the site. The site could be contained to prevent future sedimentation.

Of the four campsites analyzed for compliance with BMPs in the Sadler AU, one is contributing sediment to water. A stock holding site on the south side of Sadler Lake is adjacent to an ephemeral stream, and small drainage ditches have been dug to remove water from the campsite and empty the drainage into the ephemeral stream. The ditches and the site itself contribute sediment directly to the ephemeral stream, and the stream was slightly incised, possibly due either to campsite impacts or grazing on the adjacent meadow. There is no room to contain the site in its current location to prevent sedimentation.

Fish Creek/Convict/McGee

The Fish Creek/Convict/McGee Geographic Unit drains partially to the San Joaquin River on the west side of the crest, and partially into the Owens River on the east side of the crest. Its western portion (Fish Creek) is entirely within the Fish Creek HUC5 watershed, and covers over 90% of that watershed. The portion of the Geographic Unit that drains to the East (the Convict/McGee portion) is within the Upper Owens River Watershed. The unit covers about 10% of the watershed, but in the headwaters. The conditions in the Convict/McGee area can be assumed to have some bearing on overall watershed condition.

The Fish Creek/Convict/McGee Geographic Unit has some of the most widespread hydrologic and soil alteration of all units, second only to Ansel Adams West. However, most effects are still local. The alterations are mainly due to trail and meadow impacts. The most heavily impacted AUs are in the Fish Creek area of the unit: the Upper Fish Creek, Silver Divide, Cascade Valley, and Purple Bench AUs. The Convict, McGee, Margaret and Crater Creek portions of the geographic unit do not have extensive or severe hydrologic impacts. The Cascade AU is discussed below to give an idea of the localized conditions in the geographic unit.

In the Cascade Valley AU, Fish Creek is incised throughout Cascade Valley in the segments that are not bedrock. According to historical accounts (Michael Morse, Forest Service, personal communication, 2004), the stream incised in 1982 during a very heavy hurricane-induced rainstorm. It is unknown whether meadow or trail impacts adjacent to the stream or upstream made any contribution to Fish Creek incision, or whether it was a natural process due to high flows and previous drought conditions that reduced vegetative cover. Its current incised state makes it less able to withstand high flows without further incision and widening. The creek continues to widen, and it is possible, although not verifiable, that meadow conditions contribute to lack of recovery. Meadow conditions could contribute to lack of recovery because the compacted surfaces with reduced vegetative cover reduce infiltration rates. Rainfall and snowmelt therefore runs off on the meadow surface at a higher velocity and at greater volumes than under natural conditions. The high flows enter streams and are transported downstream at higher velocities and higher discharge more capable of eroding stream banks. This process has contributed to incision of streams in Grassy and Jackson Meadows, but it is unknown whether it has contributed to incision of Fish Creek in Cascade Valley downstream.

The storm in September 1982 that resulted in Fish Creek downcutting created the second largest flow in recorded history (since 1922) in the San Joaquin River, just downstream of its confluence with Fish Creek (at the Miller's Crossing stream gauge). In December 1955, a larger flow was recorded, which did not incise Fish Creek. It is impossible to determine the combination of conditions required for incision, and whether human causes contributed. However, it is likely that there was some human contribution. Gully erosion may be triggered by any, "changes in the watershed or climate which result in more flow, less sediment, reduced vegetation cover, a downstream base-level change, and increased valley floor slope, or a change in subsurface process," (Hagberg, 1995). Both climate and grazing impacts can result in more flow and reduced vegetation cover, and therefore could contribute to stream incision. Many researchers have correlated gully erosion and stream incision with grazing impacts (Hagberg, 1995; Woods, 1975; Warren et al., 1986), although there remains uncertainty about the exact conditions and mechanisms that lead to gully erosion.

The Convict and McGee Analysis Units generally have good hydrologic and soil condition, although a few trails and meadows have severe erosion or other soil or water resource impacts. Much of the analysis unit, is highly erosive with very little soil development, and tends to have landslides and rock slides during heavy rainfall and snowmelt. The natural erosivity makes the area vulnerable to human uses. Although the factors that make the McGee and Convict areas erosive are partially natural, human uses combined with severe weather often trigger erosion. For example, in 2003, a local storm dropped very heavy rains within the McGee Creek watershed. During this storm, some meadows and trails with existing slight erosion or nickpoints rapidly eroded, causing large volumes of soil loss and sedimentation onto meadows and into streams. There were also natural landslides and stream migration unrelated to human uses.

Meadows

The Fish/Convict/McGee GU contains 141 meadows (assumed to be wetlands) covering about 1,100 acres. Fifty-four of those meadows (560 acres) were visited in the field.

Of the analyzed meadows in this geographic unit, 18% (by area) have severe hydrologic function alteration, and 8% have moderate hydrologic function alteration. Over 60% (by area) of analyzed meadows have some hydrologic impact (Figure 3.12). This unit has the highest percentage of meadows with at least slight compaction, and the second highest percentage of meadows with at least some sod fragmentation. The results of PFC evaluations show that this unit has a similar proportion of meadow with streams that are functional at-risk to the Ansel Adams East and Mono/Rock Creek Geographic Units.

Table 3.37, the *Geographic Unit Meadow Table* summarizes resource conditions of the meadows in this GU. This table includes meadows used or identified for use by commercial pack stations. The area with the most use is in the Fish Creek Watershed, including the Cascade, Purple Bench, Silver Divide, and Upper Fish Creek Analysis Units. Almost 70% of the evaluated meadows in these analysis units have some hydrologic function alteration. Of particular concern in these four analysis units is that they comprise the entire headwaters of Fish Creek, and the large meadows are along Fish Creek's main tributaries.

The Cascade Valley Analysis Unit runs most of the length of Fish Creek, and contains the portions of Fish Creek that are incised. Much of Fish Creek that is not bedrock is incised up to six feet between Second Crossing and the Minnow Creek junction. There are few meadows along the creek, but they have severely altered hydrologic function due to a flood event that incised the creek, resulting in a lowered water table.

In the McGee AU, the narrow canyon in the McGee Creek drainage often constrains travel to the creek and meadow areas. Baldwin Meadow was historically used by stock supporting mining activity, and there is a large trail and constructed pond, with continued associated disturbances, such as severe erosion from the trail and sediment deposition covering about 1/3 of the pre-existing meadow. There are trampling and sediment deposition impacts to Second Meadow and Chute Meadow.

When the IDT visited Martin's Meadow in summer 2001, there were some moderate-sized headcuts on a stream through the meadow, and some raw banks. When the meadow was revisited after the 2003 storm, the headcuts had advanced tens of feet, and deepened by a few feet (see photo below). When revisited after heavy snowmelt runoff in July 2005, the headcuts had advanced and deepened measurably. Currently, the headcuts in the lower portion of Martin's

meadow are some of the largest and most rapidly advancing of any headcut known within the AA/JM Wildernesses. It is unknown what triggered the nickpoints and incision. The trigger is likely one or a combination of trails that crossed the creek at the point of headcutting, recent pack stock grazing, historical livestock grazing, and naturally occurring severe weather and erosive soils. Martin's meadow has erosive, sandy soils with little organic matter below six inches. Round Meadow, the next meadow downstream of Martin's, has been partially covered by sediment eroded from Martin's meadow since 2003.

Headcut in the unnamed stream in Martin's Meadow after the 2003 storm. When the IDT visited the site in 2001, the stream had a few raw banks, and was about one foot wide and one foot deep. The headcut shown in the middle/top portion of this photo is about three feet high.

Trails

This Geographic Unit has the third highest portions of analyzed trails that are causing soil and water resource impacts. Of the 43 analyzed trails, 12% are causing severe, 26% are causing moderate, and 40% are causing minor alteration of soil or hydrologic processes. Table 3.19 shows trails (system/user) that have a resource rating of moderate or severe and their specific soil/water impacts.

Table 3.19 Trails within Fish Creek/Convict/McGee GU causing moderate to severe overall impacts to soil and water resources. A total of 43 trails were surveyed in the field, and these 14 caused at least moderate impacts.

Trail Name ST = system trail UT = user trail	Analysis Unit	Resource Rating	Specific soil/water concern (n/a indicates unknown values)						Risk Factors

Campsites

The Fish Creek/Convict/McGee Geographic Unit has a slightly higher than average proportion of stock campsites causing water quality concerns, but is roughly the same as the other Geographic Units. Numerous campsites within this geographic unit are too close to water and contributing substances to surface water, especially near the Purple Lake Outlet and downstream on Purple Creek (see summaries of BMPEP Protocol Campsite Results Table, available in the project record.). Although the sites are known to not meet BMPs, the extent and severity of water quality impacts in the GU are unknown.

Campsites in the McGee Creek AU are generally not causing soil or water quality concerns. One stock holding campsite, however, called “Sheep Camp” on Lee Creek is located on a hill in a meadow, and the site is causing rilling that is depositing sediment into the adjacent stream. The site does not meet Best Management Practice requirements.

In the Coldwater AU, there are high densities of campsites around Skelton Lake and Barney Lake, but little erosion or sedimentation into the lakes was observed.

In the Purple Bench AU, there is a high density of campsites around Purple Lake, the outlet of Duck Lake, and at the Virginia Lake inlet. Many of these sites are within 100 feet from water and are not in compliance with BMPs. Three of the four pack stock holding sites evaluated for BMPs are causing sediment and/or manure to enter surface water. The access trail to Ram Camp, north of Purple Lake, is causing slight hydrologic function alteration of the very wet meadow near the camp. There is evidence of stock-related trampling at the meadow.

There is a high concentration of campsites along the Fish Creek corridor, particularly near Horse Heaven and Tully Hole. These sites are possibly contributing sediment to Fish Creek, but the severity and extent of water quality degradation is unknown.

There is a moderate density of campsites along Fish Creek in the Cascade Valley Analysis Unit. Although BMP evaluations were not completed at the sites at Iva Belle Hot Springs, there is a high density of campsites near the springs and wet meadows with many social and user trails, possibly affecting surface flow patterns in the wet meadows surrounding the springs. The camp used by commercial pack stock operators below Iva Belle hot spring does not meet BMP requirements.

Silver Divide AU has a large proportion of campsites that do not meet BMPs. Of the seven campsites evaluated for BMP compliance, six were not in compliance. These campsites were in Long Canyon, one site at Olive Lake, two sites at Grassy Lake, and a site each at Peter Pande Lake and along Sharktooth Creek.

Mono Creek/Rock Creek

The west portion of the Mono Creek/Rock Creek Geographic Unit drains to the San Joaquin River, and the eastern side drains toward the Owens River. Most of the unit is within the Mono Creek HUC 5 watershed, a tributary to the San Joaquin River. The west side of the Unit also covers a small portion of the Upper South Fork San Joaquin River watershed. The eastern portion of the Geographic Unit falls into two watersheds, the Owens River/McGee Creek watershed and the Upper Owens River watershed. It covers small portions of those watersheds, and conditions within the unit likely have little watershed-wide effect.

Within the main trail corridors along Hilton Creek, Little Lakes Valley, and Mono Creek and its tributaries, soil and hydrology conditions have been moderately altered by human use. The trails, campsites, and grazing within the main Mono Creek trail corridor and its tributary trail corridors have altered hydrologic function along Mono Creek. Within the Graveyard AU, at the western end of the Geographic Unit, hydrologic function and soil impacts occur outside the main trail corridor, because the area is an active cattle allotment and cattle do not necessarily remain on trails.

The Morgan Lakes AU is within a historical mining area, with an old road acting as the trail through the unit. Mining debris, culverts and other mining artifacts are scattered around the area. The road and culverts concentrate overland flow and cause minor erosion; mining debris disintegrating in and near water may contribute pollutants to water.

Meadows

The Mono Creek/Rock Creek GU contains 142 meadows covering about 1,400 acres. All of the mapped meadows are moist to wet meadows and are considered wetlands. Of those meadows, 43 (670 acres) were visited in the field.

Table 3.37, the *Geographic Unit Meadow Table* summarizes the known resource conditions for individual meadows in the Mono Creek/Rock Creek GU. 18% of the meadow acreage analyzed in this GU shows severe hydrologic function alteration, 3% shows moderate alteration, and 33% shows slight alteration. Of the three meadows with severe hydrologic function alteration, two are in the Graveyard AU and have been grazed by cattle within the past few years. One meadow, Silver Pass Meadow in the Silver Peak AU, has not been recently grazed by cattle and has had moderate to heavy recent pack stock grazing.

The results of PFC analyses show that the Mono Creek/Rock Creek Geographic Area has a slightly lower than average proportion of functional at-risk meadow streams (Figure 3.14).

In the Graveyard GU, only half of the eight evaluated meadows have hydrologic function alteration, but by area, Graveyard has the third highest percent of total meadow acreage with severe hydrologic function alteration of all analysis units in the project area. Further, four out of five meadows on the mainstem Cold Creek have some hydrologic function alteration. These meadows have been grazed by cattle within the past few years, and impacts can be attributed almost totally to cattle grazing and/or historical impacts. Because most of the meadows along Cold Creek and 40% of the total meadow area in the analysis unit is hydrologically altered, the watershed has a reduced ability to hold water and buffer high flows. Therefore, peak flows may occur more quickly than natural and have higher velocities in lower Cold Creek.

The main creek and tributaries in Lower Graveyard Meadow are incised, with unstable banks and with some historical attempts at restoration structures. The meadow is also severely compacted over much of its area. Middle and Upper Graveyard Meadows are affected by historical impacts, mostly trampling and trail related, with some active headcuts and incisement of historical trails.

The majority of meadows in the Little Lakes Valley Analysis Unit are wet to very wet, and are therefore susceptible to trampling impacts. Meadows have good soil and hydrologic function condition overall. However, some of the meadows surrounding lakes along the main Little Lakes Valley system trail are compacted adjacent to the trail due to hikers accessing the lakes from the trail. There is little or no overnight commercial stock use or grazing in Little Lakes Valley.

One meadow in the Silver Peak Analysis Unit has severe hydrologic function alteration and a functional at-risk stream. Silver Pass Meadow has not been recently grazed by cattle and has evidence of heavy recent pack stock grazing, and, therefore, the impacts can at least partially be explained by recent pack stock use.

Trails

The Mono Creek/Rock Creek Geographic Unit has the second highest proportion of field analyzed trails with severe soil and water resource impacts. A total of 27 different trail segments were walked and analyzed in the field. It was found that about 15% are causing severe impacts, 20% are causing moderate impacts, and 20% are causing minor impacts. Table 3.20 contains trails (system/user) that have a resource rating of moderate and severe and their specific

soil/water concerns. Each sub-drainage leading to Mono Creek has one or more trails with lengthy segments of moderate to high impacts and risk factors. The main Mono Creek trail has incision leading to surface water diversion during snowmelt and rainfall over much of its length. The trail also diverts spring and seep flow along its length. Trails in Third Recess, Pioneer Basin, Hopkins, and Hilton Creek are also causing soil and hydrologic impacts through incision, headcutting, diversion of surface water, and rilling. Severe trail impacts were not observed to be widespread over the geographic unit, but are mainly in the Pioneer and Fourth Recess AUs. The Mono Creek watershed drains into a man-made reservoir (Lake Thomas A. Edison), so any water quality degradation created in the upper watershed is buffered downstream of the dam.

Table 3.20 Trails within Mono Creek/Rock Creek GU causing moderate to severe overall impacts to soil and water resources. A total of 27 trails were surveyed in the field, and these 10 caused at least moderate impacts.

Trail Name ST = system trail UT = user trail	Analysis Unit	Resource Rating	Specific soil/water concern (blank box indicates unknown values)						Risk Factors

Campsites

The Mono Creek/Rock Creek Geographic Unit has 40% of assessed pack stock related campsites causing substances to enter water. Summary BMPEP results are shown in the Summaries of BMPEP Protocol Campsite Results Table, available in the project record. In the Hilton AU, a high percentage (60%) of the campsites analyzed using the BMPEP protocol were causing substances to enter water. This AU has a high concentration of stock holding campsites, especially around the Davis Lakes, with the potential to cause local and possibly lake-wide water quality degradation. One site along Hilton Creek near Davis Lake covers about an acre of bare

soil capable of contributing substantial volumes of sediment into the creek. Although local erosion and sedimentation into lakes and streams was observed, it is unknown whether water quality effects persist beyond areas directly adjacent to campsites.

In the Little Lakes AU, there are high concentration of campsites at Ruby Lake, the south end of Long Lake, and Chickenfoot Lake. The Ruby Lake sites are the sites causing the greatest impacts. The meadow at the eastern end of the lake is moderately compacted. The compaction appears to be from campers walking to the lake from the campsite. Other sites are not causing major water quality or soil concerns.

In the Morgan Analysis Unit, the only concentration of campsites is at Lower Morgan Lakes. There are stock-holding campsites within 50 feet of the lake, with manure present at these sites. While there does not appear to be large amounts of stock use at Morgan Lakes, they are being held too close to water to meet BMPs.

Of the packstock related campsites evaluated for BMP compliance in the Fourth Recess AU, 40% are contributing sediment to water. One of these sites, at the confluence of Hopkins and Mono Creeks, is one of the campsites of highest concern in the project area. The stockholding site is within 10 feet of a stream, with substantial amounts of sediment were observed entering the stream from the site. Of the four pack stock holding or spot/dunnage sites along Mono Creek analyzed for compliance with BMPs, all are located less than 100 feet from the creek and can contribute sediment to the creek during rainfall or snowmelt. An unknown number of sites that are predominantly used by backpackers are also located within 100 feet of Mono Creek. Although many of these sites exist, they tend to be smaller and individually contribute less sediment into Mono Creek.

Campsites in the Pioneer Basin are concentrated around the three southernmost Pioneer Lakes. Multiple stock camps exist at these lakes, with Mudd Lake having the highest concentration. The campsites have caused soil compaction and the potential for soil erosion. While a number of camps are located less than 100 feet from water, some are hiker related and some are pack stock related. Three commercial pack stock-related spot/dunnage sites were evaluated, and two were found to be less than 100 feet from water. These sites appear to be contributing minor volumes of sediment into surface water, but campsites are generally not causing water quality problems or excessive soil productivity degradation. There is a high density of campsites around Lower Hopkins Lake, and a low density in most other portions of the Hopkins AU. Of 6 sites evaluated for BMP compliance at the lake, 2 are causing sediment to enter water, and 1 of those sites, on the east side of the lake, is 20 feet from water.

There is a relatively low density of campsites within the Graveyard AU except at Lower Graveyard Lake, which is a backpacker and spot/dunnage destination. Most sites at Lower Graveyard Lake are over 100 feet from water and they do not appear to be altering the lake's water quality or causing off-site soil erosion.

Bishop/Humphreys

The Bishop/Humphreys Geographic Unit is within three different HUC 5 watersheds and drains both east and west of the Sierra Nevada Mountain crest. About 1/3 of the area of the Upper South Fork San Joaquin River watershed is covered by the western side of the Bishop/Humphreys Unit. The eastern side comprises a small portion of both the Owens River/McGee Creek and Owens River/Bishop Creek watersheds.

The portion of the unit in the Owens River/McGee Creek watershed (Gable, Horton, Pine Creek and Granite Park AUs) has few recreation related hydrologic concerns, but mining in the area has altered stream morphology and groundwater flow, and, therefore, may have fundamentally altered Pine Creek. Recreational impacts are local and slight and restricted to the main trail corridors.

The portion of the unit in the Owens River/Bishop Creek watershed (Piute, Lamarck, Sabrina, Tyee, Treasure and Bishop Creek AUs) has few widespread hydrologic function impacts, but the many trails in the area are causing local hydrologic alteration with stream diversions, diversion of overland flows, and spring impacts.

The portion of the Bishop/Humphreys Geographic Unit in the Upper South Fork San Joaquin River watershed (French Canyon, North Piute, Glacier Divide and Humphreys Basin) has some of the most widespread incidence of deeply eroded trails causing diversion of springs and stream, capture of overland flow, and multiple trail creation. Impacts are most severe near Golden Trout Lake in the Glacier AU and near the junction of the French Canyon and Elba/Moon Lake trails in the French Canyon AU.

Grazing and campsites are generally not causing soil and water degradation, with a few exceptions that will be discussed below.

The Gable Analysis Unit has little soil or hydrologic degradation related to recreational use. Mining occurred in and near this area until the 1950s, affecting water quality, groundwater flow patterns, and surface flow patterns. Mining debris is in streams in some areas, particularly just below Gable Lakes, and if chemicals, petroleum products, or other pollutants are in the debris, it may be degrading water quality in Gable Creek.

Pine Creek generally has little soil or hydrologic degradation related to recreational use. However, mining occurred throughout the area, and mining-related activities such as road building, dam building, and mine shafts have affected water quality, groundwater flow patterns, and surface flow patterns.

Meadows

The Bishop/Humphreys GU contains 130 known meadows/wetlands covering about 1,200 acres. Of those meadows, 34 (650 acres) were visited and analyzed in the field, and 42 were requested for grazing by commercial pack station operators.

Table 3.37, the *Geographic Unit Meadow Table* summarizes the resource conditions for meadows in the Bishop/Humphreys GU. This geographic unit has the lowest proportion of meadows with hydrologic function alteration of all geographic units visited, and the second lowest proportion of streams in meadows that are rated functional at-risk. It is the only unit visited in the project area with no streams rated functional at-risk with a downward trend. Although the entire French Canyon corridor has reported grazing, concentrated impacts were noted only at Hutchinson Meadow, which is regularly grazed by commercial pack stock. A few areas, such as the fen just downstream of waterfall camp in French Canyon, and the meadow at the inlet of Upper Pine Lake, have severe trampling impacts, but the effects are concentrated near the trail or campsite, and are not necessarily associated with grazing.

In the Pine Creek AU, there are small meadow complexes adjacent to the lakes in the watershed. Existing conditions include local hoof punching and widening of the stream channels at

crossings at Upper Pine Lake. The majority of this AU does not appear to reach range readiness in a normal year. There are scattered dry meadows on slopes and benches. These drier sites are low in productivity, with substantial bare areas, easily fragmented sod, and highly erosive soils. Both the dry and wet sites are fragile, with thin soils and low resiliency.

In the Granite Park AU, alpine and sub-alpine meadows are in good condition.

In the Piute AU, there are very few small meadows in the area, and range from dry to wetland. No meadows in the analysis unit were requested or identified for grazing. The trails run through some of the meadows, but there are few off-trail impacts beyond one headcut in to a meadow near the East end of Piute Lake.

The Lamarck Analysis Unit has very few meadows, with a total of less than 13 acres covered by meadow vegetation. The one major meadow, at Grass Lake, is almost all wetland with standing water year-round. It has no visible impacts. No meadows were requested or identified for commercial grazing.

Trails

Trails impacts are altering hydrologic function of adjacent meadows, streams and springs. However, the impacts in most cases are not severe. Of the 58 trails analyzed for soil and hydrologic impacts, 3% are causing severe impacts, 16% are causing moderate impacts, and 26% are causing slight impacts. Table 3.21 shows trails (system and user) with a resource rating of moderate or severe and their specific soil/water concerns.

Table 3.21 Trails within the Bishop/Humphreys GU causing moderate to severe overall impacts to soil and water resources. A total of 58 trails were surveyed in the field, and these 10 caused at least moderate impacts.

Trail Name UT = user trail ST = system trail	Analysis Unit	Resource Rating	Specific soil/water concern (blank box indicates unknown information)						Risk Factors		
		1-5 (5 = Most severe impact)	Trail incision/headcuts	Off-trail erosion	Multi-trailing	Sedimentation into water	Stream flow interception	Meadow hydrologic alteration	Steep Slopes	Proximity to water	
Italy Pass (E) (Also in Pine Creek AU) - ST	Granite Park	3	Mod				Mod	Slight		Yes	No
Golden Trout Lks UT	Glacier Divide	4	Severe			Severe			Mod	No	No
Moon Lake cutoff ST	French Canyon	3	Mod			Mod		Mod		No	No
Elba to Alsace UT	French Canyon	3	Mod	Slight	n/a	n/a			Slight	Yes	No
Merriam Creek N. UT	French Canyon	3	Slight				Slight			No	Yes
L Lake-French Canyon ST	French Canyon	4	Severe			Mod	Slight	Mod	Slight	No	No
Lamarck Col UT	Lamarck	3	Mod			Slight	Slight		Slight	Yes	No
Blue Lake Inlet Camp UT	Sabrina	3	Mod	Slight						Yes	Yes

Trail Name UT = user trail ST = system trail	Analysis Unit	Resource Rating	Specific soil/water concern (blank box indicates unknown information)						Risk Factors	
		1-5 (5 = Most severe impact)	Trail incision/headcuts	Off-trail erosion	Multi-trailing	Sedimentation into water	Stream flow interception	Meadow hydrologic alteration	Steep Slopes	Proximity to water
Moonlight Falls UT	Sabrina	3	Slight		Mod			Slight	No	No
Chocolate-Ruwau ST	Bishop Crk	3	Mod		Slight		Slight		No	Yes

The L Lake-French Canyon Trail has one of the most deeply incised segments of trail within the project area, with about two feet of incision. The trail segment diverted a stream, apparently years ago, and created a new stream channel that leaves the trail about 200 feet down trail. This trail segment is about 200 feet long, as is pictured here at the right.

Trail incision on the L-Lake Trail

Campsites

The Bishop/Humphreys Geographic Unit has a similar proportion of stock related campsites found to be causing substances to enter water as the other units, at about 35%. For a summary of campsite BMPEP results by AU, see the Summaries of BMPEP Protocol

Campsite Results Table, available in the project record.

The campsite causing the most severe soil and water impacts is Waterfall Camp in French Canyon, in the Glacier Divide Analysis Unit, shown in the photo below.

Campsites are generally not contributing to soil and water quality degradation in the Bishop Creek Analysis Unit. There are moderate soil compaction impacts related to one spot/dunnage site at the north end of Ruwau Lake. While the site itself is not causing an unusually large area of compaction, campers are walking to the lake from the site, compacting the lakeshore meadow.

In the Pine Creek AU, campsite density is high at Upper Pine Lake and Honeymoon Lake. Most sites are over 100 feet from water, and no sites are major water quality concerns.

Granite Park has a low density of campsites, and campsites are not contributing to overall soil or hydrologic resource degradation.

There is a high concentration of campsites in the Piute AU, some within 100 feet of the lake. The sites have substantial access trails that, along with the campsites, have compacted soils and reduced infiltration rates on the east side of the lake. None of the campsites are stock holding sites, but some are used for spot and dunnage.

Waterfall Camp, in the French Canyon AU. This is a small portion of the camp, which covers about 4 acres. The camp is within 10 feet of an ephemeral stream, and manure and sediment from the site can easily enter water

There is a high density of campsites around Lower and Upper Lamarck Lakes, but campsites are not contributing to soil and hydrologic resource degradation overall.

In the Sabrina AU, there are a few campsites that are too close to water, but other than Dingleberry Crossing and Blue Lake, the hydrology concerns are slight to moderate. At both locations, the sites are within 20 feet of water. They are currently contributing only small amounts of sediment into water, but have the potential to erode during heavy runoff directly into surface water.

In the Treasure AU, campsites are concentrated around Lower Treasure Lake, and are not contributing to soil or water quality degradation.

The Glacier Divide Analysis Unit has a high concentration of sites near Hutchinson Meadow and near Golden Trout Lake. At both of these sites, many campsites are large, with a large area of compacted soil, and are less than 100 feet from water. In the Hutchinson Meadow area, few of the sites appear to be used for holding stock. Just downstream from Hutchinson Meadow, many campsites are directly adjacent to Piute Creek, and people accessing the creek from the sites has denuded the banks of vegetation. Therefore, the riparian vegetation is not being maintained and it is possible that the creek could more easily erode its banks now that they have less vegetation to hold the banks together.

Near Golden Trout Lake, there are numerous campsites along Piute creek, some with access through wetlands. One spot/dunnage campsite, about ½ mile west of Golden Trout Lake, is

accessed only through a very wet meadow/wetland. As a result of this access by pack stock, there is hoof punching and chiseling covering about 15% of the meadow's area, resulting in bare soil where the sod has been removed. This ½ acre meadow is unstable due to the very wet soil and easily fragmented sod. There are small headcuts throughout the meadow, likely due to sod fragmentation and hoof punching. The degree of sod fragmentation and headcutting suggests that surface water flow may be altered. However, there is no evidence of upland species invading or water table lowering.

The campsite at Waterfall Camp in French Canyon is one of the largest known campsites within the entire project area. The site encompasses approximately four acres of bare, loose soil, and it is adjacent to at least two ephemeral streams. The loose bare soil at this site can easily flow into the ephemeral streams during snowmelt and rainfall, and manure at the site was found in and near streams, posing a water quality concern. Although there is at least a slight water quality impact at this site, the impact of highest concern is the stock trampling of the adjacent fen. This hoof punching appears to have led to creation of small channels within the fen, diverting shallow groundwater into the channels. Currently, there is no evidence that the hoof punching and channeling is dewatering the fen, but the loss of sod could allow further erosion during heavy rainfall or snowmelt, and has the potential to dewater the fen or alter its chemical process. The campsite itself is not necessarily causing alteration to fen hydrologic function, but the stock running loose downstream from the site is the cause of the threat.

Florence/Bear

The Florence/Bear Geographic Unit drains entirely into the San Joaquin River. About 90% of the unit is the Upper South Fork San Joaquin River HUC 5 watershed and the western 10% is within the Big Creek watershed. The Big Creek watershed has little influence from its small proportion of Florence/Bear Geographic Unit, but the Upper South Fork San Joaquin River watershed could be influenced by conditions in the unit because the unit covers about 1/3 of the watershed area.

The Sallie Keyes, Seldon, Bear, and Italy Analysis Units generally have good soil and hydrologic condition, although a few meadows have been grazed heavily enough to cause hoof punching, slight to moderate hydrologic function alteration, streambank damage, and soil compaction. There are some trails in the area that are causing headcuts to propagate off the trail, diverting surface water, or altering groundwater flow in meadows, but they are generally only causing local impacts.

Meadows

The Florence/Bear GU is known to have at least 209 meadows/wetlands covering about 1,620 acres. Of those, 11 (130 acres) were visited in the field and analyzed for current condition and grazing suitability.

Table 3.37, the *Geographic Unit Meadow Table* summarizes the resource conditions for meadows in the Florence/Bear GU. Of the 17 meadows analyzed for hydrologic function, about 13% have severe hydrologic function alteration, 13% have moderate hydrologic function alteration, and about 24% have slight hydrologic function alteration.

This GU has a relatively low percentage of streams that are functional at-risk. Of the 15 meadow streams analyzed for Proper Functioning Condition, three are functional at-risk with a non-apparent trend, one is functional at-risk with an upward trend, and the rest are at PFC.

The meadows with moderate and severe hydrologic function alteration and functional at-risk streams are mostly pastures within the Hooper and East Florence Analysis Units. In these pastures, use is not associated with a commercial pack stock trip but grazing between trips. Two of the pastures, Jackass Meadow and Hell Hole Meadow, are downstream of Florence Reservoir, and their hydrologic function alteration is due mainly to the effects of flow alteration from reservoir operations.

The only non-pasture with hydrologic function alteration and a functional at-risk stream is Hilgard Meadow in the Italy Analysis Unit. Commercial pack stock use at this meadow is moderate, and has likely been heavier in the past.

Trails

Only three out of ten trails studied were identified to be causing any overall soil or hydrologic conditions more than slight in severity. Trails are generally not leading to water and soil impacts in the Florence/Bear Geographic Unit. Table 3.22 shows trails (system and user) that have a resource rating of moderate or severe and their specific soil/water concerns.

Table 3.22 Trails within the Florence/Bear GU causing moderate to severe overall impacts to soil and water resources. A total of 10 trails were surveyed in the field, and only one is causing at least moderate impacts.

Trail Name UT = user trail ST = system trail	Analysis Unit	Resource Rating	Specific soil/water concern (blank box indicates unknown information)						Risk Factors	
		1-5 (5 = Most severe impact)	Trail incision/headcuts	Off-trail erosion	Multi-trailing	Sedimentation into water	Stream flow interception	Meadow hydrologic alteration	Steep Slopes	Proximity to water
Italy Lake (West) ST	Italy	3+	Mod		Mod				Yes	No

Campsites

Almost 35% of the nine stock-related campsites evaluated have some evidence of small volumes of substances entering water. However, none of the campsites evaluated are causing major water quality concerns or have potential for major water quality concerns.

While one campsite evaluated for BMP compliance in the Italy AU was found to be contributing minor amounts of sediment into Hilgard Creek, campsites are generally not contributing to water or soil resource degradation.

In the Sallie Keyes AU, two campsites were found to be contributing small amounts of sediment into surface water. This small volume of sediment is likely not contributing to soil or water resource degradation beyond a very local area. The evidence that sediment had entered surface water in the past was related to user trails, not the campsite itself. The user trails were not used by stock, but by campers.

John Muir Southeast

The entire Geographic Unit drains to the Owens River, and is within four different HUC 5 watersheds: Owens River/Tinemaha, Middle Owens River, Lower Owens River, and Owens Lake West Shore.

The John Muir Southeast GU receives less precipitation, on average, than the other units, because it is the farthest south and is entirely on the eastern side of the Sierra Crest. Average annual precipitation ranges from about 35 inches in the upper elevations in the north portion of the Unit, to 15 inches at the southern end of the unit. Precipitation decreases rapidly with elevation loss in this unit.

Little of this GU was evaluated in the field as part of this project. Other than Cottonwood Lakes and North Fork Big Pine Creek, there is little commercial pack stock use beyond through travel on well-developed system trails. Therefore, soil and water resource impacts related to commercial pack stock use and other recreational use are assumed to be focused on trails.

Meadows

This GU contains 100 known meadows/wetlands covering about 1,500 acres. One meadow was grazed for nine stock nights between 2001 and 2003, and no meadows were analyzed in the field.

Most of the meadows in this GU are located along steep stream channels on the eastern Sierra escarpment. These meadows are often dominated and protected from disturbance by boulders and riparian woody vegetation such as willow (*Salix* spp), Alder (*Alnus* spp), and Water Birch (*Betula* spp.). Some meadows have also formed where bedrock or moraines have constricted water flow.

There is one large glaciated basin commonly accessed by pack stock at Cottonwood Lakes with multiple large wet meadow wetland complexes. According to Del Hubbs, Inyo National Forest Range Conservationist, a small proportion of meadows have hydrologic and sod impacts. Most impacts appear to be historical, possibly related to cattle and sheep grazing.

Trails

Trails are generally in good condition throughout this GU and not causing major hydrologic or soil impacts. Trails in this GU were not visited as part of this project, but past information from Marty Hornick, Trails Specialist with the Inyo National Forest, indicates that there are minimal impacts to water quality or soil productivity outside of the trail tread.

Campsites

There were only 31 campsites requested by commercial pack station operators in the entire GU. The John Muir Southeast GU has a requested campsite density of 0.3 sites per 1,000 acres, the lowest of any GU. The highest density was about 4 sites per 1,000 acres.

In the Cottonwood Analysis Unit, there is a high concentration of campsites at Muir Lake and 3rd Lake, possibly slightly contributing to water quality degradation in those lakes. However, we do not have enough information to determine water quality effects. Cottonwood Lake Number 1 and Cottonwood Creek were sampled one time for coliform bacteria in summer 2003. There are commercial pack stock spot/dunnage sites at the lake, but no stock holding sites. No coliform was found in either sample, suggesting that the human and pack stock use was not contributing

fecal contamination into the lake or stream at the precise time and location of sampling. More widespread water quality effects are unknown.

John Muir Southwest

The John Muir Southwest GU drains entirely into the Kings Creek Watershed, and is within two HUC 5 watersheds, North Fork Kings River and Middle Fork Kings River.

John Muir Southwest is used lightly by commercial pack stock operators and other recreational users, and has few impacts associated with recent recreational use. However, a relatively high proportion of evaluated meadows have slight to moderate impacts, and many impacts appear historical. Impacts are assumed to be historical because there is no evidence of recent meadow use, such as hoof punching, vegetation utilization or compaction. The long-term effects remaining are incised streams, vegetation composition effects, and hummocks. Trails are generally in poor condition, and, in a few instances, poorly located in riparian-wetland habitats.

Meadows/wetlands

The John Muir Southwest GU contains 371 known meadows covering about 2,200 acres. Thirteen of these meadows had grazing reported from 2001-2003, and 10 were evaluated in the field.

Table 3.37, the *Geographic Unit Meadow Table* summarizes the resource conditions for meadows in the John Muir Southwest Geographic Unit. While John Muir Southwest has a higher than average proportion of field analyzed meadows with hydrologic function alteration and soil impacts, most of the impacts are slight and none are severe. It has one of the lowest proportions of meadow streams rated functional at-risk out of all the geographic units, but the highest proportion of meadows with sod fragmentation and soil compaction. Because most of the GU not visited in the field is not part of an active grazing allotment, and receives little commercial pack stock or other recreational use, it is assumed that effects are minor and local. Most of the areas not visited in the field were also not requested for commercial pack stock use, and therefore the lack of information about conditions in the unvisited areas does not affect the decision to be made.

Trails

Trails in the John Muir Southwest Area are generally in need of maintenance, with slight to moderate hydrologic and soil impacts including soil erosion, multi-trailing, headcutting, and some capture of spring flow. As in other geographic units, trails in some instances are located directly adjacent to streams in riparian areas, and are therefore reducing the extent of riparian vegetation. None of the 12 analyzed trails in this Geographic Unit were observed to be causing severe soil or hydrologic resource impacts, though 17% showed moderate impacts and 42% showed slight impacts. Table 3.23 shows trails (system and user) that have a resource rating of moderate or severe and their specific soil/water concerns.

Table 3.23 Trails within the John Muir Southwest GU causing moderate to severe overall impacts to soil and water resources. A total of 12 trails were surveyed in the field, and two are causing at least moderate impacts.

Trail Name UT = user trail ST = system trail	Analysis Unit	Resource Rating	Specific soil/water concern (blank box indicates unknown information)						Risk Factors	
		1-5 (5 = Most severe impact)	Trail incision/ headcuts	Off-trail erosion	Multi-trailing	Sedimentation into water	Stream flow interception	Meadow hydrologic alteration	Steep Slopes	Proximity to water
Bench Valley ST	Bench	3	Severe		Slight				Yes	Yes
Meadow Brook Lake ST	Bench	3	Severe		Slight				Yes	Yes

Campsites

John Muir Southwest has a slightly higher than average proportion of campsites evaluated using the BMPEP protocol that are contributing substances to surface water. Of the 12 stock-related sites evaluated, five (42%) did not meet BMPs. None of those sites are causing major water quality concerns because either a small source of sediment exists or is able to enter surface water. BMPEP stock-related campsite results are shown by AU in Summaries of BMPEP Protocol Campsite Results Table, available in the project record.

3.3 Biological Environment

3.3.1 Wildlife

Wilderness Scale

This sections covers Federally listed threatened, endangered, and proposed species, Forest Service Region 5 sensitive species (TES), and the Inyo and Sierra National Forest Land Management Plans Management Indicator Species (MIS). The species are discussed below if they have suitable habitat, or recorded observations in the AA/JM Wildernesses. Additional discussion of the species can be found in Chapter 4, as well as in the Biological Assessment and Evaluation on file in the Planning Record. Other species in these groups that will not be analyzed in this EIS because they do not have suitable habitat or recorded observations within the analysis area are listed below, and in the Biological Assessment and Evaluation.

Additional information on wildlife species populations and habitats that occur within the AA/JM Wildernesses can be found in the Status of the Sierra Nevada, Assessment and Scientific Basis for Management Options (1996), Volumes II and III. Chapters 3 and 4 of the Sierra Nevada Forest Plan Amendment FEIS and FSEIS provide in depth discussion and analysis of Threatened, Endangered, and Sensitive (TES) species, and focal Management Indicator Species (MIS) and their habitats that occur on a Sierra-wide perspective including the AA/JM wildernesses. Information can also be found in the Inyo and Sierra National Forest Land and Resource Management Plans (LRMP) and their accompanying environmental impact statements.

Habitat Conditions

The following are the principal wildlife habitat plant community types in the AA/JM wildernesses that provide wildlife habitats and overlap with commercial pack stock use authorization areas.

Montane forests: The Sierra Nevada Ecosystems Report (1996) lists the following forested types commonly found in the AA/JM Wildernesses: sierran mixed conifer, jeffrey pine, red fir-western white pine, jeffrey pine-fir, red fir, and lodgepole pine. These forests occupy low to mid elevations of the two wildernesses.

In general, these forested wildlife habitats are in mid to late seral condition, and are in excellent ecological condition. They provide the high quality “Old growth” wildlife habitats for sensitive species such as marten, goshawk, great gray owl, and California spotted owl as well other non-sensitive MIS species such as mule deer, blue grouse, and snag dependent cavity nesting birds, and species associated with downed logs and woody debris such as many small mammals.

Subalpine forests: These higher elevation forested habitat types include lodgepole pine, white bark pine, and mountain hemlock. Subalpine forests provide habitat for numerous birds and mammals, however, they are usually above the key nesting and denning forested habitats used by the sensitive wildlife species listed above in the montane forests. The wolverine may find suitable denning habitat within this zone.

Alpine Zone: The alpine habitats are dominated by relatively sparse, low vegetative productivity landscapes of low growing grasses and grass-like plants such as sedges and rushes, and dwarf trees and shrubs. Vast areas of talus slopes, cliffs and boulder fields dominate this

zone. There is a smaller group of wildlife species such as ground and shrub nesting birds, and small mammals such as the pika that find suitable habitat for nesting and denning. This zone is the major summer range of the endangered Sierra Nevada bighorn sheep. The white-tailed ptarmigan that has been introduced into the Sierra Nevada inhabits this zone.

Riparian Habitats: These types comprise a few percent of the land area and are key habitats for a number of sensitive and MIS wildlife species such as the Yosemite toad, mountain yellow legged frog, willow flycatcher, mule deer, yellow warbler, and riparian and meadow edge bird guilds that utilize these habitats for some or all of their habitat requirements. Wildlife habitats include a highly variable mosaic of riparian and wetland types, that include springs and seeps, ephemeral pools, wet meadows, fens, moist meadows, dry meadow types, and willow, aspen and cottonwood habitats found primarily around lake perimeters, and stream and river corridors.

Threatened and Endangered Species

Species considered were reviewed from web lists published on U. S. Fish and Wildlife Service Ventura and Sacramento Field Office web sites that have jurisdiction over the AA/JM Wildernesses in Inyo, Mono, Fresno and Madera Counties.

The following Federally listed threatened and endangered species and their habitats are not present within the AA/JM Wilderness analysis area on the Inyo and Sierra National Forests. No additional analysis is required.

- California red-legged frog (T), *Rana aurora draytonii*
- California tiger salamander (T), *Ambystoma californiense*
- Central valley and South Central California steelhead (T), *Oncorhynchus mykiss*
- Delta smelt (T), *Hypomesus transpacificus*
- Giant garter snake (T), *Thamnophis gigas*
- Lahontan cutthroat trout (T & MIS), *Oncorhynchus (=Salmo) clarki henshawi*
- Owens tui chubb (E), *Gila bicolor snyderi*

The proposed critical vernal pool invertebrate habitats proposed for the Sierra National Forest also do not occur within the analysis area boundaries. There are no other critical habitat designations within the Sierra and Inyo National Forests.

The following Federally listed threatened and endangered species occur within the analysis area or have suitable habitat. Effects of the alternatives on these species and their habitats will be analyzed as part of this EIS. No other threatened, endangered or proposed species occur within the analysis area.

Bald Eagle: The bald eagle is a federally listed threatened species that the U. S. Fish and Wildlife Service has proposed to remove from the threatened species list (delist). The species overall numbers of nesting pairs, nest success and survival of young and adults has substantially improved since listing to the point where a number of population recovery goals have been met.

Bald eagles can occasionally be observed roosting in trees or foraging for fish or waterfowl at montane lakes on both Forests in the AA/JM Wildernesses during the summer months. There are no bald eagle nest territories known to occur within the AA/JM Wilderness boundaries. The only known adjacent nesting territory is outside of wilderness on the Sierra National Forest along the north shore of Lake Edison approximately ¼ mile west of the wilderness boundary. It is highly likely bald eagles in that territory utilize perch trees along the Reservoir shoreline and

adjacent uplands that are inside the wilderness boundary. The eagles could also shift the location of the nest or build alternate nests within suitable forested habitat within the wilderness.

There were incidental observations of the bald eagle nest with two observed fledglings at Lake Edison in 2001. Two fledglings were reared at the nest site in 2002. In 2003, the nest failed. A solitary adult was observed in July 2004.

Sierra Nevada Bighorn Sheep: The species has been federally listed as endangered since 2000 after the population underwent a substantial decline from over 300 sheep to a low of approximately 100 animals (USDI Fish and Wildlife Service 2000). The primary factor that led to the precipitous decline was increased mortality of sheep as a result of mountain lion predation, as well as movement of bighorn sheep away from preferred winter range habitats in response to lion presence on these preferred ranges. Since listing and implementation of a mountain lion monitoring and limited control program, the bighorn population has rebounded to over 300 animals. The sheep have re-occupied portions of their lower elevation winter ranges as well.

The majority of the species summer range habitat occurs within the AA/JM Wildernesses including adjacent areas of Yosemite National Park west of Mt Gibbs and Mt Dana, and Sequoia-Kings National Park west of Kearsarge Pass. A draft recovery plan is currently in the review stage by the U. S. Fish and Wildlife Service. No critical habitat designation has occurred. Five herds: Mt. Langley, Mt. Williamson, Mt. Baxter, Wheeler Ridge, and the Mt. Dana herd inhabit the AA/JM Wildernesses.

Bighorn generally move to the high alpine zones of these wildernesses during the summer months, usually well out of range of typical pack stock use areas, and system trails. Bighorn can come into relatively close proximity to wilderness recreation users such as commercial pack strings at passes such as at New Army, Shepherd, or Baxter Passes where thoroughfare trail systems cross over the sierra crest and access Kings Canyon and Sequoia National Park trails and camping areas. A fifth herd from Mt. Dana south to Mt. Woods country at the north end of the AA Wilderness has virtually no habitat overlap with commercial pack stock operating areas except at Mono Pass and Parker Pass areas where the system trails cross into Yosemite National Park.

Paiute Cutthroat Trout: This species is listed as threatened on the Federal Endangered Species List and limited to two locations within the planning area: Sharktooth Creek in the John Muir Wilderness, and Stairway Creek, in the Ansel Adams Wilderness both within the Sierra National Forest. Both creeks are designated Critical Aquatic Refuges in the SNFPA. The trout were introduced into these areas in 1968 and 1972 respectively. Sierra NF personnel surveyed Sharktooth Creek in 1999 and 2004 (Strand and Eddinger, 2000) and Stairway Creek in 1996 and 2000 for population status and stream condition. The total length of occupied stream channel is estimated at about five miles. The overall habitat condition of these streams is good, with no deficiencies noted in bank and channel stability, water temperature, or water quality (Strand and Eddinger, 2000). The access to both creeks is relatively difficult via Level 1 trails that are not signed, intermittent, overgrown, and do not appear on most maps.

Forest Service Sensitive Species

The Biological Evaluation prepared for this EIS (on file in the planning record) has determined the following sensitive wildlife species may occur or have habitat on the two national forests involved, but they are not affected directly, indirectly, or cumulatively by this proposed project.

The rationale for this determination is that there would be no effect from the commercial pack station activities or trail systems since the species do not occur within the two wilderness areas due to lack of habitat, or the wilderness areas are outside the natural range of the species. No further evaluation is required.

- Sage grouse (*Centrocercus urophasianus*)
- Volcano Creek golden trout (*Oncorhynchus mykiss aguabonita*)
- Owen's Valley springsnail (*Pyrgulopsis owensensis*)
- Northern leopard frog (*Rana pipiens*)
- Panamint alligator lizard (*Elgaria panamintina*)
- Kern Plateau slender salamander (*Batrachoseps robustus*)
- Inyo slender salamander (*Batrachoseps campi*)
- Relictual slender salamander (*Batrachoseps relictus*)
- Limestone salamander (*Hydromantus brunus*)
- Western yellow-billed cuckoo (*Coccyzus americanus occidentalis*)
- Swainson's hawk (*Buteo swainsoni*)
- Foothill yellow-legged frog (*Rana boylei*)
- Hardhead (*Mylopharodon conocephalus*)
- Northwestern pond turtle (*Clemmys marmorata marmorata*)
- Southwestern pond turtle (*Clemmys marmorata pallida*)
- Western red bat (*Lasiurus blossevillii*)
- Wong's springsnail (*Pyrgulopsis wongii*)

The Biological Evaluation has determined the following sensitive wildlife species are known to occur or have habitat present in the Ansel Adams and John Muir Wildernesses. Species status and habitat availability and condition in the two wildernesses are discussed below. Effects of the alternatives on these species and their habitats will be analyzed as part of this EIS.

- Yosemite toad (*Bufo canorus*)
- Mountain yellow-legged frog (*Rana muscosa*)
- Willow flycatcher (*Empidonax trillii*)
- Northern Goshawk (*Accipiter gentilis*)
- Great Gray Owl (*Strix nebulosa*)
- Pacific fisher (*Martes pennanti*)
- California Wolverine (*Gulo gulo luteus*)
- Sierra Nevada Red Fox (*Vulpes vulpes necator*)
- American marten (*Martes americana*)
- California Spotted Owl (*Strix occidentalis occidentalis*)
- Peregrine Falcon (*Falco peregrinus anatum*)
- Pallid bat (*Antrozous pallidus*)
- Townsend's big-eared bat (*Corynorhinus townsendii*)

Species Accounts

Yosemite toad: The Yosemite toad is endemic to the Sierra Nevada mountains at mid to high elevations extending northward from the North Fork of Bishop Creek, east of the Sierra Crest, and west of the crest six miles south of Wishon Reservoir, and north to the Toiyabe and

Stanislaus National Forests near Ebbetts Pass at the north end of the range. The U. S. Fish and Wildlife Service determined the moving forward with a listing process to determine if should be listed as threatened or endangered was warranted; however, the species was placed on the “Candidate” list because of higher listing priorities. Since that time the Service also determined the species ranked in its lowest priority category for going forward with the listing process.

Suitable habitat for breeding is found throughout the AA/JM Wildernesses in wet meadows that contain shallow water zones such as are found in topographically flooded depressions such as fens, non-fen wetlands, spring channels, slow-moving side channels of streams, and to a much lesser degree shallow marsh-like lakeshores. Yosemite toad breeding meadows can be found from the mixed conifer zone up into the subalpine zone. Known populations range from approximately 7,950 feet on the western slope of the Sierra to over 11,350 feet in elevation.

The adults congregate at breeding sites in meadows from late May through early July depending on the snow year, and the spring melt-off rate. Female toads deposit their eggs in the shallow water sections of the meadows that are generally less than two inches in water depth. The eggs hatch after approximately 7 to 14 days into tadpoles. Tadpoles stay in the shallow water pools and complete metamorphosis into juvenile toads (metamorphs) anywhere from 48 to 63 days after egg laying (Karlstrom, 1962; Sherman, 1980). The metamorphs are approximately 3/8 inch long and spend the remainder of the summer in or adjacent to the pool from which they emerged. Adult toads disperse after breeding and can be found in meadows or uplands. Some move into the uplands in areas such as rodent burrows, and rock crevices, while others remain in the wet meadows in rodent burrows and willow areas. The species hibernates for more than eight months a year in places such as rodent burrows.

The status and locations of the toad on National Forest lands was poorly understood before 2001. Since then, the Sierra Nevada Forest Plan Amendment directed surveys to be undertaken range-wide on National Forests. The SNFPA FSEIS stated there were 292 historical sites identified throughout the historical range of the species with 229 of these sites confirmed since 1990 to the time of publication of the FSEIS. There have been additional sites found since then, but the exact tally for Sierra Nevada is not available at this time. Within the AA/JM wildernesses there are 267 meadow areas where surveys have detected Yosemite toad breeding populations. Of these meadow areas, approximately eighty one breeding sites overlap with identified commercial pack stock operations, primarily the meadow grazing aspect of the operations, and trail and camp use to a much lesser extent.

Mountain yellow-legged frog: A species that historically occupied ponds, tarns, lakes and streams from 4,500 to over 12,000 feet and was once the most common amphibians in high elevation aquatic ecosystems of the Sierra Nevada. Most populations occur today at higher elevations in National Park and Forest Service Wilderness Areas. Large groups of populations in the northern Sierra Nevada and local populations elsewhere have since become extinct and have disappeared from 70-90% of its historic range. The U. S. Fish and Wildlife Service determined the species warranted moving forward with a listing process to determine if the species should be listed as threatened or endangered; however, the species was placed on the “Candidate” list because of higher listing priorities.

Approximately 86 breeding sites have been identified within the AA/JM Wildernesses where adults and tadpoles were found. The largest concentration of frog populations have been found in the Mono Creek watershed (28 sites) at Second, Third, and Fourth Recesses (Mono Creek/Rock

Creek Geographic Unit), the high lakes on the east side of the Ritter Range (17 sites) from Ashley Lake north to Donahue Pass (AA East Geographic unit), Gables Lakes, Humphrey Basin, Treasure Lakes (26 sites, Bishop Humphreys Geographic Unit), and the upper North Fork of Big Pine Creek (John Muir Southeast Geographic Unit) within the AA/JM Wildernesses. Bear Ridge has a disjunct isolated population within the Mono Creek/Rock Creek Unit. Overall the metapopulation has become highly fragmented with a number of isolated populations. This fragmentation has occurred since the introduction of fish began into the high Sierra lakes, and the subsequent extirpation of numerous frog populations from the effects of fish predation.

Most frog populations breed in small lakes, and occupy inlet and outlet stream channels that are for the most part unaffected by pack stock operations. Adult and juvenile frogs have also been found in streams and spring channels where they have been observed utilizing undercut and vegetated banks for cover. Two stream habitat locations in the AA/JM Wildernesses were found to have overlap with pack stock operations at Mono Creek near Mono Rock in the Mono Creek/Rock Creek Geographic Unit, and at Upper Rush Creek at Donahue Camp in the AA East Geographic Unit.

Willow flycatcher: The willow flycatcher subspecies *Empidonax traillii brewsteri* occurs predominantly west of the sierra crest, while the Great Basin subspecies *E. t. adastus* occurs on the east side of the mountain range. Both subspecies likely pass through the AA/JM wildernesses on spring and fall migration and may have nested historically in the lower portions of the wildernesses with the highest likelihood west of the sierra crest below 8,000 feet.

There are no records of the species nesting in the wildernesses. Parker Meadow on the Inyo NF in the Ansel Adams East GU, and Poison Meadow on the Sierra NF in the Florence Bear GU have had historical observations of willow flycatcher dating back to 1936, and 1985 respectively. Protocol surveys to detect willow flycatchers at both meadows since 2001 have failed to detect the species. Observational fieldwork during interdisciplinary team field trips across the AA/JM Wildernesses from 2001 through 2004 also did not detect the species presence.

Suitable habitat has been identified for the Sierra and Inyo National Forests as part of the Sierra Nevada Forest Plan Amendment (SNFPA) effort. Habitat has been divided into two occupied categories: “Occupied site” defined as a meadow that has been occupied during the established breeding season per SNFPA direction by a territorial willow flycatcher or nesting pair since 1982; and “Historically occupied site” defined as a meadow that has had a historical nesting record, or a territorial male, or nesting attempts prior to 1982. The SNFPA also established the “Emphasis habitat” category. This category is defined as wet meadows larger than 15 acres with at least some riparian deciduous shrubs (woody vegetation). The category was established to define larger suitable habitat meadows since the majority of known willow flycatcher breeding occupancy meadows have been shown to be greater than 19.8 acres (Sierra Nevada Forest Plan Amendment, Final EIS). Willow flycatchers have, however, been documented to nest in meadows less than one acre in size. The SNFPA defined “Potential habitat” as emphasis meadows, and in addition all “small wet meadows” less than or equal to 15 acres that have shrubby vegetation.

It should be noted that the Willow Flycatcher Conservation Assessment prepared by Green et al. (2003) noted that 88% of all meadows used by breeding willow flycatchers in the Sierra Nevada are below 8,000 feet. Such areas in the AA/JM Wildernesses are typically within a short distance of trailheads, and include lower elevation commercial pack station pastures on the Sierra

National Forest, however, it also excludes the majority of higher elevation destinations where the majority of commercial pack station camping and associated grazing activities take place.

An “Occupied site” as defined in the SNFPA does not mean the site currently has willow flycatchers using it, in fact the vast majority of over 90% of the occupied meadow sites identified in the SNFPA on the Sierra and Inyo National Forests have no willow flycatchers detected in them from recently completed multiple year protocol survey efforts since 2001. The species appears to be declining across its range and cannot even be detected at many of the occupied sites it was observed to be territorial, or confirmed to nest at in the past.

There are no SNFPA designated occupied sites within the two wildernesses. Parker Lake Meadow and Poison Meadow discussed above are “Historically Occupied Sites” per SNFPA direction.

Table 3.24 identifies the meadows 8,000 feet and lower in elevation that would be the highest probability zone of willow flycatcher potential occupancy (Potential habitat). These meadows have been identified from preliminary analysis of satellite imagery as well as limited field reconnaissance within all analysis units. There are 13 emphasis meadows larger than 15 acres below 8,000 feet. Five meadows are within identified pack stock grazing areas. Also within this zone are thirteen small meadows two of which are identified as stock grazing areas.

Table 3.24: Willow flycatcher unoccupied emphasis and small meadow habitat 8,000 feet and below in the Ansel Adams and John Muir Wildernesses and reported grazing use by commercial pack stock

The second zone of lower suitability habitat is between 8,000 feet and 9,500 feet identified by Green et al. in the 2003 Willow Flycatcher Conservation Assessment. Table 3.25 displays 43 emphasis and small meadows up to 9,000 feet in elevation and the reported commercial pack stock grazing from 2001 through 2003.

Table 3.25: Willow flycatcher unoccupied emphasis and small meadow habitat above 8,000 feet to 9,000 feet in the John Muir and Ansel Adams Wildernesses and reported commercial pack stock grazing.

*Reported Use in Stock Nights

The meadows above 9,000 feet that were observed in the AA/JM Wildernesses begin to lose suitable tall willow habitat structure and, therefore, are not considered as potential habitat for this analysis.

It must be noted that many of the sierra meadows identified in Tables 3.24 and 3.25 have had no field validation of the suitability determinations made from satellite imagery analyses. Field validation would be useful to ultimately determine the meadow suitability, since, in general, there is considerable inaccuracy in satellite imagery habitat analyses.

There is a very low probability that the species may ultimately be found nesting in the lower elevation meadows of the AA/JM wildernesses on both sides of the Sierra. The majority of the potential habitat meadows are considerably isolated and disjunct from known willow flycatcher nesting areas. If the species experiences a population recovery in the future the most likely areas where the species would be encountered first are in historical non-wilderness breeding habitats that are of higher suitability. The species appears to be declining across its range and cannot even be detected at the majority of the sites it was observed to be territorial or confirmed to nest in the past.

Northern Goshawk: One active goshawk nest territory is known within the AA/JM Wilderness areas at North Lake in the Lamarck Analysis Unit, Bishop-Humphreys Geographic Unit. Six other territories are found within the Wildernesses; one on the Inyo National Forest, and five on the Sierra National Forest along the western portions of the AA/JM Wildernesses displayed in the following table.

Table 3.26 Goshawk territories – Inyo and Sierra National Forests

Geo Unit	Analysis Unit	Site Name	Forest Number	Status
Mono Rock Creek	Hilton Creek	Davis Lake	n/a	Old nesting territory now abandoned at known nest sites. Recent surveys cannot detect birds
Bishop Humphreys	Lamarck	North Lake	n/a	Active nest territory
John Muir Southwest	Dusy	Maxon Dome	SieGH4	Sightings and habitat, but no known nest site
John Muir Southwest	South Woodchuck	Chimney Lake	SieGH9	Sightings and habitat, but no known nest site
John Muir Southwest	Finger	Hoffman Mountain	SieGH15	Historic, exact location of nest unknown
John Muir Southwest	Rodgers	Crown Valley	SieGH17	Sightings and habitat, but no known nest site
John Muir Southwest	Cassidy	Granite Creek	SieGH36	Sightings and habitat, but no known nest site

Four of the five goshawk territories on the Sierra NF in the Ansel Adams and John Muir Wildernesses were surveyed from 2002 through 2004. The goshawk network guidelines for the Sierra NF defines a goshawk territory as a contiguous area composed of 50 acres around the nest site, 50 acres of post-fledgling area, and 75 acres of foraging habitat. There are no known existing nest sites for the five territories shown in the table above. The territories were surveyed according to the May 2002, Survey Protocol for the Northern Goshawk in the Pacific Southwest

Region. Four territories (SieGH4, SieGH9, SieGH17 and SieGH36) are based on incidental sightings and/or suitable habitat. One territory (SieGH15) is based on historical nest information.

Maxson Dome (SieGH4) territory was surveyed in 2002 and 2003. In 2002 there was a visual observation, no vocal response. In 2003 there was no response. The territory may be occupied with the nest(s) location(s) unknown.

Chimney Lake (SieGH9) territory has incidental sightings from the 1990s. The territory was surveyed to protocol in 2004 and determined to be unoccupied that year. No birds were heard or seen.

Hoffman Mountain (SieGH15) territory is based on a sighting in 1991 and several years of historic nesting; however, exact location of nest is unknown. The territory was surveyed to protocol in 2004 and determined to be unoccupied that year. No birds were heard or seen.

Crown Valley (SieGH17) territory is based on center of approximate sighting location. In the historical sighting records and database it is noted as one adult with one young. The territory was surveyed to protocol in 2004 and determined to be unoccupied that year. No birds were heard or seen.

Granite Creek (SieGH36) territory is based on sightings from 1994. No surveys have been conducted since that time.

A limited one year survey was also conducted along the South Fork of the Kings River in the Florence Bear Geographic Unit in suitable habitat along Meadowbrook Creek in the Big Maxson Analysis Unit.

Visual surveys to locate territorial goshawk or their nests were conducted on the Inyo National Forest from 2001 through 2004 while traveling in suitable habitat along trail system corridors, and around destinations and camps. No birds or nests were found. Individual goshawk were observed on a few occasions moving rapidly through forests along system trails during field trips. The trail observations were well away from destinations or camps where a goshawk nesting territory could be adversely affected by human uses of these areas. As a result it was determined that the sightings do not warrant protocol surveys.

All other suitable potentially occupied habitats within the wilderness have not been surveyed to protocol survey standards since the majority of goshawk habitat around trails, camps and destinations where commercial pack stock operations occur has been observed to be in excellent condition from a structural habitat suitability standpoint.

The table below displays the estimated acres of suitable goshawk habitat below 10,000 feet, the highest elevation for a nest site recorded on the Inyo National Forest.

Table 3.27: Distribution of suitable goshawk nesting habitat below 10,000 feet on the Inyo and Sierra National Forests within the John Muir, Ansel Adams and Dinkey Lakes Wildernesses

Geographic Unit	Suitable Acres Sierra NF	Suitable acres Inyo NF	Total Acres
Ansel Adams East	0	13,475	13,475
Ansel Adams West	14,315	852	15,167
Fish Convict Mcgee	7,879	2,759	10,638

Geographic Unit	Suitable Acres Sierra NF	Suitable acres Inyo NF	Total Acres
Mono Creek/Rock Creek	5,194	361	5,555
Bishop/Humphreys	314	257	571
Florence/Bear	11,534	0	11,534
John Muir Southwest	16,325	0	16,325
John Muir Southeast	0	1,335	1,335
Total Acres Suitable Habitat	55,561	19,039	74,600

Great gray owl (*Strix nebulosa*): According to Beck and Winter (2000) the great gray owl prefers to nest in the broken-off tops of snags at least 24 inches in diameter within mid to late successional conifer forests that are within 300 yards of montane meadows at elevations up to 8,000 feet. The birds may nest as high as 9,000 feet and also utilize the nests of other raptors such as goshawk. Montane meadows greater than 25 acres in size provide preferred foraging habitat adjacent to the nest site. Owls hunt predominantly in the meadows for voles and pocket gophers that comprise 90% of the owl's diet. Owls arrive in late March to early April in high elevation sites to begin their breeding activities. Nesting including egg laying at higher elevations usually occurs in late April to mid May. Young typically fledge approximately 56 to 58 days after egg laying which would likely put it at late June to early July in montane forests of the Wildernesses.

Preferred suitable nesting habitat exists in the AA/JM Wildernesses in old growth mixed conifer, red fir and lodgepole pine forests adjacent to the meadows identified in Table 3.28 predominantly on the Sierra NF, west side of the Sierra Nevada crest. Habitat may extend up to 9,000 in the red fir zone (Beck and Winter, 2000). There are no records of nesting great gray owls, and only one historical record of an observed bird. That sighting occurred in the Ansel Adams Wilderness on the Sierra NF near Grassy Lake in the Silver Divide Analysis Unit in Fish Creek/Convict/McGee Geographic Unit. The sighting was considered reliable. No follow-up surveys were conducted. The owl was observed at 9,500 feet; well above the generally recognized preferred habitat upper elevation limit so there is a low probability that it was a nesting bird.

The only known nesting population centers around Yosemite Valley in Yosemite National Park, and at Clover Meadow on the Sierra National Forest a few miles west of the Ansel Adams West Geographic Unit outside of wilderness. Table 3.28 identifies suitable nesting habitat areas within the two Wildernesses.

Table 3.28. Great gray owl suitable habitat identified within the AA/JM Wildernesses

*GIS Satellite imagery analysis minimum habitat suitability acreage estimate. It is likely field analysis would determine substantially more suitable habitat.

The Inyo and Sierra National Forest Plans as amended by the Sierra Nevada Forest Plan Amendment S&G 35 directs forest managers to conduct additional surveys to established protocols to follow up reliable great gray owl sightings. No recent reliable sightings have occurred in the AA/JM Wildernesses that would initiate a protocol survey effort and one is not warranted at this time until a sighting occurs.

A non-protocol survey by the Sierra NF was conducted in August 2003 in Double and Blayney Meadow. No great gray owls or their sign were detected. The survey would have had a very low probability of detection of hooting owls since it was outside of the protocol period. Wilderness interdisciplinary field trips from 2001 through 2004 also did not detect any great gray owl sign.

Pacific fisher (*Martes pennanti pacifica*): The SNFPA FEIS (2001) notes the fisher is not known to occur on the Inyo National Forest. Numerous years of camera detection sampling efforts have failed to document fisher presence on the Forest. The SNFPA Final Supplemental EIS (2004) noted that the recent monitoring for the two years before publication indicated the fisher was well distributed on the Sierra National Forest as part of the Southern Sierra fisher population subregion. According to the SNFPA FEIS fishers use large areas of coniferous forests with fairly dense canopies and large trees, snags and downed logs. The California Wildlife Habitat Relationships (CWHR) types of importance to fisher include structure classes 4M, 4D, 5M, 5D, and 6 (stands with trees 11 inches diameter at breast height (DBH) or greater and greater than 40% canopy cover (Zeiner et al., 1990). Forest types in the CWHR model include ponderosa pine, mixed conifer, montane riparian, aspen, red fir, Jeffrey pine, lodgepole pine, subalpine conifer, and eastside pine.

The species is most likely to occur within the Sierra NF portion of the AA/JM Wildernesses at lower elevations below 8,000 feet in ponderosa pine, and pine associated mixed conifer forests on the west slope of the Sierra Nevada, and especially in the Kings River watershed. Intensive

survey efforts to understand the species range in these wildernesses has not been conducted. The 2003 Sierra Nevada Forest Plan Implementation Monitoring Accomplishment Report indicates that fisher has been detected in 60 sample units in the southern Sierra Nevada on the west slope, outside of wilderness based on a two year regional survey effort. No detections of fisher occurred within limited sample areas of the AA/JM Wildernesses. The species range is most likely to overlap with commercial pack stock operations along the lower portions of system and user trails and low elevation camps and destinations in the John Muir Southwest, Florence-Bear, and Ansel Adams Geographic Units.

California wolverine (*Gulo gulo luteus*) and the Sierra Nevada red fox (*Vulpes vulpes necator*) have not been verified to occur in the Sierra Nevada for over 60 years (Zielinsky, 2004). Their status in the wilderness is unknown. A survey effort would not be productive at this time since a widespread multi-year survey effort of 334 sample units from 1996 through 2002 as part of the Sierra Nevada Ecosystem Project did not detect the two species in sampled areas of the Sierra Nevada in and outside wilderness areas.

Marten (*Martes americana*) are widespread and likely common throughout the wildernesses primarily utilizing old growth mixed conifer, red fir, and lodgepole pine forests for denning and foraging habitats. They have been found in all forest types as well as the high elevation subalpine and alpine zones.

California Spotted Owl: There are 15 Protected Activity Centers (PACs) for the California spotted owl that are located in the two wildernesses for the Sierra National Forest. The table below shows the status of those PACs. Of the 15 PACs, three have nesting status.

Table 3.29 Status of California spotted owl Protected Activity Centers

Analysis Unit/Protected Activity Center #	Status	Year surveyed
Junction AU

MA041	Pair with young	1992
MA082	Pair with young	1990

Peregrine Falcon (*Falco peregrinus anatum*) There are two known peregrine aeries within the planning area on the Sierra NF. Three more on the Sierra NF are located in areas in close enough proximity where the falcons may be foraging within the planning area. No known active, or historic peregrine aeries are located on the Inyo NF portion of the planning area.

The **Townsend's big-eared bat** (*Corynorhinus townsendii*) roosts primarily in caves and cave analogues such as lave tubes, and abandoned underground mine adits. It forages across a wide-range of forested and shrub habitats, particularly along riparian corridors. The species utilizes caves and abandoned mines to give birth to young in maternity roosts, and also hibernates in these habitats during the winter months. There are no known maternity or hibernation sites within the Ansel Adams and John Muir Wildernesses, however, hibernation sites in old mines may exist in the mid elevation zones up to 10,000 feet if the mine openings remain open during the winter months.

No information is available to know whether the **western red bat** (*Lasiurus blossevillii*), or the **pallid bat** (*Antrozous pallidus*) occur within the wilderness boundary. The pallid bat occurs in non-wilderness on the Inyo National Forest primarily in shrub foothill habitats and in the ponderosa pine belt on the Sierra National Forest, mostly below 6,000 feet in elevation. It likely forages in the lower elevations of the wildernesses.

Management Indicator Species

Mule Deer: The Inyo and Sierra National Forest Land Management Plans and the California Department of Fish and Game Deer Herd Plans (CDFG, various dates) provide descriptions of the deer herds that utilize the AA/JM Wildernesses. Field trip observations showed deer presence or sign occurring in the majority of montane and subalpine forest and riparian habitats visited. Most montane meadows in the lodgepole pine zones showed considerable deer sign. Meadows with shrub and tree cover provide important mule deer fawning, and fawn rearing habitat, though this species also utilizes upland shrub and dense tree thickets for fawning. The changes to meadows from historical and existing pack stock use that were observed and reflected in the meadow analyses showed highly variable levels of modification of mule deer habitat in terms of changes in plant species composition to lower seral stages, or a reduction of wetland, and wet meadow areas in the meadows where the water tables have been affected. These effects were not observed to substantially change habitat suitability of the meadows for mule deer since cover and forage availability was relatively unaffected, as well as the fact that any given watershed has a substantial area of undisturbed habitat that deer can utilize. Riparian habitats where pack stock use occurs were observed to contain good mosaics of shrubs for cover and

forage species availability. Pack stock use was observed to have only minor effects to the willow shrub component of a meadow under light to moderate grazing utilization levels.

Field observations for this analysis indicated that the majority of high country montane and lower subalpine meadow riparian zones and the immediate surrounding forests are important deer habitats. These key habitats provide suitable deer fawning, and fawn rearing habitat, are the most limited habitats, and are probably the most valuable habitats on deer summer range. Commercial packer campsites, destinations, and grazing areas that overlap with riparian habitats were observed to be the principal areas where flight reaction and displacement disturbance effects to deer, especially does with fawns were occurring during the period of commercial pack stock operations. It was also observed that substantial riparian habitat was available in wilderness away from trails and campsites where deer could recover from disturbance events.

Commercial pack stock activities were sporadic in an area for varying time periods, and highly variable from year to year. There is available habitat and periods when pack stock activities are not occurring that may provide mule deer with the ability to shift their locations during disturbance overlap periods to other less disturbed or undisturbed riparian habitat areas.

Riparian bird guild/meadow edge bird guild/yellow warbler/blue grouse

The MIS riparian dependent/associated bird species and species groups for the Inyo and Sierra National Forests are considered together since the assessment of riparian conditions related to structural habitat conditions affects some aspect of the nesting/brood rearing, and foraging habitat requirements of all these species. Late seral riparian conditions provide high quality habitat for these wilderness riparian dependent or associated species. Montane and subalpine riparian and meadow edge bird guild MIS species have not been identified in the Sierra NF Land Management Plan. The yellow warbler (Management Indicator Species, Inyo NF) was observed primarily at lower elevation meadows dominated by a tall bushy willow shrub component at elevations below 9,500 feet. As a result it was observed to be a poor management indicator species for most upper montane/subalpine meadow habitats. Bird species commonly observed in these habitats during field surveys included white-crowned sparrow, dark-eyed junco, dusky flycatcher, fox sparrow, and American robin. Less common species that nest and that were observed at montane elevations of the wilderness were the Wilsons warbler, McGillivrays warbler, song sparrow, black-headed grosbeak, warbling vireo, and northern oriole; the latter three species more commonly found in lower elevation cottonwood and aspen areas. Blue grouse were found where riparian areas were mixed with montane mixed conifer forests containing fir trees, generally below 9,500 feet. Blue grouse broods utilize riparian habitats, as well as upland shrub and forest for cover and foraging for insects.

No studies or monitoring are available for these species or guilds to adequately assess their population status in wilderness. Field observations of pack stock operation effects on habitat were not observed to have materially changed use of riparian habitats by these species. What was observed was increased vulnerability to disturbance with some riparian bird guilds species such as the dark eyed junco and white crowned sparrow that either nest on the ground or in low shrub habitat.

Wilderness habitats provide some of the least disturbed habitat conditions for these species compared with non-wilderness landscapes, even with the recognition that historical disturbances have substantially changed the structural habitat conditions on some of the more heavily used

areas such as Jackson, Grassy, and Silver Pass Meadows. Five meadows that overlapped with identified pack stock grazing areas were observed to have lost water table with a probable gross loss of wetland/wet meadow habitats. Another 19 meadows (see Table 3.30) identified as grazed by pack stock showed several aspects of meadow habitat structure substantially modified or at risk such as wetland habitat availability, stream channel profile, and spring habitat. It is unclear how these changes have affected riparian bird guilds and blue grouse use of these meadows.

Wildlife Habitat Ratings

A general wildlife habitat rating was determined for a sample of meadows visited in the wilderness and identified as pack stock grazing areas. This rating looked at departure of habitat conditions away from good ecological, late seral condition. The rating is an index of habitat condition that assesses meadows from a multi-species perspective with the assumption that a late seral meadow condition provides the most favorable structural habitat conditions for focal wildlife species such as amphibians and riparian songbird guilds, as well as other species such as deer, blue grouse, waterfowl, and obscure species such as meadow voles. A departure substantially away from late seral stages is assumed to correlate with less favorable habitat conditions for riparian associated and dependent wildlife species. At the same time it is also recognized that habitat changes away from late seral favor some wildlife species. These changes, however, are rarely beneficial for the focal wildlife species mentioned above.

A rating of zero indicated a late seral meadow showing no signs of recent grazing. A one rating indicated a minor departure from late seral condition and also an observed pack stock grazing area; a rating of two indicated that the meadow had localized changes from late seral conditions that were degrading riparian habitat, and also overlapped with observed pack stock grazing; and finally a rating of three indicated that there were substantial habitat changes away from later seral conditions such as meadow loss of hydrological function in parts or all of the meadow enough to substantially affect wet meadow and wetland riparian habitat availability for wildlife, and change the potential natural vegetation (PNV) of the site. The meadows also had observed pack stock grazing.

One hundred eighty five meadows were analyzed and given a wildlife habitat rating during field work from 2001 through 2004. Nineteen meadows were rated as a category 3 or modified from late seral meadow conditions from loss of hydrologic functioning where wet meadow and wetland wildlife habitat was substantially lost or in the process of being lost through active headcut spring and stream channel erosion. Five of these meadows had existing commercial pack stock grazing.

Table 3.30 Category 3 meadows

Meadow Name
McClure to Sadler Lake Meadow
West of Joe Crane Meadow
Fernandez Meadow
Fernandez Creek Meadow
Knoblock Meadow
Detachment Meadow

Meadow Name
Grassy Meadow
Jackson Meadow
Box Canyon above Jackson Meadow
Below Lee Lake at Tarn
Chetwood Cabin Meadow
Graveyard Meadow
Upper Graveyard Meadow
Cascade Valley
Lee/McGee Trail Junction
Silver Pass Meadow
Big Maxson Meadow
Below Lee Lake at Tarn
Baldwin Scheelore

Fifty-nine meadows were given a “2” rating, 33 of which were observed to have commercial pack stock grazing use where some aspect of meadow habitat condition was inconsistent with management direction such as, widened stream and spring channels, sod fragmentation, headcuts, or heavily trampled and chiseled wetland and wet meadow areas including spring and stream channels. Another 88 meadows were given a “1” rating to indicate pack stock grazing was not observed to have any substantive effects on the maintenance of key wildlife habitat features and the meadows were in good ecological condition. Nineteen meadows received a “0” rating.

Geographic Unit Scale

Ansel Adams East

Overall AA East provides high quality wildlife habitats in all ecological zones. Montane-forested habitats are, for the most part, in an old growth condition and are primarily in the red fir-mixed conifer-lodgepole pine zones.

Forty-one meadows were rated for wildlife habitat conditions. No meadows rated in category 3, the most degraded meadow condition; eleven meadows rated in category 2 noting localized areas of meadows that have some level of impacts to key habitat features. Twenty-nine meadows rated in category 1 (meadows with no substantive changes away from late seral conditions). One meadow was in the zero category.

Riparian habitat impacts from pack stock use of trails were observed in wet meadow areas such as the system and user trails to Emily Lake, Upper Ediza and Iceberg Lakes, Laura Lake, and a new stock user trail to Rodgers Lake grazing area from Davis Lake. The impacts were small portions of the meadow where the trail tread was either substantially incised or trampled and widened.

Breeding populations of Yosemite toads were found in 29 meadow areas of which 13 were observed or identified as pack stock grazing areas.

There are 11 known populations of mountain yellow-legged frog in this geographic area primarily inhabiting small lakes and stream channels adjacent to the high lakes at the base of the Ritter Range peaks. Seven populations have habitat that are within identified pack stock grazing areas. Five of these areas showed no evidence of pack stock use and appeared unaffected.

The old growth fir and lodgepole forests below 9,600 feet provide excellent goshawk nesting habitat. There is abundant suitable habitat for goshawks to select nest sites without adverse effects associated with existing pack stock use of the trails and destinations.

Riparian habitat for MIS species was, for the most part, in high quality condition. Localized riparian habitat degradation was associated with trails at Ediza Lake, Emily Lake, Laura Lake, Rodgers Lake stock use trail, and Upper Crater Meadow where trails were incised or coursed through a meadow affecting small portions of the meadows suitability for use by the above species.

Overall wildlife habitat for nesting songbird guilds and mule deer habitat was observed to be in good condition with localized areas of lower condition habitat along stream channels and some springs such as at upper and lower Spooky Meadows and the meadows mentioned above. Destination camps and trails showed low impacts to wildlife habitats.

The upper and lower River Analysis Units that encompass the Middle Fork of the San Joaquin are high use deer areas particularly in fall when deer utilize the aspen sagebrush types as a fall holding area. The two units also provide high quality fawning habitat especially on the eastern slopes where lush spring fed aspen and willow stands intermix with open sagebrush parks. The High Trail courses through this area and is used as a main pack stock day ride trail and thoroughfare to Thousand Island Lake. Stock is not present when deer congregate in the fall months.

In the Parker AU, Parker Meadow just below Parker Lake at 8,300 feet is a designated historically occupied willow flycatcher site based on an observation in 1936. No willow flycatchers have been detected in any surveys since that time. It is the only site inside the wildernesses with a record of willow flycatcher occupancy. The site is not an identified pack stock grazing area.

Upper Alger Creek Meadow and Lower Alger Creek terraces are both occupied Yosemite toad habitats (three breeding sites) within identified pack stock grazing areas. Both meadows were monitored in 2003 and 2004 and observed to have light stock trampling and chiseling impacts that overlapped with occupied Yosemite toad breeding pool habitats. Small headcuts were found in both meadows but are currently not adversely affecting toad habitat. Four other breeding sites outside identified pack stock grazing areas occur in the analysis unit, all in excellent condition. Upper and Lower Spooky Meadow have pack stock related habitat impacts such as trampled and chiseled spring and stream channel areas (wildlife habitat rating 2) that may be having minor habitat suitability impacts for ground and low shrub nesting birds.

Rodgers Lake Meadow was observed to have localized moderate pack stock trampling and chiseling impacts in Yosemite toad breeding habitat in 2003 and light impacts in 2004. Davis Lake Meadow had no impacts in 2003 (when it was occupied by toads) and moderate impacts in 2004 (when it was occupied by toads). Marie Meadow had light pack stock impacts that overlapped with occupied Yosemite toad breeding habitat.

Donahue Camp meadow has an eroded creek trail crossing. The creek crossing leading to a packer campsite is adversely affecting a localized section of streambank where adult mountain yellow-legged frogs utilize the undercut bank. The crossing is resulting in collapse of undercut bank habitat and a loss of a small portion of available cover.

The western meadows of Thousand Island Lake showed light to moderate trampling and chiseling impacts to toad habitat both in 2003 and 2004 that overlapped with occupied Yosemite toad breeding habitat. Mountain yellow-legged frogs were also observed in one of the small stream channels in these meadows with no apparent impacts from pack stock grazing. The system trail along the northern perimeter of the lake has small areas of heavily trampled and widened riparian stringers at three trail crossings.

The user trail along the inlet of Ediza Lake and the system trail to Iceberg Lake were incised and eroded, resulting in a minor loss of riparian wildlife habitat. There appears to be meadow habitat loss and changes in the identified grazing area above Shadow Lake.

Wildlife habitat is in excellent condition in the River Corridor and River High AUs. The old growth lodgepole pine forest mixed with aspen and red fir is high quality nesting habitat for goshawks where the system trail courses through. No birds, however, were observed. The River High AU is also high quality mule deer fawning habitat.

Overall, the Minaret AU provides high quality wildlife forested and riparian habitats. Minaret Creek was rated a wildlife habitat rating of two because of an incised channel as it courses through Johnston Meadow. The stream appears to no longer access its floodplain and as a result there may be some loss of wet meadow/wetland habitat. There appears to be substantial wet meadow/wetland habitat at the southern end in spite of the stream incision, probably because of tributaries and springs that feed water into the meadow. Light evidence of pack stock trailing was observed though it was an identified grazing area. The South Fork of Minaret Creek has several ponds with mountain yellow-legged frogs that are not affected by pack stock operations.

In the King Creek AU, the trail to Superior Lake Meadow has five parallel ruts that are affecting mesic meadow habitat.

The Crater Creek/Deer Creek watershed is a designated Critical Aquatic Refuge for Yosemite toads from the SNFPA. No adverse pack stock grazing impacts were observed to the eight meadow areas where breeding populations of Yosemite toads were found. Pack stock use in that watershed appears light. Upper Crater Meadow has occupied toad-breeding habitat that is situated within 25 feet of the system trail. A severe trampling and chiseling event from what appeared to be recreational pack stock occurred in a small 400 square foot meadow patch along the stream. The grazing event resulted in denuded areas of bare soil where the vegetation had been chiseled, including streambank loss and erosion gully formation. It did not overlap with the critical toad habitat in the meadow.

Ansel Adams West

The northern half of this geographic area has four analysis units that show low use with no identified grazing areas: Chiquito, Jackass, and Iron Creek. Similarly low pack stock use in Cargyle, Bridge Crossing, Iron Creek, Lake Catherine, Chiquito, and Jackass AUs suggests that there are no substantive impacts to wildlife habitats occurring.

Cora, Lillian, and Sadler AUs have eight meadows where impaired hydrologic functioning of these meadows from historical uses has led to probable loss of wet meadow and wetland habitats for wildlife. Another six meadows were observed to have moderately impaired hydrologic function.

The southern half of Ansel Adams West has eight known Yosemite toad locations and one mountain yellow-legged frog population identified in the eight analysis units named above. There appears to be no overlap with any pack stock operations that would affect these populations.

Fish Creek/Convict/McGee

In this geographic area, nine meadows were assigned a wildlife habitat rating of three, or the most severe degradation rating: Baldwin-Sheelore, Martins, Round, Grassy, Jackson, Box Canyon above Jackson Meadow, Cascade Valley, Lee McGee trail junction, and Below Lee Lake at Tarn. They were observed to have degraded hydrologic function that has resulted in historical loss of areas of probable wet meadow/wetland habitat. These meadows also have a substantial threat to continued loss of habitat.

Where localized degradation of areas of meadows was observed to be altering habitat, or threatening localized areas of the meadow, such as critical areas, a “two” rating was assigned to 19 meadows.

Overall, forested wildlife habitats were observed to be in excellent condition. Suitable goshawk nesting habitat is present in lower Fish and McGee Creeks in the old growth lodgepole, red fir, and aspen types where system trails course through the stands.

There are no mountain yellow-legged frog populations in the geographic area.

The Convict and McGee watersheds were designated a Critical Aquatic Refuge in the SNFPA because of numerous breeding populations of Yosemite toads. There are 12 populations in McGee Creek and 10 in Convict Creek. There are also Yosemite toads in the Genevieve Meadow, but there are no hydrologic function concerns. With the exceptions of the situations mentioned below—Baldwin-Sceehlore Meadow, Martin’s Meadow, Round Meadow, and Edith Lake Meadow—the breeding habitats are, for the most part, in excellent condition.

In Edith Lake Meadow inlet, pack stock trampling and chiseling in the meadow are overlapping with a Yosemite toad breeding area, as well as at Martins Meadow inlet where a trail was recently located out of the breeding pool.

In the McGee AU, one visit was made to the McGee Creek drainage during the 2004 Toad/pack stock monitoring effort with eight meadows and ten sites visited. Four of these meadows had signs of pack stock impact including chisels and manure, all of which appeared to be related to trail or camp use as no grazing was observed. Light impacts were observed in Round Meadow where an end of season inspection of the meadow showed light grazing, trampling and chiseling that probably occurred after Yosemite toads had metamorphosed and dispersed from the dried out breeding pool areas.

Martin’s Meadow and Steelhead Lake Meadows also showed light pack stock trailing impacts in Yosemite toad breeding habitat. Martin’s Meadow has severe sediment loading, poor trail location, and trail incision at the low end of the meadow that threatens the long-term viability of the lower wetland portion of the meadow. The system trail through the breeding area in Martins

Meadow was re-routed out of the breeding area in August of 2004 to keep pack stock and hikers from passing directly through the wet meadow breeding pool where tadpoles and metamorphosing toads occur.

In addition the incision is causing stream down-cutting, bank collapse, and substantial sediment deposition downstream in Round Meadow in an existing Yosemite toad breeding pool.

The second meadow above Martins was observed to have moderate stock trailing trampling and chiseling impacts in a Yosemite toad breeding area in both 2003 and 2004.

Baldwin-Scheelore Meadow is occupied Yosemite toad breeding habitat that is being severely degraded by the system trail (old mining road) above its perimeter. A 2003 rainstorm incised the road and deposited a massive sediment flow into the meadow that has covered part of one toad breeding pool and threatens the long-term viability of the breeding habitat.

The McGee AU is naturally very erosive because it is a steep drainage with a large portion of metasedimentary rocks. The natural erosivity makes the area vulnerable to human impacts such as trails and grazing because there is a low threshold for triggering major erosion events.

In the Purple Bench AU, there is one known Yosemite toad breeding population discovered in 2004 that also overlaps with an identified grazing area at the north end of Duck Lake.

In the Upper Fish Creek AU, three Yosemite toad breeding populations have been identified around Tully Lake and Red Slate Meadow, all of which are in identified grazing areas. There were no observed pack stock impacts in 2001 or 2003.

Silver Divide AU has eight known Yosemite toad breeding populations. Seven are in identified grazing areas. The 2004 monitoring study found Grassy Meadow and Stringers West of Squaw Lake to have substantial evidence of pack stock grazing, chiseling, trampling, and manure that overlapped with Yosemite toad breeding areas where toad metamorphs were present. The Stringers West of Squaw Lake was not identified as a grazing area, yet it contained heavy impacts from grazing and chiseling in the wettest portions of the meadow, located along the Pacific Crest Trail. In the meadow between Lake of the Lone Indian and Grassy Lake, moderate impacts including grazing and chiseling were found at the breeding site where metamorphs were present along the outlet of Wilbur May Lake. In Squaw Lake Meadow, the most northwest site contained new pack stock signs including chiseling, trampling, and manure; these signs were observed in areas directly occupied by metamorphs.

The Margaret AU has a population of Paiute cutthroat trout in Sharktooth Creek already discussed in the Wilderness Scale section. There are sixteen Yosemite toad breeding areas in the analysis unit. Frog Lake Meadow and North of Frog Lake Meadow are identified grazing areas with toad populations, neither of which showed any grazing impacts to the toad populations.

Mono Creek/Rock Creek

Forested habitats are in excellent mature and old growth condition. The most substantial impact observed from camps was at a main stock camp at Third Recess along Creek Meadow area in a lodgepole forest where about two acres of severely compacted denuded understory occurs in a lodgepole stand.

Wildlife habitat was evaluated in a sample of 21 meadows that were identified as grazing areas. Three meadows rated a “3” in the Graveyard Analysis Unit: Silver Pass Meadow, Upper

Graveyard, and Graveyard. They are substantially degraded from stream incision events that have resulted in probable loss of wetland-wet meadow habitats.

Another eight meadows rated a “2” with localized problems similar to other meadows in the wilderness where sod fragmentation, headcuts, stream channel widening, and trampling and chiseling impacts to wet meadow/wetland, spring channels, and streambanks were observed to have adverse effects to meadow habitat structure. The remaining meadows are rated either “0” or “1”.

The system trail in Hopkins Analysis Unit has substantial trail incision as it courses through the Hopkins Creek meadow complex. It is unknown what this incision is doing to the meadow wildlife habitat.

Mountain yellow-legged frog populations occur in a number of areas of the geographic area. The largest concentration occurs in Fourth Recess and Second Recess AUs. One other frog population was identified in the Bear Ridge AU (BER9) and in Evon Meadow in the Silver Pass Analysis Unit. Neither meadow has been identified as a grazing area.

Seventeen meadow complexes were found to have twenty-two Yosemite toad breeding sites identified in Devils, Graveyard, Silver Pass, Laurel, Pioneer, Volcanic, Morgan and Little Lakes Valley Analysis Units. Twelve meadow breeding sites overlap with identified pack stock grazing areas. There was no grazing reported in any of these meadows over the last three years, nor were any impacts observed from pack stock grazing. The Pioneer Basin has been closed to pack stock grazing for a number of years.

In the Hilton AU, one goshawk nest territory is present in the Hilton Creek Analysis Unit around the eastern shore of Davis Lake. Anecdotal reports suggest packer camps and stock holding areas may have been located in close proximity to the nesting area. Goshawk can habituate to human presence if it is non-threatening, and it is possible they may have habituated at Davis Lake. The territory has been on record since 1982; however, it has been inactive for several years. It is unknown why the birds are currently absent from the territory. Abundant suitable nesting habitat is available throughout the watershed that is well away from human use areas so the birds may have shifted their nest location, although searches in many of these areas have failed to turn up any sign of goshawk.

In the Little Lakes AU, meadows above Long Lake and SW of Long Lake have breeding populations of Yosemite toads that overlaps with an identified grazing area. The population is vulnerable to extirpation since very few toads or egg masses appear at the breeding pools.

In the Tamarack AU, wildlife habitat is in excellent condition. The old growth lodgepole forests near Dorothy Lake appear to be highly suitable goshawk nesting habitat.

In the Morgan Lakes AU, wildlife habitat is in excellent condition. Occasionally Sierra Nevada bighorn sheep descend off the mountain slopes of Mt. Morgan close to the old mining operations and trail area.

Five populations of mountain yellow-legged frogs were found in Fourth Recess with one in an identified grazing area North of Mono Rock. One frog was found in the meadow in a spring channel. The channel did not appear to be adversely affected by grazing. A nearby sedge wet meadow 100 feet away was substantially trampled and chiseled from a recent grazing event. A small spring headcut was observed.

All of the Pioneer Basin Meadow has been closed to grazing for years to allow for meadow restoration. Camp Meadow, Mudd Lake, and East of Mudd Lake have breeding populations of Yosemite toads that overlap with an identified grazing area. Camp Meadow complex has trail incisement problems in the meadows but it does not appear to be adversely affecting toad breeding sites.

The Laurel AU has relatively undisturbed wildlife habitat conditions. Laurel Creek Complex and North Laurel Lake Complex have breeding populations of Yosemite toads that overlap with an identified grazing area.

In the Second Recess AU, a significant population of mountain yellow-legged frogs can be found in the upper lakes basin. Six populations were identified in Second Recess with two overlapping an identified grazing area.

In the Silver Peak AU, Silver Pass Meadow has a breeding population of Yosemite toads that overlaps with an identified grazing area.

Volcanic Knob Meadow and the meadow past of Volcanic Knob (in the Volcanic AU) have breeding populations of Yosemite toads that overlap with an identified grazing area.

Devils Bathtub (in the Devils AU) has a breeding population of Yosemite toads that overlaps with an identified grazing area.

Bishop/Humphreys

Forested wildlife habitats were observed to be in excellent mature and old growth landscape conditions.

The vast majority of meadow habitats are in excellent condition throughout the Geographic Unit. Six meadows discussed below were rated a “2” with identified problems primarily associated with incised system trails, or pack stock grazing areas.

Treasure, Gable and Humphrey Basin AUs have populations of mountain yellow-legged frogs associated with high alpine lake basins. No substantive amount of pack stock use occurs around these populations since they are in very high subalpine/alpine lake basins difficult to access by pack stock except possibly for dunnage trips to drop off gear for hikers. California Department of Fish and Game has been removing fish for several years in an attempt to restore Gables Lakes and Treasure Lakes frog habitats.

Yosemite toad breeding populations were found in 24 meadow complexes at 39 breeding sites in Granite Park, Pine Creek, French Canyon, Glacier Divide, and Piute Analysis Units. Seventeen meadow-breeding sites overlap with identified pack stock grazing areas. There was no grazing reported in any of the meadows over the last 3 years except for Merriam Lake Meadow where 15 stock nights were reported in 2003

Yosemite toad breeding sites that overlap with identified pack stock grazing areas are: West of Honeymoon Lake, Honeymoon Lake Meadows, Upper Pine Lake, Pine Creek Stringers, and East of Pine Creek Pass. The Upper Pine Lake site had moderate trampling and chiseling impacts in 2003 that overlapped with metamorph Yosemite toad presence. Pack stock users appear to veer off the system trail in this area and trail through the breeding area. A similar situation was identified above Honeymoon Lake that was rectified by relocating the trail away from the breeding area.

The Pine Creek Yosemite toad/Pack Stock Monitoring Study visited the Pine Creek drainage in late July 2004. Eleven meadows were assessed containing 14 breeding sites. Yosemite toads were observed in an additional five meadows with no pack stock sign observed.

In the Granite Park AU, six Yosemite toad breeding sites were found in the Upper Chalfant Lakes Basin. No pack stock use was observed in the area. Two breeding sites have been found in Granite Park. One site is close to the system trail where five metamorphs were observed trampled in the trail tread from hiker traffic.

In the Horton AU, habitat is in excellent condition throughout the analysis unit.

In the Piute AU, the system trail up the North Fork of Bishop Creek is within 20 feet of the perimeter of a Yosemite toad breeding pool in the Loch Leven Lake area. This trail is the main route for pack stock up to Piute Pass. Trail use and toad breeding success are being monitored to determine if the trail is having any effect in toad use of the habitat. Preliminary observations are that while the trail is in an undesirable location, Yosemite toads continue to occupy the site with no discernable impacts to their breeding success.

In the Lamarck AU, there is an active goshawk territory in the Grass Lake area of the north fork of Bishop Creek. It has been active since 1982. Nest territories have also been known in the South Lake and Sabrina Lake areas from the early 1980s although surveys throughout the 1990s have failed to detect nests or birds present. The Grass Lake birds have constructed nests starts along the system trail in wilderness but have placed their active nest away from the trail area and appear to utilize the habitat in spite of the heavy human use centered on the trailhead and North Lake Campground just outside the boundary of the wilderness.

In the Treasure AU, a population of mountain yellow-legged frogs was found in the Upper Treasure Lakes area. No commercial pack stock use was observed. Wildlife habitats are in excellent condition throughout the analysis unit.

Wildlife habitats are in excellent condition throughout the Bishop Creek AU.

In the Glacier Divide AU, there are six meadow breeding sites that overlap with identified pack stock grazing areas.

In Bishop/Humphreys AU, there is one occupied Yosemite toad breeding site in the West of Lower Desolation meadow.

In the French Canyon AU, Merriam Lake Meadows, Waterfall Camp to Merriam Creek, and West Elba Lake Meadow all had small, localized areas of meadow sod fragmentation evident from pack stock trailing. The system trail through Waterfall Camp to 10760 Meadow was deeply incised with parallel ruts. The most severe meadow degradation was in the meadow adjacent to Waterfall Camp. There were numerous small erosion gullies fragmented fen sod observed from recent pack stock hoof chiseling impacts in 2002. Five or six meadow breeding sites overlap with identified pack stock grazing areas.

Florence/Bear

Forested wildlife habitats were observed to be in excellent mature and old growth landscape conditions.

The vast majority of meadow habitats are in excellent condition throughout the geographic unit. Five meadow complexes were rated a two with identified problems primarily associated with

incised system trails, or pack stock grazing areas. Rosemarie and Hilgard Meadow were observed to have problems with stream incision and possible lowered water table, along with vegetation species composition shifts, and headcuts from historical grazing use. Old Trail, Boot Meadow, and Shooting Star Meadows had localized areas of sod fragmentation, and vegetative species composition changes. It is unknown how these meadow impacts are currently affecting wildlife populations.

Yosemite toad breeding populations were found in 45 meadow complexes at 51 breeding sites in Italy, Bear Lakes, Apollo, Seldon, Bolsillo, Ershim, and Dutch Analysis Units. The latter three units about the Dinkey Lakes Wilderness and adjacent non-wilderness where another forty plus Yosemite toad breeding populations have been identified. Along with John Muir Southwest (discussed below with 55 breeding sites) that makes this area and adjacent southern populations the most abundant and highest density portion of the metapopulation of the species in and adjacent to the AA/JM Wildernesses.

Eight meadow breeding sites overlap with identified pack stock grazing areas.

In the Dutch AU, DUT3 Meadow has a population of Yosemite toads that overlaps with an identified grazing area.

In the Ershim AU, Lake Camp Meadow has a breeding population of Yosemite toads that overlaps with an identified pack stock grazing area.

In the Apollo AU, Marcella Lake Meadow is an occupied Yosemite toad breeding site that overlaps with an identified pack stock grazing area.

In the Bear Lakes AU, the upper lakes basin has a population of mountain yellow-legged frogs, and two sites where breeding populations of Yosemite toads have been found.

In the Seldon AU, Lou Beverly, Low Meadow Terrace NE of Marie Lake, Marie Lake Meadows, and Rose Lake Meadows all have breeding populations of Yosemite toads that overlap with identified pack stock grazing areas. No pack stock sign or impacts were noted in the 2003 interdisciplinary team survey of the Lou Beverly and Marie Lakes Meadows grazing areas.

John Muir Southeast

The Unit has excellent wildlife habitat conditions throughout. No substantive amount of pack stock grazing occurs in any of the analysis units.

In the NF Big Pine, a population of mountain yellow frogs was found at Sam Mack Meadow.

The Sawmill and Baxter AUs are part of the range of the Mt. Baxter bighorn sheep herd. The herd primarily utilizes the high alpine habitats during the summer months. Winter snows usually drive the herd onto the lower slopes of Sand Mountain and Sawmill Canyon. Sawmill Meadow occasionally has bighorn sheep moved down into it for foraging. There is little overlap with commercial pack stock operations except where pack stock travel over Sawmill Pass.

In the Kearsarge AU, Mountain yellow-legged frogs occur in Matlock, Slim and Bench Lakes. California Department of Fish and Game has an active restoration program in this basin.

The Mt. Williamson area in the Shepherd AU has a population of Sierra Nevada bighorn sheep. Their range does not appear to overlap commercial pack station use of the Shepherd Pass trail area.

The Mt. Langley area in the Cottonwood AU has a population of Sierra Nevada bighorn sheep. Their range does not appear to overlap commercial pack station use of the trail system over New Army Pass area.

The old growth lodgepole forests appear to be suitable goshawk nesting habitat.

John Muir Southwest

Forested wildlife habitats were observed to be in excellent mature and old growth landscape condition in Post Corral, Fleming Mountain, Red Mountain, Bench, Basin, and Big Maxon Analysis Units.

The vast majority of meadow habitats are in excellent condition throughout the Geographic Unit. Above Fleming Lake Meadow was assigned a wildlife habitat rating of “2” as a result of observed streambank collapse, stream widening and incisement, and meadow hummocking. Big Maxson Meadow was assigned a “3” rating since it appears to have lost portions of its water table to historical downcutting events on the South Fork of the Kings River.

The lower elevation mixed conifer and old growth lodgepole forests appear to be excellent habitat for goshawk nesting. No commercial pack stock use issues were observed in these habitats that would affect goshawk use of the habitat.

No mountain yellow-legged frog populations were found in this unit.

Yosemite toad breeding populations were found in 53 meadow complexes at 55 breeding sites in Hobler, Dusy, Post Corral, Fleming Mountain, Red Mountain Basin, Bench, Big Maxson, Crown Basin, Rodgers, Crown Lake, Spanish, Finger, and South Woodchuck Analysis Units.

Eleven meadow breeding sites that overlap with identified pack stock grazing areas are: Burnt Corral Meadow, Upper Meadowbrook Creek, Middle Meadowbrook Creek, McGuire Lakes Meadows, Colt Lake Meadow, Horsehead Lake Meadows, Filly Lake Meadows, Roman 4 Meadows, Scepter Meadow, unnamed meadow (FIN1), and Round Corral. No grazing stock nights were reported for these meadows; however, a number of these meadows have been grazed during the 2001 through 2003 period. The meadows visited in Post Corral, Fleming, Red Mountain, Bench, and Big Maxson showed little evidence of stock use where it overlapped with Yosemite toad habitat except at Upper McGuire Lake Meadows.

3.3.2 Vegetation

Wilderness Scale

Introduction

The Ansel Adams and John Muir Wildernesses span the range of east and west side Sierra Nevada habitats. Elevations range from as low as 3,500 feet in the foothills on the west side to 14,495 feet at Mt. Whitney.

Along the western edge of the wildernesses, there are small areas of foothill grassland, but most of the lower slope, up to roughly 10,500 feet in the southern Sierra and 10,000 feet in the central Sierra, is covered with montane forest, montane scrub, or rock outcrop. Low to mid elevation forest associations are primarily composed of jeffrey pine, red fir, lodgepole pine, western white pine, sierra juniper, white fir, ponderosa pine, and mountain hemlock. Tree species occur in highly variable assemblages depending on elevation, slope, and aspect. At lower elevations, drier slopes contain higher percentages of sierra juniper and jeffrey pine, while slopes with cooler, moister microclimates such as north and east exposures, and in drainage bottoms have higher percentages of firs. Lodgepole pine occurs across the spectrum in varying densities, usually at higher elevations with more open forests on drier sites. Some canyon live oak and black oak is present in the southwestern Ansel Adams. Willow, lodgepole, and aspen are common in the riparian areas.

In the subalpine zone, forests are characterized by shorter tree heights and lower density. The Sierra Nevada Ecosystem Project (USFS, 1996) lists the following types: whitebark pine-mountain hemlock, whitebark-lodgepole, foxtail pine, whitebark pine. There is an existing closure to campfires and associated downed wood gathering above elevation 10,000 feet in the north and 10,400 feet in the south.

This closure is designed to protect the sparse subalpine vegetation, primarily whitebark pine, and the elevational limits were based on the known distribution of whitebark pine-dominated vegetation. An estimate of the percentage of campsites above the closure in each geographic unit was made, using campsite locations mapped by the packers.

On the east side, lodgepole and Jeffrey pine stands dominate the montane zone, grading into the sagebrush scrub and pinyon-juniper zones of the eastern escarpment. Riparian corridors are dominated by lodgepole, willow, and aspen, with some cottonwood and water birch at lower elevations.

The Vegetation Types by Geographic Unit table (available in the project record) shows approximate acreage for vegetation types in the Geographic Units, based on available digital vegetation maps of the Sierra and Inyo National Forests.

Riparian Vegetation

Distributed throughout the analysis area in and along the drainages are riparian communities, including meadows, aspen stands, and willow stringers. They are typically in valley bottoms, especially above constrictive rock outcrops or moraines, and are most commonly associated with lakes or streams. Historically and currently, human activities in the analysis area, including

livestock grazing, backpacking, and pack stock use, have been concentrated in or near these riparian areas.

Riparian areas are important habitat and foraging locations for wildlife as well as being important for human recreation and pack stock use. A highly complex, and variable mosaic of riparian areas are found throughout the wildernesses, accounting for 1 to 6 percent of the total acreage in the identified geographic areas. Because of their importance there is management direction, particularly in the SNFPA to protect and maintain streams and “special aquatic features,” including meadows, lakes, and fens (RCO #2, 5) and the Wilderness Plan requires a suitability for grazing determination by an interdisciplinary team (IDT).

This analysis implements the process described in the Wilderness Pack Stock Management Guide, Appendix G, page 11, (Wilderness Plan, 2001) to determine suitability for grazing at specific locations. The IDT surveyed and evaluated approximately 227 meadows for several factors relating to suitability for grazing, including vegetation composition changes away from PNV, range readiness characteristics, presence of fens, and the hydrologic factors described in the Hydrology section 3.2.2. The analysis is focused on identified representative (key) or important areas of special concern (critical) areas within a larger proposed grazing area. The use of key and critical areas is further defined in Chapter 3 of the Rangeland Analysis and Planning Guide, (USDA Forest Service, Pacific Southwest Region, 1997).

High-seral meadow in the Lodgepole Pine forest understory

Meadow Condition Indicators

Vegetative Composition: This analysis is not intended to be a comprehensive wilderness-wide assessment of vegetative conditions. The intent of this analysis is for an interdisciplinary team to collect and document the site-specific information needed to implement grazing as described in the Wilderness Plan Appendix G, Pack Stock Management Guide (Wilderness Plan, 2001) in those locations where a need for grazing has been identified.

A wilderness-wide assessment of vegetative conditions was done and is documented in the Final Environmental Impact Statement for the Ansel Adams, John Muir, and Dinkey Lakes Wildernesses and a detailed assessment of vegetative conditions relative to the grazing resources is found in the Wilderness Plan Appendix F, Ecological State and Transition of Rangelands, (Wilderness Plan, 2001). The vegetative composition of meadows is generally in satisfactory condition with an upward trend as defined by and described in the Final Environmental Impact Statement (Wilderness Plan, 2001, Chapter 3, page 27 and Appendix F). There have been several studies of meadows with heavy use in the AA/JM Wildernesses. In 1982, areas used by Frontier Pack Station were studied and soil and vegetation conditions trends were determined. The trends were stable or upward except at Gem Pass Meadow, where soil condition was judged to be in a downward trend. Utilization rates ranged from 25-42%. A 1987 analysis showed good to excellent conditions at Long Canyon, and Fish Camp, but only fair conditions at Grassy, 2nd-3rd Recess, and Pioneer Basin. Pioneer Basin conditions had deteriorated from good to fair between 1963 and 1986. A 1990 report, using condition/trend and residual forage assessment methods, found good to excellent conditions at Purple, Horse Heaven, Red Meadow, Spooky, and Alger, fair conditions at Minnow Creek Meadow (=Cascade Meadows in this analysis), and poor conditions at White Meadow (=Martin's Meadow). The "poor" rating for White Meadow is based on the dominance of a rhizomatous native sedge that is apparently unpalatable to stock, but is a normal component of high elevation meadows. These studies established permanent 1 m square plots at several meadows, but these small plots provide only limited information. Between 2000 and 2003, permanent monitoring plots were set up in several wilderness meadows as part of the USFS Region 5 Range Monitoring Project (USDA Forest Service, 2004). These plots have established baseline conditions and will be re-read every five years to determine meadow condition trend.

The conclusion of this analysis is that while most meadows are in satisfactory condition as defined and described by the Wilderness Plan, there are some local changes to the vegetative composition of meadows, and of locations within meadows, away from the desirable, late-seral vegetation (see Table 3.31). The seral status of the vegetation within the identified key areas determine the utilization levels for grazing under the Wilderness Management Plan (Wilderness Plan, 2001, pages 23- 26).

Table 3.31 Vegetative composition change (percentage of number of meadows assessed)

Geographic Unit	Little or No Change	Some, Isolated over <1/3 of Meadow	Well Defined: over >1/3 of Meadow
Ansel Adams East	50	43	7
Ansel Adams West	20	28	52
Fish Creek/Convict McGee	59	35	6

Geographic Unit	Little or No Change	Some, Isolated over <1/3 of Meadow	Well Defined: over >1/3 of Meadow
Mono Creek/Rock Creek	40	47	13
Bishop/Humphreys	53	42	5
Florence/Bear	54	18	28
Total	47	36	17

Although most meadows are in satisfactory condition, there are changes to the vegetative composition of some meadows. This photo shows Purple Meadow near a packer camp with observable altered vegetative composition due to stock use. Changes away from desired conditions include increased forbs, decreased grasses and grass-like plants, and increased bare soil. The two large bare areas were created by stock rolling after the packsaddles were removed.

Range Readiness

In addition to being useful to implement the Wilderness Plan direction to establish grazing start dates range readiness is an important component of the suitability evaluations. Our surveys indicate that significant numbers of meadows or substantial portions of meadows assessed in the project area never become dry enough to support the weight and impacts of grazing livestock without permanent damage to the vegetation or soil, that is, they never reach range readiness (see

Table 3.32). If a meadow does not reach range readiness it cannot be counted as part of the available forage from that area.

Table 3.32 Percent of number of meadows assessed by rating of range readiness

Geographic Unit	<5%	5% to 25%	26% to 75%	> 76%
Ansel Adams East	0	16	59	25
Ansel Adams West	0	12	68	20
Fish Creek/Convict McGee	0	19	55	26
Mono Creek/Rock Creek	0	40	33	27
Bishop/Humphreys	0	9	30	61
Florence/Bear	0	9	54	37
John Muir/Southwest	0	40	50	10
Total	0	20	51	29

A meadow which never reaches range readiness due to season-long wet conditions

Grazing Resources

The meadows throughout the project area were used by livestock including pack stock, sheep, and cattle, beginning in the middle to late nineteenth century and continuing through the present

time (Sierra and Inyo N.F. 2200 files; Sierra N.F. Land and Resource Management Plan FEIS, 1991; Inyo N.F. Land and Resource Management Plan FEIS, 1988; Ratliff, 1982 and 1985). Historical writings, such as *My First Summer in the Mountains* by John Muir (1911) and *History of the Sierra Nevada* by F.P. Farquhar (1965), indicate that undocumented historical sheep grazing, from the late 1800s to the early 1900s, likely exceeded the numbers and geographical reach of the cattle grazing that occurred from the early 1900s to the present time. Historical grazing, including sheep and cattle as well as pack stock, was likely many times greater in numbers (stock nights), for a longer season of use, and more widespread than is permitted today (Sierra N.F., 2200 Files; Inyo N. F., 2200 Files, various dates).

Sheep and cattle grazing has been regulated in response to acknowledged resource concerns, and continually reduced, in both numbers and geographic extent, since the early 1900s. There is currently no permitted sheep grazing in this project area. Total currently permitted grazing use by cattle throughout the entire project area is 1,549 animal months (46,470 stock nights) with most of this use occurring in the Ansel Adams West geographic area and some of this use occurring in those portions of the Dinkey Lakes and John Muir Wilderness areas adjacent to the Ansel Adams Wilderness area (Wilderness Plan FEIS, Chapter 3, pages 26-33).

Historical pack stock use in support of sheep and cattle grazing, mining operations, logging operations, and for recreation purposes likely greatly exceeded the numbers and geographic extent of today's use. Table 3.36 at the end of the chapter contains a summary by geographic unit of the reported commercial pack stock grazing nights at meadows throughout the project area.

Fens

Fens are areas where peat (undecomposed plant material) accumulates in groundwater-fed, perennially saturated areas. They are “special aquatic features” (SNFPA), often developing around spring heads, and can be degraded by loss of vegetation, soil disturbances that expose peat to the atmosphere, or small-scale changes in hydrologic condition (Cooper et al., 2004). Fens are partially defined in the SNFPA by the presence of plant species *Sphagnum* spp., *Meesia* spp., or sundew (*Drosera rotundifolia*). A more complete definition, that will be used for this analysis, includes saturated organic soil at least 40 cm deep (USDA Forest Service, 1999), groundwater supported hydrology, and fen plant species. There is no known historical information about the extent and condition of fens in these wildernesses but survey and mapping efforts are ongoing as well as research on fen function and resiliency. Under present management, there are grazing restrictions at only 16 of the more than 1700 meadows, so any existing fens are vulnerable to trampling and hoofpunching by pack stock.

Based on deep organic soil depths and saturated soil, fens were identified in 26 meadows of the 227 visited. There were 34 more meadows with fen characteristics such as saturated organic soil, where further measurements are needed. These will be considered fens for this analysis. *Sphagnum* sp. was found in an additional 31 meadows that would qualify as fens under the definition in the SNFPA, but are probably not fens under the expanded definition and will not be analyzed as fens.

Because fens depend on groundwater and form around springs, the IDT assessment of spring impacts and changes to hydrologic function are used to determine “at risk” fens (Table 3.33).

Table 3.33 Meadows where fens or areas with fen characteristics are at risk due to spring impacts or changes in hydrologic function identified by an IDT.

Geographic/ Analysis Unit	NAME	Spring Impacts	Hydrologic Function Changes	Reported Commercial Pack Stock Use (2001-2003)
RUS	Lower Alger Creek	Moderate	None	High of 296 Stock Nights
RUS	Upper Spooky Mdw	Severe	Slight	High of 44 Stock Nights
CCD	Upper Crater Meadow	Severe	Slight	No restrictions, no reported use
CCD	Deer Creek Meadows	Severe	Slight	95 in the grazing zone
CCD	Upper Deer Creek	Moderate	Slight	95 in the grazing zone
CCD	Deer Lakes Meadows	Moderate	None	95 in the grazing zone
SAD	McClure to Sadler	Severe	Severe	High of 127 Stock Nights
CAR	Between Stairway and Cargyle	Moderate	Moderate	No restrictions, no reported use
CAR	Middle East Fork Mdw	Moderate	None	No restrictions, no reported use
CAR	Cargyle North	Moderate	None	No restrictions, no reported use
CAS	Second Crossing	Severe	Slight	High of 207 Stock Nights, currently closed
CAS	Third Crossing	None	Moderate	High of 91 Stock Nights
PPB	Ram Meadow	Moderate	Slight	High of 164 Stock Nights
UFC	Tully Hole	Moderate	Moderate	High of 105 Stock Nights
MAR	Coyote Grazing Area	Moderate	Slight	High of 84 Stock Nights
GRA	Upper Cold Creek Complex	Moderate	Slight	No restrictions, no reported use, part of cattle allotment
FOR	North of Mono Rock	Moderate	None	High of 174 Stock Nights
FOR	Third Recess along Creek	Moderate	None	At least 174 Stock Nights
FRE	Adjacent to Waterfall Camp	Severe	Slight	62 Stock Nights in the general area

Sensitive Plants

No plants on the federal threatened or endangered species list are known to occur within the planning area. There is a documented population of slender moonwort, *Botrychium lineare*, a candidate species that has been determined to warrant listing (US Fish & Wildlife Service, Federal Register, 2004), but this listing has been deferred because of higher priority listing actions. Father Crowley's lupine (*Lupinus padre-crowleyi*), endemic to a limited area of the Eastern Sierra, is listed as rare by the State of California.

General or intuitive controlled surveys were conducted at meadows, campsites and trails in the areas with most packstock use, but there is much unsurveyed habitat, especially in little used areas. The information used in this analysis is based on these surveys, historical records and field reports from various agency and private botanists. Known populations of sensitive plants tend to be near trails or campsites, which reflects the areas that have been searched. Because

there is so much unsurveyed suitable habitat, potential habitat was determined based on the elevation and habitat types (rock outcrop, upland, or riparian) for each sensitive species.

Seventeen Forest Service sensitive plants are known to occur in the Ansel Adams and John Muir Wildernesses and potential habitat exists for fifteen others. Refer to the Biological Evaluation for this project for more complete analysis for the sensitive species, particularly those of rock outcrop and upland habitats. Region 5 is in the process of updating its sensitive plant list and three additional species that are proposed as sensitive species in this update occur in the analysis area and will be included in this analysis. There are 10 known “watch list” plants in the analysis area, and another just outside in a meadow that is partly in the wilderness. The project records contains a list all these Sensitive, Proposed Sensitive, and Watch List species with the habitat designation(s) (rock outcrop, riparian, and/or upland). Brief descriptions of the proposed sensitive and watch list plant species and the riparian habitat sensitive species that are present in the AA/JM wildernesses are included below. More site specific information about occurrences of all rare species is discussed at the Geographic Unit scale.

Rock Outcrop and Upland Habitat Rare Plants

Species of rocky habitats may occur in crevices, tucked in among rocks on talus slopes, or in shallow pockets of soil on rocky ledges, often on steep slopes. Nineteen of these sensitive, proposed sensitive, and watch list plants of rock outcrop occur or have potential habitat in the two wildernesses and comprise the majority of the known rare plant populations. Most of the known populations are near trails, reflecting where most surveying has occurred. Since more than a third of the wilderness area is rock outcrop, there is extensive unsurveyed habitat for all of these species in the AA/JM Wildernesses, most in areas without commercial packstock use.

Species of upland habitat generally occupy non-riparian openings or shaded areas with low to moderate gradient that are not dominated by rock outcrops. There are seven species of sensitive plants that occur in upland habitats, but no known occurrences or habitat of proposed sensitive or watch list plants of this habitat type.

For additional information on the 22 sensitive plants of rock outcrop and upland habitat, see the Biological Evaluation.

Proposed sensitive species of rock outcrop habitat

Marble rock mat (*Petrophyton caespitosum* var. *acuminatum*) The habitat of this species is carbonate or granitic rock (cliffs) in montane coniferous forests. It is known from three occurrences in Tulare, Fresno, and Inyo Counties, one near the boundary of the John Muir Wilderness on a cliff across a stream from a trail.

Dedecker’s clover (*Trifolium dedeckeriae*) This clover grows in granitic soils among rocks and boulders or in rock crevices, and potential habitat is widespread. It is known from 12 occurrences on the east slope of the Sierra Nevada, the Kern Plateau, and the White Mountains, several of more than 1000 individuals. Three of these occurrences are in the JM Wilderness and two more are just outside in areas without trails. Those in the wilderness have been visited since 2000 and have no reported negative impacts. All known populations are on FS lands (INF or Sequoia NF).

Watch list species of rock outcrop or upland habitats

Congdon's sedge (*Carex congdonii*): This large sedge grows in talus fields in subalpine zones. It is known from seven California counties and there are five known populations in the AA/JM Wildernesses. There is another population just north of the wilderness and there is much unsurveyed potential habitat.

Fell-fields claytonia (*Claytonia megarhiza*): This species grows in granitic gravels and rock crevices in alpine or subalpine environments. The California Natural Diversity DataBase (CNDDDB) lists nine occurrences, four in Yosemite, three on other National Forests, and two in the Ansel Adams Wilderness on the Inyo NF, and it also grows in Oregon and elsewhere (CNPS, 2001).

Mt. Whitney stickseed (*Hackelia sharsmithii*): This plant occurs along the crest of the Sierra Nevada and in the Toiyabe and Toiyabe ranges of Nevada. Eleven occurrences are known from the JM Wilderness and at least ten from Sequoia-Kings Canyon NP. The habitat is dry gravelly soils or talus on north facing slopes.

Alpine jewelflower (*Streptanthus gracilis*): This species grows in granitic sand and gravel in rock outcrops in the Kings-Kern Divide area. There are at least 16 occurrences reported from Sequoia-Kings Canyon N.P. and 3 occurrences on the Inyo N.F., all in the John Muir Wilderness.

Riparian Habitat Rare Plants

Eleven sensitive, one proposed sensitive, and seven watch list plant species of riparian habitats occur or have potential habitat in the Ansel Adams and John Muir and most occur in lower elevation meadows in drainages on the west slope. The following sensitive plant potential habitat descriptions are based on the known range of the species, by both elevation and watershed. Although there are no specific studies of these species, plants of riparian habitats are dependent upon properly functioning streams and meadows to maintain their habitat. The interdisciplinary team evaluated the meadows with the most pack stock use in the AA/JM Wildernesses to determine their current condition. Table 3.34 displays the meadows with moderate to severe stream impacts or changes in hydrologic function within the elevational ranges of the riparian sensitive species.

Sensitive Species of Riparian Habitats

Moonworts (*Botrychium lineare*, *B. lunaria*, *B. ascendens*, *B. minganense*, *B. crenulatum*). There are several species of rare moonworts that may be found in meadows, seeps, fens, marshes, upper or lower montane forests, or subalpine forests. Meadows with non-granitic soils, especially limestone-based, are considered to be more likely habitat for these rare species (Farrar, 2004). Part of the moonwort's life cycle is underground and in some years it may not grow above ground at all.

There is one documented population of *B. lineare* in a granitic rock crevice and one of *B. minganense* in a calcareous soil meadow. The more common species of moonwort, *B. simplex* and *B. multifidum*, known associates of the rarer species, were found in 68 (29%) of the 227 meadows visited.

Because of the wide range of habitats for the rare *Botrychium* species, all meadows in the wilderness areas are considered to be potential habitat for at least one species and any alteration of meadow hydrologic conditions may adversely affect that habitat. Approximately 9% of the mapped meadows in the wilderness had reported use by commercial packstock in 2001-2003 and about 15% of those visited (227 meadows in highest packstock use areas) had moderate or severe changes to hydrologic function.

A Conservation Assessment will be completed for the *Botrychium* species in 2005.

Bolander's candle moss (*Bruchia bolanderi*). This moss grows on streambanks in meadows, currently only known from outside the wildernesses on the west slope of the Sierra at elevations between approximately 5575 and 9200 feet. There are 518 meadows within the reported elevational range of this species, 37 (7%) with reported use. At six of these meadows, there are moderate to severe streambank impacts reported; four of these in AA West are degraded mostly by historic impacts, not current packstock use.

Tioga Pass sedge (*Carex tiogana*). Tioga Pass sedge is known from meadows around high elevation lakes in the northern Ansel Adams Wilderness at two locations on or near trails that have no recent reported use by commercial packstock. Potential habitat was identified at 14 other meadows, 4 (25%) with reported use. The habitat is in good condition at three meadows with reported use, but there are lakeshore trampling impacts at one, Marie Meadow (Upper Rush AU).

Subalpine fireweed (*Epilobium howellii*). Subalpine fireweed, a small perennial species, grows at the drier edges of meadows, usually with other species of fireweed, at elevations of 6550-8850 feet. There are at least 34 populations outside of wilderness on the Sierra National Forest and 1 on the Inyo. Two populations were recently found in the Deer Creek Meadows area (identification to be confirmed). There are 368 meadows within the reported elevational range, 23 (6%) with reported use. There are moderate to severe hydrologic function changes in three of these meadows; Chetwood is degraded mostly by historic impacts, not current packstock use.

A Conservation Assessment for alpine fireweed will be started in 2005.

Mosses (*Meesia triquetra* and *M. uliginosa*). These mosses are fen indicator species (SNFPA) with wide distributions outside of California, found in continually wet areas with deep peat and a moderate to high pH at elevations of approximately 6100-9200 feet on the west slope of the Sierra. There are no known *M. triquetra* occurrences in the AA/JM and the only known population of *M. uliginosa* is near a meadow with no reported use. Although probably less than 20% of them actually have the fen habitat required for these species, 182 other meadows are within the reported elevational range of these species, 13 (7%) of them with reported use. Of these, Johnston Meadow is the only one with stream impacts and hydrologic function changes that could negatively affect the potential habitat.

A Conservation Assessment will be completed for the *Meesia* species in 2005.

Veined water lichen (*Peltigera hydrothyria*, previously *Hydrothyria venosa*). This water lichen grows in streams at elevations below 8200 feet on the west side of the Sierra Nevada. There are no known populations in the Ansel Adams and John Muir Wildernesses, but four populations are known from the Sierra NF, the closest about two miles outside the wilderness. There are 197 meadows within the reported elevational range, 18 (9%) with reported use. There are moderate to severe hydrologic function changes in four of these meadows.

Bolander's clover (*Trifolium bolanderi*). Bolander's clover grows in meadows on the west slope of the Sierra Nevada at elevations of 6800-7300 feet. There are no known populations in the Ansel Adams and John Muir Wildernesses; the closest population of the 46 known is less than one mile outside the wilderness. There are 257 meadows within the elevational range of this species, 17 (7%) with reported use. Three of these meadows have moderate to severe hydrologic function changes.

Proposed sensitive species of riparian habitats

Blandlow's feather moss (*Helodium blandlowii*): This moss forms mats and small hummocks, often under willows, in montane fens, usually with calcareous groundwater (Christy and Wagner, 1996). It is known worldwide, but in California from only Kings Canyon National Park and three sites, two in the John Muir Wilderness, in Rock Creek and Hilton Creek on the Inyo National Forest.

Watch list plants of riparian habitats

Least moonwort (*Botrychium simplex*) Least moonwort has similar habitat to the other moonwort species, but is common in the AA/JM Wildernesses. Investigation by Don Farrar has shown that there are two western subspecies, which may have different status when *B. var. fontanum* is officially described. As noted above, the species was found in at least one third of the meadows visited, but the plants were not identified to subspecies level. Because this species was so common, site specific information will not be included.

Round-leaved sundew (*Drosera rotundifolia*): This species is found in coastal California, the Cascades, the Sierra Nevada, and is widespread in northern latitudes, but grows only in bogs or fens and is a SNFPA fen indicator species. There are three populations known from the AA/JM Wildernesses.

Yosemite mousetail (*Ivesia unguiculata*): This species is found in meadows and seeps on the west slope of the Sierra Nevada. There is one population known from a meadow on the border of the study area.

Seep kobresia (*Kobresia bellardii*): This species is one of the Rocky Mountain disjuncts in Convict Basin and there is a second California population on the Humboldt Toiyabe N.F. It grows in carbonate soils or mesic boulder and rock fields.

Short-fruited willow (*Salix brachycarpa*): This dwarf willow is another of the Rocky Mountain disjuncts in the Convict Basin. There is one other population on the Inyo N.F. outside of the AA/JM Wildernesses. It is found throughout the western US at high elevations on carbonate substrate.

Dwarf bulrush (*Scirpus pumilis*): Another of the Rocky Mountain disjuncts in the Convict Basin, this species grows in alpine dwarf scrub on carbonate soils. It also grows in the Cottonwood Creek drainage in the White Mountains on the Inyo N.F.

Prairie wedge grass (*Sphenopholis obtusata*): This perennial grows in meadows and seeps from 1,000'-6,500' elevations. There is one occurrence in the JM Wilderness and others in the Sierra Nevada and Peninsula Ranges in California.

Table 3.34 Meadows with moderate to severe stream impacts or changes in hydrologic function within the elevational ranges (potential habitat) of the sensitive riparian species

Geographic/Analysis Unit	Name	Stream Impacts	Hydrologic Function Changes	Reported commercial pack stock use (2001-2003)
AAEA/MIN	Johnston Meadow	Severe	Moderate	High of 20 stock nights (SN)
AAEA/CCD	Crater Meadow	Severe	Slight	No current use

BIHU/GLA	Hutchinson Meadow	Moderate	Moderate	High of 290 SN
JMSW/BIM	Big Maxson	Severe	Moderate	Unknown current use

Weeds

Because most of the wilderness is presently weed free, preventing introduction and spread of non-native species is of great importance. There are no known Federal or State designated Noxious Weeds in the AA/JM, or at pack station facilities. Several species of non-native plants,

some highly invasive wildland weeds, do exist inside or at the edges of the wilderness boundaries. A table in the project record lists known non-native plants present in the Wildernesses, at the pack stations, corrals, pastures, or near the trailheads.

Standards and Guidelines for weed management are in the SNFPA ROD (2004), including direction to encourage use of weed free hay and straw, develop a program for certification of hay and straw, and phase in the program as certified weed free forage becomes available. A Memorandum of Understanding among California agencies is currently in place to develop a weed free forage program. At present, the very limited availability of certified weed free hay and straw does not support requiring it, but it is expected that the requirement will be in place before the end of the permit term.

Because these non-native species differ in their degree of invasiveness and competitiveness, each weed warrants different levels of concern (Sierra Nevada Forest Plan Amendment, 2001).

Cheatgrass and red brome (*Bromus tectorum*, *B. madritensis* var. *rubens*) are the most invasive of the weeds, can invade intact native vegetation, and may shorten fire intervals in shrublands (Allen, 2004). The bromes are common from the base of the eastern escarpment of the Sierra up to at least 9,000 feet, particularly in recently burned or disturbed areas, and around the reservoirs on the west side. **Zorro fescue** (*Vulpia myuros*) is another annual grass, but is not known to be as invasive as the bromes.

Bull thistle (*Cirsium vulgare*), although not as highly invasive as other noxious thistles, can pose problems in native ecosystems and is found as high as 7,000 feet elevation, often in disturbed meadows (Bossard, et al., 2000). It was present in Devil's Postpile, but a removal program has been underway for several years.

Russian thistle (*Salsola tragus*), or tumbleweed, is common on the eastern slope of the Sierra Nevada, but is mostly limited to already disturbed areas.

Several weedy members of the mustard family are known from pack stations and trailheads, including **tansy mustard** (*Descurainia sophia*), **tumble mustard** (*Sisymbrium altissimum*), **hoary cress** (*Cardaria* spp.) and **penny-cress** (*Thlaspi arvense*). Tansy mustard and tumble mustard are moderately invasive and probably limited to disturbed areas (CalIPC, 2005). Penny-cress is not known to be invasive and only one occurrence is known. Hoary cress forms dense infestations that exclude native vegetation, with deep root systems that compete with native plants for moisture and nutrients. Hoary cress is extremely difficult to control once established (CDFA, 2005). It occurs on both sides of the Sierra outside of wilderness.

There are also several weedy species from the pea family, including **white sweet clover** (*Melilotus alba*), **yellow sweet clover** (*M. indica*), and **birds foot trefoil** (*Lotus corniculatus*) occurring in or near the AA/JM in riparian habitat. None of these species are considered to be very invasive.

Dandelion (*Taraxacum officinale*) is present in meadows in and near the wilderness, especially where there has been heavy grazing in the past by livestock and packstock. Its ability to invade undisturbed sites is unknown, but it is difficult to eradicate it.

Other species not known to be very invasive or disruptive to native plant communities include **mullein** (*Verbascum thapsus*), **foxglove** (*Digitalis* sp.), **mallow** (*Malva neglecta*), **knotweed** (*Polygonum arenastrum*), **dock** (*Rumex crispus*), and **bassia** (*Bassia hyssopifolia*). Mullein has been reported in several locations near the wilderness boundaries on both sides of the Sierra,

bassia from only one location, although it may be more common. Foxglove is a garden escapee near one of the pack stations. Knotweed and mallow are found at several pack stations, but appear to be limited to parking lots or other disturbed, somewhat compacted areas. Dock is a weed of meadows, but was found at only one location and is of low concern in wildlands (CalIPC, 2005).

Spotted knapweed (*Centaurea maculosa*) a very invasive and difficult to control weed has been eradicated from a road near the Dinkey Lakes Wilderness (J. Clines, Sierra National Forest Botanist, pers. comm., 2005)

Geographic Unit Scale

Ansel Adams East

Vegetation

The northern part of Ansel Adams East is entirely on the eastern slope of the Sierra, with a high percentage of subalpine, alpine, and rocky peaks and ridges. The lower elevation vegetation is pinyon pine and sagebrush, grading into montane Jeffrey pine and lodgepole, with sparse whitebark and lodgepole in the subalpine zone. The southern section of AA East is the headwaters of the Middle Fork of the San Joaquin River and the vegetation is more characteristic of the west side mixed conifer forest, dominated by red fir, Jeffrey pine, and lodgepole with montane chaparral. Willows and aspen are common riparian tree species along with lodgepole pine.

Thousand Island Lake in the Ansel Adams East Geographic Unit, elevation 9830 feet

Approximately 11% (19 sites) of the campsites historically used by the packers are above the 10,000 foot fire closure.

Grazing Resources

Table 3.37, the *Geographic Unit Meadow Table* contains a summary of the recorded pack station grazing nights at meadows throughout the geographic area. Table 3.36 at the end of the chapter has a summary of the reported commercial pack stock use and meadow conditions by geographic unit. Many of the meadows and riparian systems in the Ansel Adams East Geographic Area have an east to northeast aspect, or exposure. This aspect combines with high elevations and abundant snowfall to result in wet meadow conditions throughout the summer at many locations.

Approximately 65% of the areas with reported grazing were not used all three years (2001-2003), most only once in that period. Six of the nine analysis units had reported use by two pack stations and the three others were used by one pack station.

In recent years, there have been significant efforts to implement sound grazing management practices in the Upper Rush Creek and Rush Creek Analysis Units. These include identifying and implementing carrying capacity estimates, range readiness criteria, and rotational grazing systems (Inyo National Forest Files, various dates).

The majority of the key area meadows assessed in the Ansel Adams East Geographic Area (93%), have localized vegetative alteration over less than one-third of the area or little to no observed vegetative alteration (43% and 50% respectively). Seven percent of the meadows assessed have well defined vegetative changes away from the potential natural community over more than one-third of the meadow.

The following discussion describes some of the resource conditions and site-specific grazing activities in the Ansel Adams East Geographic Unit:

- Alger Lakes Meadows are relatively large, with substantial forage in upland sites and few resource issues are present. In 1982, soil and vegetation condition trends were stable or upward, and in a 1990 report (USDA Forest Service, 1990) it was reported in excellent vegetative condition.
- Gem Pass Meadow was found to have a downward soil condition trend and stable vegetation condition trend in a 1982 evaluation.
- Spooky Meadows is relatively small and resource conditions include areas of trampled and unstable streambanks. In 1982, soil and vegetation condition trends were stable or upward and in 1990 it was determined to be in good vegetative condition (USDA Forest Service, Inyo National Forest, 1982)
- New grazing use patterns are becoming established in the Rodgers Lakes area. Existing conditions include sod fragmentation on a new access trail and soil displacement and sod fragmentation of meadow areas with saturated soils.
- Davis Lakes and Marie Lakes meadows were found to have stable or upward soil and vegetation condition trends in a 1982 evaluation.
- Permanent transects were established to monitor vegetation trend at Thousand Island Delta and Garnet Meadow (USDA Forest Service, 2004) and the baseline vegetation and soil score was moderate condition in 2003.
- Although the Cabin Lake area has not been recently used for commercial packstock activity, there are changes in hydrological function and plant species composition associated with the

access trail to Cabin Lake, along the trail through the wet meadow at Cabin Lake meadows, and at the meadow used for grazing along Shadow Creek. A permanent transect was established to monitor vegetation trend at Shadow Creek Meadow (USDA Forest Service, 2004) and the baseline vegetation and soil score was moderate condition in 2003.

- The only recent documented grazing use in the River High AU is in the meadows near and to the south of Badger Lake. These small montane meadows are currently used at light to moderate levels by pack stock. There is altered vegetative species associated with several active headcuts in the stream and trampled spring areas in these meadows.
- Moderate pack stock use is occurring at some locations such as Ashley Lake and Anona Lake. There are areas of trampled and fragmented sod especially near campsites and at the outlets of these lakes. There are localized trailing impacts in the meadows on the south side of Holcomb Lake, trampling impacts near the campsite at Davis Lake, the meadows above Trinity Lake, and stream channel instability with associated vegetation composition changes at upper Johnston Meadow. A permanent transect was established to monitor vegetation trend at Johnston Meadow (USDA Forest Service, 2004) and the baseline vegetation score was low condition in 2000.
- Meadows in the Crater and Deer Creek area are lightly used. Deer Creek Meadows and Crater Meadows, remain too wet to be range ready throughout the summer. Only portions of the meadows at Middle Deer Creek and Summit Meadow reach range readiness.

Fens

Fourteen meadows with fens or fen characteristics were identified among the fifty meadows visited in this geographic unit. One area with fen characteristics was bisected by a trail.

- Rush Creek AU: The spring area in Upper Spooky has fen characteristics and severe trampling impacts. At Lower Alger/Alger Terraces, there are moderate spring impacts, but the fen has only slight trampling and appears to be in good condition.
- Thousand Island AU: Incision may be lowering the water table at Garnet, where part of the meadow has fen characteristics.
- Minaret AU: The Emily Lake Trail goes through an area with fen characteristics that shows deep trampling. The spring with fen characteristics at Gladys/Rosalie has slight impacts.
- River High AU: The spring portion of Badger Meadow with fen characteristics is in a part of the meadow that appeared to receive little use and is in good condition.
- Crater Creek AU – The three meadows with fens in the Deer Creek drainage (ccd15, ccd18a, ccd19a) have reported grazing and are at risk because of moderate to severe spring impacts. In Crater Creek drainage, at ccd5b, there is damage to the fen from access from the PCT to a campsite, possibly used mostly by private packstock, and ccd4 has severe spring impacts. At Crater Meadow, the fen is in good condition, although the stream is in a downward trend and at Upper Crater Meadow, moderate spring impacts were noted.

Rare Plants

There are 11 populations of sensitive and watch list plants known from in or near this Geographic Unit, 3 are in remote areas away from trails, 4 are on or near trails, and 4 are in meadows. There are a total of 52 meadows with habitat for riparian dependent species, 6 of which have moderate to severe stream or other hydrologic impacts. There has been no recent

reported commercial packstock use in the northern part of this geographic unit (Glacier Canyon, Gibbs, Bloody AUs).

- Glacier Canyon AU: There is a population of Congdon's sedge near the Glacier Canyon Trail in talus.
- Gibbs AU: There is a reported population of Tahoe draba in the Mt. Gibbs area, not accessible by trail, that may be in Yosemite NP. There is potential habitat, if not an actual population, in the Gibbs AU.
- Bloody AU: There are two populations of Tioga Pass sedge in small meadows, one along a lakeshore away from the main trail and another near Mono Pass away from the trail.
- Parker AU: There is a population of Tioga Pass sedge near the Alger Lakes Trail, but it is north of Alger Lakers where there is no reported or observed recent commercial packstock use.
- Northern AA East: There is potential habitat for the sensitive plant Tioga Pass sedge in the upper basins at 14 meadows. There are some lakeshore trampling impacts of this habitat at Marie and Rogers Lakes Meadows.
- Upper Rush AU: There are two populations of fell-fields claytonia, one near Mount Davis and another near Mount Lyell, most likely away from trails, but their exact location is unknown.
- Crater Creek AU: There are two populations of subalpine fireweed at ccd4 and ccd5b, neither meadow with any noted hydrologic function problems. There is a population of short-leaved hulsea along the Fish Creek Trail in the Rainbow Fire area.
- River High AU: There is a population of Pinzl's rock cress just outside the wilderness along San Joaquin Ridge and potential habitat in the wilderness along the ridge. The San Joaquin Peak use trail goes through this habitat and continues over the ridge.
- Southern AA East: Approximately 38 of the lower elevation meadows in the San Joaquin drainage are potential habitat for at least one of the west side sensitive riparian species (subalpine fireweed, Bolander's clover, veined water lichen, and mosses Bolander's candle moss and *Meesia* spp). Four of these meadows have reported use. There are degraded hydrologic or stream conditions at Johnston Meadow (pasture), Crater Meadow, JMT/Shadow Creek Junction Meadow, and Summit Meadow that put the potential habitat for these species at risk. At Crater Meadow, the degraded condition is apparently due to trail impacts rather than grazing impacts.
- There is potential habitat for short-leaved hulsea in Crater Creek, River Corridor, and Minarets AUs.

Weeds

Known locations of non-native species in AA East are as follows:

- Rush AU: Cheatgrass is present along the lower slopes of the main Rush Creek Trail. There are many vectors for weeds along this trail, including tram tracks for use by the hydroelectric facilities, packstock and hikers. Six species of non-native plants are growing in the vicinity of Frontier Pack Station and Silver Lake Resort: cheatgrass, Russian thistle, tansy mustard, mallow, knotweed, and mullein. Dandelions are present in Rodeo pasture used by Frontier Pack Station.
- Crater Creek AU: Four species of non-native plants are growing in the vicinity of Reds Meadow Pack Station and resort: cheatgrass, mallow, yellow sweet clover, and penny-cress.

Bull thistle occurs along the trail to Rainbow Falls and inside the Devils Postpile National Monument, but there is a removal program that has been going on for several years and most has been removed.

Ansel Adams West

Vegetation

The lower elevations of this area are dominated by mixed conifer forest with patches of montane chaparral. Jeffrey pine, red fir, and lodgepole are the dominant trees. In the subalpine zone, there is whitebark pine, lodgepole, and mountain hemlock.

There were no campsites historically used by the packers above the 10,000 foot elevational closure in this geographic unit.

Fernandez Lake, Lillian AU in the Ansel Adams West Geographic Unit

Grazing Resources

Table 3.37, the *Geographic Unit Meadow Table* contains a summary of the recorded pack station grazing nights at meadows throughout the geographic area. Table 3.36 at the end of the chapter has a summary of the reported commercial pack stock use and meadow conditions by geographic unit. None of the meadows in this geographic unit were used all three years (2001-2003 reports).

Three of the seventeen analysis units in Ansel Adams West had grazing reported by two pack stations; four had only one pack station with grazing use.

There are multiple trips with grazing by commercial pack stock during each trip during the summer season at several sites, including Sadler Lake, and Joe Crane Lake. Fernandez Creek Junction is used by private pack stock.

The current condition of the grazing resource in the geographic area is likely the result of historic production livestock activity (see photo below) (2200 Files, Sierra National Forest, various dates). Permitted use by cattle on the Jackass Common Allotment, mostly within the western Ansel Adams Wilderness area and some nearby locations in the John Muir Wilderness, reached a high of 5,000 animal months (approximately 150,000 stock nights) in 1921. Cattle grazing was reduced gradually between 1921 and the 1960s, and was reduced or eliminated throughout much of this geographic area in the early 1990s (Sierra N.F., 2200 files, various dates). Currently the permitted grazing use by cattle is 1,549 animal months (46,470 stock nights) with most of this use occurring in the Ansel Adams West geographic area and some of this use occurring in those portions of the Dinkey Lakes and John Muir Wilderness areas adjacent to the Ansel Adams Wilderness area (Wilderness Plan FEIS, Chapter 3, pages 26-33).

Fens

Six meadows with fens or fen characteristics were identified among the thirty meadows visited in this geographic unit, with conditions as follows:

- Sadler AU: The spring area with fen characteristics at McClure to Sadler Meadow is heavily trampled and the hydrologic function change is rated severe, putting it at risk.
- Lake Catherine AU: About 30% of Stevenson Meadow is a fen, with no reported adverse impacts.
- Cargyle AU: There are fens in four meadows with no recent reported use (Between Stairway and Cargyle, Cargyle North, Lower East Fork, and Middle East Fork Meadows) and in all but Lower East Fork Meadow, which has no visible impacts, there are moderate spring and hydrologic function impacts (see Table 3.34).

Rare Plants

There are 22 populations of sensitive and watch list plants known from in or near this Geographic Unit: 3 are in remote locations, 3 are in meadows, and 16 are near trails. One of these trails (Timber Creek) has moderate resource risks/impacts. In this geographic unit, approximately 76% of the meadows (about 209 meadows) are within the elevational range of at least one of the west side riparian sensitive species. Only seven of these meadows have reported commercial packstock use, but many were or still are used for cattle grazing and six have moderate to severe stream impacts or changes to hydrologic function.

- Fuller Buttes AU: The French Trail goes through a population of Mono Hot Springs evening primrose. Maintenance of this trail is currently done yearly by a volunteer group (M. Ketcher, Sierra National Forest Trails Coordinator, Pers. Comm., 2004). There is a population of Yosemite lewisia in this AU, but it is not accessible by trails.
- Cassidy AU: There is a population of Yosemite lewisia on the wilderness boundary away from any trails or grazing areas.

- Lower Mono Creek AU: The Mono Hot Springs Cutoff Trail goes through a population of Mono Hot Springs evening primrose. The trail has very low use, mostly from hikers.
- Hot Springs AU: The Mono Hot Springs Trail bisects a population of Mono Hot Springs evening primrose. Stock use on this trail is mostly limited to Forest Service stock accessing a pasture.
- Staniford AU: There are two populations of Kettle dome buckwheat near the Lillian Lake Loop Trail and two on the Walton Trail, one inside and one outside the wilderness.
- Jackass AU: There are populations of Kettle dome buckwheat outside the wilderness near the Norris and Fernandez Trailheads that access the Ansel Adams.
- Lake Catherine AU: There is habitat for all the west side riparian sensitive species at Stevenson and Hemlock Crossing Meadows, where commercial packstock use occurs, but which have only slight meadow hydrologic function problems. There are two populations of Kettle Dome buckwheat near the Stevenson Trail.
- Lillian AU: There is a population of the Congdon's sedge on a ridge that is not accessible to pack stock and a population of Kettle Dome buckwheat along the Timber Creek Trail. There is potential habitat for the sensitive Bolander's candle moss in this AU, but there is no recently reported commercial pack stock grazing in the meadows within its range. There is no longer cattle grazing in these meadows, but there are remaining impacts from previous use. Fernandez Junction Meadow has severe changes to hydrologic function and stream function was rated FAR with no apparent trend.
- Cargyle AU: Round-leaved sundew, watch list plant and fen indicator species, is present in Cargyle Meadow, Cargyle North, and Upper East Fork Meadow where there is no current reported use, but there are some moderate spring impacts. There is potential habitat for the west side riparian sensitive plants in most of the meadows in this unit, but there is very little current use and conditions are generally good. An exception is the meadow between Stairway and Cargyle, where there is moderate hydrologic function change, but no reported use.
- Triple Divide AU: There is potential habitat for Bolander's candle moss, but there is no recently reported commercial pack stock grazing in the meadows within its range. There is no longer cattle grazing in these meadows, but there are remaining impacts.
- Sadler AU: There is potential habitat for Bolander's candle moss at the Joe Crane Trail Junction meadow where there are moderate to severe stream impacts degrading the habitat. Commercial packstock grazing use is unknown at this meadow.
- Cora AU: Although there is potential habitat for subalpine fireweed, Bolander's clover, Bolander's candle moss, and the rare moonworts, no sensitive plants were found at Detachment, Knoblock, or Chetwood in an intensive 2004 survey. The habitat is degraded by historic grazing impacts and there is very little current commercial packstock use. There are populations of Kettle Dome buckwheat near the Stevenson Trail and the Chetwood Cabin Trail, and two near the Isberg Trail, one outside of wilderness.
- Bridge Crossing AU: There is habitat for all the west side riparian sensitive species, but no reported use in this unit.
- Arch AU: Most (24 of 26) of the meadows in this analysis unit are potential habitat for the West Side riparian sensitive plant species, but there is no reported commercial pack stock use.
- There is potential habitat for Congdon's lewisia in the San Joaquin watersheds on rocky outcrops.

Weeds

There are weed populations, including cheatgrass, mullein, and bull thistle, at Edison Lake near the ferry landing and along the trail on the north side of the lake.

Non-native species were found at all of the pack stations that use this area (see *Undesirable plants present in the AA/JM, at pack station facilities, or trailheads table* in project record).

Fish Creek/Convict/McGee

Vegetation

This geographic unit includes the Fish Creek drainage on the west slope and Convict and McGee drainages on the east side.

Fish Creek is on the west side of the sierra crest and reaches its lowest elevation at the western end, at approximately 5500 feet. Montane chaparral communities, including bush chinquapin and greenleaf manzanita, occupy much of the lower elevation area near the bottom of the Fish Creek drainage. As the elevation increases to over 11,000 feet in the eastern and southern portions of the analysis area, the vegetation communities change to montane and subalpine forests, and finally to sparsely vegetated or barren rocky areas at the highest elevations.

The drainages on the east side of the Sierra are steep canyons with soils influenced by metamorphic rocks, limestone being of particular interest. The lower elevations are in sagebrush scrub with cottonwood and aspen in riparian areas. The montane vegetation is Jeffrey pine and lodgepole, grading in to the subalpine whitebark pine and lodgepole.

The vegetation of the Convict Basin, in particular the Convict Canyon and Mildred Lake area, is notable because there are several plant species whose populations there are widely disjunct from the rest of their range (Major and Bamberg, 1963). Three of these are watch list plants that are endemic to the limestone/marble derived soil.

Mildred Lake Meadow in the Fish Creek/Convict/McGee Geographic Unit

Approximately 34% (117 sites) of the campsites historically used by the packers are above the 10,000 foot campfire closure in this geographic unit.

Grazing Resources

Table 3.37, the *Geographic Unit Meadow Table* contains a summary of the recorded pack station grazing nights at meadows throughout the geographic area. Table 3.36 at the end of the chapter has a summary of the reported commercial pack stock use and meadow conditions by geographic unit. Meadows with little to no alteration of vegetative composition are common throughout this geographic area, occurring at 59% of the key areas assessed. Localized alteration of vegetative composition, over less than one-third of the area, is observed at 35% of the key area meadows assessed. Locations with a well-defined altered vegetative species composition over more than one-third of the meadow, are observed at 6% of the key areas assessed. The western portion of this geographic area, the Fish Creek watershed, receives higher use and more overnight stock use than the eastern portion.

Repeated overnight trips by commercial pack stock with associated stock holding and grazing use occurs throughout the summer each year at Grassy Lake, Jackson Meadow, Long Canyon, in the Purple Lake area, between Sheep Camp and Lee Lake, Horse Heaven, Third Crossing, and Island Crossing.

In the Convict AU, Genevieve is the only meadow with reported grazing; 14 reported stock nights in 2002 by MLPO, but no reported grazing in 2000 or 2001. In this AU, little or no alteration of vegetative composition is documented. In upper Convict Basin there is some evidence of historic grazing and vegetative recovery, such as below the mine at upper Mildred Lake Meadows, where historic grazing use was likely high by stock in support of the mining operations. Since the mid-1980s, use by stock has been limited in the Convict Basin area due to a lack of access. Within the last few years Convict Basin has been accessed by pack stock entering from Laurel Canyon.

In the Cascade Valley AU, the meadows in Cascade Valley near the confluence of Fish Creek with Minnow and Purple Creek were closed to grazing in 1988 due to concerns with resource condition. Existing conditions such as trailing, dusting areas, soil compaction, excessive sediment deposition, stream bank instability, channel incisement, lowered water tables, and, alteration and loss of riparian vegetation is documented at several areas including: the meadow areas along the trail to Lee and Cecil Lakes, the tarn pond below Lee Lake, Purple Meadow, Purple Bench, Ram Tarn meadow along the trail above Purple Meadow, Jackson Meadow, and Grassy Meadow. In some locations there is a shift toward early-seral plants associated with alteration of the soil and water process, such as at Tully Lake meadow in Upper Fish Creek, the spring near Tarn Lake, Horse Heaven, lower Long Canyon Meadow, Island Crossing (Fox) Meadow, and Second Crossing Meadow. In a 1987 study of differences in ecological status between 1963 and 1986 (USDA Forest Service, 1987), Long Canyon Meadow had improved from good to excellent in that time, and Grassy Meadow had maintained fair condition. A 1990 study (USDA Forest Service, 1990) found that Minnow Creek Meadow (Cascade Meadows) was in fair vegetation condition, while Purple and Horse Heaven were in good condition.

In the McGee Creek drainage, White Meadow (Martin's) was found to be in poor condition in a 1990 study (USDA Forest Service, 1990) due to unpalatable forage species, and Red Meadow (between Martin's and Big McGee Lake) was in good vegetative condition.

Drift fences at Purple Lake, Horse Heaven, Tully Hole, and east of McGee Pass allow wranglers to release stock at various camping locations throughout this area, allowing grazing stock to roam freely with uncontrolled access to locations within and between the associated meadows.

The Fish Creek/Cascade Valley and Minnow Creek areas have a high level of historic use, including sheep, cattle, and pack stock supporting mining operations near Jackson Meadow, and traveling recreational pack stock parties. The drift fence near Coyote Lake allows wranglers to release stock in the Silver Creek drainage, allowing grazing stock to roam freely with uncontrolled access to locations within and between the associated meadows and the pass above Coyote Lake.

Fens

Fourteen meadows with fens or fen characteristics were identified among the fifty-six meadows visited in this geographic unit, with conditions as follows:

- McGee AU: The fens at Grass Lake and Steelhead appear undisturbed and there is no recent reported grazing use.
- Convict AU: There are two fens on benches above Mildred Lake Meadow. The meadow itself is not a fen by soils definition, but has many plant species characteristic of Rocky Mountains fens, including some watch list species. This area has not been used by packstock for about 20 years and there are no visible negative impacts from the historic mining use and structures.
- Purple Bench AU: There are meadows with fen characteristics near High Camp and Ram Camp in the Purple Meadow area, with only slight impacts to springs or hydrologic function in these areas despite high use at Purple Meadow. Although not in the saturated area with fen characteristics, there is soil compaction and sod fragmentation at Purple Bench Meadow.
- Upper Fish Creek AU: There are only slight impacts to the Red Slate and Tully Lake Meadows that have some fen characteristics. At Tully Hole, however, moderate hydrologic changes and moderate spring impacts may have degraded the area with fen characteristics.
- Cascade Valley AU: Second Crossing Meadow is almost entirely fen, most of it never reaching range readiness, and there are headcuts and other trailing impacts near the bottom of the meadow that led to its closure to pack stock grazing in 2001. At Third Crossing, moderate hydrologic function changes have taken place that may lead to degradation of the fen.
- Silver Divide AU: At Peter Pande tarn, a meadow with fen characteristics, there is no reported use, although there is evidence of recent use and slight alteration of the hydrologic function. There is a fen at Iva Belle Hot Springs where overnight stays by pack stock are not permitted.
- Margaret AU: At the Coyote grazing area, there is heavy trampling impact that has only slightly affected the hydrologic function of the meadow and there are moderate spring impacts that may be affecting the function of the area with fen characteristics. Convict AU: There are fens on benches above Mildred Lake meadow. The meadow itself is not a fen, but has many plant species characteristic of fens in the Rocky Mountains, including some watch list species. The meadow is in very good condition and has no current grazing.

Rare Plants

There are six populations of sensitive and watch list plants known in or near this Geographic Unit; four are in meadows where there is no recent packstock use, one is near a trail open to all uses, and one is on a use trail just outside the wilderness with little current use. There are 20 meadows with potential habitat for sensitive species, 4 with some resource concerns.

- Cascade Valley AU: There is potential habitat for the west side riparian sensitive species in the Fish Creek drainage and there are three meadows, two of which are currently closed, with moderate to severe impacts that may negatively affect this habitat. There is a small population of short-leaved hulsea just off the main trail near Island Crossing.
- Purple AU: Subalpine fireweed occurs along the main trail near Purple Bench.
- Silver Divide AU: There is potential habitat for the Bolander's candle moss in Long Canyon, where there is slight streambank trampling.
- Convict AU: Mingan moonwort occurs in the meadow area near Mildred Lake in the Convict Basin. Watch list plants seep kobresia, short-fruited willow, and dwarf bulrush are also present in this meadow, in populations very disjunct from the rest of their distribution. The meadow has not been used for grazing recently and gets very little use.
- McGee AU: There is a population of Inyo beardtongue outside the Wilderness near the McGee pack station.
- There is potential habitat for Congdon's lewisia in the San Joaquin watershed on rocky outcrops.

Weeds

There is cheatgrass in the sagebrush scrub around Convict Lake, outside the wilderness. The trail from Convict Lake accessing the wilderness is currently outside of the packers' use area.

There are patches of cheatgrass along the Fish Creek Trail on the slope north of Island Crossing bridge and near Iva Belle Hot Springs. These areas are heavily used by both hikers and pack stock. Red's Pack Station has several species of non-native plants, including cheatgrass. In McGee Canyon, cheatgrass is present at the pack station and along the main trail accessing the canyon.

Mono Creek/Rock Creek

Vegetation

The Mono Creek drainage has montane mixed conifer forest at the low elevations grading in to subalpine and alpine environments at the higher elevations. The north facing side canyons, in particular Second and Third Recesses, have denser vegetation and more moisture than the south facing ones like Laurel and Hopkins (see photos).

Photo on left Third Recesses; Photo on right Laurel

The Rock Creek Trailhead is in the subalpine zone and is a very popular day hiking setting. The low riparian vegetation along the stream and lakeshores has been trampled by anglers and hikers in many locations.

Approximately 29% (104 sites) of the campsites historically used by the packers are above the 10,000 foot fire closure.

Grazing Resources

Table 3.37, the *Geographic Unit Meadow Table* contains a summary of the recorded pack station grazing nights at meadows throughout the geographic area. Table 3.36 at the end of the chapter has a summary of the reported commercial pack stock use and meadow conditions by geographic unit. Although the Hilton Lakes Basin receives intensive stock use, there is little overnight stock holding or actual grazing occurring the area.

At the outlet of Dorothy Lake in the Tamarack Analysis Unit, much of the perennial grass portion, approximately half of the meadow area, has recently died and the remnant sod is being lost to wind erosion in the meadow. There are also areas of fragmented sod, hummocks, and bare areas within this meadow. There has been no recent reported packstock grazing in this unit, and the cause of the die-off is unknown. The interdisciplinary team identified historical water diversions, some still functioning that are likely related to historical sheep operations in this meadow. Elsewhere in the Tamarack AU, accessible portions of the meadows reach range readiness and there is little change from high-seral vegetation except at localized trail stream crossings.

In the Morgan AU, there are a series of small meadows (none larger than ¼ acre) and a constructed pond with associated riparian area along the creek above Morgan Lakes. The riparian vegetation in these areas is in high-seral condition with high vigor and high productivity. Historical use was likely high in support of the mining operations. Current pack stock related use is relatively low and little actual grazing use occurs.

In the Fourth Recess AU, the meadows along Mono Creek below the junction with the Golden Lake Trail are generally wet, with trampling related impacts along the trail shortcut to Mono Pass. No grazing appears to be currently occurring in these meadow areas. Most of the

meadows downstream of that junction, including at Mono Rock, the confluence with Hopkins Creek and at Fourth Recess Creek, are used for grazing as stock roam freely throughout the Mono Creek drainage. The most heavily and repeatedly used meadow, Hopkins Bench Camp, is located adjacent to an often-used pack stock campsite along Mono Creek. Indicators of repeated recent use include bare areas, soil compaction, and changes in plant species, sod fragmentation, and headcuts. This meadow appears to be in early to mid-seral condition, with low plant vigor and an increase in forbs.

In the Mono Creek drainage, the 1987 study (USDA Forest Service, 1987) determined that 2nd-3rd Recess was in fair condition and Fish Camp was in good condition, both sites in the same ecological status in 1963 and 1982.

Pioneer Basin has been closed to grazing since 1988 due to concerns with resource condition. A 1987 study (USDA Forest Service, 1987) showed that ecological status had declined from good to fair between 1963 and 1986. The sub-alpine meadows in the upper basin are fragile with thin, highly erosive sod, and poor soil development. Trails are located in the streamside meadow corridors resulting in trail incisement, erosion, and associated localized changes toward low-seral vegetative species. In the lower portion of the basin, the upland moist or dry meadow areas surrounding Mudd Lake and extending to the east and south do become dry enough to support stock. There are some old headcuts and gullies in these meadows. There are visible impacts to Camp Meadow, but the meadow is recovering.

In the Hopkins AU, areas with higher levels of current use (such as at Lower Hopkins Lake) exhibit indicators of repeated disturbance by pack stock including fragmented sod in wetter portions of the meadow, wallowing sites, or bare areas within the mesic portions of the meadow, incised trails, and multiple trails. There is active erosion, including headcuts on user define trails on the west side of Lower Hopkins Lake. Vegetation is late seral condition, with some local bare areas, low vigor, and low ground cover.

The Volcanic AU contains two large meadows over 30 acres, and neither has reported grazing. There are very few soil or hydrologic impacts.

The Graveyard area was part of the Jackass Common Allotment on the Sierra N.F. and has been heavily used by cattle as described in the Allotment Management Plan (USDA Forest Service, 1961). One of the early riders thought the Graveyard portion of the Jackass Community Allotment was “heavily overgrazed in the early days by early season use when over 1200 head of cattle were concentrated in a small area waiting for snow to leave the upper reaches” (USDA Forest Service, 1961). Trend monitoring transects were set up in several meadows in the Mono allotment, including Graveyard, Lower Graveyard, and Twin Meadows. Baseline information gave vegetation scores of low to Graveyard Meadow and moderate to the other two.

An active cattle allotment extends through the entire Graveyard watershed; however, the current use by cattle does not appear to occur often above the lowermost and largest Graveyard Meadow and no use by cattle currently occurs at Quail Meadow. There were no substantial negative current stock related impacts noted at Kip Camp. The presence of standing dead lodgepole pine in saturated soils and debris deposits in the creek at Kip Camp do indicate there may have been a recent historical change in hydrologic conditions.

Fens

Eighteen meadows with fens or fen characteristics were identified among the forty-four meadows visited in this geographic unit.

- Little Lakes Valley AU: There is no reported grazing use in the five meadows with fens or fen characteristics in this analysis unit, Marsh, N. of Long Lake, Gem, Heart, and Above Long Lake Meadows. Most of the impacts noted were from hikers and fishermen. At Marsh Meadow, one of the fen areas was dried out when spring water was channeled, but the cause of the channeling is unknown.
- Fourth Recess AU: North of Mono Rock Meadow with fen characteristics has moderate spring impacts that may negatively affect the fen. Third Recess along Creek Meadow has fen characteristics and there is some spring trampling damage from the trail.
- Volcanic AU: There is no reported use of the large Volcanic Knob Meadow that has scattered areas with fen characteristics and is in good condition.
- Graveyard AU: There is a fen in Goodale Pass Meadow with headcuts in the spring channel. There are several other fens lower in the drainage, most in steeply sloping meadows that receive little current use from either cattle or packstock. There is an active cattle allotment in the drainage and cattle use is the source of most impacts. There is a fen at Feather Lake in good condition and there is no recent use reported or evident.
- Hilton AU: There is a fen at the upper end of Turk meadow, and there is compaction and vegetation composition change in the lower end. The outlet of Davis Lake and East of Davis meadows have fen characteristics, but no reported recent use.
- Pioneer AU: Camp Meadow has fen characteristics and not been grazed since the closure in 1988, but there are moderate changes to hydrologic function due to the incised trail.
- Second Recess AU: Second Recess Meadow with fen characteristics is in good condition and light use has been reported, although the access trail is not easily passable by stock.
- Bear AU: There is a meadow with fen characteristics near Kip Camp where there are some impacts to the springs. There has been only light grazing reported recently.

Rare Plants

There are eight populations of rare plants known from in or near this Geographic Unit, two are in meadows open to grazing, one is in a pasture, four are near trails open to all uses, and one is on a trail used only by hikers. There are 17 meadows with habitat for sensitive species:

- Hilton AU: Blandlow's feather moss is present in the upper, very wet, portion of Turk meadow under the willows and in a meadow near the Hilton Lakes Trail. There is currently very light grazing at Turk Meadow (seven reported stock nights in three years), with some soil compaction and vegetation composition change in the lower portion of the meadow. There is a population of subalpine fireweed near the outlet of Lake 3. Inyo beardtongue grows along the Hilton Lake Trail just outside the wilderness boundary.
- Fourth Recess AU: The potential habitat for Bolander's candle moss in Bench Camp meadow (for8) may be negatively affected by the Functional at Risk stream conditions and moderate changes in hydrologic condition. There is a population of Congdon's sedge along a hiker trail above Golden Lake in talus.
- Silver Peak AU: The streambank potential habitat of Bolander's candle moss in Pocket Meadow has moderate impacts.

- Graveyard AU: There is a population of Mono Hot Springs evening primrose near Quail Meadow and the intersection of the Mono Creek (Edison) Trail and the PCT. The trail is the main access from High Sierra Pack Station in to Mono Creek and there is currently packstock grazing at Quail Meadow. The sensitive plant habitat in Graveyard Meadow has been degraded by cattle use. There is potential habitat for the west side sensitive riparian species at Quail Meadow, where there are slight hydrologic changes and moderate spring impacts.
- Bear AU: There is habitat for the west side sensitive riparian species at nine meadows, including Kip Camp. There were no apparent negative impacts at Kip Camp, where there has been no recent reported use, although there was heavy use in the past. The Bear Creek and Bear Creek Cutoff Trails bisect a population of Mono Hot Springs evening primrose and there is a second population along Bear Creek Trail to the east. These trails have moderate use by commercial pack stock, partly for “dead heading” stock between pack stations, and have no reported resource problems.
- There is potential habitat for Congdon’s lewisia in the San Joaquin watershed on rocky outcrops.

Weeds

There are several species of non-native plants at Edison Lake and at the Hilton Lake Trail head. Non-native species were found at Rock Creek, High Sierra, D&F, and Pine Creek Pack Stations, the outfits that use this geographic unit (see *Undesirable plants present in the AA/JM, at pack station facilities, or trailheads table in the project record*).

Bishop/Humphreys

Vegetation

Much of this area is in the subalpine zone dominated by sparse whitebark pine and lodgepole. The Humphreys Basin is an open rocky basin with very little vegetation. French Canyon has large meadows along the stream with wetter, fen-like areas particularly at the confluence of streams from the side canyons. The area around Hutchinson Meadow is in the montane mixed conifer forest. The Bishop Creek drainage is east side jeffrey pine and lodgepole forest grading in to subalpine terrain.

Golden Trout Lake in Humphreys Basin in the Bishop/Humphreys Geographic Unit

The elevational fire closure is 10,000 feet in the northern part of this area and 10,400 feet in the south. Approximately 71% (87 sites) of the campsites historically used by packers in the north and 95% (72 sites) in the south are above the fire closures in this geographic unit.

Grazing Resources

Table 3.37, the *Geographic Unit Meadow Table* contains a summary of the recorded pack station grazing nights at meadows throughout the geographic area. Table 3.36 at the end of the chapter has a summary of the reported commercial pack stock use and meadow conditions by geographic unit. Five percent of the key areas assessed in the Bishop/Humphreys Geographic Area are locations with a well defined altered vegetative species composition over more than one-third of the area. Forty-two percent of the key area meadows assessed have vegetative species alteration over less than one-third of the meadow area and fifty-three percent have little or no alteration of vegetative species composition.

In the North Piute, Lamarck, Sabrina, Tyee, Treasure, and Bishop Creek Analysis Units, little to no grazing use occurs and no grazing key areas are identified in these analysis units. There are few identified concerns with identified grazing areas.

In the Glacier Divide AU, at Hutchinson Meadow the meadow nearest the large packer camp is dominated by aster and similar mid-seral to low-seral plant species. Elsewhere in the Hutchinson Meadow area in the meadows under the lodgepole forest and along the creek, the vegetation is dominated by Canada reedgrass (*Calamagrostis* spp.).

Most of the meadows along Piute Creek between Hutchinson Meadow and Summit Lake remain too wet to be range ready throughout the summer. There are some benches and lakeshore terraces in the vicinity of Golden Trout Lakes that may reach range readiness in some years, such as during drought conditions; these likely do not reach range readiness during normal years. This area is used infrequently for grazing.

In the northern section of the geographic unit, Humphreys Basin is a large, open and rocky basin, with difficult off trail travel conditions. Much of this area is high, 10,000 to 12,000 feet in elevation. The wet meadows in this area remain too wet to be range ready during a most years. In drier locations the soils are thin, with thin and easily fragmented sod. Areas of frost heaving, with fragmented sod and bare soils were observed (see photo).

The stream corridors and the tributaries in upper French Canyon, above the Elba Lake and French Lake confluences, are narrow, steep and dominated by wet meadows and sphagnum wetlands. Drier vegetation is found adjacent to the wetland areas and stream corridors. Below the Elba Lake confluence, the main French Canyon is a large, “U” shaped, glaciated valley with a rock-controlled stream in the valley floor, with a Forest system trail in the valley along the north side of the creek. There is a wetland complex of springs, sphagnum, and very wet meadows at each tributary confluence in French Canyon. Areas of hoof punching, fragmented sod, damaged or missing sphagnum, and rutted trails were noted in this wetland complex. Between the wet confluence areas and on the side slopes, such as toward Merriam Lake, are meadow complexes including streamside meadows moist to dry forest understory meadows, dominated by upland sedges (*Carex filifolia*), upland rushes (*Juncus drummondii*) and grasses (*Poa wheeleri*) with few changes to hydrological function or vegetative species composition. Permanent transects for studying meadow condition trends have been set up in Merriam, French

Canyon, Hutchinson, and Piute Creek. The baseline vegetation condition at all these meadows was scored as moderate (USDA Forest Service, 2004).

Among granite shelves and benches above French Canyon, are lakes such as Elba, Moon, L, Merriam, and Royce. Meadows and riparian vegetation in these areas is located on narrow lakeshore terraces or along narrow, moderately steep creekside corridors. There are some dry meadows dominated by upland sedges (*Carex filifolia*) on the upland benches. These upland areas typically have thin poorly developed sod, highly erosive soils, and are low in productivity.

Fens

Twelve meadows with fens or fen characteristics were identified among the thirty-two meadows visited in this geographic unit, with conditions as follows:

- French AU: “Adjacent to Waterfall Camp” there was severe trampling damage to the fen and the stream was rated Functional at Risk with a downward trend. There are several other meadows with fen characteristics in this drainage, all in good hydrologic condition. Grazing reporting from the canyon has not been consistent, so actual use is unknown.
- Bishop AU: The meadow at Hurd Lake has fen characteristics, but no reported grazing or resource concerns.
- Lamarck AU: Grass Lake has fen characteristics, but there is no grazing reported and it appeared to be in good condition.
- Pine AU: East of Pine Creek Pass Meadow has fen characteristics, with no observed hydrologic function or spring impacts.
- Glacier Divide AU: Packsaddle and below Packsaddle meadows have fen characteristics but no observed hydrologic function problems.

Rare Plants

There are nine known populations of sensitive and watch list plants in or near this geographic unit, six are on or near trails and three are in locations without known trails or packstock use. There are two meadows with habitat for sensitive species, one has resource concerns.

- North Piute AU: There is a recorded population of slender moonwort in Piute Canyon near the Piute Canyon Trail, but it has not been relocated since a collection in 1968. The plants reportedly grow in a rock crevice. This population of *Botrychium lineare* is one of 32 reported (16 known to be extant) populations in the country. There is extensive unsurveyed habitat for this plant in the planning area and over much of the country, although “its sporadic occurrence is probably a true reflection of its rarity” (Farrar, 2004).
- Horton AU: There is a population of Inyo beardtongue bisected by the Longley Reservoir Trail.
- Bishop Creek AU: There is a population of Congdon’s sedge bisected by the Chocolate/Ruwau Trail. This species was also found in talus above Saddlerock Lake where there appears to be no pack stock use.
- Lamarck AU: There is a population of Inyo beardtongue along the Grass Lake Outlet Trail.
- Sabrina AU: Outside the wilderness there are populations of Inyo beardtongue along the Sabrina Basin Trail and in the North Lake area.
- French AU: There is potential habitat for veined water lichen in the Merriam Confluence to Chevaux Confluence Meadow, where there is no recent reported use. There are slight

vegetation composition changes, but no problems with hydrologic or stream function in this meadow.

- Glacier AU: Hutchinson Meadow, where there has been heavy human and packstock use, both historically and pre-historically, is within the elevational range of veined water lichen. The meadow has moderate changes to hydrologic function and the stream is Functional at Risk, which has a negative effect on the potential habitat of this species.
- There is potential habitat for Congdon's lewisia in the San Joaquin watershed on rocky outcrops.

Weeds

There are several species of non-native plants at the Bishop Pack Station and three species on the Piute Pass Trail within a mile of the trailhead, bird's foot trefoil, dandelion, and clover. One non-native species was found at Rainbow Pack Station and several at Pine Creek Pack Station.

Horton AU: The lower slopes near the trailhead have moderate cheatgrass cover.

Florence/Bear

Vegetation

The vegetation in this unit is montane mixed conifer forest at the lower elevations, grading into subalpine whitebark pine and lodgepole above about 10,000 feet.

43% (41 sites) of the campsites with historical packer use are above the 10,000 foot fire closure.

Trail near Sallie Keyes Lake in the Florence/Bear Geographic Unit

Grazing Resources

Table 3.37, the *Geographic Unit Meadow Table* contains a summary of the recorded pack station grazing nights at meadows throughout the geographic area. Table 3.36 at the end of the chapter has a summary of the reported commercial pack stock use and meadow conditions by geographic unit.

Twenty-eight percent of the key area meadows assessed in the Florence/Bear exhibit well defined altered vegetative species composition over more than one-third of the area. Eighteen percent of the key area meadows have vegetative species alteration over less than one-third of the meadow area and fifty-four percent have little or no alteration of vegetative species composition.

The Bolsillo, Dutch, Dutch Boulder, Ershim, Ward, East Florence, and Apollo Analysis Units are not often used for overnight trips; most use is to drop off dunnage and the pack stock return to the trailhead or travel through to other analysis units at higher elevations. Little or no grazing use occurs and no grazing key areas are identified in these analysis units.

Jackass, Poison and Hellhole Meadows have been used by the High Sierra Pack Station as pastures and are located in the Hooper Analysis Unit. Jackass Meadow is used to pasture varying numbers of pack and saddle stock throughout the season. The Forest Service has one administrative pasture within the meadow complex used during the season. A majority of this 135 acre meadow complex, which is adjacent to the South Fork San Joaquin River area below Florence Lake dam, is currently used by the High Sierra Pack Station for pack stock grazing. A drift fence adjacent to the Jackass Campground helps to keep their stock out of the campground area. The IDT estimated that 75% of meadow is suitable for pack stock grazing, with meadows in the northeast primarily unsuitable due to wet pond-like conditions that favor species unpalatable to stock.

Poison and Hellhole Meadows are located in the John Muir Wilderness. These meadows are not used annually, but use has been authorized in the 1995 Environmental Assessment for High Sierra Pack Station.

Poison Meadow is a 20 acre meadow that has historically been used by the High Sierra Pack Station periodically throughout the season for their broodmares and foals. Although portions of the meadow are dry and have some sagebrush encroachment and some isolated changes in vegetation away from potential natural plant community, roughly 80% of meadow is suitable for pack stock grazing. Poison Meadow has good access for stock watering as the meadow borders the South Fork of the San Joaquin. The small channel within the meadow was rated as Proper Functioning Condition (PFC). This meadow has an aspen and willow component with regeneration evident. The system trail goes through the eastern, drier portion of the meadow, but the trail is not causing any detrimental impacts.

Hellhole Meadow has been used by High Sierra Pack Station for grazing broodmares and foals. A PFC assessment was conducted and the PFC rating is functional at risk rating due to a stream diversion at Crater Creek. Since the water from this channel does not reach or flood the meadow on a regular basis, the riparian vegetation appears to be supported by groundwater/snowmelt recharge only. There is a dominant willow community throughout the meadow and vegetation condition is good with a high percentage of late seral species composition for this meadow.

In the Sallie Keyes Analysis Unit, Double Meadow and Blayney Meadow are used by Lost Valley and Muir Trail Ranch. Double Meadow is a 60 acre meadow, grazed seasonally by stock owned by Lost Valley Pack Station and Muir Trail Ranch, has moderate to high forage production, with the average forage production. Muir Trail Ranch uses Double Meadow in the fall of the year (September-October) and typically graze between 15-30 head of stock for up to 5 weeks.

Lower Blayney Meadow is a 32 acre (includes private acreage) meadow and includes private land owned by the Lost Valley Pack Station, Muir Trail Ranch, and another owner. Both Lost Valley Pack Station and Muir Trail Ranch use this Forest Service portion of this meadow for turning out their stock during the season. The meadow is used by recreational stock and there is a potential for conflict between commercial and recreational use, due to stream conditions that have been altered from historic improper grazing, continued heavy grazing upstream on the private sections, and current use by stock to access water at the South Fork of the San Joaquin. Streambank disturbance was recorded at 25% at reach below private property on North Fork San Joaquin River, based on toe-point method sampling conducted in August, 2004. Although a PFC assessment was not conducted, the stream reach below the private land appears functional at risk.

It may be possible to enter into an agreement with the private land owners to create gaps in their fence so that stock do not concentrate at the fenceline and have access to both the private and Forest Service land during the grazing season. This may facilitate better distribution and lessen negative effects from the heavier grazing on the private land. Carrying capacity was not estimated for the private land, only the Forest Service portion.

Light to moderate forage utilization was observed as of August, 2004 and the meadow itself is in good condition with over 85% of meadow suitable for pack stock use. Lost Valley stock may be using Blayney Meadow disproportionate to Muir Trail Ranch use of this area.

Resource conditions such as widened stream crossings, trampled spring areas, sod fragmentation, and localized alteration of vegetation species, are present in Quail Meadow, Hilgard Meadow, Rose Marie Meadow, Shooting Star Meadow, and the meadows around Sallie Keyes Lake.

Due to concerns with resource impacts the Sierra Nation Forest has closed and then opened Hilgard Meadow with rest-rotation grazing at Rose Marie and Hilgard meadows. In 1961 there were concerns over early season “misuse” at Rose Lake Meadow, watershed degradation at Rose Marie Meadow, and overall vegetative conditions. The 1961 Annual Management Plan contained a number of recommendations including requiring packing feed; minimizing over night use; prohibiting at large grazing above 8,000 feet elevation prior to July 1st; prohibiting picketing at Hutchinson Meadow near Pilot Knob Camp, Rosemarie Meadow, and in the Margaret Lake Basin; closing Pocket Camp Meadow due to “severe overgrazing”; prohibiting overnight stockholding along the Muir Trail in the Bear Creek drainage; grazing in the backcountry only in conjunction with an actual recreation trip; and keeping “accurate records.”

In the Italy AU, almost all recreational pack stock use is concentrated around Hilgard Meadow. This meadow has severe impacts and is regularly grazed by commercial pack stock. The meadow is compacted, the stream through the meadow is widened and likely incised, and banks are sloughing into Hilgard Creek. However, the meadow only has moderate hydrologic function alteration because it still has intact water sources.

Most of the Seldon Analysis Unit has low concentrations of trails and campsites, and few hydrologic or soils impacts. However, the area around Rosemarie Meadow is more heavily used and shows some alteration of soil productivity and hydrologic function. Rosemarie Meadow has slight soil compaction, some streambank trampling, and headcuts propagating up tributary channels to West Fork Bear Creek. The headcuts appear to be recovering.

Fens

Two meadows with fens or fen characteristics were identified among the 11 meadows visited in this geographic unit, with conditions as follows:

Italy AU: There is a fen in Upper Hilgard Meadow with no hydrologic problems noted.

Sallie Keyes AU: Big Fen Meadow is almost entirely fen, with no reported recent grazing, and no problems observed.

Rare Plants

There are 10 known populations of sensitive and watch list plants in or near this geographic unit, 4 are on or near trails, 1 may have impacts from wandering grazing stock, 3 are in remote areas (1 near a pipeline), and 2 are in meadows (1 in the vicinity of a hot spring). There are 51 meadows with potential habitat for sensitive species. In this geographic unit around Florence Lake are the most extensive known populations of Mono Hot Springs evening primrose and several trails intersect these populations.

- Hooper AU: There is a population of Mono Hot Springs evening primrose at the north end of Florence Lake in the vicinity of Jackass Meadow. There are no trails through this population, but there is grazing at Jackass Meadow by both commercial and Forest Service pack stock. There is a population of Mono Hot Springs evening primrose at the Hooper Creek Gaging Station on the Hooper Diversion Trail. There are subpopulations of the evening primrose outside the wilderness at the north end of Florence Lake, where there is recreational and dam maintenance activity. There is a reported population of Yosemite mousetail in Jackass Meadow outside of the wilderness and the meadow is within the elevational range of the west side sensitive riparian species. Jackass Meadow has severe hydrologic function changes due to the proximity of Florence Dam, the stream is Functional at Risk, and there is plant composition change over a large portion of the meadow. Poison and Hell Hole are also in the elevational range of the sensitive riparian species and both have moderate plant composition change. Hell Hole also has severe hydrologic function change because of a water diversion. All these meadows are being used as pastures for packstock. There is a population of grey-leaved violet on Mount Hooper, inaccessible by trail.
- Dutch/Boulder AU: The Florence Lake and Thompson Lake Trails go through populations of Mono Hot Springs evening primrose. The Florence Lake Trail is used by pack stock, some hikers, and 4WD vehicles accessing private property. The Thompson Lake Trail may be blocked by downed trees.
- East Florence AU: The Florence Lake Trail bisects populations of Mono Hot Springs evening primrose. The trail receives more hiker use than in Dutch/Boulder or Ward Mountain because the ferry drops off hikers. Grazing occurs in Double Meadow near one occurrence and burros from Lost Valley Pack Station were observed freely roaming near the ferry landing. There are two other populations of Mono Hot Springs evening primrose on the north shore of Florence Lake where there are no pack stock trails.

- Italy AU: There is potential habitat for veined water lichen at Hilgard Meadow, which has moderate hydrologic function changes and the stream condition is Functional at Risk.
- Ward Mountain AU: A small segment of the Florence Lake Trail intersects a population of Mono Hot Springs evening primrose.
- There are 51 meadows within the elevational range of at least one of the west side riparian species in this geographic unit. Six of them have reported grazing and five of these are used as pastures (see Hooper and Sallie Keyes AUs). Five of these meadows have moderate to severe changes to hydrologic function and stream condition (Table 3.34).
- Sallie Keyes AU: Three of the meadows with pack stock use are within the elevational range of the west side sensitive riparian species. Shooting Star meadow has severe vegetation composition changes over much of the meadow. Lower Blayney is used as a pasture and has moderate hydrologic function changes and moderate plant composition change. There is a population of Prairie wedge grass near Blayney Hot Springs, but the exact location is not known and may be on private land.
- There is potential habitat for Congdon's lewisia in the San Joaquin watersheds on rocky outcrops.

Weeds

Weeds are present in the Florence Lake area and on the trail between Florence Lake and the PCT that is used by vehicles, hikers, and pack stock.

Non-native species are present at the pack stations of all operators who use this area (see *Undesirable plants present in the JM and AA, at pack station facilities, or trailheads* table in the project record).

John Muir Southeast

Vegetation

The vegetation in this area is pinyon/juniper woodland at the low elevations, with some oaks, willows, and cottonwoods in the riparian zones. Trails rise quickly through Jeffrey pine and lodgepole montane forests to subalpine whitebark pine and lodgepole. Foxtail pine occurs in the southern AUs of this geographic area. There is a Research Natural Area with foxtail pine as the target element just outside the wilderness; this subspecies only occurs in the southern Sierra.

Approximately 55% (17 sites) of the campsites historically used by packers are above the 10,400 foot elevational fire closure.

Grazing Resources

Table 3.37 the *Geographic Unit Meadow Table* contains a summary of the recorded pack station grazing nights at meadows throughout the geographic area. Table 3.36 at the end of the chapter has a summary of the reported commercial pack stock use and meadow conditions by geographic unit. Most commercial pack stock use is by groups moving through to access Sequoia Kings Canyon National Park. Little grazing use occurs in this geographic area. Anvil Camp meadow was used historically, including by commercial pack operations, until closed due to stock related impacts in the early 1990s. Sawmill Meadow has been used historically, and is currently used lightly and intermittently. Windy Flat was used as a pasture by a commercial pack station until

the early 1990s and has not been used in the last decade. There is an unmaintained drift fence at Windy Flat. Light, intermittent private stock grazing may occur in this geographic area mostly associated hunting parties in the fall.

Second Lake in Big Pine Creek drainage in the John Muir Southeast Geographic Unit

Fens

There are no known fens in John Muir SE, but very few meadows were visited due to low use by commercial packstock.

Rare Plants

There are 31 known populations of sensitive and watch list plants in this Geographic Unit. Twenty-two of these populations are on or near trails in the wilderness. Nine of the populations are in relatively inaccessible locations. Four of those near trails are in areas that are likely to be used for camping or fishing. There are two more populations just outside the wilderness on access trails.

- Taboose AU: There are populations of Raven's milkvetch, Inyo beardtongue, and alpine jewel-flower on the Taboose Trail, with no reported negative impacts from the light to moderate use over this pass. There is another population of Inyo beardtongue not accessible by trails.
- Sawmill AU: There is a population of Raven's milkvetch on the Sawmill Pass Trail, where there are no reported negative impacts.
- Kearsarge AU: There are populations of Mt. Whitney draba and Sharsmith's stickseed within 0.1 mile of the Bench Lake and Matlock/Slim Lake Trails. There is another population of Mt. Whitney draba with no known access trails. There are two inaccessible populations of Sharsmith's stickseed, one on the border with the Sequoia N.P. and another in Pinyon Creek drainage, and another near the terminus of the Grand Group Trail. There are two populations of alpine jewel-flower, one on the Golden Trout Lake Trail, and one at Heart

Lake. There is also a population of Congdon's sedge on the Golden Trout Lake Trail. There is a population of Big Pine biscuitroot near the Parker Canyon Trail. Along the Shepherd Pass Trail there are two populations of Dedecker's clover and a population identified as marble rock mat. The rock mat population is inaccessible to pack stock and hikers.

- Shepherd AU: There are populations of Father Crowley's lupine and Sharsmith's stickseed along the Shepherd Pass Trail. These populations were visited in 2000 and the trail appeared stable with no off-trail travel occurring. There is low commercial pack stock use in this area, but very high overall hiker use. There are also two populations of Dedecker's clover with no trail access.
- Whitney AU: There is no pack stock use allowed in this analysis unit. There are two populations of Mt. Whitney draba and two of Sharsmith's stickseed near the main trail, but these populations were visited in 2000 and limited trampling by hikers was noted, mostly confined to trail tread.
- North Fork of Lone Pine AU: There is a population of Sharsmith's stickseed away from any trails.
- North Fork Big Pine AU: There are populations of Father Crowley's lupine and Inyo beardtongue along the North Fork Big Pine Trail. These were surveyed in 2000 and no problems were noted for these populations.
- South Fork Big Pine AU: There are populations of Inyo beardtongue and Father Crowley's lupine along the South Fork Big Pine Trail, an access route to the wilderness.
- Baxter AU: There is a population of Dedecker's clover bisected by the Baxter Pass Trail. There are no known resource concerns.
- Cottonwood AU: There is a population of sweet-smelling monardella between Lakes 4 and 5 near the end of the Cottonwood Lakes Trail, where there are many social trails. There are two populations of the watch list plant Sharsmith's stickseed in this AU on rock outcrops away from trails and another near Lake 4 in talus near a use trail to Long Lake. A site visit in 2000 found no adverse impacts to the stickseed near Lake 4, but the monardella was not located.

Weeds

There are populations of cheatgrass, red brome, and Russian thistle at many of the trailheads in this geographic unit. Cheatgrass has been found as high as 9,000 feet along these trails (K. Nelson, Inyo National Forest Botanist, pers. comm.).

At Glacier Pack Station, four species of non-native plants were found, most in the client's parking lot. Rock Creek and Pine Creek use trailheads in this area and non-natives species are present at their pack stations.

John Muir Southwest

Vegetation

The montane mixed conifer forest is limited in this area to the lower elevations of the Middle and North Forks of the Kings River. Much of the area is subalpine with higher alpine zones along the eastern side.

McGuire Lake, John Muir Southwest Geographic Unit

Approximately 12% (12 sites) historically used by packers are above the 10,400 foot elevational fire closure.

Grazing Resources

Table 3.37, the *Geographic Unit Meadow Table* contains a summary of the recorded pack station grazing nights at meadows throughout the geographic area. Table 3.36 at the end of the chapter has a summary of the reported commercial pack stock use and meadow conditions by geographic unit. Vegetative species composition change was not documented in this geographic area. Current reported grazing use is light throughout this geographic area.

Some localized trailing related sod fragmentation and hoof punching are documented at locations in the McGuire Lake, Meadowbrook, and Fleming Lake areas. Trailing related erosion is present in the meadow at Fall Creek. Historical sheep and cattle grazing, was high especially in the montane meadows, such as Big Maxson, which exhibit indicators.

Fens

In John Muir SW, of the ten meadows visited, there is only one, Meadowbrook, with a fen and there are no reported hydrologic function or spring impacts. The *Meesia uliginosa* occurrence at Spanish Lake is an indicator that there is a fen there as well. There is no information about its condition, but there has been no recent reported use by commercial packstock.

Rare Plants

Of the three populations of sensitive and watch list plants known from in or near this Geographic Unit, two are inaccessible with no threats and one is in a meadow with no reported use. There is habitat for six other sensitive and watch list plants of rock outcrop or upland habitats. In the John Muir SW Geographic Unit, about 45% (178) of the meadows are within the elevational range of at least one of the west side sensitive riparian species. Only two of these meadows have reported grazing, Geraldine Lake Meadow and North Fork Kings River near Fleming, neither with reported hydrologic or stream problems.

- Spanish AU: There is a population of the fen indicator and sensitive moss, *Meesia uliginosa* near Spanish Lake. There was no use reported at Spanish Meadow in 2001-2003.
- Rodgers AU: There is a population of Tulare County bleeding heart near Spanish mountain, not accessible by any known trail.
- Crown Basin AU: There is a population of Kettle Dome buckwheat on Kettle Dome, inaccessible by trail. There is potential habitat for unexpected larkspur, Muir's raillardella, and Hall's daisy in the Kings River watershed in the southern part of this analysis unit in rocky outcrops. The raillardella may also be found in openings in montane forest. Monarch goldenaster is also found in this watershed, but on limestone. There is potential habitat for Tehipite Valley jewel-flower also in this drainage on granitic or carbonate soils in forest openings.
- There is potential habitat for Congdon's lewisia in both the Kings and San Joaquin watersheds on rocky outcrops.

Weeds

Two non-native species were found at Clyde Pack Station, the main operator in this area. There were also weeds found at High Sierra, Lost Valley, and D&F Pack Stations, occasional users of the area.

Table 3.35 Pack station use by analysis unit

This table uses self reported data by pack stations from tally sheets. It includes both spot and dunnage trips and full service trips. However, since full service trips are recorded as on e trip, some assumptions were made to calculate nightly destinations for the traveling trips. A two way spot and dunnage trip were counted as two trips with the same number of people, with stock numbers counted for each trip. These numbers reflect the collective use of all pack stations in these two wildernesses.

Geographical Unit	Analysis Unit	2003			2002			2001

Chapter 4 Environmental Consequences

Chapter 4 – Environmental Consequences

Introduction

The National Environmental Policy Act (NEPA) requires that environmental documents disclose the environmental impacts of a proposed federal action, reasonable alternatives to that action, and any adverse environmental effects that cannot be avoided should the proposed action be implemented. This chapter analyzes the environmental impacts of the alternatives on natural resources, cultural resources, the visitor experience, and social resources. This analysis provides the basis for comparing the beneficial and adverse effects of the alternatives. In compliance with NEPA, the environmental analysis evaluates the potential effects of the alternatives on all of the wilderness's physical, natural, cultural, and human resources.

This analysis addresses environmental consequences associated with the implementation of alternatives necessary to meet the direction of the District Court of San Francisco and the Ninth Circuit Court of Appeals. The remaining management elements, as previously described and analyzed in the 2001 Wilderness Plan, are not revisited or reanalyzed in this analysis.

Following this introduction, Chapter 4 discloses the environmental effects associated with each of the six alternatives. The impact analysis sections are organized by resource function at two scales. First, each resource function analyzes the six alternatives at the Wilderness Scale. This scale is an analysis at a broad geographic and programmatic scale. A second analysis considers the effects of actions at a more site-specific scale, referred to as the Geographic Scale. The geographic unit section is organized by eight regions. Under each geographic unit is the resource effects analysis of the six alternatives.

Cumulative Impacts

The District Court in San Francisco ordered that a cumulative environmental analysis be conducted prior to site-specific analysis for the pack station permits. (*High Sierra Hikers v. Jack Blackwell* January 10, 2002). This document provides that cumulative environmental analysis.

A cumulative impact is described in regulations developed by the Council on Environmental Quality (CEQ) under regulation 1508.7, as follows:

Cumulative impact is the impact on the environment, which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

The catalogue of past, present, and reasonably foreseeable actions combined with the establishment of time and space boundaries for each resource area provide the foundation of the cumulative impacts analysis in Chapter 4.

The alternatives were designed to combine multiple actions on the landscape. Had the agency separately undertaken the Trail Plan, or the grazing actions, the cumulative effects would have

been more substantial. In combining these actions, the analysis examined multiple actions. For this reason, potentially cumulative effects are often described as direct and indirect effects and, where relevant, the synergistic effects of the various actions are contained in the “Analysis” section that describes direct and indirect impacts. Where relevant, cumulative impacts are based on the following list of past, present, and reasonably foreseeable actions.

Table 4.1. Catalog of past, present, and reasonably foreseeable actions

Past Actions			
Type	Action	Affected Area	Timeframe under which actions have or will occur
Dams	Gem Lake Dam	Rush Creek	Completed 1915
	Waugh Lake Dam	Rush Creek	Completed 1920
	NF Big Pine	Second Lake; NFBP	Currently used for downstream power generation. Built in 1920s/30s.
	Lower Sardine Lake Dam	Bloody Canyon	Built for mining under outlet of lake in early 1900s 1900-1910. Abandoned.
	McClure Lake Dam	Sadler Lake	Built approximately 1960 for stream flow management for fisheries. No longer used or maintained.
	Rutherford Lake Dam	Triple Divide	Built approximately 1960 for stream flow management for fisheries. No longer used or maintained.
Impoundment Structures	McGee/Longley	Horton Lake	Built approx. 1930s
	Birchim Lake Impoundment	Pine Creek	Built approx. 1930s
	Davis Lake Impoundment	Upper Rush Creek	Built in 1940s
	Chiquito Lake Impoundment	Chiquito	Built approximately 1960 for stream flow management for fisheries. No longer used or maintained.
	Lillian Lake Impoundment	Lillian Lake	Built approximately 1960 for stream flow management for fisheries. No longer used or maintained.
Mines	Mono Pass Mine	Bloody Canyon	Mining activity and cabins circa 1880s-90s
	Minaret Mine	Minaret Creek	Built in 1920s operated through 1940-50s. Used as a retreat until early 1990's. Abandoned
	Panaminas Mine	Morgan; Little Lakes Valley	Active in the 1920/30s until the late 1980s when it was decommissioned.
	Pick N Shovel Mine and cabin	Silver Divide	Cabin and unpatented mining claim from the 1940s operated until 1960s. Forest Service acquired in early 2000s.
	Cabin Lake Mine	Shadow Creek	Mine and cabin built in early 1900s. Abandoned
	Nydiver Mine	Shadow Creek	Early 1900s
	Gable Creek	Gable Lakes	Active in the 1930s -40s. Abandoned

Past Actions			
Type	Action	Affected Area	Timeframe under which actions have or will occur
Mines (con't)			since then. Remnant equipment present today.
	Horton – Hanging Valley	Horton Creek	Mine and cabin. Active in the 1930s/40s. Abandoned.
	Sheelore-Baldwin	McGee Creek	Active in 1930s-40s
	Baldwin Mine	Convict Creek	Active 1940s -1970s. Abandoned.
	Iron Lake	Iron Creek	Active mine in the 1930s-1940s. Private in-holding, inactive
	Pincushion		Active mine in 1930s. Abandoned
	Rex Montis	Kearsarge	Active 1962-1991
Cabins	Snow and Stream Survey Cabins	Millers Crossing; Sallie Keyes; Mono Pass (Trail Lake); Bishop Lake; Piute lake; Agnew Pass; Iron Creek; Rosemarie meadow; Meadow Brook; Burnt Corral; Big Pine 1 st and 2 nd Lakes; Volcanic Knob; Big Maxon; Coyote Lk; Iron Creek	Most of the cabins were built from 1912-1952 by California State Department of Water Resources, and cooperators. They are used and maintained today for winter snow surveys.
	Heidi Cabin	North Fork Big Pine	1930s
	Cabins associated with grazing	Chetwood; Perkins;	Built between 1920s and 1940s
	Shorty Lovelace cabin	Various	Primitive shelters built by trapper in 1940s to 1950s.
	Administrative Cabins	Muir Trail Cabin Post Corral; Crown Valley; Heitz Meadow Mono Meadow	Tool cache cabin built for the construction of the Muir Trail in 1912. Administrative cabins built in 1950s Built in 1914
	Leffingwell Cabin	John Muir Southwest	Built in the 1923 as a resort, recreation residence. Forest Service acquired in 1971.
	Department of Fish and Game Cabin	Cottonwood Lakes	Built in late 1920s, early 1930s. Still in use today.
	Baker Cabin	Rush Creek	Recreation residence built in 1934. No longer in use.
	Chaney Cabin	North Fork Big Pine	Built in the late 1920s

Past Actions			
Type	Action	Affected Area	Timeframe under which actions have or will occur
Grazing	Historic Grazing	Throughout Ansel Adams West Florence-Bear east to headwaters Graveyard - Goodale John Muir Southwest Ansel Adams East Fish Creek	Extensive production livestock grazing of cattle and sheep occurred throughout the analysis area dating back to the late 1800s. This activity reached its peak in these wildernesses 1940s and began to decline in the 1950s. In the Ansel Adams East, and north John Muir (Fish Creek) there was grazing in support of mining operations from the late 1800s to the 1940s. Active management of the allotments on the Sierra national Forest occurred in the 1960s with the development of Allotment Management Plans. In the Ansel Adams West production livestock grazing occurred until the mid 1990s.
Snow Survey Sensors		Gem Pass; Agnew Pass; Big Pine ; Blackcap basin; Upper Burnt Corral; Woodchuck; Volcanic Knob	1980s-1990s
Other	Convict Pack Station	Convict	Operated until the mid 1980s
	Hilton Pack Station	Hilton	Operated until the late 1970s early 1980s
Present Actions			
Trail Projects	Capital Investment Project	Pine Creek Trail	2004-2006
	Capital Investment Project	Bishop Pass	2002-2005
	Capital Investment Project	Pacific Crest Trail - Agnew Pass to Donahue Pass	2005
Grazing		AAW; Graveyard; Lower Mono, John Muir Southwest.	Active allotments for cattle grazing
Reasonably Foreseeable Actions		Affected Area	Assumptions
Backpacking Use		All areas	Backpacking use will generally remain stable with fluctuation increasing or decreasing by 10-15%
Day hiking		All areas	Day hiking use will continue to increase in popularity. This activity could increase by as much as 30% over the next 10-20 years.
Private equestrian use		All areas, with the majority of this use on the west side.	Private equestrian use will likely remain stable or increase slightly over the next 10-20 years.

Reasonably Foreseeable Actions	Affected Area	Assumptions
Outfitting and Guiding	All areas	These activities will continue at current use levels that have been capped with the 2001 Wilderness Plan.
Research permits	All areas	Applications are received annually; between 10-20 projects throughout the analysis area for short-term research on climate, water, wildlife, vegetation.
Hunting	All areas	Hunting will continue at low levels, defined by California State Fish and Game permits.
Trail maintenance	All areas	Basic trail maintenance will continue to occur.
California Department of Fish and Game (CDFG) Mountain Yellow Legged Frog (MYLF) Restoration Projects	All areas	CDFG Management Plans determine restoration areas for MYLF. Project work is not subject to CEQA compliance.
CDFG Fish Stocking	All areas	Fish Stocking is determined by CDFG and subject to their management.
Maintenance activities associated with Dams (above)	Rush Creek; North Fork Big Pine;	Project work can be expected to maintain and repair dams on a regular basis.
Mammoth Mountain and associated Resort expansion	Ansel Adams East and Eastern portions of John Muir wilderness.	Mammoth Mountain as a destination resort will draw more visitors, and population will grow both creating urban pressures on wilderness, including recreation use, and visual effects.
Federal Energy Regulatory Commission (FERC) re-licensing – Big Creek Project	South Fork San Joaquin River	May affect stream flow regimes in South Fork San Joaquin.

4.1 Human Environment

4.1.1 Commercial Pack Station Operations

The effects analysis for Commercial Pack Station Operations is in Section 4.1.5, Socioeconomics and Operations.

4.1.2 Wilderness

Wilderness Scale

Introduction

Methodology

This section evaluates the effects of the alternatives on the wilderness resource at the Wilderness and Geographic Scale. The Wilderness Scale section discusses wilderness-wide effects and is coarse and broad. The Geographic Scale provides more details on the local scale, including projected levels of stock by alternative. Cumulative effects are discussed, where relevant, at both scales.

A key component of the wilderness resource is wilderness character. The concept of wilderness character comes from Section 2(a) of the Wilderness Act: “... for the use and enjoyment of the American people in such a manner as will leave them unimpaired for future use and enjoyment as wilderness and so as to provide for the protection of those areas, the preservation of their wilderness character.”

Wilderness character is, in part, an intangible concept, yet provides a basis for significant disagreement over whether the agency is managing wilderness in a manner that meets the legal requirements of the Act. For this reason, this analysis will use concepts from the Act to help frame the discussion. The four qualities will be referred to throughout this analysis and used to represent wilderness character. These four qualities are derived from the definition of Wilderness, Section 2(c) of the Act, which contains distinct attributes that link to the concept of wilderness character:

A Wilderness, in contrast with those areas where man and his own works dominate the landscape, is hereby recognized as an area where man himself is a visitor who does not remain. An area of wilderness is further defined to mean in this Act an area of undeveloped Federal land retaining its primeval character and influence, without permanent habitation, which is protected and managed so as to preserve its natural conditions and which (1) generally appears to have been affected primarily by the forces of nature, with the imprint of man's work substantially unnoticeable; (2) has outstanding opportunities for solitude or a primitive and unconfined type of recreation; (3) has at least five thousand acres of land or is of sufficient size as to make practicable its preservation and use in an unimpaired condition; and (4) may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value.”

The four qualities or concepts of wilderness character that will be addressed throughout this analysis are:

1. **Untrammeled** – wilderness ecosystems are essentially unhindered and free from human control or manipulation.

2. **Undeveloped** – wilderness is essentially without permanent improvements or modern human occupation.
3. **Natural** – wilderness ecological systems are substantially free from the effects of modern civilization.
4. **Outstanding opportunities for solitude or a primitive and unconfined type of recreation** – wilderness provides outstanding opportunities for people to experience solitude or primitive and unconfined recreation, including the values of inspiration and physical and mental challenge.

Landres et al. (2005) describes the use of these qualities in monitoring wilderness character. In this approach, wilderness character is the primary administrative responsibility mandated by the Wilderness Act, but it is not defined by the Act. Wilderness character is also the biophysical, experiential, and symbolic relationships and meanings that distinguish wilderness from all other lands, is supported or degraded by stewardship decisions and action, and is unique to each wilderness.

The wilderness resource discussion in this chapter will use these qualities for evaluating the effects of management actions on the wilderness character. In addition to the use of the four qualities of wilderness character in the evaluation, the context, intensity, duration, and type of effects provide boundaries for the effects analysis. For the purpose of this analysis, the following approach is used.

Context: Local effects are those that occur at site-specific locations within the wilderness. **Wilderness-wide impacts** would be effects to the entire wilderness. **Regional** effects would be impacts to adjacent lands, such as the adjacent and contiguous National Parks, Yosemite to the north and Sequoia Kings Canyon to the south.

There are activities outside the wilderness boundary of the Ansel Adams and John Muir Wildernesses that may have cumulative effects. Developed recreational sites, such as campgrounds and recreational facilities, exist in many locations adjacent to the wilderness boundary. In these cases, activities outside the wilderness boundary may have effects inside wilderness areas.

Intensity: The intensity of the impact considers whether the effect to wilderness character is negligible, minor, moderate, or major. **Negligible** effects are considered not detectable to the visitor and therefore expected to have no discernible outcome. **Minor** effects are slightly detectable, though not expected to have an overbearing results on wilderness character. **Moderate** effects would be clearly detectable to the visitor and could have an appreciable effect on one or more aspects of wilderness character. **Major** effects would have a substantial, highly noticeable influence on the visitor's experience and could permanently alter more than one aspect of wilderness character.

Duration: The duration of the effect considers whether the impact would occur in a short- or long-term period. A **short-term** effect would be temporary in duration, such as an encounter while traveling or camping. A **short-term** effect (to physical qualities of wilderness character) would be 1 to 2 years. A **long-term** effect would have lasting effects on the wilderness character, such as an impression from noticeable ecological impacts or the permanent closure of an area. Long-term physical effects to the wilderness character are 10 to 20 years.

Type of effect: Impacts were evaluated in terms of whether they would be beneficial or adverse to wilderness character. **Beneficial** effects would enhance one or more of the qualities of wilderness character. **Adverse** effects would harm one or more of the qualities of wilderness character.

Organization of the analysis is to focus on relevant and significant issues. The topics addressed in this section include use levels, party size, campsites, campfires, and trail suitability. To assist in analyzing the effects of use levels on wilderness character, maps of current use levels by analysis unit were developed, along with data on use levels and impact ratings at destinations that were evaluated by the interdisciplinary team. These displays were used to assess proposed changes by alternative.

Data

Use data has been compiled using the most accurate data available. Commercial pack stock use is measured by the number and type of trips and the people and stock used to reach each destination. Records for the entire planning area for this level of analysis are only available from 2001 through 2004. Some data gaps and margins of error exist due to data interpretations. Reports of use provided by the pack stations occasionally recorded vague or unknown destination locations. Also, for all-expense trips, the trip is recorded with no indication of which locations were used for each night. Grazing reports provided additional information that could be tracked, but a best estimate given knowledge of the trips is all that could be tracked. At the analysis unit scale, this information is more accurate, but at the destination scale, there may be a larger margin of error. It is the best information available (up to 95 percent accurate) for use of pack stations. This level of accuracy is more than adequate for this analysis. More detailed use data, or data that goes back farther in time, is not essential and is not critical to the analysis of wilderness character attributes. Any improvements to wilderness character that may be unknown as a result of not having more precise data, or data that goes farther back in time, is not likely to affect the decision making process. Current conditions and future uses are the most relevant factors to consider.

For the use levels discussion, specifically at the Geographic Scale, commercial stock and clients are referred to as very low, low, moderate, high, and very high. These categories were used throughout this analysis to compare and assess changes in use levels. The categories are defined as:

Categories used to describe stock and commercial use levels

Very low	1-10 stock or people per year
Low	11-50 stock or people per year
Moderate	51-200 stock or people per year
High	201-350 stock or people per year
Very High	351-800 stock or people per year

In summary, the objective of this analysis is to forecast identify potential environmental effects of the proposed actions and alternatives on wilderness resources with particular attention to qualities of wilderness character. Wilderness character is described by using four qualities: 1. untrammled; 2) undeveloped; 3) natural; and 4) outstanding opportunities for solitude or a primitive and unconfined type of recreation of wilderness character. The context of impacts, intensity of impacts, and the duration and type of impacts— as defined above— further bound the analysis. The topics focus the discussion on meaningful and relevant effects.

Alternative 1

Summary of Alternative 1 Wilderness Resource Effects

- Overall, impacts to wilderness character with this alternative will be moderate intensity at a number of site-specific locations. Less than (approximately) 50 locations out of thousands of possible destinations in these wildernesses would have moderate long-term impact to some qualities of wilderness character (naturalness).
- Impacts to some visitor's experience (solitude, unconfined recreation) would be short term, while some impacts to wilderness character may be longer term, but none would have permanent adverse effects.
- With the fewest limits on where and how frequently pack stock can go on trails, this alternative has the greatest risk of increasing the aggregate extent of impact caused by commercial pack stock use and the public.
- Campfire closures at higher elevations may disperse use to lower elevation campsites and wood depletion may increase at these locations. However, these locations will tend to be more abundant with the ability for renewal of downed wood resources.
- Campsites can expand and new stock camps can be created. However, this is not probable since stock camps are well established and the current number and location of stock camps seem to meet the needs of the commercial packers.
- Opportunities for solitude will not be high in the first six miles from trailheads and at popular destinations. Beyond this, opportunities for solitude and unconfined recreation will be very high. Areas where commercial pack stock are prohibited will have moderate to high opportunities for solitude. Once inside the wilderness, most opportunities of unconfined recreation are with the primary regulator of use, an external control, and very few internal controls.
- System trail assignments create a conflict between trail objectives and wilderness character objectives (recreation categories).
- Wilderness character is moderate to high in popular destinations, and high throughout recreation category 1 and 2 areas with localized impacts at campsites and in primary trail corridors.
- Uncontrolled growth of day hiking will have a cumulative effect on visitor's seeking solitude in a few areas during a short time of the year.

Analysis

Use Levels

Outstanding opportunities for solitude will exist in the majority of locations with this alternative. Crowding can diminish a visitor's solitude on some trails within six miles of a trailhead during the summer season, June through September. Less than 20 of the 81 trailheads have moderate-to-high-use levels. Use on trails is concentrated in the first few miles and then disperses. This is typical of many popular wilderness areas throughout the country. Visitor use is also concentrated

into four months of the year, and the remaining months see very low use because the majority of the area is under a substantial snow pack.

In this alternative, use levels for commercial packers will range from 12,000 service days to 16,300 service days. To support these operations, there are between 3,000 to 5,000 people served and 6,000 to 10,000 stock used. Primary use will be spot and dunnage type of trips with approximately 40 percent spot, 40 percent dunnage, and 20 percent all-expense traveling. These percentages vary and take into consideration three large outfits running 50 to 70 percent of the all-expense trips. The effects of the types of trips are described at the geographic unit in more site-specific terms.

Use levels for commercial pack stock are controlled primarily by the overall allocation of service days and by the trailhead quota. The service day allocation has an effect on the type of commercial pack stock trip and, consequently, the type of impact. Service days control the amount of time the service is provided. Operators can choose to run a few all-expense trips or schedule more spot and dunnage trips with their allocation. With the allocations reduced for many operators from previous historic use levels to the “actual two years of high use” there will continue to be a trend toward spot and dunnage trips to maximize service day use.

Spot and dunnage trips will have relatively less impact than all-expense trips. The all-expense trip—with the use of more stock, the duration of the time in the wilderness, the use of larger campsites, more intensive use of campsites, and use of grazing resources—will have a higher level of impact than the spot and dunnage trips which go in and out of the wilderness in one day.

Without controls on the number of stock used for these trips (other than party size), there will be more opportunities for growth in commercial services since only clients or people are the focus of the control. This is described in more detail in sections below as it has effects at the site-specific scale (geographic unit).

Trailhead quotas are effective at reducing temporal spikes in trailhead use. Controlling temporal spikes is necessary on holidays and in peak seasons, which is predictably the first two weeks of August. With a spike in trailhead use, many parties can converge on a location at once. When all sites are used, new sites are created. It is very difficult, if not impossible to predict how often this will happen. The trailhead quota control is designed to allow freedom of movement once inside the wilderness. Spikes in trailhead use typically occur on the holiday weekends, and in the first two weeks of August, at popular well-known destinations. These destinations are generally a one day ride or hike from the trailhead. This current quota mechanism is best for reducing the experiential impacts of crowding by controlling the sheer number of people allowed to enter the wilderness area each day. It provides for the most unconfined type of recreation given the fact that management is directly controlling the trailhead use.

The trailhead quota does not effectively control the spatial distribution of use. With less effective control of spatial distribution, there is a higher probability that ecological values will be impacted. With trailhead quotas, the frequency of use or number of times a destination gets used is not controlled. Once users enter the wilderness through the daily quota restriction, they can travel anywhere. Since 80 to 95 percent of commercial pack stock use is spot and dunnage, the commercial pack stock facilitates access to a starting point for the rest of the client’s trip. Clients may travel anywhere on the trailhead and are not subject to any trail use restrictions that the commercial pack stock would be limited to. In the case of spot trips, most clients tend to remain at the site where the packer drops their camp gear. The lack of control on the number of times a

destination gets used can have an effect on the trail resource, the opportunities for solitude, and naturalness characteristics.

Trailhead quota availability has a moderate and sometime critical effect on the ability of commercial operators to run a trip. Records indicate that the actual limiting of trailhead use occurs 50 days a year on 22 commercial trailheads used by the pack stations on the Inyo National Forest and 55 days on 7 commercial trailheads on the Sierra National Forest—this trend will likely continue. However, it is expected that limited available trailhead quota space is as much a factor as a party's ability to go when, where, and sometimes if at all. For example, if there are only two spaces left on a trailhead that a party of six desires in August, that party might not be flexible enough to reschedule that trip.

Commercial operators have reported difficulty in obtaining quota space for the single-use trails (Shepherd Pass is an example) where they must compete with the public for the quota space. On popular trails, the reservable amount (60 percent of the quota) can be booked up to six months in advance, and many fill quickly. This has left some operators unable to offer trips into these areas and may be the reason operators have not been able to use their allocations of service days. They simply are not able to book the trips the public wants. This trend is expected to continue with this alternative, possibly affecting pack stations from accessing desirable areas. The capping of this use is preventing spikes in use and the subsequent potential for additional impacts at campsites and crowding in areas accessed by these trailheads. Opportunities for solitude and natural conditions are protected because of limiting freedom and unconfined use of these areas.

By managing use primarily at the trailhead, the visitor can maintain a high degree of freedom once they have entered the wilderness, which achieves an important goal for protecting quality of wilderness character. Any spatial control that is achieved is based on a probability that each day the number of parties disperse to a variety of destinations. This management regime balances the effects of visitor use with the wilderness value of unconfined recreation.

Day Rides

Up to 3,900 service days for day rides can be expected to occur with this alternative. The majority of this use will occur in the Inyo National Forest portion of the Ansel Adams Wilderness. Even more specifically, most of this use will only penetrate the wilderness boundary by less than 1/4 mile. Some areas will experience occasional use further into the wilderness; on these trails, there will be more manure, smell of urine, and encounters with riding stock. Some turnarounds within the first five miles of the wilderness will show signs of impact. These sites will look like campsites, with vegetation loss, and minor tree damage from holding stock for short periods. This use is not expected to have major effects to natural conditions in the wilderness, although there will be short durations of minor effects to opportunities for solitude for visitors. The locations of these minor adverse effects to solitude will occur within an area that has other uses detracting from these qualities as well (day hiking, fishing, and sightseeing).

Party Size

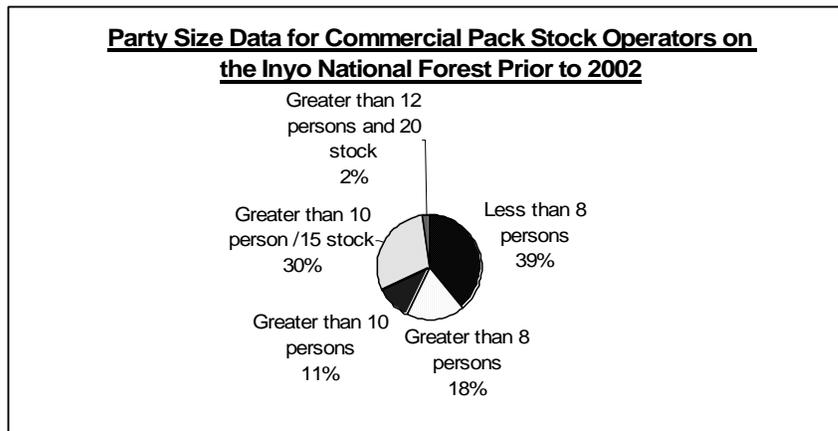

In this alternative, with commercial group size limitation of 15 persons and 25 pack stock per trip wilderness-wide, visitor opportunities for solitude in parts of the wilderness will not be affected. The effect will be short-term and minimal. Commercial operators rarely reach the maximum party size; however, some operators have a higher percentage of large parties than others (see Figure 4.1).

Large parties will tend to be associated with the all-expense trips. Spot trips are the next highest percentage of large parties since each person is riding an animal and then additional stock is needed for packing supplies and equipment. Dunnage parties are typically the smallest parties. There has been a trend towards more dunnage-type trips over the years, which may be why party-size trips have seen an overall downward trend since the early 1990s. On the Inyo National Forest, between 25 and 31 percent of all the commercial trips have a party size of greater than 10 to 15 stock. About 2 percent of all trips have a party size of greater than 12 persons and 20 stock (prior to 2002). Operators are free to change the type of trips they offer; they are only limited by the number of service days. Some operators could move from primarily a small party and dunnage operation, to running fewer large-party all-expense trips, although this is not likely.

The effects of large parties can be seen on campsites and use trails or trails that may pass-through soil or vegetation that is sensitive to disturbance. The total numbers of stock and timing of the use of stock has more bearing on this effect than the actual party size. For instance, there would be no difference on the effects to the resources between a party size of 15 and 25 and 2 parties (1 of 8 and 10 and the other party of 7 and 5). It is not the size of the party that is the most relevant factor, but the type, timing, and overall use that is the significant factor. Given the current distribution of party size by commercial operators, other than experiential effects, it is difficult to assert that party size in and of itself is the effect.

Some visitors prefer fewer large parties as compared to a large number of small parties in terms of encounter in the wilderness. Others simply do not like to encounter a large party for its effect on their opportunities for solitude and personal values. Participants of large parties are also seeking an experience; sharing wilderness with friends or relatives through primitive recreation (i.e., hiking, or riding, and stock packing). This alternative will continue to see the beneficial and adverse effects of the current party size. While the adverse effects are short-term and depending on the person's perception, minor to major in intensity, the beneficial effects can be long-term. The magnitude of the problem is quite low in context to the overall amount of wilderness lands and the excellent ability to avoid groups and find opportunities for solitude in these wildernesses.

Figure 4.1. Party size data for commercial pack stock operators on the Inyo National Forest prior to 2002 (Indicates the number of occurrences of large parties).

Campsites

Unconfined recreation can have an effect on ecological conditions. The locations visitors choose to camp at is one area where this is evident. Educational efforts have been quite successful influencing visitors to camp in existing sites. However, several new campsites continue to be created by both the commercially serviced and non-commercial public. In this alternative, there will be the effect of uncontrolled use of sites. With one exception (Rush Creek), there are no designated sites in this alternative. With no direct control on which sites the packers can use there can be incremental expansion of existing sites with the associated impacts of soil compaction, vegetation loss, and firewood depletion. These impacts will be minor at the wilderness-wide level, and moderate at the local level.

Campsites where packers drop clients and do not remain at the site with stock (spot and dunnage) have fewer effects than campsites where stock is held overnight. The spot and dunnage sites may have evidence of an impacted area where the loading and unloading takes place with stock. Sometimes this occurs in the midst of a campsites “kitchen” or “sleeping” area. When this occurs, there can be some observed effects of camping with some direct impacts of stock (manure, urine, and disturbed soils). These effects are relatively contained but can cause some expansion of the site if the party does not want to sleep or eat in the same area where the stock has been briefly held.

Some spot and dunnage sites have short-use trails that may show varying levels of impact. The overall scale or intensity of this type of impact is minor to negligible at the Wilderness Scale. Many times dunnage sites are locations on the trail where very little impact is noticeable from their use. Probably 90 percent of the impacts that will occur with this alternative are within acceptable range of conditions. The effects are minor and, although they may persist from year to year, it is generally more acceptable to have fewer moderate to heavy impacted sites than more light to moderate impacts.

While freedom to use additional spot and dunnage sites has relatively few impacts, the use of sites for holding stock tends to show the greatest impact. These holding-stock sites expand with every new location used for high-lining stock. Over time, the extent of area vegetation loss, exposed roots, and disturbed soil can and likely will expand at many sites.

Even without a requirement, most commercial packers that camp with stock will use existing campsites. Generally speaking, stock campsites have been well established for over fifty years, the result of both commercial and non-commercial stock use. On occasion new stock camps are created and, over time, the commonly used campsites are expanded. The majority of the physical and biological impacts have occurred at the established stock camps. When stock users (both commercial and non-commercial) tie stock to trees, even if just for loading and unloading pack animals, animals can paw and expose tree roots. Over time, continued tying to the same tree(s) will harm the tree. At some sites, new areas for holding stock are created due to preferences of different wranglers. This can lead to a campsite getting larger in total area and can result in both ecological and experiential effects. These types of impacts are noted in the geographic unit discussion; while these impacts do occur, it is on a very limited basis. On over 800,000 acres, there are approximately 200 known stock camps and of these, probably less than 10 percent see unacceptable impacts where the site is expanding. Unacceptable impacts include expanding the site too close to water, highly developed sites, or otherwise sites highly impacted by the use of trails. In this alternative, these sites could be improved over time, set back from water or designated areas. However, this beneficial effect of improving the sites may involve long-term wilderness-wide actions.

This alternative allows for the most unconfined recreation for the user can continue to choose where to camp. This enhances the quality of wilderness character for visitors by limiting the number of direct controls once inside the wilderness area. However, this option could lead to the expansion of additional impacted sites, which could diminish the qualities some visitors look for when seeking solitude and naturalness in the wilderness.

Campfires

Campfires enhance some visitors experience in wilderness. At the same time, the impacts associated with campfires can diminish another visitor's experience. Areas where campfires are allowed or occur illegally have the potential for impacts, both experiential and environmental. Fire rings fill with ash, foil, and other non-burnable garbage over time and in popular areas require cleaning more than once a season. The fluctuation of this type of impact is dependent on Forest Service ranger presence and personnel levels, which can be dependent on a budget that has been declining for many years.

With the implementation of the 2001 Wilderness Plan, campfires have been prohibited above 10,000 feet in the north and 10,400 feet in the south. Compliance issues will continue to exist at locations where the prohibition is not signed. Visitor compliance, which will improve over time with this alternative, declines without adequate notification of rules, especially new rules. When non-compliance leads to fire-ring proliferation, others who may be aware of the regulation can be confused and think that the presence of a fire ring indicates fires are allowed. Currently the fire closure is still in the process of implementation and the effects of campfires are still occurring. These effects include wood depletion, soil and vegetation loss, and the scarring of rocks. Over time, compliance will probably improve. Newly closed areas that have been cleaned up from fire-rings have a higher potential to achieve compliance. Packers are responsible for educating their clients about wilderness regulations and it has been noted that clients of pack stations comply with the prohibition of fires at the higher elevation. There have been some instances of non-compliance and packing in of charcoal into closed areas by packers, perhaps unknowingly.

Overall, limiting campfires to locations where available firewood is more abundant has the effect of enhancing the naturalness qualities of wilderness character while diminishing some of the experiential (unconfined recreation) qualities for other visitors. The effects of campfires in open areas of the wilderness have low to moderate intensity impacts on naturalness in a limited portion of the wilderness.

Trail Suitability

In many places in this alternative, the established and recognized system of trails conflicts with the recreation category desired conditions identified in the 2001 Wilderness Plan. If this system of trails were to be maintained or built to the prescribed level in the 2001 Plan, many areas identified by the prescribed recreation category for low-use would be subject to a high level of maintenance and development. This indicates a conflict between current wilderness management goals and past trail inventories. The management direction is to align the trail system goals with the desired condition.

Although some trails will ultimately be identified as “not recommended for stock” (NRFS) in this alternative, no trails are currently identified as such. However, there are still remnants of a system of educational postings for NRFS on visitor maps and some trail signs on the Sierra National Forest.

The effects of commercial stock on all system trails are moderate- to-high intensity on both effects to naturalness and visitor’s experience in the more pristine areas. At the wilderness scale, the number of such inconsistencies amount to a relatively low percent of trails. In the current system, only approximately 7 percent of the trails are considered for NRFS or a not suitable for commercial stock classification. This amounts to a minor to moderate effect on the wilderness character quality of naturalness and some, not all, visitor perceptions of solitude.

Some effects occur with commercial pack stock on non-system use trails. Under the trailhead quotas scheme, annual decisions allow remote areas to be accessed with no limits on frequency of use. The decision to limit packer activities is the responsibility of the line officer. To date, 102 use trails (half of the total requested amount) are approved for continued use. General guidelines for frequency of use are provided for a small number of these trails that allow use into pristine areas. It is possible additional effects to natural conditions, including soil and vegetation, are occurring to a very small percent of the wilderness with this use. Some of these areas, if sensitive, can experience irreparable harm. No known new effects of use trail approvals has occurred yet, though into the future the use of some trails could lead to more persistent and permanent effects to both naturalness and solitude.

Cumulative Impacts of Alternative 1

Past levels and types of visitor use, when added to the current “No Action” alternative, have effects on the natural characteristics of the wilderness. In the context of altering wilderness ecological systems—in contrast to activities such as production livestock grazing, mining, and hydro-projects—the combined effect of past and present visitor use is very insignificant in its effect on naturalness.

Ecological processes are, at the wilderness scale, greatly undisturbed by this level of continued recreational use by commercial and non-commercial publics. Visitor behaviors in the past have left effects upon the landscape that persist and add to the effects of current use. Campfire use is

an example. Past high use and a more common practice of cutting live limbs and trees for firewood have affected both the level of ecological systems as well as the experiential qualities of naturalness. Trees that have been mutilated (e.g., cut limbs and stumps) will show this impact for many years. Some areas show these impacts from over 50 years ago, even when current use is not adding to this effect. This effect is only present in a very small percentage of the landscape and only a small number of visitors are affected.

At the wilderness scale, these effects are not likely to affect the wilderness ecology although there may be site-specific locations where effects are more intense. Similar, but with even less effect, are practices from the past such as burying garbage and camping close to water. These effects (garbage dumps and sedimentation into water from campsites) may persist for a long time. However, management actions such

This photo shows a number of tree branches that have been cut. Some are quite recent, while others are scars that are many years old.

as active removal of sites close to water and garbage, along with

education efforts to change visitor practices, have greatly improved the condition of the wilderness today. The No Action alternative maintains this trend toward a slow improvement, elimination of past effect, and reduction of new effects. Actions in the 2001 Wilderness Plan such as closing areas to campfires, further setbacks from water, and pack-out trash requirements all support this trend.

Past actions of commercial livestock grazing, mining, water diversions and retention structures, and fish stocking are actions that have a persistent and lasting effect on both the naturalness and untrammled qualities of wilderness character. Effects of current pack stock use, when added to these past conditions are negligible at the wilderness scale. These actions (specifically, mining, hydro-projects, and fish stocking) have changed the wilderness environment and have the effect of human controls on natural processes and ecosystems. However, few occurrences persist today. Dams will have lasting effects that far outweigh recreational impacts in the areas of wilderness ecosystem disturbances. Currently no mining occurs, yet the effects of past mining activities persist with few abandoned structures but no known pollutant effects.

Past activities have had minor effects on the undeveloped character of wilderness. The wilderness has, and continues to be, essentially without permanent improvements and human occupation. Fourteen snow survey cabins and a few abandoned mining cabins exist on the landscape. The effect of cabins is minimal, but can be an intrusion on a visitor's experience. In

some areas, where current visitation is high, commercial pack stock is also high and the cumulative effect of the presence of these cabins can be one of significant diminished experiences to some visitors. However, other visitors may not perceive the presence of cabins as a negative effect on their experience. In fact, their visit may be enhanced if the cabin is historic or not perceived to be in contrast to the environment.

The level of commercial pack stock activities, combined with non-commercial recreational overnight use, commercial day rides, and day hiking can simultaneously occur and affect the wilderness experience in some locations. The number of locations where all or many of these activities converge are relatively few. Day hiking is an increasingly popular activity and current management does little to control this use of trails. If this is an identified issue, a foreseeable action is to consider control measures for day hikers. The impacts of additional day hikers in the wilderness is primarily experiential, diminishing opportunities for solitude while at the same time providing primitive recreation to a sector of the population who chooses that activity. The locations where these converging activities have effects are very limited and usually occurs on the first 6 to 10 miles of a trail. High-day use occurs on less than 20 of the trails in the planning area (Inyo National Forest day use study, 2003). In the wilderness scale context, these areas are few and only affect a small portion of the visiting public. At the local scale, in perhaps a dozen locations, this may be considered a moderate effect on solitude and wilderness experience.

Overlap of pack station operations occurs primarily because of all-expense traveling trips. Overlap of operations can cause overuse of some site-specific destinations and grazing areas. Without coordination of the all-expense trips, there is a chance that overuse can occur. Few areas will experience such effects, but where this occurs, the impacts can be of a moderate intensity.

Presently no mining, and very little production livestock grazing occurs. There would be no cumulative effect to wilderness character.

Future management and restoration on Mountain Yellow Legged Frog habitat and populations is a reasonably foreseeable action. These activities are subject to California Fish and Game management. Restoration efforts entail removal of fish from some locations and stocking of fish in other locations. These activities have an effect on the untrammeled qualities of wilderness character by manipulating the ecosystem and wilderness environment to meet other objectives. Such manipulations may have unintended long-term affects that are unknown at this time. More immediate and potential cumulative effects of pack stock supported recreation could be the displacement of use to new areas where fish are stocked. This would occur if use currently is concentrated at a lake that has fish and now and then the fish are removed and another less popular lake becomes stocked with desirable fish. Results of changing use patterns can occur to trails and have effects to solitude. Actions such as this have a potentially minor to moderate affect on wilderness character at the wilderness scale.

No other reasonably foreseeable actions have been identified, other than the ones proposed in this planning effort.

Alternative 2 – Modified

Summary of Alternative 2 – Modified Wilderness Resource Effects

Generally, the effects of Alternative 2 – Modified are very similar to Alternative 2. The distinguishing feature in both alternatives is the manner of controlling use, the destination quota.

Overall, the intensity of impacts to wilderness character with this alternative will be low to moderate and moderate to high at less than 25 site-specific locations. These moderate to high impacts will be at fewer locations than in Alternatives 1, 2, and 3. Moderate impacts will occur in locations that can sustain higher levels of use and have been popular for decades by both commercial and non-commercial visitors. These locations will be consistent with the recreation category desired conditions. Most locations of moderate impacts to wilderness character are the same in all action alternatives.

Impacts to wilderness character are primarily to naturalness and opportunities for solitude and unconfined recreation. Impacts to naturalness are minor in the long-term. Impacts to opportunities for solitude occur in high-use corridors and occasionally in other areas of the wilderness. They also tend to be short-term and avoidable. In this alternative, where travel is either prohibited or limited, opportunities for unconfined recreation are moderate to a portion of the public (clients of commercial pack stock and visitors wanting few to no encounters with pack stock).

Impacts to a visitor's experience would be short-term, particularly at popular destinations and on primary trails. While some impacts to natural conditions may be longer term, they are not likely to have permanent adverse effects. Some long-term site-specific adverse effects to wilderness character may result because of trail development decisions. Some affected trails can lose their primitive characteristics when improved and developed to facilitate uses. However, the same actions (trail development) that may occur over the long-term could enhance ecological and natural qualities of wilderness character.

In this alternative, there would be no regional, long-term adverse impacts. Beneficial effects in this alternative include improved wilderness character of many destinations where impact sources (pack stock) are removed. However, there will still be sources of impacts from other visitors at these locations. It is expected that the severity of the impact will be reduced over the short-and long-term. Some visitors that rely upon commercial pack stock support would be permanently affected by closure of these areas.

There would be no irretrievable or irreversible adverse effects from this alternative, since a strong element of the alternative is managing for conditions and adapting techniques, controls and regulations to achieve the desired conditions. A monitoring component identifies indicators and thresholds for when to implement adaptive measures. This monitoring strategy is embedded in this alternative to provide the assurance needed to modify and manage actions over time to prevent any irretrievable losses to the wilderness resource.

Analysis

Use Levels

The most significant aspect of this alternative for wilderness effects is the replacement of trailhead quotas with destination quotas. The determinations for use trails, identification of trails not to be used by commercial stock, locations of party size limitations, and locations where stock camps are designated will work in combination with destination quotas to achieve a reduction in adverse effects to wilderness character by limiting where and to what extent commercial pack station use will occur at each destination. Use levels and site-specific restrictions respond to resource concerns, risk factors and an assessment of the capability of the destination.

This alternative, unlike the trailhead quotas of Alternatives 1, 3, and 4, controls the frequency of use to destinations. In this alternative, use levels will remain similar to current levels at the Wilderness Scale, but will greatly change the distribution and frequency of use throughout the wilderness. The effect of this will be to provide more opportunities for solitude and contain and reduce the potential for physical impacts at destinations. With controls on the number of times stock go to a location, there is a direct relationship between use and impact and more precision in managing impacts.

Destination quotas provide site-specific spatial controls on commercial pack stock operators. Since these quotas were derived based on an assessment of the capability of each destination, the destination is managed for an allowable determined level of use. There is higher consistency with the desired condition of the destination when the number of trips or frequency of use to the destinations is controlled. Where needed, additional mechanisms (such as limiting the number of stock seasonally to the destination, party size and number of parties) are also employed to control the setting and character of each destination.

Visitor solitude, while not guaranteed everywhere at all times, has a higher probability of not being affected by commercial pack stock operations in this alternative. This is particularly effective at the more remote locations since the number of times the packer can go there is limited. In these locations, there may be more of an effect to solitude based on visitor expectations. Trailhead quotas do not offer this level of control over destination use.

In addition to the actual destination having higher wilderness character, the trails accessing the destination also benefit from the control on frequency of use. Under this alternative, the approval for use is specifically considered in the level of use. The control on frequency of use is often the factor for reducing or maintaining a certain level. There are continued effects on these trails, but the effects are minimized by limiting the number of trips to a level considered consistent with the capability of the trail.

There is an effect on the commercial pack stock operator's ability to choose when, where and how often they want to travel to the destinations. This effect involves their freedom of use, and the public they serve. This also diminishes the unconfined recreation opportunities of a wilderness experience. The allocated trips to each destination is within the range of current (2001-2004) trips to those destinations. If a party is denied access to a desired destination through the rationing system of this alternative, they will be able to go to another location since the overall level of trips is consistent with existing use levels. The difference is the commercial pack stock operator's use will occur where it is determined to have the least effect on wilderness resources. While the overall amount of use remains relatively constant, the effect of controlling this amount, so it occurs at suitable levels by destination, will have a beneficial effect on wilderness qualities. Areas protected from overuse will improve the natural characteristics of wilderness.

Those seeking to have few or no encounters with commercial pack stock will be affected by the use levels in this alternative in about 10 to 20 percent of the wilderness¹. Opportunities for solitude will be outstanding in locations in these wildernesses most of the time. There will be

¹ The physical area of impact is estimated to be 9 percent (all trails and campsites) while the area subject to experiential effects is estimated at 20 percent (all trails available to commercial pack stock with a ¼ mile buffer).

some locations where pack stock use is intense. These locations will be in areas where the effect of this use on the physical and biological resources is contained and will have less of an extent of impact and noticeable effects to visitors. Daily stock use limitations (stock at one time in the wilderness) are not tied to trailheads but to daily commercial stock use in the wilderness. In the absence of direct temporal controls, this at one time limitation on stock becomes the means by which spikes in use are capped. With the limitation derived from the past use, there would be the same temporal dispersion of use as Alternative 1 (trailhead quotas).

This alternative provides commercial pack stock operators flexibility to respond to year-to-year business fluctuations and client destination requests. Operators are not likely to use all the trips assigned to them each year. Some years destinations may never get used. Other years, destinations may receive maximum use. By imposing a limit on the number of stock each operator can have in the wilderness at one time ensures there are no spikes in use and use levels will remain similar to recent and past levels of use.

There are also limits, and in some cases reductions, in traveling trips. These limits curb the trend towards the overlap occurring in Alternative 1. This may have the single most direct effect. Since all-expense and traveling trips use stock for the duration of their trip and tend to have a larger number of stock and people in the trip, they have a greater potential for impacts to campsites and grazing areas. Campsites tend to be larger with increases in the extent of soil compaction, vegetation loss, and total area of disturbance. By reducing the number of all-expense trips, and preventing the growth of these types of trips, there will be a reduction in the type of impacts. In addition, the requirement that all trips holding stock in designed and contained designated wilderness camps will improve the conditions of these sites and prevent deterioration over time. Similarly, the establishment of grazing management strategies, including stock numbers, will help maintain meadows in acceptable conditions. Collectively, these actions provide significant improvement in the wilderness character from the current situation (No Action), where fewer controls translate to a higher potential for impacts. Conditions at stock camps, routes of the traveling trips, and grazing areas being used are testimony to the current conditions.

The allowances for a small amount of commercial llama use, (250-service-day allocation) for east side entry, would likely have no noticeable effect. The service will be provided from a variety of high use trailheads, with itineraries managed through annual operating plans. When the llamas operate in areas where commercial pack stock use is moderate to high, there will be a need for coordination to ensure that conflicts between stock and llamas are minimized. Currently, a small level of private llama use occurs and commercial pack stock operators are familiar with methods to minimize conflict.

A small-scale commercial burro operator would probably not have any additional effects on resources. This operation takes one long trip a year. As long as the itinerary is coordinated and grazing regulations are adhered to, there would be little effect. Often the trips begin on the Inyo National Forest and go into Sequoia-Kings Canyon National Park where the National Park Service regulates the use.

Day Rides

Wilderness-wide, proposed day-ride levels will be similar to Alternative 1 – No Action. In two areas where commercial day-ride levels are high and contribute to crowding and loss of wilderness qualities (Inyo portion of Ansel Adams Wilderness), the day rides are capped at

existing levels. The locations for this intensive day-ride activity barely penetrates the wilderness. Most of the ride takes place outside wilderness areas and, although there are intensive experiential effects, the ride is short and localized. A very small area is affected by this use.

The primary effect of the day-ride activities will have minor- to moderate-adverse effects on experiential qualities of wilderness. These adverse effects will be short-term in duration, and minor in scale, affecting a small portion of the wilderness. As in Alternative 1, the commercial day rides occur in the first ½ mile to 6 miles of the wilderness. The use would occur on highly developed trail systems. Other than some minor contribution to overall trail deterioration with this relatively low level of stock use, effects would be negligible to the natural conditions of these wildernesses but moderately adverse to solitude.

Party Size

The direct effects of the wilderness-wide party size (15 persons and 25 stock) will typically be the same as the effects described in Alternative 1. Spot and dunnage trips tend to be smaller in party size than all-expense trips. In this alternative, as under the No Action alternative, operators could not change from offering spot and dunnage to all-expense trips. This provides some assurance that current patterns of a limited number of large parties are likely to continue.

When ranked against other perceived problems, party size is consistently amongst the lowest ranked problem, though this varies by wilderness (Monz et al. 2000). In the John Muir Wilderness, it ranked as 13th in the list of problems identified by hikers (Watson et al. 1993). Group size clearly is a perceived problem, but by a minority of visitors. Conflicts can become acute when there is an expectation in remote locations of low or no encounters with large or small horse groups. With capacity guidelines that look at remote locations differently than primary use areas, and responding with such things as limited trips, party size and stock number limits, there will likely be a decrease in perceived problems in these wildernesses.

As described in Alternative 1, large parties will tend to be associated with the all-expense type trips, with spot trips making up the next highest percentage of large parties. Dunnage parties are typically the smallest parties. In this alternative, there is a slight reduction in all-expense trips. This has the potential for fewer large parties. However, with no controls on spot versus dunnage distribution, operators could change towards more spot trips with the associated shifts in party size.

The effects of larger parties occur primarily on campsites and use trails where the larger parties have traveled through soil or vegetation sensitive to disturbance. The total number of stock and timing of the trail use has more bearing on the effect to campsites and trails than the actual party size as is described in Alternative 1.

There are arguably more experiential effects of larger party sizes. This will continue with this alternative. However, the magnitude of the problem is quite low in the context of the overall amount of wilderness lands. There will be even greater ability to avoid groups and find opportunities for solitude in these wildernesses with fewer trails open to commercial stock. The frequency of use to destinations, particularly more remote locations where generally only 1 to 4 trips a season are authorized, reduces the probability of experiential conflicts between commercial stock parties and hiking parties.

There is one potentially significant indirect effect of the destination quota on party size. Operators have indicated that if they are limited to the number of trips per destination, they will

desire to maximize the party size for those trips. For example, some indicate they would turn down a party of two and wait for a larger party in order to maximize income. This is a possible strategy; however, to have an operator turn down a trip in wait for a larger party is contingent on the market and the interest of large party customers. Since there is no indication there is a demand for large party groups, it seems unlikely operators would turn down smaller parties. It is also possible that pricing structure will change from a “price on the number of people or stock” to a “price for a destination.” In addition, the majority of the destination quotas are not set at the lowest level of use and do not create real scarcity compared to current levels of use to these destinations.

Additional site-specific party size limitations insure protections where there is not adequate capacity for large groups. By preventing a large party from camping where the site capacity is not suitable, or where the recreation category may not be consistent with a large group, there will be site-specific protection of the solitude and naturalness qualities of wilderness character. This comes at some expense to unconfined freedom qualities of wilderness character. The impact to this quality would be minor and short-term since other locations will likely be available and the party is not categorically excluded from the wilderness.

As in the discussion of party size effects in Alternative 1, there are experiential effects to wilderness character. These effects tend to be short-term and negligible to moderate depending on a person’s perception. Given the limited occurrences of large parties and the ability to control additional impacts at areas not suitable for large parties, the effects of maintaining the wilderness-wide party size would be negligible to minor wilderness-wide, with some people benefiting and others perceiving an adverse impact of the large group.

Campsites

Designated stock campsites would have the effect of concentrating stock related impacts at a limited number of locations. All commercial pack stock trips that hold stock overnight would be required to stay in a designated site. By containing the size of these sites, expansion would be prevented, thereby having a beneficial effect to the wilderness character qualities of naturalness.

Although there may be fewer impacted sites, intense stock-related impacts would exist at these designated campsites. Repeated use of fewer sites may further soil compaction and vegetation loss. Over time, these sites could see an increase in tree mortality if improper tying to trees were to occur. Other effects of the concentration of use would be wood depletion (where downed wood is available and campfires are allowed), human waste deposition concentration, and the general appearance of a highly used site. The effects would be moderate to major at the local scale, and minor at the wilderness scale. Most effects would be offset with ongoing management of the site to prevent adverse effects from being anything more than negligible.

By designing the features and managing for the expected use, most adverse effects would be mitigated. Determining appropriate access would reduce any trail related impacts associated with the site. With containment to existing historically used sites, improved access, site design for access, and stock holding areas, there would be an overall improvement to stock camps and an assurance that commercial stock camps do not proliferate. This would have experiential benefits to other visitors as well as clients of commercial packers. The direct effects of reducing the size of camps, improving access, and setting sites further back from lake and stream banks will also result in positive effects to social and experiential qualities of wilderness character.

Campfires

Alternative 2 – Modified proposes boundary changes to the elevation fire closure in eight areas. Because firewood is available at these locations, there are minor effects on the environment. Some of these locations are at the 10,000 or 10,400-foot elevation. Camping locations at the same destination are either in or out of the closure, making the closures somewhat ineffective. This combined with an assessment that firewood is available, results in few effects to naturalness. Commercial pack stock operators will be encouraged to collect firewood in areas of abundant availability well below the elevation closure to reduce potential effects of firewood scarcity over time at these elevations.

Trail Suitability

The effects of trail suitability determinations in this alternative will be beneficial to the trails identified as closed to commercial stock, adverse to the public that are prohibited from their use, and adverse to the public who may want to see less stock on fewer trails.

Eighty-nine (89) miles of system trails are identified for closure to commercial stock. These trails were determined unsuitable based on resource conditions and an assessment that continued and repeated commercial stock use would have unacceptable adverse effects on the trail. In these areas, there would be fewer impacts with the removal of the disturbance source. The effects may not go away, or in some cases may not be reduced, in the short-term, but the prevention of further degradation is a beneficial effect to both the naturalness qualities of wilderness character as well as some public's experiential qualities. Other people will feel adverse effects to the unconfined recreation qualities from being restricted from traveling on these trails. These effects, both the beneficial and the adverse are short-term minor effects to experience with long-term beneficial effects to the naturalness qualities of wilderness character.

Use trail approvals are consistent with the destination quotas and use levels. As with many of these topics, some publics are benefiting from restrictions while others are adversely affected, experientially. The resources will likely receive long-term beneficial effects at the local and wilderness scale from the removal of disturbances in locations where the risk of further degradation by pack stock disturbances are high.

Cumulative Impacts of Alternative 2 – Modified

Past, present, and reasonably foreseeable future levels of visitor use (backpacking, day use, and private equestrian use), when added to the commercial use levels prescribed in this alternative, will have minor long-term adverse effects to the naturalness and experiential qualities of wilderness character. Most of the wilderness will have high opportunities for solitude. Unconfined recreation is slightly diminished for all users with the use of a restrictive visitor use permit system that has been in place for over thirty years. Commercial pack stock visitors will have additional restrictions over that of the non-commercial visitors as the locations of service are directly regulated.

The developed and untrammeled qualities of wilderness character are not additionally affected with any of these actions. No cumulative effects occur to these wilderness character qualities. Past uses (structures, dams stocking, grazing, mining) have major long-term impacts that current uses and proposed actions in this alternative cannot measure up to.

Locations where trail impacts are severe may be the result of many years of use and/or lack of regular maintenance or reconstruction. These trail impacts are often the result of poor or no trail design (many shared trails evolved by from the need of the users needs, not by design). Trails located in meadows and riparian areas can cause excessive erosion. This can be exacerbated made worse by stock use, and can requires substantial physical mitigations. Removing one causal agent of erosion, such as commercial pack stock, may not do much more than slow the rate of deterioration.

The proposal to allow increases in day rides, when added to the day hiking and overnight use levels, can at the local levels have an adverse cumulative impact at the local levels to a visitor's experience, opportunities for solitude, or a sense of naturalness. These effects are short-term and in some locations moderate in intensity but local in scale of the impact.

There may be some minor cumulative effects to the naturalness quality of wilderness character with the past, current, and proposed use of drift fences, the sanding of passes, and other means to facilitate commercial stock use. Maintaining a minimal number of smaller structures (drift fences) of minor size for resource protection may have minor adverse effects to the undeveloped wilderness quality. When viewed collectively with the various structures from past uses, remnants of past recreational impacts and current proposed allowable uses of commercial pack stock activities, very few areas may have an appearance of human occupation and improvements. This effect may be long-term and range from negligible to moderate intensity relative to a person's perceptions.

There would be no irretrievable or irreversible adverse effects from this alternative, since a strong element of the alternative is managing for conditions and adapting techniques, controls, and regulations to achieve the desired conditions. A monitoring component identifies indicators and thresholds for when to take adaptive measures. This strategy is embedded in this alternative to provide the assurance the Forest Service needs to modify and manage over time to prevent any irretrievable losses to the wilderness resource.

Alternative 2

Summary of Alternative 2 – Modified Wilderness Resource Effects

Overall, impacts to wilderness character with this alternative will be at a moderate intensity at fewer site-specific locations than Alternative 1. Impacts to a visitor's experience would be short, particularly at popular destinations and on primary trails. While some impacts to natural conditions such as locally severe trail impacts may be longer term, they are not likely to have permanent adverse effects. Some long-term adverse effects to wilderness character may result at specific sites because of trail development decisions. Trails lose their primitive characteristics with improvements and development to facilitate uses. The same action (trail development) that may occur over the long-term would enhance ecological and natural qualities of wilderness character.

There would be no regional, long-term adverse impacts. Beneficial effects in this alternative include the improved wilderness character of many destinations where impact sources (pack stock) are removed. However, there will still be sources of impacts. It is expected the severity of the impact will be reduced over the short and long-term. Some visitors that rely upon commercial pack stock support would be permanently affected by closure of these areas.

- Wilderness character will be moderate in high use corridors and high in most all other areas.
- Ecological impacts are concentrated and contained. The extent of impact is less than Alternative 1.
- Campsites will be contained at sites suitable for holding stock, limiting the area of impact from stock camps. There is likely to be improved conditions at stock camps.
- There are spatial controls but limited temporal controls. Daily and seasonal stock numbers provide moderate temporal controls.
- The use of internal controls will reduce the freedom for commercial pack stock operations to go where they or clients desire. Packers' freedom of movement and campsite selection will be substantially limited in this alternative.
- Site-specific party size limits will insure the campsite capacities are not exceeded, eliminating the potential for new impacts from expanding sites.
- Campfire use can create equity and compliance issues. Compliance issues lead to ecological impacts of depleted wood sources, scaring of soil, rock, and trees by campfires.
- Opportunities for solitude will probably increase by limiting areas of pack stock operations and the frequency of their use. Spatial spikes in use will not occur which will lead to a high probability that more remote locations will remain remote and lightly used by pack stock.
- System trail assignments lead to the potential for higher level of development than is currently on the ground. This may detract from wilderness character in some locations, but generally will align with the designated recreation category.

Analysis

Use Levels

In this alternative, use levels will remain similar to current levels at the Wilderness Scale. The significant difference is in the use of an internal, spatial control (the destination quota) which more directly controls the extent of the pack stock use. This alternative, unlike the trailhead quotas of Alternatives 1, 3, and 4 controls the frequency of use at destinations. The replacement of trailhead quotas with destination quotas is the most significant aspect of this alternative for wilderness effects. The determinations for use trails—identification of trails not to be used by commercial stock, locations of party size limitations, and locations where stock camps are designated—works in combination with destination quotas to achieve a reduction in effects to wilderness character compared to the No Action Alternative.

Destination quotas provide site-specific spatial controls on commercial pack stock operators. Since these quotas were derived based on an assessment of the capability of each destination, the destination is managed for a determined allowable level of use. There is a much higher consistency with the desired condition of the destination when the number of trips or frequency of use to the destination is controlled. Visitor solitude, while not guaranteed everywhere all of the time, has a higher probability of not being affected by commercial pack stock operations,

particularly at the more remote locations since the number of times the packer can go there is limited. Trailhead quotas do not offer this level of control over destination use.

In addition to the actual destination having higher wilderness character, the trails accessing the destination also benefit from the control on frequency of use. Under this alternative, the approval for use is specifically considered in the level of use. The level of use is often the factor for reducing or maintaining a certain trail maintenance level. There are continued effects on these trails, but the effects are minimized by limiting the number of trips to a level considered consistent with the capability of the trail.

There is an effect on the commercial pack stock operator's ability to travel when, where and how often they want to. This is an effect on their freedom of use and the public they serve and diminishes the unconfined recreation opportunities of a wilderness experience. The allocated trips to each destination is within the range of current (2001-2004) trips. Since the overall level of trips is consistent with existing use levels, if a party is denied access to the destination they desire they can go to another location. While the overall amount of use remains relatively constant, the effect of controlling this amount so use occurs at suitable levels by destination will have a beneficial effect on wilderness qualities of some public's experience and to the natural characteristics of wilderness, since areas will be protected from overuse.

Those seeking to have few or no encounters with commercial pack stock will be affected by the use levels in this alternative in about 9 percent of the wilderness. Opportunities for solitude will be outstanding in most locations in these wildernesses, most of the time. There will be locations where pack stock use is intense. These locations will be in areas where the effect of this use on the physical and biological resources is contained and concentrated as to have less of an extent of impact.

There is intent in this alternative to find opportunities (locations) for growth in commercial services within desired conditions for the area and resource capability. Any allowances for expansion of services from the last few years of reduced use would occur only where suitable and capable of sustaining the use. No new impacts would be expected. At locations with conditions such as poorly located or degraded trails or low camping capacities, the intensity of commercial pack stock use is proposed for reduction from the highest level of use in the past three years.

By counting dunnage trips that use less than five stock as half a trip, an incentive is provided to use less stock. Currently in Alternative 1 – No Action, there is no incentive to use less stock; in fact reduction of service days by 20 percent per the 2001 Court Order seemed to be an incentive to use more stock to make up for reduced clients. Providing five trips to destinations not identified by the user allows for occasional use of areas for regular use or for incidental use exceeding a particular quota. Five additional trips to approved destinations could have additional effects to other visitor's solitude or incremental effects to the naturalness quality if the pack stock causes any additional impact to trails, campsites, or grazing resources on this additional trip. Although possible, it is not likely, that the occasional additional use would have more than negligible effects on character qualities at the wilderness scale.

Alternative 2 establishes daily and seasonal stock quotas to act as a control feature for the total amount of commercial pack stock use so it does not substantially increase from current levels in Alternative 1. Daily and seasonal stock quotas make sure that growth in commercial pack stock services will be in number of clients rather than number of stock. This provides some incentive

for operators to decrease the ratio of the number of stock per person. Because it is the number of stock, not the number of people, that have the most effect on the condition of the resource (DeLuca et al., 1998 and Monz et al., 2000), there would be an opportunity for these businesses to survive and serve more visitors needing their services without a direct growth in stock and the associated impacts. Figure 4.2 compares the allowable stock numbers of Alternative 1 and 2.

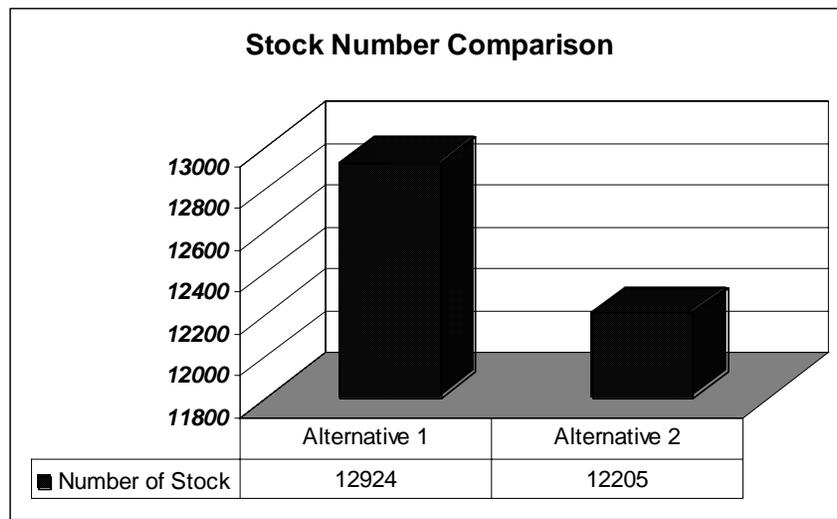

Figure 4.2 Stock number comparison Alternative 1 and 2.

Daily stock caps are not tied to trailheads but are tied to overall commercial stock use in the wilderness on a daily basis. In the absence of direct temporal controls, this daily cap becomes the means by which spikes in use are capped. With the daily cap derived from recent use, there would be the same temporal dispersion of use as Alternative 1 (trailhead quotas). It is highly unlikely that without trailhead quotas, all commercial pack stock use on any given day would utilize a single trailhead within their primary operating area. Most commercial pack stock operators are probably will not service clients into one location as this may adversely affect future business.

This alternative provides commercial pack stock operators flexibility to respond to year-to-year business fluctuations and client destination requests. It is not likely that an operator will use all the trips assigned to them each year. The overall stock number limit provides the cap on use. At most, if more trips were taken, they would be taken with less stock, again, providing incentive to service more people. Some years destinations may never get used, other years some destinations receive maximum use.

The identification of primary operating areas would reduce overlapping commercial stock operations. Currently there are 18 analysis units where 2 operators have recorded use; 10 units where there are 3 operators with recorded use; 8 units where there are 4 to 6 operators; and 3 units where there are 7 operators with recorded use. Approximately 36 destinations show overlap of two or more operators providing spot and dunnage. This alternative would reduce the number of locations of spot and dunnage overlap to 20 destinations.

The 2001 Wilderness Plan did not address operating areas. For the past few years, some packers have trucked stock to trailheads and areas where they had not historically operated. With the court reduction on service days, some operators spent more time in the adjacent National Parks.

The effect of assigning primary operating areas to those operators at a base facility will reduce overlap. Primary operating area, combined with destination quotas, will guarantee that growth in operations occur in sustainable locations and not increase multiple operators duplicating services. There are also limits, and in some cases reductions, in traveling trips, thereby curbing the trend towards more overlap that is occurring in Alternative 1.

There is a positive effect on the resources and services when a commercial pack stock operator is familiar with the destinations, grazing, trails, and use patterns. When operators frequent specified locations, business operations tend to become routine and result in camping, grazing, and watering of stock in the appropriate locations. For those operators using seasonally employed wranglers, this familiarity can also aid in these employees knowledge of the area: where to drop clients, the time it takes to get from one place to another, the ability of the animals, and limitations of trail conditions. When an operator uses an area that they are not familiar with there is a higher chance for unexpected, even unintended impacts based on the lack of knowledge of the area and its capability and history.

The allowances for a small amount of commercial llama use, (500-service day allocation) for east side entry, would possibly have no noticeable effect. The service will be provided from a variety of high-use trailheads, with itineraries managed through annual operating plans. When the llamas operate in areas where commercial pack stock use is moderate to high, there will be a need for coordination to ensure that conflicts between stock and llamas are minimized. Currently, a small level of private llama use occurs and commercial pack stock operators are familiar with methods to minimize conflict.

A small-scale commercial burro operator would not likely have any additional effects on resources. This operation takes one long trip a year. As long as the itinerary is coordinated and grazing regulations are adhered to, there would be little effect. Often the trips begin on the Inyo National Forest and go into Sequoia-Kings Canyon National Park where the National Park Service regulates the use.

Day Rides

Proposed day-ride levels will moderately increase (25 percent) wilderness-wide from Alternative 1 – No Action. The locations where increases will occur are Recreation Category 3 areas where overall use levels are high yet day-ride allocations have been low. In the two areas where commercial day-ride levels are high, and contribute to crowding and loss of wilderness qualities (Inyo portion of Ansel Adams Wilderness), the day rides are capped at existing levels.

The primary effect of this increase will be some minor to moderate adverse effects on experiential qualities of wilderness. These adverse effects will be short-term in duration, and minor in scale, affecting a very small portion of the wilderness. As in Alternative 1, the commercial day rides occur in the first ½ mile to 6 miles of the wilderness. The use would occur on highly developed trail systems. Other than some minor contribution to overall trail deterioration with this relatively low level of stock use, effects would be negligible to the natural conditions of these wildernesses but moderately adverse effects to solitude.

Party Size

The direct effects of the wilderness-wide party size (15 persons and 25 stock) will mostly be the same as the effects described in Alternative 1. Spot and dunnage trips tend to be smaller party

size than all-expense trips. In this alternative, there is no possibility that operators could change from offering spot and dunnage to all-expense trips. This provides some assurance that current patterns of very few large parties are likely to continue.

As described in Alternative 1, large parties will tend to be associated with the all expense type trips, with spot trips utilizing the next highest percentage of large parties. Dunnage parties are typically the smallest parties. In this alternative, there will be no change, actually a reduction in all-expense trips. This has the potential for fewer large parties. However, with no controls on spot versus dunnage distribution, operators could change towards more spot trips with the associated party size. The seasonal stock limit will control this from being a very significant pattern change as they are limited seasonally to the number of stock.

The effects of larger parties occur primarily on campsites and use trails or trails that may travel through soil or vegetation that is sensitive to disturbance. The total numbers of stock and timing of the use has more bearing on the effect than the actual party size as is described in Alternative 1.

There are arguably more experiential effects of party size, and will continue to be to some extent, in this alternative. The magnitude of the problem is quite low in context to the overall amount of wilderness lands and there will be even more ability to avoid groups and find opportunities for solitude in these wildernesses with fewer trails open to commercial stock in this alternative.

There is one potentially significant indirect effect of the destination quota on party size. Operators have indicated that if they are limited to the number of trips per destination, they will need to maximize the party size for those trips. Some indicate to maximize the income they would turn down a party of two to wait for a larger party to serve. This is a possible strategy; however, it is also contingent on the market and the availability of the number of large of party customers to have an operator turn down a trip in wait for a larger party. Since there is no indication that there is a demand for large party groups, it seems unlikely that operators would turn down clients. In addition, the majority of the destination quotas that were set are not set at the lowest level of use and do not create real scarcity compared to current levels of use to these destinations. There are a number of exceptions where use is limited to destinations; this may be the case, but if the destinations were not suitable for a large party, it would be subject to site-specific party size limitations.

Additional site-specific party size limitations insure protections where there is not adequate capacity for large groups at destinations. By preventing a large party from camping where the site capacity may not be suitable or the recreation category may not be consistent with a large group there will be protection of the solitude and naturalness qualities of wilderness character locally. This comes at some negligible expense to unconfined freedom qualities of wilderness character. The impact to this quality would be minor and short-term, since other locations will possibly be available and party size is not categorically excluded from the wilderness.

Like in Alternative 1's discussion of party-size effects, there are experiential effects to wilderness character. These effects tend to be short-term and negligible to moderate depending on a person's perception. Given the limited occurrences of large parties and the ability to control additional impacts at areas not suitable for large parties with site-specific limitation, the effects of maintaining the wilderness-wide party size would be negligible to minor wilderness-wide, with some people benefiting and others perceiving an adverse impact of the large group.

Campsites

Designated stock campsites would have the effect of concentrating stock related impacts at a limited number of locations. All commercial pack stock trips that hold stock overnight would be required to stay in a designated site. By containing the size of these sites, the expansion of these would be prevented, thereby having a beneficial effect to the wilderness character qualities of naturalness.

Although there may be fewer impacted sites and the extent of impact will be limited, intense stock impacts would exist at these designated campsites. Repeated use of fewer sites may further soil compaction and vegetation loss and over time, these sites could see a proliferation of dead trees, if improper tying to trees were to occur. Other effects of concentration of use would be wood depletion where downed wood is available and campfires are allowed, human waste deposition concentration, and the general appearance of a highly used site. The effects would be moderate to major at the local scale, and minor at the wilderness scale. Most effects could be offset with good design and on going management of the site to prevent adverse effects from being anything more than negligible effects locally.

By designing the features and managing for the expected use, most adverse effects would be mitigated. Determining appropriate access would reduce any trail related impacts associated with the site. Containment to existing historically used sites, the improved access, site design for access and stock holding areas there would be an overall improvement to stock camps and an assurance that commercial stock camps do not proliferate. This would have experiential benefits to other visitors as well as clients of commercial packers. It is expected that the direct effects of reducing the size of camps, improving access, and setting sites further back from lake and stream banks will also result in beneficial effects to social /experiential qualities of wilderness character.

Campfires

Alternative 2 proposes to allow commercial pack stock operators to pack in wood and charcoal and use a fire pan to provide campfires for their clients in those areas where campfires are currently prohibited. Those visitors not associated with commercial operators who are camping in a campfire closure area may have a decrease in their wilderness experience. There may be the tendency for those seeing campfires in closed areas to assume that campfires are allowed and cause more gathering of wood in areas known to be scarce in this resource. In the long-term, it may become easier to gain compliance with the campfire closures. Fire pans will be used and ash will be packed out, so there would be no residual evidence of campfires and, therefore, no campfire rings to induce future visitors to have a campfire. This may, however, generate or add to a sense of inequity between user groups, creating an adverse effect to the experiential qualities of wilderness character. The experiential effects would be minor to moderate locally and short-term; however, adding to the already tension of the hiker-stock use conflict may have long-term effects.

Trail Suitability

The effects of trail suitability determinations in this alternative will be beneficial to the trails identified as closed to commercial stock, adverse to the public that are prohibited from their use, and adverse to the public who may want to see less stock on fewer trails.

Seventy-three (73) miles of system trails are identified for closure to commercial stock. These trails were determined to be unsuitable based on resource conditions and an assessment that continued and repeated commercial stock use would have unacceptable adverse effects on the trail or destination. In these areas, there would be fewer continuing impacts with the removal of a source of the disturbance. In the short-term, the effects may not go away or be reduced, but the prevention of further degradation is a beneficial effect to both the naturalness qualities of wilderness character as well as some public's experiential qualities. Other publics will feel adverse effects to the unconfined recreation qualities from being restricted from traveling on these trails. These effects, both the beneficial and the adverse are minor short-term effects to experience with long-term beneficial effects to naturalness qualities of wilderness character.

Use trail approvals are consistent with the destination quotas and use levels. As with many of these topics, some publics are benefiting from restrictions while others are adversely affected, experientially. The resources are expected to receive long-term beneficial effects at the local and wilderness scale from the removal of disturbances in locations where the risk of further degradation by pack stock disturbances are high.

Cumulative Impacts of Alternative 2

Past, present, and reasonably foreseeable future levels of visitor use (backpacking, day use, and private equestrian use), when added to the commercial use levels prescribed, will have minor long-term adverse effects to the naturalness and experiential qualities of wilderness character. Most of the wilderness will have high opportunities for solitude but unconfined recreation is slightly diminished for all users with the use of a restrictive visitor-use permit system.

The developed and untrammeled qualities of wilderness character are not affected with any of these actions. Past uses, (structures, dams stocking, grazing, mining) have major long-term impacts that current uses and proposed actions in this alternative cannot measure up to. No cumulative effects occur to these wilderness character qualities.

Locations where trail impacts are severe may be the result of many years of use or lack of regular maintenance or reconstruction. These trail impacts are often the result of poor or no trail design (many shared trails evolved from the need of the users needs, not by design). Trails located in meadows and riparian areas can cause excessive erosion. This can be exacerbated by stock use, but is not fixed without substantial physical mitigation. Removing one causal agent of erosion such as commercial pack stock may not do much more than slow the rate of deterioration.

The proposal to allow increases in day rides, when added to the day hiking and overnight use levels, can have an adverse cumulative impact at the local levels to visitor's experience, opportunities for solitude, or a sense of naturalness. These effects are short-term and in some locations moderate in intensity but local in scale of the impact.

There may be some minor cumulative effects to the naturalness quality of wilderness character with the past, current, and proposed use of drift fences, the sanding of passes and other means to facilitate commercial stock use. Maintaining a minimal number of smaller structures (drift fences) for resource protection may have minor adverse effects to the wilderness quality of undeveloped. When viewed collectively with the various structures from past uses, remnants of recreational impacts and current proposed allowable uses of commercial pack stock activities, some (very few) areas may have an appearance of human occupation and improvements. This

effect may be long-term and range from negligible to moderate intensity relative to a person's perceptions.

Alternative 3

Summary of Alternative 3 Wilderness Resource Effects

Overall, impacts to wilderness character with this alternative will be moderate intensity at fewer site-specific locations than Alternative 1 but more locations than Alternative 2. Impacts to a visitor's experience would be short-term, particularly at popular destinations and on primary trails. There would be a higher risk of destinations becoming more impacted over the long-term than in Alternative 2 with an external versus internal control. These would likely be long-term minor to moderate local impacts.

While some impacts to natural conditions such as locally severe trail impacts, may be longer term, they are not expected to have permanent adverse effects. Some long-term adverse effects to wilderness character may result at specific sites because of with trail development decisions. Trails lose their primitive characteristics with improvements and development to facilitate uses. There would be more occurrences of this than in Alternative 2. The same action (trail development) that may occur over the long-term would enhance ecological and natural qualities of wilderness character.

Beneficial effects in this alternative include improved wilderness character of many destinations where impact sources (pack stock) are removed. There will still be sources of impacts, however, it is possible that the severity of the impact will be reduced over the short and long-term.

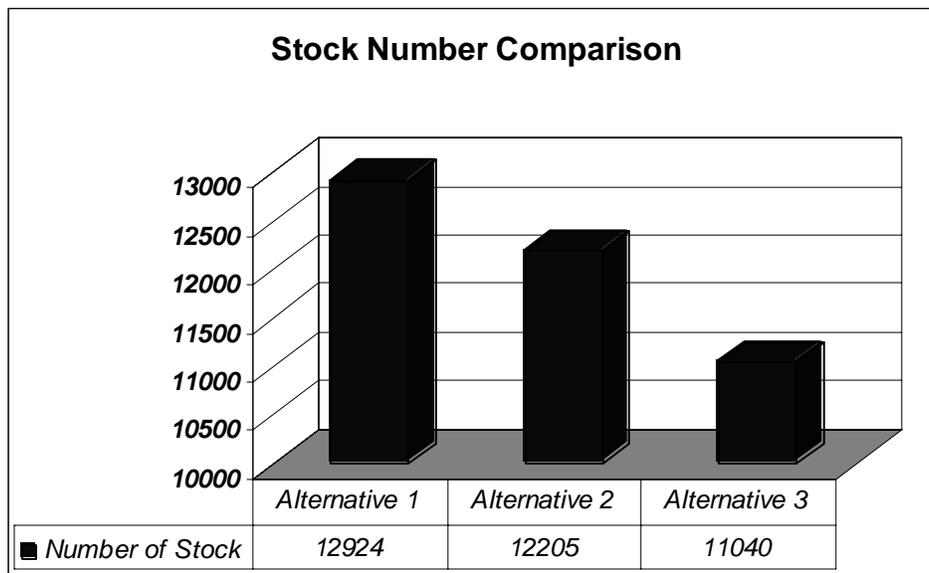

- Modified trailhead quotas allow for definitive quota space for commercial pack stock operators. Opportunities for solitude would be the same as Alternative 1. With no controls on destinations, spatial spikes in use may occur. Occurrences and frequency of occurrences at destinations may increase. Traveling trips may increase as a result of no service day control, which, if this were to occur, would lead to more encounters with stock and potential for opportunities for solitude and naturalness to be diminished.
- Trailhead quotas have a higher probability for use patterns to change than the quotas in Alternative 2. Use pattern changes can lead to new resource impacts at sites and destinations with current light use.
- Party size limits ensure the campsite capacities are not exceeded and eliminates the potential for new impacts of sites expanding at a small number of locations.
- Campfire use in closed areas creates an equity issue the same as Alternative 2, but effects are lesser than Alternative 2 because fewer locations would be affected.
- Use trail authorizations would provide some limit on the extent of operations and impacts. System trails allow for a higher level of development than Alternative 2. There may be conflicts between wilderness character and trail objectives if trails were built to standard. In some locations, needed maintenance and reconstruction could improve conditions and character of the areas.

Analysis

Use Levels

The rationing of use by daily trailhead quotas on people with seasonal thresholds on numbers of clients and numbers of stock are the essential components for controlling use levels in this alternative. Seasonal thresholds define the overall capacity of each trailhead for commercial stock operators. The effect of having an overall capacity identified is that it allows for a measuring of use and impact over time. Compared to Alternative 1, where the overall measure of capacity is service days applied wilderness-wide, this measure is more location specific and directed at the source of the impacts and the stock—not the people, the duration of people in the backcountry, or in the company of the guide (service days). However, this does not provide the same level of control on destinations as Alternative 2; with the exception of the 27 destination quotas that will be in place (see discussion below). In short, it provides more protections than Alternative 1 and fewer direct protections than Alternative 2.

Figure 4.3 Stock number comparison Alternatives 1, 2, and 3. This chart compares stock numbers that are expected wilderness-wide in Alternatives 1, 2, and 3.

As in Alternative 1, there is a higher probability for use patterns to change with trailhead quotas. Other than the 27 destinations and trail suitability determinations providing limits to destinations, commercial packers can provide service to allowable destinations as frequently as they desire or as business requires. Because of this, there may be a higher possibility that resource conditions may be affected by use patterns and changes over time as compared to the more direct controls in Alternative 2. The effects of these less direct use controls are similar to those in the No Action alternative since they are both external (trailhead quota) controls. See discussion in Alternative 1 on trailhead quotas' temporal versus spatial controls.

There will essentially be no limits on the duration of trips, as is embedded in the service day concept (Alternative 1 – No Action). Over time, service day limits had the effect of changing operations to more spot and dunnage trips to maximize service day allocations. Without this control feature there may be a trend towards more all-expense or traveling trips. Limitations on

grazing and campsite locations would ensure that if this occurs impacts of these types of trips would be limited. If more all-expense trips occur, there may be long-term moderate intensity effects to campsites and trails with more stock days in the wilderness.

Splitting out specific commercial pack stock trailhead quotas, where they were competing for quota with other outfitters and guides in Alternative 1, will have very little effect on use or resources. There may be fewer occurrences where the pack stock operator is truly limited. This may lead to a sense of inequity if the public is being limited and denied access on trailheads where the packer does not appear to be limited to the same degree. This is expected to occur on less than six trails in the planning area.

Outfitter and guide use, including the llama operator and burro operator that are proposed in this alternative, will be limited primarily by service day allocations. The daily trailhead quota established for these operators will prevent spikes in use from concurrent multiple operator use while overall capacity of outfitter and guides is controlled with the service day allocations from the 2001 Wilderness Plan. It is likely that only minor changes in use patterns or use levels will occur because of this, with no long-term effects to wilderness character.

Changing recreation category (RC) designations for 35 destinations will have very little direct effect. These category changes would align with current conditions, which are conditions that have been in place for many years. For 20 areas, this action will ensure that areas that are more remote and currently have little evidence of impact will not be allowed to change and this condition will be maintained over time. Six areas that are proposed to go from a RC3 to a RC2 also do not show signs of being a RC3 condition and would have no need to manage these areas as intensively as a RC3 implies. Eight areas will be aligned to reflect the fact that they are not and have not been as remote or pristine as the recreation category implied and in these cases, there will be no change in impact because of the category change.

Party Size

Party size limitations and effects would be the same as the proposed action (Alternative 2), a wilderness wide limit of 15 persons and 25 head of stock with limits below the maximum party size at 15 locations. There would be insurances that larger parties would not be accessing areas where capacity or capability does not allow for that party size. It is not likely that parties greater than 12 persons and 20 stock will be any different from use patterns in the past, with only 2 percent (approximately 100 groups) of all commercial stock parties exceeding 12/20.

The effects of the wilderness-wide party size are the same as for Alternative 1 and 2. The difference with this alternative comes from the possibility that operators could shift to more all-expense trips. Since larger parties occur with the all expense type trips, there could be more large parties as a result of this alternative over time, if operators change the distribution of trip types. The effects of larger parties can be seen on campsites and use trails or trails that may travel through soil or vegetation that is sensitive to disturbance. As noted in Alternative 1 and 2, total numbers of stock and timing of the use has more bearing on the effect than the actual party size.

Experientially, there could be some moderate adverse effects of a short-term nature associated with more large parties, if that were to happen. The magnitude of the problem will be low, since overall limits are still in effect. With fewer trails open to commercial stock than in Alternative 1, there are more locations where large commercial pack stock parties can be avoided.

Campsites

Campsites would be designated for all trips by pack stations where there is overnight holding of stock. These sites are the same as in the proposed action, Alternative 2. Trails would be identified to access the site in the most durable and appropriate location and would have the effect of reducing existing resource impacts associated with poor location and stream crossings. There would be a general improvement in the condition of these sites. Sites would be contained to insure that continued expansion of the impacted areas (areas of stock holding where vegetation is lost and the soil is compacted) would be limited and contained. See discussion under Alternative 2, campsites. Camping limitations would be the same with few exceptions, noted in the geographic unit section of this discussion.

The only difference with this alternative comes if, again, use patterns and the distribution of type of trips change. If more all-expense trips occur, the frequency of use of designated sites will increase. When a site gets more repeated use, there will be additional impacts of concentration of use. However, with designated site direction the site will be designed and managed and will not increase in size, there may be further soil compaction, root exposure in the holding areas. Over time there could be an increase in dead trees from soil compaction and continual girdling of trees even if each occurrence is temporary. The site will generally have an appearance of more use. Human waste concentration may become an issue with repeated use of sites. These potential impacts would not happen immediately and may take up to ten to twenty years to occur, if they occur at all. The impacts would be long-term but not irreversible as impacts can be mitigated with on going management.

Campfires

Campfires would be conditionally allowed in areas above the elevation closure, at a designated site with an employee of the pack station present. This would greatly limit the locations where campfires would be in conflict with the closure and may greatly limit the effects described in the proposed action of compliance to the closure by other non-commercial parties.

Even with reduced numbers of campfires above the elevation closure, there could likely be a proliferation of campfire rings above the elevation closure over time. This would be a result of confusion among the public about whether or not campfires are actually allowed. The proliferation of campfire rings will reduce the untrammled character of the wilderness and probably result in reductions to the natural character of the area, as vegetation is expected to be removed from living trees and bushes in this sparsely vegetated area. Perceived inequities between commercial pack operators and the generally public would create user conflict. These effects may be long-term in duration, with lasting impressions of impacts in visitors if the impacts of campfire use do increase from the current situation. The effects to the naturalness qualities of wilderness character will be of moderate intensity and short to long-term in duration if compliance issues go unresolved and wood sources are depleted.

The allowance may also increase the numbers of pack stock used for a party. To bring in firewood from outside the wilderness for a campfire will require more pack stock, possibly up to 1 or 2 more mules per trip, depending on the duration of the parties stay. With an overall cap on stock numbers there will not be an increase in the number of stock (since the overall cap is at existing levels). This effect will be negligible in the long-term since the overall cap will be in place.

Trail Suitability

In this alternative the Trail Plan upgrades the trail class on 48 trails from the proposed action. Most of the 48 trails would be changed from a TC1 to a TC2, while some are added to the system from Alternative 2 and a few are proposed being changed from a TC2 to a TC3. This may have some negative effect on wilderness character and perceptions of those visitors that desire primitive, unconfined experiences in wilderness. A higher percentage of TC2 trails may also affect opportunities for solitude in the future in areas where access may improve from current conditions that either impede access or just not draw visitors due to difficult trail conditions. These experiential effects could be long lasting in duration and of moderate intensity for some visitors seeking more primitive conditions in the wilderness.

Trail suitability determinations in this alternative are not substantially different from Alternative 2 (proposed action). Approximately 30 more miles of system trail (of 1,056 miles) is available to commercial operators in this alternative from Alternative 2, which cumulatively is not significant, but site specifically will have some short-term adverse minor effects on solitude, crowding and potentially use conflict between user groups.

Sanding on passes (by line officer approval) allowed in this alternative will reduce the natural and untrammelled qualities of wilderness character. Sanding does not allow nature to be the primary force acting upon the wilderness. It may lead to some effects on the trail system where soft, wet soils could be trampled at a higher rate than dry, firm soils. This could effect wilderness experience and ecological values at site-specific locations and cause long-term adverse effects of moderate intensity associated with the early access to areas (wet areas) that may be vulnerable to impacts.

Use trails provide more access in this alternative than in Alternative 2 with approximately 17 more trails approved of 190 use trails considered. Overall, this is not a substantial change, a less than 10 percent difference. However site specifically, increased access may affect the character of some locations if pack stock operators were to change use patterns and frequent these locations. Without limits on most locations (i.e., destination quotas) and with limits only on entry, there could be use pattern changes that would lead to more use at destinations that currently do not get much use and this could affect the wilderness experiences of others. More use of these less developed and unmanaged use trails could have minor to moderate effects to naturalness if increased visibility of faint trails occurs over time. Soil compaction and vegetation loss effects could be long-term in duration.

Cumulative Impacts of Alternative 3

Overall, there would be no long-term adverse effects of major proportion to any of the qualities of wilderness character as a result of the proposed actions in this alternative. No significant changes to wilderness character are expected to occur wilderness wide, though there may be locally moderate adverse effects, there are primarily locally moderate beneficial effects from these actions, that when added to the other uses, other adjacent landscapes, and past actions, do not constitute significant effects.

When viewing the proposed actions of Alternative 3 in conjunction with current uses and past actions of trailhead quotas from the public there is then the potential for a cumulative effect of moderate intensity from on both experiential (solitude) and naturalness qualities of wilderness character. The actions of splitting out a specific pack station quota and managing multiple quotas

for different user groups could negate the actions of the 2001 Wilderness Plan for reducing spikes in use. With multiple user groups accessing their own quotas, spikes in use would probably occur more often than in Alternative 1.

Cumulative beneficial effects to naturalness qualities of wilderness character are at the expense of moderate intensity impacts to freedom and unconfined recreation. The past actions of 30 years of management, combined with these additional actions have led to a highly restrictive management regime for commercial pack stock operators and the public. Additional party size limits, use trail prohibitions, grazing restrictions and campsite limitations, combined with past actions such as food storage requirements, campfire prohibitions, and trailhead quotas, all contribute to a highly regulated wilderness experience for all users. This has the effect of providing some protection to visitors from overcrowding while at the same time limiting visitor freedom, a highly prized wilderness value.

There are a number of layers of restrictions on pack stations in this alternative. Some actions reverse past actions and create a less restrictive environment for operating (such as campfires use, no service day requirement). Some actions are additional restrictions (party size, trail suitability determinations) and these past and present actions have a cumulative effect on the ability of the operator to conduct the business that on the surface appears to be authorized. The effects accumulate to the point of making it more difficult to operate and while there may be long-term beneficial effects to the naturalness qualities of wilderness character there are adverse effects to the public ability to use the services of a pack station as a result of the multiple layers of restrictions.

Over time if seasonal client or stock thresholds are reached, there may be a reasonably foreseeable action to either further limit use or to increase thresholds. Since this would be the result of a thorough analysis of the conditions of the areas of operations and their capability to sustain more use or the existing use, it is reasonable to expect that any additional use would occur with full assurance than no change in resource conditions would result. It is not likely that these thresholds would be reached for a number of years, if ever.

Alternative 4

Summary of Alternative 4 Wilderness Resource Effects

Overall, impacts to wilderness character with this alternative will be moderate intensity at fewer site-specific locations than Alternative 1, 2, and 3. Impacts to a visitor's experience would be short-term, but could be greater at popular destinations and on primary trail compared to Alternatives 1, 2, and 3. While some impacts to natural conditions such as locally severe trail impacts may be longer term, they are not likely to have permanent adverse effects. Beneficial effects in this alternative include improved wilderness character at many destinations where impact sources (pack stock) are removed. There will still be sources of impacts; it is expected that the severity of the impact will be reduced over the short and long-term.

- Trailhead quotas provide an external control for limiting use. Quotas are decreased in some areas, which has a probability—but not a guarantee—of improving the conditions of internal destinations. Without direct, internal controls the frequency of use is not controlled.

- With a reduction in people serviced and controls on people, not stock, there is a potential for stock numbers to increase.
- Compared to other alternatives, there are fewer use trail authorized and this greatly reduces area of operation and reduces possibility of new impacts in more remotes areas that use trail access. Pack stock is concentrated in fewer areas.
- The extent of impact is greatly reduced in this alternative. Intensity of impacts may be higher in locations of concentrated use.
- Opportunities for solitude are less on primary trails and corridors where stock use is concentrated.
- Party size limitations would reduce encounters between large commercial stock parties and other visitors.

Analysis

This alternative has fewer direct adverse effects to the environmental components of wilderness character. With trailhead quotas (external control, see discussion in Alternative 1 and 3 on external controls and spatial and temporal effectiveness) there are fewer direct controls, which results in fewer direct consequences. Consequences become a matter of probability, which is more difficult to determine or predict. Secondly, Alternative 4 actions have fewer, but in many ways more potent effects on commercial pack stock operations because in general, it greatly limits the area and extent of commercial pack stock operations in the project area. By limiting the area and extent of commercial operations there will likely be further concentration of this type of use into fewer areas. With concentration of use there may be effects of intensive impacts in fewer areas.

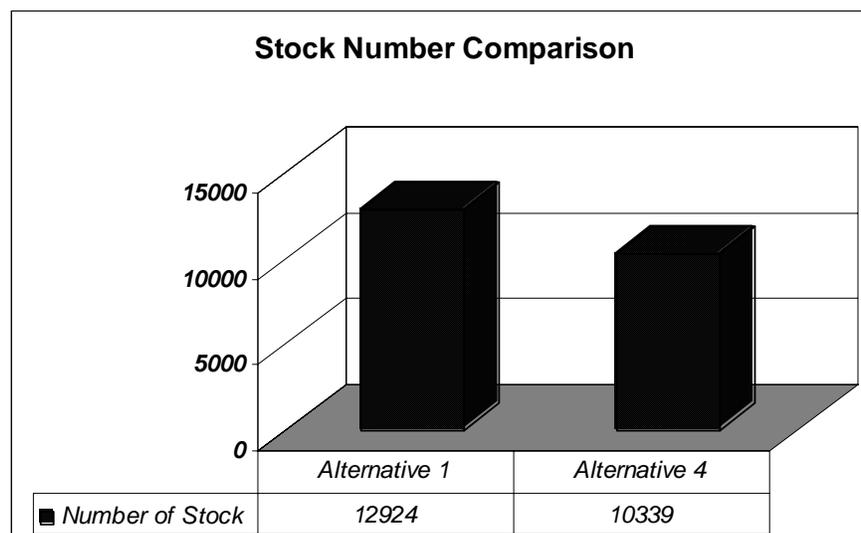

Use Levels

This alternative will reduce the overall level of commercial operations by approximately 20 percent below those prescribed in Alternative 1, No Action by reducing the allocation of service days. Service days measure people and the duration of the client's time in the wilderness with an outfitter or guide. Service days do not measure or control stock numbers. The effect of reducing service days is that some operators will have over time, a higher ratio of stock per client. This is evidenced by the 2001-2004 commercial pack stock use comparisons where some operations tally sheets indicate that more stock was used per client to compensate for the reduction placed on people being serviced (Inyo National Forest tally sheet data 2001-2004). So while an overall cap is placed that is lower than current it is likely that there may not be a corresponding difference in stock numbers wilderness-wide.

With fewer areas available to commercial operators, there will be more stock on fewer trails and more stock at fewer destinations in this alternative. The primary control mechanism in this alternative then becomes limitations on where the stock can go and trail suitability. This will result in more intensive impacts in fewer areas. This may reduce the adverse effects to natural conditions of wilderness and improve more areas where stock will no longer have a disturbance to vegetation and soils on trails and at campsites. It will also probably result in more crowding and some corresponding loss of solitude and moderate long-term effects to some visitors (clients of pack stations) visitor freedom and unconfined recreation opportunities.

Commercial pack stock use is rationed by daily trailhead quotas on people. Some trailhead quotas are proposed for lower than current quotas based on resource concerns in areas accessed by the trailhead. Trailhead quotas are most effective as timing (temporal) controls rather than site-specific (spatial) controls and based on a probability that ecological impacts will be reduced if overall numbers are reduced. It is expected that improvements to the destinations that were intended for the reduced quota will see limited beneficial effects in the short-term unless the commercial stock is entirely prohibited from the area. That is because the quota only limits the entry, not the frequency of the use to destinations. It is the type, timing, and frequency of the use more than the overall amount of use by trailhead that affects impacts to campsites and trails.

Figure 4.4 Stock number comparisons Alternatives 1 and 4

Trailhead quota availability will likely be a substantial limiting factor for commercial operators. With lower quotas, the quota will possibly be filled more regularly. As described in the effects of Alternative 1, just having a small amount of quota available may limit access for a party. This effect will happen more often than the effects described in Alternative 1, and are likely to affect the operators to the point where service days cannot be used. This will have long-term moderate adverse effects to visitor freedom and recreational opportunities for the clients and potential clients of pack stock operators. By making access difficult, the public whose experiences are diminished by pack stock use will see moderate beneficial effects to their wilderness experience.

Overall, use levels will be lower than Alternatives 1, 2 and 3 and there will be a probability that lower use will have beneficial effects to wilderness character. With many more locations closed to commercial stock, there will be higher concentration of commercial stock at fewer locations and the overall extent of impacts by commercial pack stock will be greatly reduced. There will be minor to moderate impacts to naturalness wilderness wide, with some locations seeing increased impacts while others seeing a reduction in impacts.

Day Rides

Day ride allocations would be reduced from those prescribed in Alternative 1 at locations where the potential for social or resource conflicts exist. This would result in some minor reductions in

encounters with commercial stock, in some locations, since day rides are not a major use currently, little change would be noted wilderness wide.

Party Size

Reducing the party size from 15 persons and 25 head of stock to 12 persons and 20 head of stock will affect less than 6 percent of commercial pack trips. Some operators have a higher number of large parties and will be affected more than other operators will. It is probably fair to estimate then that a small portion of the commercial pack stock use would be affected by the party size change.

Because this alternative would not allow commercial operators the practice of “borrowing” trailhead quota from the following day to accommodate groups larger than six on some trailheads, group size would, in effect, be reduced further still. It is predicted that this would have a far more significant effect on party size than the wilderness-wide limitation. Of the 55 trailheads with commercial pack stock daily quotas, 39 (or approximately 70 percent) of the trailheads servicing the project area would not be available for a group of 12 commercial pack stock clients at any time. In all probability this would significantly reduce the opportunity for larger groups to utilize commercial pack stock services in the planning area. Other wilderness visitors would still be able to borrow available quota from the following day to provide for either larger groups or multiple small groups to enter a particular trailhead.

It should be noted though, that Cole and others (1987) suggest that in order to have a significant improvement on social or ecological resources, party size would have to be reduced substantially (to 10 persons or less). This would be occurring on a local basis with the trailhead quota determining party size. This more directly affects areas accessed by low quota trails, which should correspond to meeting management objectives for more pristine conditions (Recreation Category 1 areas) and higher opportunities for solitude.

Limiting large parties can lead to beneficial effect on solitude and experiential values of wilderness. Some people prefer to encounter one large group rather than multiple small groups throughout a day. However the research does not definitively find that a certain number of stock, such as 8, 12, or 20 stock, is the threshold for experiential values. It is well documented that stock parties are known to have more potential impact on the environment than hikers to both accelerated erosion and vegetation damage (DeLuca et al., 1998). Research has suggested that group size limitations may be important for horse and mules (Monz et al., 2000).

Other actions in this alternative (such as prohibiting commercial pack stock on many trails) address the threats to ecological components of the wilderness resource better than party size reductions. The use impact relationship where light or low levels of use generally cause the initial and most persistent impacts (Cole et al.) is countered, in this alternative, by a combination of party size reduction, designated sites, and limited use trail approvals. In this alternative, many of the remote lightly impacted locations would not be authorized for commercial pack stock use. Use trail approvals are significantly fewer in this alternative than in alternatives 1, 2 and 3; with only 44 approved use trails compared to 110 in Alternative 3, 100 in Alternative 2, and 103 in Alternative 1. Many of these use trails access the more remote and less impacted locations.

Research findings suggest that party size limitations can be most effective for reducing or preventing ecological impacts in remote, lightly impacted portions of wilderness (Monz et al., 2000). This is consistent with research of Cole and others that describe the curvilinear

relationship between use and impact in regards to ecological impacts. Where use and pre-existing impact levels are high, party size changes will probably be minimal. In undisturbed locations however, large groups can have a significant impact to soil and plant communities and possibly other resources such as heritage resources. It is well documented that stock parties are also known to have more potential impact on the environment than hikers to both accelerated erosion and vegetation damage (DeLuca et al., 1998). However, research has also shown that a reduction of stock use to almost zero is required to significantly reduce the impact stock have on accelerating erosion. According to Hendee et al. (1990) “Numerous studies have concluded that [ecological] impacts on trails and campsites are unlikely to be greatly diminished merely by reducing [stock] use, unless use levels are cut to almost nothing. Reducing [stock] use can help minimize social and ascetic impacts (horse user-hike conflicts, manure, and so on), but other less drastic measures can also be taken.”

Campsites

Commercial pack stock use-patterns are also limited by designated campsites. There will be no discretion or flexibility to camp or drop clients at new locations. No new campsites will have a long-term beneficial effect wilderness wide on the preserving the natural characteristics of wilderness. Limiting the locations of sites will prevent proliferation of impacts into new locations and concentrate the impacts of stock camps and drop camps where loading and unloading of stock takes place. There will however be moderate long-term effects on freedom and unconfined recreation to the clients of commercial pack stock, by eliminating the flexibility and spontaneity.

There may be conflicts in use at designated campsites with fewer sites available. One hundred and fifty five locations are identified for camps, 59 as stock camps, and the remainder as locations where spot and dunnage parties can be serviced. This greatly limits the geographic extent of commercial pack stock operations. When the numbers of locations are fewer, and a site is occupied by another packer or by the public, there may become conflicts of supply and demand. This will probably require intensive management over the long-term.

The sites that will get used will get repeated use. Overtime these sites will likely show signs of deterioration. Soil compaction and vegetation loss will occur and though the stock camps will be confined and managed to avoid expansion, the effects of concentration will be evident. There may be an increase in dead trees as a result of soil compaction, human waste concentration will occur. These effects are similar to those described in Alternative 2 and 3, however with fewer sites; the concentration effects will be somewhat greater.

By reducing the geographic locations and extent of commercial operations, especially eliminating use of sites in remote areas and currently less impacted, the effect may be to protect and insure that further degradation from commercial packs stock operations does not occur. Those areas however would continue to be available to the public (both stock users and hikers, and non-commercial pack stock users. Wilderness visitors (including physically challenged those with special needs, and some of the elderly and very young) who prefer or depend on pack stock support would be limited to fewer choices for locations compared to Alternatives 1, 2 and 3.

Trail Suitability

With 159 miles of trails identified as Not Suitable for Commercial Stock, almost twice as much as the Proposed Action – Alternative 2, which is the next highest mileage not available for

commercial use, many locations will be inaccessible to commercial stock. Clients however, once they have ended the service provided by pack stock, however, would have no restriction on hiking to these areas. Although the freedom to use stock into these locations is restricted, travel by foot by the clients is not. Many clients use the stock to get to the destinations and often travel by foot once there. There would be a minor adverse effect to some clients of pack stations.

With fewer trails accessible to commercial pack stock, the extent of commercial pack stock use is limited. Use patterns will change and this may have some adverse effects on some areas that will see an increase in use. The areas that remain suitable for commercial pack stock use would experience some increase in use. Some of the areas where use was light due to current patterns that disperse use, could become more affected both from the natural characteristics and experiential with some loss of solitude as more pack stock use occurs.

There would be long-term beneficial effects to natural characteristics of wilderness in all the areas where commercial pack stock is prohibited, and a corresponding adverse effect to the experience of visitors that are restricted.

The system trail inventory, with a higher percentage of trails maintained at the TC1 and 2 level, will have more primitive characteristics than the trail system of Alternative 1, 2 and 3. Trail development is minimized in this alternative and this will bring about long-term beneficial effects to the trammled, undeveloped, experiential, and natural qualities of wilderness character, wilderness wide. Locally, there may be trails that are under maintained or developed for the use levels, as use patterns are less predictable in this alternative.

Cumulative Impacts of Alternative 4

Past action of maintaining commercial stock on existing trails and subject to trailhead quotas achieved through the 2001 Wilderness Plan greatly limited the geographical extent of commercial pack stock operations. This alternative provides additional controls that further reduce the locations where these commercial services can be provided and the amount of commercial service. These limitations would have a moderate adverse effect on unconfined type of recreation for those who choose or need the assistance of commercial pack stock services. There would be a beneficial long-term effect to the wilderness resources with the elimination of one source of disturbance.

Past actions of reducing the extent of trails and cross-country travel (2001 Wilderness Plan) greatly reduced the areas where commercial pack stock use could occur. With additional restrictions to commercial pack stock operators greater opportunities for solitude may occur in identified areas due to commercial pack stock limitations; but because no other wilderness visitors would be restricted from using those areas, an increase in opportunities for solitude would not likely be realized.

No major long-term effects to any quality of wilderness character wilderness wide occur as a result of implementing this alternative. There are cumulative effects of additional restrictions on top of decades of incremental restrictions on both the public and the commercial pack stock. Cumulatively, with past, present and proposed actions of this alternative, moderate intensity impacts occur wilderness wide to visitor freedom and unconfined recreation opportunities.

Alternative 5

Summary of Alternative 5 Wilderness Resource Effects

In this alternative, commercial pack stock use would be eliminated. Without commercial pack stock there would be a reduction of encounters and less crowding between parties—especially on the primary trails—leading to an improvement to the experience of hiking visitors.

Impacts associated with commercial pack stock use would diminish over time but may persist as sites, trails, and use trails will still receive public use. The majority of visitation would continue but some visitors that choose to use pack stock for their experience will not be able to find that opportunity.

In this alternative, minor to moderate impacts would occur locally and wilderness wide with continued visitation. The intensity of these impacts would diminish over the short to long-term. Moderate impacts that were associated or partially attributable to pack stock would likely diminish in the long-term (10-20 years). There would be beneficial affects to wilderness character with the reduction of site-specific impacts and increased opportunities for solitude that would occur by reducing overall wilderness use by 10 percent. There would be adverse impacts to a large sector of the public that desires or depends on pack stock support for their wilderness experience.

Analysis and Cumulative Impacts

Use Levels

Currently, between 5,000 and 7,000 visitors are serviced by commercial operators, which amount to 7 to 10 percent of overall use in the 2 wildernesses. Under this alternative no commercial pack stock use would occur. There would be no visitors accessing the wilderness with pack stock commercially. Less than 500 visitors would still access with private stock and the remainder of the visitors would access the wilderness by foot. The demographics of visitors would change to favor the more fit and experienced. Those less fit, less experienced, with special needs, some elderly, and others desiring to experience the historical/cultural aspects of pack stock use in these two wildernesses would be far less likely to access these federal lands without the support of commercial pack stock.

More significant than the number of people would be the number of stock. Approximately 10,000 commercial stock access the two wildernesses currently. With no commercial stock on the trails, there will be a noticeable change in these areas. Stock has been present and a constant use type in these wildernesses since prior to their designation in the National Wilderness Preservation System. With no commercial stock on the trails, there would be less conflict between hiker-stock user group and a substantial reduction in stock related impacts to campsites and trails.

There would be some loss to wilderness character with the elimination of commercial pack stock use. Wilderness and wilderness values are largely rooted in the early recreation use in the mountains where travel was primarily by horseback and pack stock. The 1964 Wilderness Act emphasizes the values of primitive and unconfined recreation use. Tremendous support for the Wilderness Act was provided by recreation stock visitors as a way to protect these lands for this type of recreation. This is not to say that the National Wilderness Preservation System was

created for one user type over another, but that there are various ways to value and enjoy wilderness. With this in mind, the 1964 Act probably did not intend to exclude one type of use, but rather recognized the values of primitive recreation, including riding and pack stock use.

The opportunities for solitude in these wildernesses would possibly increase. This would be more evident and noticeable at destinations and in corridors where commercial pack stock operate. Primary trails where pack stations are located would have a noticeable change in solitude and encounters. Encounters with pack stock will be rare in places where they are currently moderately frequent during July, August, and early September. Although there will be less encounters with stock parties in these primary corridors, there would continue to be frequent encounters with backpackers and day hikers. With the removal of stock, there may be an increase in backpackers. Those hikers and backpackers that have avoided areas where pack stock use is high may plan more trips than they currently do.

Since the vast majority of the wilderness is not visited by commercial pack stock, and commercial operations are concentrated in a relatively small part of the overall project area (9 percent), there would be minor long-term benefits at the wilderness scale to natural characteristics of wilderness. Experiential qualities, however, would be affected as both pack stock use and other visitors tend to be concentrated in the same area. This concentration of use often leads to conflicts between user groups.

Campsites

The majority, if not all of the campsites used in conjunction with commercial pack stock operations will continue to get used. It is expected that the same destinations will continue to receive high levels of use with or without commercial pack stock use. Destinations that packers favor will see less use and at some destinations, there will be a noticeable change with long-term beneficial effects to naturalness with the elimination of a major source of disturbance. These will be addressed in the geographic unit scale. Campsites will likely not improve significantly since they will continue to receive use and impacts have already taken place. Only with additional management would campsite rehabilitation, containment, and improvement to the site take place

Party Size

Party size for the public will continue to be 15 persons and 25 stock. It is not likely there would be any groups that reach the 25 stock limit. Private stock visitors generally travel in small groups. However, this alternative would not limit non-stock commercial outfitters who travel in maximum group sizes. Fewer encounters with large parties would occur and this may improve the sense of solitude for visitors and have short-term beneficial affects to the experiential qualities of wilderness.

Trail Suitability

Improvement to trail conditions and the visitor's experience on trails would probably occur over time. This would improve the character of the area in that trail conditions do affect a visitor's experience and stock impacts to trails are evident and noticeable in these wildernesses. With trails not needing to be maintained for heavy stock use, more primitive trails would likely be more prevalent than they are today. Trails that are more primitive would probably improve some aspects of a visitor's wilderness experience.

Geographic Scale

Ansel Adams East – Alternative 1

Analysis

In this alternative the northern units, Glacier, Bloody Canyon, and Gibbs are managed for low use with single quota trails. A case-by-case approval is needed for Bloody Canyon. Although use is not prohibited in these units, there has been no commercial pack stock in these areas, with the exception of one trip to Bloody Canyon in the late 1990s by a commercial operator. It is not likely that commercial stock use would occur in the future due to the condition of the trails and lack of desirable destinations for pack stock or pack stock support. Although it is possible in this alternative for commercial stock use, it is not probable.

Commercial stock use will be very low in the Parker unit. Day rides will occur up to the wilderness boundary but will not go into the Ansel Adams Wilderness. The day ride allocation is not specific to trailheads so it is possible that day ride use could increase into Parker if the packer chooses to change their current pattern. There could be effects to solitude. Impacts would be concentrated on existing trails and there would be negligible effects to natural conditions of wilderness character if day rides would increase.

Rush Creek will continue to receive a very high level of commercial stock use in this alternative. Over 300 commercial stock a year will travel through the Rush Creek corridor and 700-800 stock will circuit between multiple destination in the Rush Creek unit, primarily Alger Lake, Clark Lakes and along Rush Creek between Gem and Waugh. Stock numbers could increase in this alternative since the only mechanism for stock numbers is the 110-herd limit for the packer at Silver Lake. The ratio of commercial packer clients to total use is one of the highest in the planning area at 34 percent. Though this number is relative to the total use and Rush Creek receives only moderate public use, commercial stock will be noticeable in the drainage.

With this high level of stock use, there will be experiential impacts between hikers and stock users. Visitors in this drainage are likely to have multiple encounters with pack stock and the trail. The high level of manure and the pulverized tread can have an effect on a visitor's experience.

Alger, Clark, Davis, and Waugh Lakes will continue to receive a high concentration of commercial pack stock use. This operator has and will probably continue to operate with designated camps at these and other identified locations, though it is not required. The effect of this is to allow intensive impacts at a limited number of camps. These stock camps may show expansion over time, but the effect of limiting the stock to these designated sites will prevent widespread impact of multiple stock camps and stock impacts throughout the drainage. Upper Rush Creek will continue to be an area of high commercial pack stock with multiple operators.

Donahue Pass, with its access to Yosemite National Park, will draw operators who conduct traveling trips from trailheads to the south. Competition for campsites and grazing resources has the effect of increasing the potential for new sites to be created when multiple operators converge. Davis Lake is a destination with a designated stock camp used primarily by the operator out of Silver Lake. The site will receive moderate to high use with possible expansion in total area but will generally contain the intensive impacts of repeated stock use. Grazing resources near Rodgers Lake show signs of impacts that have developed in a very few years, the

effects of trailing stock to the grazing area and wrangling them back to camp in the morning have had local adverse effects on the riparian conditions and effect natural characteristics of the area. This demonstrates that new impacts to an area develop quickly, but as research indicates, these impacts will likely remain stable now that they have reached this condition (Cole 1987).

Use is currently authorized to Upper Davis Lake but little evidence that commercial stock use occurs. With this being an option in the future, there could be further impacts to the lightly visible trail and the alpine lake destination if stock use were to increase. Marie Meadow is a designated site that gets less use now that the campfire closure has prohibited campfires at this site and this pattern will probably continue, with Marie meadow receiving fewer stock trips and the campsite and grazing area will over time show less impact. Use is allowed to Marie Lake by commercial pack stock in this alternative but is currently not occurring and is expected not to change in the future.

The Thousand Island /Garnet Lakes area is also an area of very high commercial stock use. Multiple trailheads can access this area and the effect of placing trailhead quotas on the commercial pack stock have been minimal since there are multiple access points and it is unlikely that the combined quota space would limit access for the commercial operator. Spikes in use still occur, especially on weekends and holidays. In addition, with no direct internal controls all use can converge on Thousand Island or Garnet Lakes from these multiple quotas. Both these locations are also subject to multiple pack station operators' use. Traveling trips are not managed to avoid conflicts at campsites or grazing areas and there could be multiple large commercial stock parties at these destinations at the same time. Garnet Lake is used intensively by the commercial packer at Reds Meadow. Noticeable resource effects to the old John Muir Trail between Garnet and Thousand Island, which is being approved for use as a use trail affects wilderness quality with the active continued degradation that is occurring and associated stock holding camp along the trail.

Shadow corridor and Ediza Lake both receive a high level of commercial stock use in this alternative. The commercial trailhead quota acts more like a destination quota here and, therefore, has a more direct effect on reducing the spikes in use that occurred prior to the 2001 Wilderness Plan. Still, effects of commercial transportation services to Ediza Lake are caused by lack of trail design to the only camping area north of the inlet to the lake. While frequent commercial stock use plays a part in contributing to the resource impacts of this trail, lack of management is a bigger contributor. Continued use at current levels will maintain the condition until it is fixed. Stock camps in the Shadow corridor get used each year. Poorly located stock holding areas (close to water) and trailing impacts are noticeable and will likely persist for a time in this alternative. Trail impacts to Laura Lake are noticeable and the number of trips to this location has been low but could increase with the freedom that only external controls provide for destination selection. Other more remote destinations that are available to the operators in this alternative include Cabin Lake, Nydiver, Clarice, and Altha (Thousand Island unit) yet the operator is currently not utilizing these destinations. With even low levels of use to any of these destinations, new impacts could emerge.

Minaret unit has a trailhead quota where commercial stock use continues to fluctuate year to year. The highest recorded stock use since 2000 was 200 stock in 2003. As in most other areas of Ansel Adams East, service day caps and trailhead quotas have not limited stock numbers. Use will probably continue to be moderate here, packers can access Deadhorse Lake, a remote

location, yet there is no evidence of stock use. Impacts could quickly emerge if stock were to use this area, as no trail is visible even though it is currently listed on the system.

Multiple destinations will continue to get used by commercial pack stock in the King Creek unit with a high level of stock. All-expense trips to Fern, Anona, Ashely, Holcomb, and Superior have led to affected stock campsites. These sites will continue to degrade without management. Trailing impacts, exposed roots in the stock holding areas, trash left behind, and mutilated trees from holding stock are evident at these destinations. A campsite with these attributes was closed to commercial stock use in 2000, and more could be closed in the future without improvements. Current direction in this alternative does not directly effect a change in this condition.

Crater Creek will continue to receive moderate stock use, primarily trips that are traveling through. Use could increase here since no direct trailhead quota controls the level of use. Areas where traveling trips occur are subject to more use level changes. Grazing resources can draw more use into the area as well.

Cumulative Impacts

The dams at Waugh, Agnew, Gem, built in the early 1900s, are and will continue to be non-conforming uses in wilderness. The presence of these structures diminishes the wilderness character of the area. The presence of the structures, the on going maintenance needs, and the fluctuation of the water levels have an effect far greater effect on wilderness character than the recreational uses in this area. The dam exemplifies one of the few situations in these wildernesses where there are major, long-term adverse effects to the untrammled and undisturbed qualities of wilderness character,

Public use in the Reds Meadow area has a growing cumulative effect on wilderness resources in this region. Developed campgrounds and the development of the town of Mammoth Lakes attract visitors that seek wilderness opportunities, especially day use. The level of day use, (not controlled) has a short-term moderate adverse effect on solitude with crowding and considerable encounters with visitors seeking fishing, hiking, running, sightseeing opportunities within the 10-15 miles of trailheads in this area. Minor long-term effects to naturalness can occur over time locally with the development and deterioration of social trails for fishing access and popular stopping areas where vegetation loss may occur. Areas where this concentration of multiple user groups is particularly noticeable and more severe in effects are Duck Pass (Lakes Basin), Parker Lake, Shadow, Ediza, River trail, High Trail, Mammoth pass (Red Cones).

Use shifted more to Davis from Marie Meadow after 2001 because Davis is just under the elevation fire closure. This has had a beneficial effect to natural and experiential qualities of wilderness at Marie meadows with the reduction of disturbance. Minor adverse effects to experiential qualities occur at Davis with use that is more frequent and consequently fewer opportunities for solitude by other visitors.

Past site-specific closures have affected use and impact distribution. The closure to camping and campfires at Ediza Lake has concentrated camping at the inlet of the lake. This has concentrated impacts to this one area, which has led to a reduction in the extent of impacts around the lake but may have led to some loss of solitude and unconfined recreation. Not establishing a system trail to the camping location has led to a trail that is poorly located and not adequately designed or built to sustain the use. This trail shows some severe impacts for a short distance but is the only access to the campsites.

In the 1960s and early 1970s, the Shadow Lake and Shadow Creek Corridor above the lake received a high concentration of use and impacts. Impacts were severe in the riparian corridor. A camping closure at Shadow Lake and along Lower Shadow Creek was put into effect in the 1970s. A significant effort to remove campsites and fire-rings greatly restored the area to a more natural condition. The action dispersed camping to locations higher up in the drainage but greatly improved the riparian corridor from Shadow Lake to the John Muir Trail junction. The Shadow Lake and corridor closure occurred prior to limits on use and once limits were put in effect, they considered the closure in the capacity of the area. There have been noticeable improvements in the Shadow Lake and creek corridor because of these actions combined with current use pattern controls achieved through quotas on all users. Day hikers remain uncontrolled and a growing use in this area. Impacts associated with day hikers are mostly social, with a potential to increase crowding.

A campsite at the inlet of Holcomb Lake was closed to packer use in 2000 due to severe impacts. This had the effect of displacing use to the other side of Holcomb Lake, but greatly improved the inlet area. Substantial recovery of the access (creek crossing) was noted in 2003 because of removing the disturbance.

Ansel Adams East – Alternative 2 – Modified

Analysis

In this alternative, the overall number of trips for spot and dunnage are increased from Alternative 1 by 60 trips over 39 distinct destination areas. This equates to a potential for 30 additional 2-way services (30 additional parties serviced and distributed over 39 locations) and an estimated 60- to 80-day season. For perspective, although not likely to occur, at the average it increases by one additional party per destination. For growth to be realized it would have to occur with the same level of stock use and be temporally dispersed by the stock at one time in the wilderness. More probably, the use would be similar to current and past levels, but would be limited in areas where capacity or other resource concerns were identified.

Increased trips, if they occur, will occur primarily at six locations the interdisciplinary team determined could sustain a higher level of use. These locations include Parker Lake, Alger Lake, Rosalie/Gladys Lakes, Minaret Creek, Fern Lake, River Trail, and the King Creek zone. Three areas, Lost Lake, Crest Creek, and Lion Point are managed for use during hunting season, based on availability of state game tags. No one destination would see an increase of more than eight trips, which equates to four parties serviced in to and out of a location. The effects to these locations would be minimal, with essentially up to 8 days of experiential effects, and probably between 4 and 30 more stock at these locations, if the use were to occur. All these locations lack vulnerability and risk factors for physical and biological impacts. The effects would be minor in intensity and extent of impact and short-term.

These increases are balanced by some significant decreases in use in some locations. Areas where use will be reduced include Superior Lake, Emily Lake, Clarice Lake, Ediza Lake, Ashley Lake, Deer Creek and Laura Lake, Thousand Island Lake and Garnet Lake. No spot and dunnage is allowed at Island Pass in this alternative. Superior, Ediza, and Laura will be monitored and if trail conditions improve incremental increases may occur over the length of the permit. The effect of these reductions will be the number of stock at the locations, and fewer associated impacts of stock on trails. At Thousand Island Lake, there will likely be a minor reduction in

crowding as a result of the reduction in commercial pack stock trips. The effects of these reductions in use and corresponding impacts will be long-term, moderate in intensity and will have minor to moderate improvements to the quality of the wilderness character at these locations.

Overall, in this geographic unit, there will be a decrease in all-expense trips. All-expense trips remain the same for the Rush Creek packer. This packer currently runs primarily all-expense trips between designated camps. There will continue to be heavy stock use, up to 1,000 head of stock on this trail a season, most of that in July and August, with an intense peak the first two weeks of August. Designated camps at Alger Lake, Clark Lake, below Waugh Dam, Waugh Lake, Marie Meadows, and Davis Lake will continue to see use. The condition of these sites will likely not change and they are already considerably denuded of ground vegetation, soils are compacted and the areas of use including holding areas are well defined. The perimeter of these sites will be contained. Access to the Waugh Lake site will be stabilized to prevent further erosion. By doing this, the site will be hardened and stabilized becoming capable of handling the level of use prescribed.

Conditions in the Rush Creek drainage are expected to remain the same. No additional adverse effects to wilderness character are expected.

Packers that travel through the area from Mono Creek are reduced from their recent high by up to 15 trips. These types of trips typically access Yosemite National Park via Donahue Pass. There will be a net reduction in trips accessing the Park and there may be improved conditions at campsites and grazing area as a result. The beneficial effects of this reduced use will likely be moderate with less frequent use of sites. As a result, there would generally be fewer encounters with pack stock on this corridor, with minor increases in opportunities for solitude, since other users will still frequent the area.

Packers may adjust by accessing the Park to the west and coming back through Upper Rush. This is not likely, but without further controls on use in the Park, this may occur.

Thousand Island Lake and Garnet Lake could see slight reductions in use. The operator who frequents Garnet Lake with all-expense trips is being reduced in their all-expense trips. In addition, grazing that is typically needed and associated with the all-expense trips will be eliminated. It is likely that there will be less packer activity at these destinations. Only one stock camp will be approved at Garnet Lake and the camp and grazing along the use trail from Garnet Lake to Emerald Lake will not be authorized for packer use. The possible effect of fewer all-expense trips, as well as the direct reduction in spot and dunnage trips to Garnet Lake, will combine to create an overall reduction in stock related impacts at this location. Over time, with a major source of disturbance removed, the conditions of this trail, meadow, and stock camp will improve the natural conditions; however, that will take up to twenty years unless management actions are taken to facilitate restoration.

Thousand Island Lake will remain a high use area for pack stock. The level of use is consistent with its designation as a Recreation Category 3. There will be no growth in services to this area. Most packer trips here are spot and dunnage via the High Trail, so use on that trail will remain at levels similar to today, about 700-800 stock a year.

Badger Lake could see a slight, probably unnoticeable increase in packer use. Opportunities for solitude are low to moderate. The location is not a desirable location for because most of the

public prefers to go to the spectacular and scenic Thousand Island Lake. Stock use at this destination is probably more suitable than at Thousand Island as sites are hardened and screened. The designation of a stock camp here would further protect the total area from campsite expansion and reduce the proliferation of stock camps that has occurred with past use. With grazing being limited to 19 stock nights, there may be fewer trips holding stock than is occurring currently.

In the Shadow–Ediza Analysis Unit, use will remain similar to current levels, with up to 300-400 stock per year. There will be a slight reduction in stock numbers to Ediza Lake. This high use area will remain high use and the prescribed packer use is consistent with the Recreation Category 3 desired conditions. There will be low opportunities for solitude along the main corridor, but some of the outlying areas, such as Iceberg, Cecile, Laura, Cabin and Nydiver Lakes will have moderate to high opportunities for solitude and very few encounters with commercial pack stock. Trail impacts between Iceberg and Cecile Lakes will continue even though stock use will not be authorized and has not been the contributor to the current condition. The condition of the Iceberg Trail will likely not improve until substantial rehabilitation work occurs.

Use in the Minaret Analysis Unit will be similar to current client and stock levels. The effect of this will be continued minor to moderate intensity impacts at very few sites in the unit. Most of the impacts will be experiential and limited to those visitors that find stock encounters undesirable. These impacts will be short-term and unlikely to occur more than 20 days a season. Areas such as Deadhorse Lake, where stock will be prohibited, will have improved opportunities for solitude and no further commercial stock impacts.

In the King Creek Analysis Unit, use will be distributed to areas that can sustain the stock use. Fewer trips to Ashley Lake will probably have a beneficial effect to the experiential qualities of the lake, with the non-commercial pack stock visitors having higher opportunities for solitude. Clients can travel to these lakes easily from the King Creek corridor, and the effects of fewer stock impacts at the lakes will have minor to moderate long-term beneficial effects to natural conditions and recreation experiences.

Cumulative Impacts

The high level of continued commercial use combined with high private day and overnight use will not improve opportunities for solitude at many locations, including Thousand Island Lake, Garnet Lake, Shadow Lake, Ediza Lake, and along the Pacific Crest and John Muir Trails. However, by reducing commercial pack stock use at Thousand Island Lake, Garnet Lake, and Ediza Lake in particular, there will be an overall reduction in adverse effects of pack stock contributing to the other effects of public use at these locations.

The type and level of visitation (public and commercial) has been high for over thirty years. Past actions in the late 1970s and 1980s including the limiting of overnight use (see Alternative 1 Cumulative Effects); site-specific closures to camping and campfires, and grazing limitations have all helped to reduce physical impacts, improving the natural character of the area. These actions also diminish the freedom and unconfined nature of a wilderness experience. The multiple actions of this alternative, (grazing restrictions at Garnet, trail restrictions at Ediza, designated campsites and direct controls on how many trips to each location) will likely result in moderate improvements of conditions by insuring sites are not overused and impacts are

concentrated and contained. However, these same actions also contribute to the gradual and continued erosion of the qualities of unconfined types of wilderness recreation.

Holcomb Lake has improved in the past few years by closing the packer site at the inlet. This site still has evidence of heavy past use but the stream channel adjacent to the camp has improved considerably. Continued improvement would occur with this alternative by not allowing use to the site or to the grazing area (beyond the campsite). It is expected that the incision through the meadow will not recover without physical mitigation, even with removing commercial pack stock use.

As stated in Alternative 1, the dams at Waugh, Agnew, and Gem Lakes are a non-conforming use in wilderness. The presence the structures, the on-going maintenance needs that will continue in this alternative and the fluctuation of the water levels have a diminishing effect far greater on wilderness character than the recreational uses (see Alternative 1 discussion).

Public use in the Reds Meadow area has a growing cumulative affect on wilderness resources in this region. Developed campgrounds and the development of the Town of Mammoth Lakes attract visitors that seek wilderness opportunities, especially day use. The level of uncontrolled day use has an affect on solitude and crowding within the first 10-15 miles of trailheads in this area.

Cumulative Effects Conclusion

There are no adverse cumulative effects as a result of any of the actions in the Ansel Adams East in this alternative. If anything, the cumulative effects of multiple activities are reduced in this alternative through the reduction of commercial pack stock use at locations of concentrated public use (e.g., Thousand Island Lake).

Wilderness character qualities of untrammled and undeveloped are adversely affected by the water storage dams (Waugh, Agnew, and Gem Lakes) with no comparative effects or cumulative effects to these qualities by the actions in this alternative. The scale and level of physical impact from these dams greatly diminishes the recreational impacts of commercial pack stock and public use in these areas.

Minor long-term cumulative effects to a visitors unconfined recreation opportunities are possible to the commercial pack stock visitor in this alternative. Past actions of closures and restrictions combined with actions prescribed in this alternative do create a cumulative effect. The actions that contribute to this effect however, remove any potential for cumulative effects to natural conditions by managing and manipulating the level and intensity of commercial pack stock use throughout the geographic unit.

Ansel Adams East – Alternative 2

Analysis

In this alternative overall number of trips for spot and dunnage are increased by 75 trips to 43 distinct destination areas. This growth in number of trips does not equate to growth in number of stock. Overall, stock numbers will remain the same as No Action. Increased trips, if they occur, will occur in locations that either are managed for high use destinations, or can sustain a higher level of use. These include allowing for incremental increases to Anona (+1), Fern (+2), King Creek (+4), Minaret (+1), Badger (+1), Summit (+2), Alger (+4), Clark (+1), Rosalie (+2),

Shadow Creek (+4), and Thousand Island (+2). More significant increases are allowed for Deer Lake (+5), Johnston (+6), Waugh (+5), and Island Pass (+5). These increases are balanced by some significant decreases in use. Areas where use will be reduced include Superior (-6), Emily (-8), Gem (-8), Clarice (-4), Ediza (-6), and Laura (-3). Superior, Ediza, and Laura will be monitored and if trail conditions improve, incremental increases may occur over the length of the permit.

Overall, in this area there will be a decrease in all-expense trips. All-expense trips remain the same for the Rush Creek packer. This packer currently runs primarily all-expense trips between designated camps. Packers that travel through the area from Mono creek are reduced from their recent high by over 15 trips. These types of trips typically access Yosemite National Park over Donahue Pass. There will be a net reduction in trips accessing the Park and there may be improved conditions at campsites and grazing area as a result. The beneficial effects of this reduced use will likely be moderate with less frequent use of sites. There would be fewer encounters with pack stock generally on this corridor as a result, with minor increases in opportunities for solitude, since other users will still frequent the area.

Packers may adjust by accessing the Park to the west and coming back through Upper Rush. This is not expected but without further controls on use in the Park this may occur.

Conditions in the Rush Creek drainage will likely remain the same. No additional adverse effects to wilderness character are expected.

There will continue to be heavy stock use, up to 1,000 head of stock on this trail a season, most of that July and August with an intense peak the first two weeks of August. Designated camps at Alger, Clark below Waugh Dam, Waugh, Marie Meadows, and Davis Lake will continue to see use. The condition of these sites will possibly not change and they are already considerably denuded of ground vegetation, soils are compacted and the areas of use including holding areas are well defined. The perimeter of these sites will be contained. Access to the Waugh site will be stabilized to prevent further erosion. By doing this the site will be hardened and stable and capable of handling the level of use prescribed.

Thousand Island Lake and Garnet Lake could see slight reductions in use. The operator who frequents Garnet on all-expense trips is being reduced in their all-expense trips. In addition, grazing will be eliminated that is typically needed and associated with the all-expense trips. It is possible that there will be less packer activity at these destinations. Only one stock camp will be approved at Garnet and the camp and grazing along the use trail from Garnet to Emerald will not be authorized for packer use. Over time, with a major source of disturbance removed, the natural conditions of this trail, meadow, and stock camp will improve. However, that could take up to twenty years unless management takes actions to facilitate restoration.

Thousand Island Lake will remain a high use area for pack stock. The level of use is consistent with its designation as a Recreation Category 3. There will be no growth in services to this area. Most packer trips here are spot and dunnage via the High trail, so use on that trail will remain at levels similar to today, about 700-800 stock a year.

Badger Lake could see a slight, probably unnoticeable increase in packer use. Opportunities for solitude are low to moderate. The location is not a desirable location for most of the public as most of the public goes on to the spectacular and scenic Thousand Island Lake. Stock use at this destination is probably more suitable than Thousand Island as sites are hardened and screened.

The designation of a stock camp here would further protect the total area of the campsite from expanding and reduce the proliferation of stock camps that has occurred with past use. With grazing being limited to 19 stock nights, there may be fewer trips holding stock than is occurring currently.

In the Shadow-Ediza unit, use will remain at current levels, with up to 300-400 stock per year. The common destination is Ediza Lake and use to this destination will be reduced until trail conditions improve to the camp location at the inlet of the lake. Until this improvement occurs, stock use will be reduced by 4 trips a year or up to 50 fewer stock. This high use area will remain high use and the prescribed packer use is consistent with the Recreation Category 3 desired conditions. There will be low opportunities for solitude along the main corridor but some of the outlying areas, such as Iceberg, Cecile, Laura, Cabin and Nydiver Lakes will have moderate to high opportunities for solitude and very few encounters with commercial pack stock. Iceberg-Cecil trail impacts will continue even though stock use will not be authorized and has not been the contributor to the current condition. The condition of the Iceberg Trail will likely not improve until substantial rehabilitation work occurs.

Use in the Minaret unit will not change from current levels; however, it will be distributed differently. Use will not be allowed to Emily until the trail is improved. This may be up to ten years out, possibly longer. In the interim public use will continue and there will be high opportunities for solitude. When, and if, packer use resumes to Emily there will be no more than eight trips authorized. A designated stock camp will contain impacts and the expansion of the site. The capacity at the lake is low and other parties camped there would be within sight and sound of another party. There will be no change to other destinations in Minaret. Packers have identified Deadhorse Lake as a destination; however, there is no recorded use. In this alternative use would be denied, thereby increasing the chances that Deadhorse would remain pristine with very high opportunities for solitude. The public can and will continue to be able to access this destination and it could receive more use by the public over time. The character of the destination may change over time if use patterns were to change, however it is not likely that use patterns of the public will change and prohibiting commercial pack stock use increases the chance that no change will occur.

In King Creek, use will distribute to areas that can sustain the stock use. Up to 500 stock have used the area in the past and it is predicted that that number will decrease to 300 stock a year with this alternative. Trips to Superior Lake will be reduced from 14 to 8 until the trail is improved. When the trail and the campsite are contained, packer use will be allowed to resume. Use to Anona and Ashley will need to be monitored to insure conditions do not deteriorate with allowing the current use leave to continue. Campsite improvements would occur by implementing standards for designated sites. At Fern Lake, a party size limit will insure that the size of campsites do not increase. The lake has a low capacity for campsites. By limiting the party size, opportunities for solitude will increase. This small lake is infrequently used by the public because it lacks some of the outstanding character that other destinations in the vicinity have. It is therefore an appropriate location for packer use by reducing conflicts with other visitors.

Holcomb Lake will have up to six trips a year. A relocated site will insure that past impacts do not persist. It is doubtful that a trail will be rerouted to the upper grazing area and packer use will probably be light. The probability that further change would occur is low. Public use is moderate to this destination, altogether there will be moderate opportunities for solitude, and conditions will likely continue to improve.

Deer Creek is identified for increases in use in this alternative. The area receives primarily only pass-through use by the public and is a good location for packers to avoid conflict with the public. Although the prescribed use effectively increases the potential for packer, it is not a highly desirable area. It will probably reach the quota only in response to hunting season requests and game quotas for the unit. This is not likely to occur on an annual basis, but perhaps once every few years at most.

Cumulative Impacts

The high level of continued commercial combined with high private day and overnight use will not improve opportunities for solitude at many locations, including Thousand Island Lake, Garnet Lake, Shadow Lake, Ediza Lake, and along the Pacific Crest and John Muir Trails. This type and level of use has been high for over thirty years. Past actions of limiting overnight use (see Alternative 1 Cumulative Effects), and putting in place site-specific closures to camping and campfires, and grazing limitations, have all helped to improve the natural character of the area by reducing physical impacts. Such actions also can diminish the freedom and unconfined nature of a wilderness experience. Additional actions of the alternative, the grazing restrictions at Garnet, trail restrictions at Ediza, designated campsites and direct controls on how many trips to each location all will likely result in gradual improvements of conditions by insuring sites do not get overused and impacts are contained and concentrated.

Holcomb has improved in the past few years by closing the packer site at the inlet. This site still has evidence of heavy past use but the stream channel adjacent to the camp has improved considerably. Continued improvement would occur with this alternative by not allowing use to the site or to the grazing area (past the campsite) until or unless a more appropriate trail location is identified. It is expected that the incision through the meadow will not recover without physical mitigation, even with removing the commercial pack stock use.

As stated in Alternative 1, the dams at Waugh, Agnew, and Gem are a non-conforming use in wilderness. The presence of these structures diminishes the wilderness character of the area. The presence the structures, the on-going maintenance needs that will continue in this alternative and the fluctuation of the water levels have an effect far greater on wilderness character than the recreational uses (see Alternative 1 discussion).

Public use in the Reds Meadow area has a growing cumulative affect on wilderness resources in this region. Developed campgrounds and the development of the town of Mammoth Lakes attract visitors that seek wilderness opportunities, especially day use. The level of day use not controlled and has an affect on solitude and crowding within the 10-15 miles of trailheads in this area.

Ansel Adams East – Alternative 3

Analysis

In this alternative, trailhead quotas and stock and client thresholds will limit overall numbers of people but not specifically to any location. This increases the probability for use pattern changes. It is possible that where currently stock numbers are low, there could be a shift in patterns and commercial stock use could increase at site-specific locations. This has the potential to change the character of some destinations particularly those that are low use and currently show few resource impacts.

Areas where single quota trails regulate use will have a higher potential for commercial stock use to be maintained at current levels. No stock use will be authorized to Glacier, Gibbs, and Bloody Canyon Analysis Units except on a case-by-case basis. While no commercial stock use currently goes to these locations, commercial stock use is currently not prohibited. With a stock number of zero, it effectively prohibits future use except a rare possibility of infrequent use. There is a very low probability that use patterns in these areas will change or that any effect to the character of these areas would occur. These areas are low use and opportunities for solitude are very high. Public use is limited by low quotas, which protect these areas from use pattern changes by the public as well.

In this alternative, Rush Creek stock numbers remain consistent with average current use for Rush Creek. It is not likely that the character of the area will change from present conditions with this alternative. Growth in services can only occur within the seasonal limitation on stock numbers. Daily limits will prevent high spikes in use but will generally allow current patterns to continue. This will mean that use will generally be concentrated in a five-week period from the end of July thru the first week of September. The Rush Creek drainage is mostly within a Recreation Category 3, and use will remain high, with a continued commercial stock around 35 percent of total use. Encounters with commercial riding and pack stock will be frequent along the primary trail corridor. The only use trail approvals will be for hunting access in Crest Creek.

A party size restriction at Weber Lake will be implemented with this alternative, same as the proposed action, 10 persons and 20 stock. This will insure that campsites do not increase in size, as camping is currently limited with small capacity sites. Stock holding would be allowed with a designated site identified. It is possible that with stock holding there would be an increase in impacts and a larger area of impact at Weber. There could be diminished opportunities for solitude and minor to moderate adverse impacts to natural conditions at the lake with an increased area of impact. No grazing is associated with this destination so it is likely that the destination will be used primarily for spot and dunnage services. The area will continue to be depleted of firewood unless packers pack in firewood for clients. If wood is depleted it could be site specifically closed to fires in the future. Special allowances at stock camps in this alternative would result in inequities described above.

Upper Rush Creek destinations, Davis Lake and Marie Lake could receive more use than presently occurs. Use to these destinations currently is a part of full service trips with associated grazing. This pattern will probably remain. Campfires, which are currently prohibited at Marie, will be allowed at the stock camp with wranglers present. Allowing campfires will have the potential to cause conflicts between user groups and non-compliance by the public though generally no other campers are near the Marie Meadow campsite.

The Upper Rush unit will continue to be a location of overlapping pack stations. Overlap that occurs in trips accessing Yosemite National Park will continue unless the park makes a determination to reduce this use. Whereas these trips were reduced in the Proposed Action, there would be no controls on this since levels of use are managed at the trailhead, by seasonal stock numbers and no service day allocations would effect the length of the trip and no internal controls would affect the spatial movement of the service once they have entered the wilderness. Unless Yosemite National Park was to control the use over the boundary, there would be a possibility that use would increase along this corridor. This trail is highly developed and would possibly support the use although maintenance and reconstruction would need to increase. Encounters between hikers and stock may be more frequent if traveling trips increase but it is

currently a high use corridor and would be consistent with desired experiential conditions of a Recreation Category 3. Pressures on grazing resources would be likely if all-expense trips were to increase. If packers were to pack in feed as a substitute for grazing, more stock would be needed to support the operation. At this point, the seasonal stock numbers may become a slight deterrent for this use.

River High Analysis Unit will continue to have a high level of stock use. Use will be primarily accessing destinations in the Thousand Island Analysis Unit and to a lesser extent Summit Lake and Clark Lakes where some occasional overlap in operators will continue. Encounters between stock and hikers (day and overnight) will be frequent, especially late July through August. Occasional use during hunting season will be authorized to San Joaquin Peak. This use would be infrequent and would likely not have any effects on solitude. Opportunities for solitude would continue to be high off trail and would possibly stay moderate to low on the trail with this alternative. This is consistent with a Recreation Category 2.

Thousand Island Analysis Unit is accessed via the River High Analysis Units where stock numbers remain high, with a combined limit of 830 head of stock via the closest trailheads. Again, here there will be opportunities for overlapping operations as described above due to the popularity of trips accessing Yosemite National Park. Stock camps at Thousand Island and Garnet Lake will concentrate that use and grazing will be limited so operators will either choose to pack in feed choose to reduce these types of trips. If competition for camps and/or grazing resources exists or becomes accentuated a future action may be to limit the number of operators traveling to Yosemite. Opportunities for solitude will be low to moderate, as they are currently, at these locations. The scenic qualities of these locations tend to minimize expectations for solitude or pristine experiences.

Allowing commercial pack stock to Altha Lake may have some impacts over time. The trail is steep, narrow and the capacity at the destinations is very low. Opportunities for solitude may be diminished if use were to increase to this area. If use remains low and infrequent it is expected there will be no change.

Shadow Ediza unit will be managed for 280 stock nights a season from the Shadow trail. This is a 20 percent reduction in stock from recent high years (365 stock in 2002). Some additional use may occur as a result of traveling trips circuiting through adjacent units, entering the High trail and exiting via the John Muir trail that accesses the Shadow Ediza unit. Use will concentrate in the Shadow corridor and Ediza but has the potential for shifting some use to Nydiver Lake, Cabin Lake without direct controls on those destinations. The Nydiver system trail is proposed to be upgraded in this alternative to TC2. The cumulative effect may be to facilitate more commercial stock use and public use to Nydiver. This may affect the wilderness character of the area, which presently is remote and experiences very low use, and is a Recreation Category 1. Laura Lake would be limited to two trips a year, thereby insuring that the trail deterioration is limited. Use to Clarice would be prohibited in this alternative, reducing the potential for this trail to facilitate use and change use patterns by either the public or commercial pack stock. Pack stock use to the upper reaches of this drainage will be closed, including to Iceberg Lake and above Ediza. Trail impacts will likely continue at these locations until needed restoration work is done. This is not expected to occur for 10 to 15 years. The identification of two stock camps in this corridor will improve existing sites that have on occasion been used to hold stock and are not suitable. The site at the junction of the John Muir Trail will be identified for spot and dunnage or full expense trips with no holding of stock. Only one site in this drainage will be used for the

overnight holding of stock. All other services will be spot and dunnage. This may reduce the opportunities for traveling trips or all-expense trips to be utilized in this area. With this area being a heavily used location for day hiking and backpacking, this will help reduce crowding. There will still be low to moderate opportunities for solitude as a result of the combination of high commercial stock, day hiking, and backpacker use.

Minarets Analysis Unit will maintain a low to moderate level of stock use. Seasonal stock totals from the JMT north and Minarets trailheads total 240. This is slightly higher than reported stock numbers the past few years, but amounts to a 15 percent potential increase. This area is suitable for increases as the capacity for camping is high; crowding is low as use levels are low compared to surrounding analysis units. There would be one stock camp designated in this corridor where any overnight holding of stock in the drainage would take place. Concentrating use would insure that impacts would not be extensive. Use would be concentrated along the main trail corridor, which is designed and durable for stock use. It is possible that this drainage would receive some overflow use resulting from traveling trips that need an alternative stop to Thousand Island, Garnet Lakes, and Upper Rush Creek.

Stock number limits in the King Creek Analysis Unit will reduce stock levels from recorded use levels the past few years. This reduction is less than 10 percent. Multiple destinations are accessed from the Beck and Fern and Minaret trailheads and even with stock limits in place on each trailhead, use can shift to another trailhead (i.e. from Fern to Beck) to access the other destinations. This will allow use to shift trailheads without necessarily having a direct effect on the intended destinations.

Party size limitations will be implemented for the commercial packer at both Fern and Anona Lakes. Both these destinations have limited capacity for camping and with 10 persons/ 20 head of stock limit it will insure that sites do not expand and impacts are contained. Stock camps at Ashley, Anona Holcomb, and Superior will also contain impacts associated with holding stock in the backcountry. Under the current management regime (Alternative 1 – No Action), stock camps could be created and multiple stock camps at these locations are possible. At Superior Lake, the designation of a stock camp and the implied access standards will improve the current access trail issues at the inlet of Superior Lake. This short use trail to the campsite will likely be improved and made durable within the first few years of implementation.

Access to grazing at Holcomb (particularly on the south side of the lake) poses many constraints for sustainable pack stock use as the trail goes through a meadow to access the grazing. Relocation of the trail is neither feasible nor likely to occur. This will affect the packer's ability to graze in the analysis unit and may lead to packing in feed or an adjustment in type of service provided to more spot and dunnage and less full service trips requiring the overnight holding of stock.

Cumulative Impacts

The presence of dam structures at Waugh, Gem, and Agnew diminishes the wilderness character of the area. The presence of the structures, the on going maintenance needs, and the fluctuation of the water levels have an effect far greater on wilderness character than the recreational uses in this area. (See discussion in Alternative 1, Ansel Adams East, Wilderness Resource).

Public use in the Reds Meadow area has an increasing cumulative effect on wilderness resources in this region. Developed campgrounds and the development of the town of Mammoth Lakes

attract visitors that seek wilderness opportunities, especially day use. The level of private day use, (not controlled) has an affect on solitude and crowding within the 10-15 miles of trailheads in this area. Actions in this alternative do not increase day rides for commercial pack stock, despite the demand. The effect will be to insure that commercial stock use does not contribute to crowding and diminishing the wilderness experience. Present use is not controlled in the same way and, contributes to moderate adverse cumulative effects on solitude and to the natural conditions. (See discussion in Alternative 1, Ansel Adams East, Wilderness Resource).

Past site-specific closures in the region have affected use and impact distribution. This alternative would prevent further dispersal of use into areas not already impacted and suitable for pack stock impacts. It is not expected that impacts would become more intense or extensive in this alternative however, they will persist at locations where use has already caused impacts. Such impacts are minor long-term, local effects to natural conditions.

Many past management actions in the Shadow Lake area to respond to high levels of private and commercial use going back forty years (see Alternative 1 – cumulative effects). Nothing in this alternative would reverse the trend towards continued improvement and recovery.

A campsite at the inlet of Holcomb was closed to packer use in 2000 due to severe impacts. This had the effect of displacing use to the other side of Holcomb, but greatly improved the inlet area. Substantial recovery of the access (creek crossing) was noted in 2003 as a result of removing the disturbance. Commercial pack stock use would continue to be prohibited at the campsite in this alternative and use of the trail to access grazing would be prohibited insuring that the trail impacts do not deteriorate because of the commercial stock use. The trail will need physical mitigation to recover natural conditions.

Ansel Adams East – Alternative 4

Analysis

At four of the six commercial trailheads, accessing destinations in the Ansel Adams east region the quota is slightly reduced. This, combined with the 20 percent reduction in service days will reduce the overall amount of commercial pack stock throughout the season and possible more than 20 percent if access is being limited during the peak season. Commercial use will either spread into July and September, or be reduced if this shoulder season cannot be utilized. As a result, there will be minor beneficial local effects to solitude and probably only negligible beneficial local effects to natural conditions with the implementation of this alternative, since other uses will continue to have some degree of disturbance to the same areas.

Shadow, the High Trail, JMT North, and River Trail trailheads are reduced by a total of 14 persons a day collectively. Without direct controls on where this use disperses to, the controls will have a positive effect on the destinations that most need the improvements. Thirty-two destinations will be authorized for commercial pack stock services, compared to the only limitations in Alternative 1, 2, and 3 being achieved by trail suitability determinations. These destinations will likely receive more use with crowding and low opportunities for solitude. Most of these locations are in settings where the desired condition allows for more intensive management in Recreation Category 3 and along main trail corridors of Recreation Category 2. This would be within the standards and guidelines for these areas. By concentrating the impacts, there would be a loss of some experiential wilderness values at these relatively few locations.

There will likely be improvement to the destinations where commercial stock currently occurs and ecological impacts will be diminished over time with the removal of commercial stock.

Only two use trails would be approved compared to eight in Alternative 2 and Alternative 3 and twelve in the No Action, Alternative 1. Many bypasses and access to grazing would no longer be approved. The biggest effect would be to limit access to locations that are currently more remote and less impacted, thereby achieving a beneficial effect of protecting these from receiving disproportionate impacts that may occur with even low levels of stock use. Destinations such as Clarice, Cabin, Nydiver, Sullivan, Upper Davis Lake, and Marie Lake are examples of these types of locations.

Cumulative Impacts

See discussion in Alternative 1 – Cumulative Effects Ansel Adams East on Waugh, Gem, and Agnew dams. Any beneficial effects to wilderness character (solitude, natural conditions) will be limited in comparison to the adverse long-term effects to wilderness character (untrammelled, natural, and undeveloped) that occurs with the presence of these structures.

Present non-commercial use levels will contribute to effects in the same areas where use is being prohibited, reduced or where the commercial pack stock use is allowed to continue. The added effects will be negligible to minor adverse local effects to solitude and natural conditions.

With commercial pack stock use being concentrated at fewer locations, it is possible that the other user groups disperse to new locations to avoid camping where heavy commercial use is occurring. Destinations such as Thousand Island, Garnet, Ediza, and Shadow will continue to see high levels of overnight and day use, and day use levels are expected to increase in this region due to the ongoing development of the Town of Mammoth Lakes.

The additional restrictions in this alternative on where commercial pack stock services can go, the substantial food storage requirements in this area, and the considerable limitations on campfires that were put in effect with the Wilderness Plan all contribute to an overall loss of freedom and unconfined type of recreation that wilderness visitors desire.

Trips to Yosemite National Park may increase without corresponding regulations on use from the Park. Increases in trips may equate to increase in impacts if use occurs in new locations or expands existing impacts.

Although commercial stock use will be prohibited at many destinations currently used by the operators, private stock use is not being limited nor is public hiker use into these areas. It is possible that use patterns from these user groups could shift over time and impacts associated with moderate levels of hiker use to remote locations such as Clarice and Marie, could lead to both ecological impacts and loss of solitude and changes to the existing wilderness character. Low levels of private stock use, particular at vulnerable times in the season, (e.g., early season) could have as much if not more of an impact than low levels of commercial use.

Ansel Adams East – Alternative 5

Analysis and Cumulative Impacts

The northern portion of this analysis unit currently receives no commercial pack stock use. The remainder of this unit receives moderate to high commercial pack stock use currently. The high

stock numbers currently recorded in the Rush Creek, Thousand Island Analysis Units will be eliminated in this alternative, and only light stock use may occur. However, due to the very steep trail from Silver Lake to Agnew Lake with precipices and drop offs, it is not expected that many private stock parties will travel in this area.

Cumulatively, there will be a moderately noticeable change in recreation impacts and use levels in this geographic area as the majority of the use is private hikers, “thru” hikers on the JMT/PCT and day hikers. However, there will be some location specific effects that may be noticeable and measurable.

Thirty three percent of the use on the Rush Creek trail is commercial pack stock use. With the elimination of this use, the lower Rush Creek area would likely receive very low use and opportunities for solitude would be very high. However, the low wilderness character due to the manmade dams would not change and overall experiential values would be only partially affected with the elimination of commercial pack stock.

Upper Rush Creek would likely see little noticeable difference, as stock encounters are only moderately frequent. This area does see overlapping operators that travel through on the JMT/PCT on their way into Yosemite. This area receives a very high amount of visitor use traveling on the JMT/PCT but very light use on trails stemming from the JMT. This condition would not change in this alternative.

Thousand Island and Garnet Lakes will see slight effects to overall use levels and impacts as a result of eliminating commercial pack stock. The highest year of recorded use in the past four years showed 70-90 trips to Thousand Island by primarily one commercial operator, just under 300 people and 700 head of stock. This is a high level of stock and with elimination of commercial pack stock, there would be a noticeable experiential difference, primarily in the month of August, when much of this use takes place. Thousand Island is used as a stop on traveling trips by one other operator, which provides some overlap operation. This level of use is a small percentage of the overall use at this very popular destination.

The River and River High units are primary used as travel through to destinations in Thousand Island and Shadow/Ediza. Encounters with commercial stock use are currently very high especially in the month of August. This is a crowded area with day hikers, backpackers, and pack station operations. There would be a noticeable difference in the number of encounters with stock in this area. Trails would not need to be constructed to as high a level as currently constructed. There would be very little effect to campsites in this area since this is only a pass-through area.

The Shadow/Ediza unit will decrease from just over 300 head of stock per year to none. The character of the area will improve in regards to trail conditions. Trails will not need to be built to a very high standard and may over time be more primitive, and less substantial in their development features which would enhance the character of the area, by providing a more primitive experience. Cabin Lake and Laura Lake will likely become more remote with higher opportunities for solitude. Ediza and Shadow Creek Corridor will remain very popular with high use from the non-stock visitor.

Minaret unit will decrease from 50 to 100 visitors a year serviced by commercial pack stock and under 200 stock used in conjunction with this service to none. Pack stock does not go to Minaret Lake but stops just below the final switchbacks to the lake, so impacts at the lake will likely not

be changed. One stock site in the corridor that is used by the packers may improve over time, but generally, there will not be a noticeable change. Encounters with commercial pack stock are relatively low in this area and a change would be only slightly noticeable to a very few visitors if commercial pack stock were eliminated. Trail development would not be needed in the future and the trail may revert to a more primitive condition.

Currently packers primarily use five destinations in this unit: Superior, Ashley, Anona, Holcomb, and Fern. Less than 200 visitors a year are serviced by commercial pack stock and 300-500 stock are used in conjunction with the service. These destinations receive light use by other visitors and would become more remote with the absence of the commercial service. Campsites at these destinations would also improve, particularly at Anona and Superior, where large sites with stock holding facilities would become more contained as campsite work is done to restore and minimize the disturbed area. This would likely take a number of years to see any noticeable difference, but with the removal of the disturbance, natural restoration would begin to occur the first year. Very little private stock use occurs at these locations. Sites that are currently used by the packers would be contained but maintained for stock use. The size of the site could be greatly reduced and still accommodate private stock parties.

Very light commercial stock use occurs in the Crater Creek unit. Less than 100 stock and people are serviced by packers. The Deer creek area is the primary destination and with the use and impacts currently very light, the noticeable effect of eliminating this use would be minimal. Encounters with stock parties are infrequent currently and the experiential effects of this change would be minimal to most visitors.

Campsite impacts will improve in some locations. The sites used by commercial pack stock for holding stock overnight will decrease in size; soil disturbance and vegetation loss will be diminished and over time may recover to a near natural condition. It is not expected that these sites will receive much continued use by the general public and not in a manner that they are currently being use. Stock holding areas are neither desirable nor suitable for tent sites or communal areas for camping. In particular, sites at Shadow Creek, Garnet Lake, Rosalie Lake, Anona, Superior, Holcomb, Davis Lake, Marie Meadows, Clark Lakes, and lower Rush Creek may see noticeable improvements in campsite conditions.

Ansel Adams West – Alternative 1

Analysis

Commercial pack stock use will be concentrated in 10 of 19 analysis units in this geographic unit. Most use is concentrated in the northern portion of the unit. Commercial pack stock use is authorized for all the trailheads in this geographic unit, but little is likely to occur in nine of the analysis units. Fuller Buttes, South Fork, Arch, Onion Springs, Lower Mono Creek, and Hot Springs units would only be used by commercial packers for some hunting and occasional day use rides. Use is so infrequent that impacts will not be noticeable unless the commercial packer chooses to change their use into these locations. This is not expected since there is no attraction or popular destination that may draw this use.

In general, trailhead quotas for this geographic unit will be utilized less than 10 percent of the days/season of use. Because trailhead quotas combine with service day limitations for commercial pack stock operations in this alternative, it is highly unlikely that commercial pack-stock use patterns will be altered substantially within this region.

The Chiquito Analysis Unit is and will continue to be used only as a travel route to destinations in Yosemite National Park. No stops or day rides occur within the project area. Use is controlled by the trailhead quota of 35 persons a day including both commercial and non-commercial use. In 2003 the quota, which is shared by all users, was reached only 1 percent of the days in the use season.

The Jackass Analysis Unit would probably continue to receive low levels of commercial stock use even though a specific commercial quota of eight persons a day is identified for the packer. Full commercial quota was reached on 10 percent of days in the 2003 season, which is almost entirely attributable to non-stock commercial use. The packer will likely use their service day allocation on more preferable and popular locations. Yet the possibility does exist in this alternative for more use to occur and for flexibility for the packer to use Jackass more than they currently do. This is likely only to have minor long-term local effects to natural and experiential conditions, if it were to occur, with the potential for new impacts to be created with campsite use and more crowding than currently.

Staniford Analysis Unit will continue to see moderate levels of commercial stock use. The trailhead quota specifically for commercial pack stock (Fernandez Trailhead) is eight persons per day. In 2003, the commercial pack stock quota was fully utilized 14 percent of the season. This trailhead accesses many popular destinations. The 2001 Wilderness Plan identifies a portion of the unit as a Recreation Category 3. Because trailhead quotas limit use to this unit, it is unlikely that historical commercial pack-stock use patterns would shift to the areas identified as Recreation Category 3 in such a way as to substantially alter the existing conditions adversely. For example, the plan would allow for more use by all wilderness visitors at Lady, Vandenburg, and Staniford Lakes based on the definition of Recreation Category 3. Opportunities for solitude could be diminished over time at Lady, Vandenburg, and Staniford Lakes. The multiple trailing into Staniford Lake with a substantial cutoff trail used by the packer to access sites at Staniford Lake would probably continue since no existing system trail can provide access to these camps. Chittendon, a remote destination with no evidence of stock use or impact is available for packer use in this alternative, and minor to moderate impacts to solitude may occur if use were to increase in this area, given the low capacity of the destination.

The Lillian Analysis Unit will continue to see moderate to high stock use with this alternative. The trailhead quota specifically for commercial pack stock (Fernandez) is eight-persons per day (in addition to eight persons per day for any commercial use through the Walton trailhead). In 2003, the commercial pack stock quota was fully utilized 14 percent of the season on the Fernandez quota. Because trailhead quotas limit use in this area, it is doubtful that historical commercial pack stock use patterns would shift to currently lightly used areas like Flat, Monument, and Fernandez Lakes. Stock camps at Flat Lake and the multiple stock camps at Fernandez Meadow will likely continue to show a high degree of development and expansion over time.

The Triple Divide Analysis Unit will continue to have a low level of commercial stock use. Less than 20 people and 50 stock have used the area with commercial operations the past few years. This area is also accessed by the Fernandez trailhead (eight commercial pack stock clients/day) and the Walton trailhead (eight any commercial clients/day). Impacts would persist both at the stock camp at Anne Lake and in the grazing area north of Anne.

Sadler Analysis Unit has the highest level of stock use in this geographic region and up to 300 commercial pack stock per year will continue in this alternative. Most of the use is concentrated at Sadler Lake even though multiple destinations are accessible to the packers in this alternative. The trailhead quota specifically for commercial pack stock (Isberg) is nine persons per day. In 2003, the commercial pack stock quota was fully utilized 11 percent of the season. Pack stock services could disperse to Joe Crane and Isberg Lakes but will be at the demand of public and are not predictable. Stock camp impacts at Sadler and Joe Crane would persist in this alternative.

Use will continue to disperse in low to moderate levels throughout the Bridge Crossing, Iron Creek, Cargyle, Cassidy, and Junction Analysis Units. There will be low levels of people serviced by commercial packers and low to moderate stock numbers associated with the use. It is expected that no additional trails or campsites will be used and impacts therefore are not expected to increase to any measurable degree with this low level of use.

Cumulative Impacts

The past action of camping closures has had the effect of dispersing use and impact to other areas while directly improving the closed sites. The full closure to camping at Rainbow Lake for example, may have displaced use to Flat Lake where some concentrated impacts are noticeable. Rainbow has recovered with considerable re-vegetation of the shores where camping impacts had been. Lillian, as noted is now receiving intensive impacts in the area not closed to camping.

Cattle grazing in the Lower Mono area will continue to impact the natural and untrammelled characteristics of wilderness in this area, even though an increase in commercial stock use or private use is not expected.

The structures in place that dam the waters of Lillian, Rutherford, Chiquito, and McClure have an effect on wilderness character of the area. These structures impede the natural processes and represent human development within the wilderness. Most do not currently serve any function. This development has minor long-term adverse effects on wilderness character (natural, untrammelled, undeveloped) at these locations, but is minor relative to the dams in the Ansel Adams East.

At Lillian Lake, the combination of current commercial use (pack stock and hiking operators), public use, camping restrictions, and the dam at the outlet do have a cumulative effect on the wilderness character of the destination.

An effect on Yosemite National Park by the pack station use and public use occurs from the Chiquito trailhead. Use from this trailhead enters the Park and concentrates in the South Fork of the Merced River drainage, mostly Chain Lakes and Royal Arch Lake. The trailhead quota that has been in effect for about ten years has reduced the potential for spikes in use and may be improving the social conditions at the destinations in the Park as a result. Actions by the National park Service to cap use has been consistent with the 2001 Wilderness Plan.

There is a considerable amount of non-stock commercial outfitter guide use in this region. It is common for these permitted non-stock outfitter guides to utilize commercial pack stock operators to provide food supplies and search and rescue services. In most cases, non-stock outfitter use authorizations would continue to be authorized on an annual basis. Some of these outfitter guides qualify for 10-year permits.

Wood resources at Rutherford Lake are scarce and depletion of scarce wood resources may affect ecological processes. A reasonably foreseeable action may be to site specifically limit campfires at this location based on scarcity of firewood.

Ansel Adams West – Alternative 2 – Modified

Analysis

Overall, in this region up to 266 trips to 28 discrete destinations or zones would be managed for commercial pack stock use. As with all other locations, it is not likely that destination quotas would be reached on a recurring annual basis. Some destinations might reach their limit, but others would not reach their limit. With stock limitations (stock at one time in the wilderness) there is an effect of limiting the use of stock to levels consistent with current and past use levels. Only in areas where no known concerns existed or where risks were low for unacceptable stock related impacts was use increased above use levels experienced under current management. Many locations in this region were capped or even reduced to encourage an upward trend in resource condition. These are listed below.

Overlap in commercial pack stock services will remain minimal. Three operators use this region with some traveling trips from additional operators 1-2 times/year. Some years there are no traveling trips. These traveling trips access the region by way of Yosemite National Park. If use is allowed to increase in the Park over time, this pattern might change, but that is not likely. Some overlap will continue to occur but is mostly limited to the Chiquito Analysis Unit. The majority of the region will have only one operator for the destinations.

In the Staniford Analysis Unit, two destinations would receive a moderate amount of commercial stock use. A reduction in use to Lady Lake will likely have the effect of maintaining moderate to high opportunities for solitude. With limited capacity for camping and outstanding experiential qualities and setting, the reduced use will ensure that impacts that are more intensive do not occur over time. Commercial stock use is increased at Vandeburg Lake in order to concentrate impacts at a less vulnerable and more sustainable location. Impacts at Vandeburg will be locally intense with moderate effects to solitude, physical resources, campsites, and trails. The Vandeburg and Lake areas will be changed from a Recreation Category 3 to Recreation Category 2, which appropriately reflects the current use and observed impacts. This change will ensure that the current experience levels will be improved or at least maintained.

Staniford Lakes will continue to see moderate use and the potential for minor to moderate effects to solitude with the limited camping potential and campsites being within sight and sound of each other. The effects of continued moderate use will be minor effects to the physical resource, as the campsites are well defined and suitable for moderate levels of use. Access to the campsites will remain awkward as no access from the south and east end of the lake is authorized. This will reduce the effects of trailing stock through steep terrain and riparian vegetation and improve the natural qualities at the destination.

Chittendon, with its trail suitability determination that limits use to the lake, will maintain high opportunities for solitude. Use limitations on the commercial pack stock will have beneficial effects on the trail and destination by preventing stock related impacts to the limited capacity destination with high risk factors (riparian).

The Lillian Analysis Unit will have moderate to high levels of use concentrated at Lillian Lake. There will be low to moderate opportunities for solitude as a result of limited camping imposed by a camping closure around a portion of the lake. Although the effects of commercial stock use at Lillian Lake may be moderate intensity, the other destinations (Flat Lake, Monument Lake, Fernandez Meadow, and Fernandez Lake) in this area will receive only occasional and light commercial stock use. In these locations there will be moderate to high opportunities for solitude with commercial stock use having only minimal effect on those conditions. Stock use will be most noticeable on the trail, and trailing impacts may have the most effect on a visitor's experience. Even so, this level of experiential effect is minor to moderate compared to other portions of the wilderness. Opportunities for solitude while camping, other than at Lillian Lake, will be high.

Triple Divide (Anne Lake and Rutherford Lake) will have low levels of commercial stock use. These areas are light public use and packer facilitated use will likely not change the character of these two locations. A prohibition on campfires at Rutherford Lake will reduce impacts associated with gathering firewood and have beneficial impacts to natural conditions by increasing the potential for scarce dead and downed material to add nutrients to the soils. Campsite impacts are noticeable because of the limited number of places to camp. This will not change. Limited pack stock use will prevent contributing to camping impacts.

With direction to limit trips to Sadler Lake, allowing continued use or increase use to McClure Lake, the impacts at Sadler Lake may be reduced. Moderate effects to opportunities for solitude and natural conditions will be present at Sadler Lake with continued commercial pack stock use. The existing impacts will be mitigated by designating an appropriate campsite and rehabilitating the existing site. This will have moderate beneficial effects to natural conditions at the lake. The destination quota for the Joe Crane unit would be capped at existing levels. This scenic destination could become more popular over time and impacts to solitude or experiential qualities may be affected if use were to increase. The location has limited camping and campers are within sight or sound of each other. Any effect to solitude because of the commercial pack stock use would probably occur only four to eight nights a season.

Cora Lake Analysis Unit would continue to experience high use. This use would be mitigated by commercial pack stock campsite management needed to reduce the heavy impacts associated with camping. Commercial pack stock is a small percentage of this use. Capping commercial use would aid in maintaining wilderness character, but will not guarantee wilderness values will be unaffected with continued high non-outfitted public use. Chetwood unit is a location where growth in commercial pack stock use could be realized. It is a suitable location for stock but does not contain the scenic qualities many wilderness visitors desire.

The Cargle Analysis Unit would continue to receive light use and moderate to high opportunities for solitude would be preserved.

Light and infrequent commercial pack stock use would continue in Bench Canyon, Iron Creek, Bridge Crossing, Fuller Buttes, South Fork, Arch, Onion Springs, Lower Mono, and Hot Springs Analysis Units. The only recent recorded commercial pack stock use has been to pass through these areas and that will likely continue. Prior to 2001, there has been infrequent camping use in some of these areas. The effects of this use are considered minor adverse effects to physical conditions (particularly trails) and short-term. With non-commercial public use very low in this areas effects to the experiential qualities (solitude, use conflicts, crowding) would be minimal.

Cumulative Impacts

There are no cumulative adverse effects as a result of this alternative in the Ansel Adams West Geographic Unit. Past actions of camping closures at Lillian, McClure, and Sadler Lakes have led to a concentration of use into small areas around the lakes. The additive allowances for commercial use at these destinations will not contribute to any additional affects above those already present, specifically a loss of solitude while camping and a sense of crowding at these destinations. The past camping closure at Rainbow Lake has caused a dispersal of use and impacts to Flat Lake, and continued commercial pack stock use is allowed for in this alternative. The dispersed use resulting from the closure may have had an adverse effect on Flat Lake. Increasing use and camping impacts at the lake are evident. The action in this alternative to designate a stock camp for use will reduce the impacts of camping at Flat Lake, not contribute to more effects.

Cattle grazing in the Lower Mono area will continue to affect the natural and untrammelled characteristics of wilderness in this area, even though an increase in commercial stock use or private use is not expected.

The combined actions of closures and trailhead quotas on commercial operators (2001) added to the limitations on where camping can occur (designated campsites) of this alternative have an adverse effect on the wilderness value of providing unconfined recreation opportunities to a sector of the visiting public. It also has the positive effect, when combined with limitations on overall use levels by commercial pack stock, on the wilderness value of minimizing human influences in this region.

Allowing for continued and concentrated use in specific areas has an effect on the wilderness value of naturalness by maintaining impacts to site-specific locations. However, concentrating the use, and impact, protects less used areas in the wilderness from receiving dispersed impacts across a larger area. These areas also receive moderate levels of non-commercial use (specifically Cora, Sadler, Isberg, Lillian, Vandeburg, and Staniford Lakes). These combined uses will have a potential to maintain impacted levels at campsites and on trails. There is not likely to be an increase in the extent of the effects, but possibly just a minor to moderate increase in the intensity of impacts.

The human influence noticeable by the dam at McClure Lake, and less noticeable with the smaller water control dams at Lillian and Rutherford Lakes, has an effect on the untrammelled and undeveloped qualities of wilderness character. There are no comparable effects from actions in this alternative that affect these elements of wilderness character.

Ansel Adams West – Alternative 2

Analysis

Overall, in this region 28 discrete destinations or zones would be managed for commercial pack stock use. There would be a potential increase of 65 trips to these 28 locations. As with all other locations, it is doubtful that these destination quotas would be reached on a recurring annual basis. It would, however, allow for fluctuations of client demand. Because of the daily and seasonal cap on total number of stock per commercial operator, if the entire quota were used it would be used with the same level of stock that has currently serviced less trips. Only in areas where no known concerns existed or risks were low for unacceptable stock related impacts was

use increased above use levels experienced under current management. Many locations in this region were capped or even reduced to encourage an upward trend in resource condition. These are listed below.

Overlap in commercial pack stock services will remain minimal. Three operators use this region with some traveling trips from additional operators utilizing this region 1-2 times/year. Some years there are no traveling trips. These traveling trips access the region by way of Yosemite National Park. If use is allowed to increase in the Park over time, this pattern might change, but that is not foreseeable. Some overlap will continue to occur but is mostly limited to the Chiquito unit. The majority of the region will only have one operator for the destinations.

Much of the growth potential may never be realized. Although suitable for additional commercial pack stock operations, it is not likely that growth would occur in those areas that have not been historically desirable to visitors. For example, the Bridge Crossing and Cassidy units are low elevation, are hot and dry in the summer season, and have few, if any, water sources. Fire restrictions may even be in effect at these low elevations during high fire danger years.

In the Staniford Analysis Unit, there would be a shift in use to Vandeburg, where there is growth potential. There would be a reduction of commercial pack stock use at Staniford Lake until, and if, a trail is improved to the campsites used by commercial pack stock parties in Alternative 1. A use trail to Staniford that bypasses the system trail would be prohibited reducing the moderate trail damage now occurring. Concentrating the use may increase encounters with stock on the trail but will concentrate the impacts caused by stock travel. Improved access at Vandeburg will similarly concentrate the impacts (compared to Alternative 1, trail encounters with commercial pack stock parties are expected to increase) and generally improve the conditions in the area, stock camps will be designated and a proliferation of campsite development will be curbed. Camps here are well impacted but have many structures, including benches and tables that will be removed in the first few years as a condition of use. The campsite closure at Lillian has caused camping to be concentrated to the other side of the lake with poor trail access to these sites. Improved access will help this situation. This will have minor long-term local beneficial effects on wilderness character (natural conditions).

Limits on trips to Flat and Monument lakes will insure that use does not grow and change the character of these destinations over time. Use had been displaced from Rainbow to Flat lakes with the closures in the 1970s; impacts were also displaced. Capping use everywhere in this area will prevent displacement of commercial pack stock to new areas.

Triple Divide will see a little growth potential at Anne and Rutherford. These areas are light use and packer facilitated use will likely not change the character of these two locations. Firewood is scarce at Rutherford and may need to be addressed in the future. Camping is limited here and campsite impacts are noticeable because of the limited number of places to camp. This will not change. Packers could choose to pack firewood into this area for the clients staying here to help alleviate the need for a fire closure in the future.

Packer use in the Sadler unit would be capped at recent high levels. This unit is the most popular unit in the Ansel Adam West Geographic region for private stock users. Though commercial pack stock camps would be designated, it is unclear if a reduction in the heavy impacts associated with these camps would noticeably decline. One campsite would be closed and/or relocated if needed. Relocation would insure that the site is in an appropriate location suitable for

stock camp. The destination quota for the Joe Crane unit would be capped at existing levels. This scenic destination could become more popular over time. Limiting commercial pack stock use would aid in maintaining wilderness character and intimate setting, but will not guarantee wilderness values would not be affected over time with increased use.

Cora Lake unit would continue to experience high use. This use would be mitigated by commercial pack stock campsite management needed to reduce the heavy impacts associated with camping here. Commercial pack stock is a small percentage of this use. Capping this use it would aid in maintaining wilderness character, but will not guarantee wilderness values would not be affected over time with increased use. Chetwood unit is a location where growth in commercial pack stock use could be realized. It is a suitable location for stock but does not contain the scenic qualities many wilderness visitors desire.

Light and infrequent commercial pack stock use would continue in Bench Canyon, Iron Creek, Bridge Crossing, Fuller Buttes, South Fork, Arch, Onion Springs, Lower Mono, and Hot Springs. The only recorded commercial pack stock use has been to pass-through these areas, that will likely continue.

Cumulative Impacts

Cattle grazing in the Lower Mono area will continue to affect the natural and untrammelled characteristics of wilderness in this area, even though an increase in commercial stock use or private use is not expected.

Past actions of camping closures at Rainbow, Lillian, Cora and Sadler lakes, trailhead quotas on commercial operators (2001) combined with the additional limitations on where camping can occur (designated campsites) of this action have an adverse effect on the wilderness value of providing unconfined recreation opportunities. It also has the positive effect, when combined with limitations on overall use levels by commercial pack stock, on the wilderness value of minimizing human influences in this region. The past action (2001) of closures to campfires above the 10,000-foot elevation combined with the opening of these same areas to campfires by one user group has the effect of creating inequities in opportunities and regulations to user groups. Allowing for continued and concentrated use in specific areas has an effect on the wilderness value of naturalness by maintaining impacts to site-specific locations while protecting less used areas in the wilderness from receiving dispersed impacts across a larger area.

Ansel Adams West – Alternative 3

Analysis

Commercial stock use in the Chiquito unit will continue to pass-through the Ansel Adams Wilderness into Yosemite National Park at a use level similar to current activity.

The Jackass unit will continue to have a low level of stock use, up to 25 stock a year. Private stock use recorded in this area has been up to 20 head a year. Overall use is low to moderate but trailhead quotas in place for the public allow for growth in use consistent with a Recreation Category 2 area. Commercial stock use will be concentrated at Jackass Lake and will not likely exceed more than five trips a year. The client threshold has been set at 20 clients per season. Opportunities for solitude will continue to be moderate depending on which lake in the basin is used.

Staniford unit will be changed to a Recreation Category 2 from a Recreation Category 3. This change from the No Action will mean that over time the area will not be managed as intensively and that use levels will be kept at a level that assure that intense management is not needed which is consistent with its current condition. With use levels currently moderate, there does not seem to be a need to apply direct controls at Vandenburg or Lady Lake destinations. Use in the Staniford unit will be most concentrated at Vandenburg Lake, Lady Lake, and Staniford Lake.

In this alternative 480 stock per year can disperse from the Fernandez trailhead and an additional 25 from the Walton trailhead to Staniford, Lillian, and Triple Divide Analysis Units. Client thresholds are set at 285 and 60 per season respectively. About half of this use will be limited to the Staniford unit and half into the Lillian unit. Very low use will continue into Yosemite National Park and the effects of this use will continue to be minimal on the Park. Lady Lake will maintain a more remote setting and character than Vandenburg as it is off the primary trail, if current commercial stock levels are maintained. Up to 18 trips have been recorded in one year. Opportunities for solitude can be diminished with more than one party camped there due to the setting that has limited camping out of sight or sound of other parties. With no stock camps identified at Lady Lake, commercial stock use will be spot and dunnage only reducing the opportunity for all-expense trips to this destination that may have the potential to change the character of the destination. Vandenburg receives a high level of public use and shows moderate impacts that will persist with camping associated with the public use. Commercial stock use will contribute very little to this condition.

Staniford Lake will continue to receive a moderate level of commercial stock use that will be limited to spot and dunnage only as no stock camp is designated. Travel to the lake along a use trail that is being used in the No Action will be prohibited in this alternative. This will reduce noticeable impacts caused by commercial stock use but will require a new user trail or system trail to be identified to suitable campsites at the lake. Opportunities for solitude will continue to be moderate and at times low throughout the summer. Camping at the lake is limited and sites are out of sight from one another but not sound. It is a suitable location for larger groups, but these larger groups tend to be packed in by pack stock and have the potential for affecting solitude. This is a popular location for other non-pack stock outfitters and guides and this use will continue to be facilitated by commercial pack stock support. Chittendon could potentially receive more stock use than Alternative 2 or 4, as the trail is not identified as Not Suitable for Commercial Stock. However, commercial pack stock rarely goes to Chittendon now, and due to the nature of the trail, increased use would not be anticipated in the future. If for some reason, use did increase the potential to affect the character of the area and the opportunities for solitude with lack of direct controls could change.

Lillian Lake unit will continue to have moderate levels of commercial stock use. The use will continue to be concentrated at Lillian Lake, with lighter use at Flat Lake, Fernandez Meadow and occasional use at Fernandez Lake. Opportunities for solitude will continue to be low to moderate at Lillian. The past action of closing the northeast side of the lake to camping has had the effect of concentrating campsites in one general location within sight and sound from one another and extending a use trail around the lake, which is poorly located and not designed for any substantial level of use. With designated sites for spot and dunnage as required in this alternative, there will be less dispersing of commercial stock trailing. This has the effect of reducing noticeable impact to the character of the area that would be caused by uncontrolled stock travel to new campsites, as there is a need to find more secluded un-impacted sites than

currently exist. Flat Lake will continue to see occasional commercial stock use. A designated stock camp will improve the condition of the stock sites that have a high degree of campsite development.

Fernandez Meadow will have occasional use and with identified stock camps and grazing resources available, stock camp standards will reduce the current impacts of campsite development and expanding areas of impact from the holding of stock in various configurations at these sites. Trail impacts at the junction will persist unless future management actions are taken to relocate or improve the trail. The Fernandez Lake will continue to receive infrequent commercial pack stock use.

Commercial stock use in the Triple Divide unit does have the potential for increasing in this alternative. With the opportunity to expand traveling trips, use to Anne Lake with a designated stock camp may be desirable for all-expense trips. With grazing resources available, and the ability to pack in feed, it is possible that use at Anne Lake could increase. Opportunities for solitude would be lowered if this were to happen. The camping capacity is low with campsites not out of site or sound from one another. Rutherford Lake would have a designated spot and dunnage site only, prohibiting traveling trips from this destination.

Use in the Sadler unit would be controlled primarily by the Isberg stock quota of 510 stock per season or 310 clients. The highest amount of stock use in this unit will continue to occur at Sadler Lake and Joe Crane Lake. The designation of stock camps at Sadler will reduce current impacts occurring in the No Action alternative with highly impacted sites, high campsite development, and expanding camp area due to configurations of stock holding. However, due to the relatively high use of private stock in these areas, impacts from holding stock will continue to occur. There will continue to be moderate opportunities for solitude at these locations and when stock parties are camped a potential for a sense of crowding and loss of solitude if other parties are camped. Camping capacity is minimal and sites will continue to be within site and sound of each other. Other parties may be displaced to other locations when stock camps are present.

The Cora unit will have no increase in commercial stock use with use controlled by the Isberg trailhead. Use will probably disperse out to the Sadler and the Lake Catherine units, but without direct controls could concentrate more intensely at Cora if commercial, demands change. Campsites at Cora will continue to be highly impacted, and will likely not change because of this alternative. Opportunities for solitude will continue to be low to moderate and the setting is such that campsites are within site and sound of each other.

The Bench Canyon unit will have no commercial stock use authorized. The use trail currently approved in the No Action alternative will be prohibited, eliminating any capability of accessing Rockbound Lake with stock. This will increase the opportunities for solitude at the Recreation Category 1 destination.

Other areas accessed by the Isberg trailhead are Hemlock Crossing, Stevenson meadow and upper Dike Creek in the southern portion of Lake Catherine unit. Up to 200 commercial pack stock per year may be utilized in these three destinations. If use patterns shift between Sadler and Lake Catherine units use could increase to the southern portion of the Lake Catherine Analysis Unit. The area has very low public use and opportunities for solitude will continue to be moderate to high with this level of commercial pack stock use.

The Bridge Crossing and Caryle units are accessed by the Mammoth trailhead, which has a seasonal stock threshold of 105 stock. A significant amount of the commercial pack stock use in these areas is related to hunting. There are few attractions for the public (lakes etc.). Some of the commercial pack stock use in the Caryle unit comes from the Mammoth area, especially during hunting season. Commercial trips are occasionally taken to Junction Butte for fishing in the San Joaquin River. Overall, the opportunities for solitude remain very high in these units except during hunting season.

The Cassidy unit, including the Cassidy and Miller trailheads, will have low to moderate commercial stock use primarily to Cassidy Bridge and Miller Crossing providing spot and dunnage service only, as no designated stock camps are identified at these locations. Up to 80 stock seasonally will be allowed from the Cassidy trailhead, and 55 stock from the Miller trailhead. This will maintain conditions of low use and high opportunities for solitude in this unit.

The Junction unit will see low to infrequent commercial stock use and a high opportunity for solitude by all visitors will be retained consistent with a Recreation Category 1 area.

Use in the Arch unit will also see low to infrequent stock use and a high opportunity for solitude.

Onion Springs will have a seasonal quota of 25 stock maintaining low and infrequent commercial stock in this area. Most use will be associated with hunting and may not occur every year. The area is remote with high wilderness character, and high opportunities for solitude that will not be affected by this low allowance for commercial stock use.

Cold creek is a pass-through area with use traveling through to the Devils and Graveyard unit. The Graveyard cutoff is also used as a pass-through area with to access Graveyard Meadow, Graveyard Lakes, and Goodale Pass. Multiple trailing exists in this area due to range cattle. Day ride use is also in this area. Cold Creek will see moderate opportunities for solitude, and character will be affected by moderate to high traffic on the Goodale Pass Trail.

Lower Mono creek area is used primarily for day rides. The public uses this unit for day hikes to Doris and Tule lakes. Opportunities for solitude will remain moderate at Doris and Tule lakes, and will remain high in the rest of this area, where use by all parties is light.

Cumulative Impacts

Cattle grazing in the Lower Mono area will continue to affect the natural and untrammelled characteristics of wilderness in this area, even though an increase in commercial stock use or private use is not expected.

The resource impacts on the Graveyard Cutoff, Devils Bathtub, and String Meadow trails can be primarily attributed to the fact that they were originally constructed as four-wheel drive routes.

Ansel Adams West – Alternative 4

Analysis

In this alternative, no quotas change from Alternative 1 No action. There would be a change in the overall level of commercial services due to the overall 20 percent reduction in allocated service days. The 20 percent reduction would have no direct effect on any one location. There is the probability that the reduction would be dispersed across the destinations and that some

improvement to campsites and trails may occur with a reduction in one source of disturbance. Limits on trail use would have more effect than the reduction in overall use. Only 5 of the 18 use trails in this geographic region would be authorized for use. Three system trails are designated as not suitable for commercial stock. This limits the geographic extent of commercial pack stock operations and has a more direct effect on the wilderness than overall use reductions.

Commercial stock use in the Chiquito unit will continue to pass-through Yosemite National Park with no overnight stops. Stock numbers can be expected to be the same as in Alternative 1. If other wilderness visitor use does not change, conditions at Staniford, Lillian, Vandeburg, Anne, Rutherford, Sadler, and Cora may experience some slight reductions in crowding and produce minor to moderate beneficial short-term effects to wilderness character (opportunities for solitude).

Overlap in commercial pack stock services will remain minimal. Two operators use this region with some traveling trips from additional operators utilizing this region 1-2 times/year. Some years there are no traveling trips. These traveling trips access the region by way of Yosemite National Park. If use is allowed to increase in the Park over time, this pattern might change, but that is not foreseeable. Overlap will continue to occur mostly in the Chiquito unit. The majority of the region will only have one operator for the destinations.

No commercial pack stock clients would be allowed to camp at Monument Lake or Joe Crane Lake. This would produce short-term beneficial effects to some aspects of wilderness character (solitude, natural conditions with a disturbance source removed). It will also have adverse long-term effects to some segments of the public's ability to access these areas without commercial pack stock.

Light and infrequent commercial pack stock use (only dunnage or spot trips) would continue in Iron Creek and Bridge Crossing units. No camps or dunnage, spot or full service trips would be authorized in Fuller Buttes, South Fork, Arch, Onion Springs, Lower Mono, and Hot Springs units. As the only recorded commercial pack stock use has been to pass through these areas, this limitation should not limit clients from choice. Unless non-commercial pack stock use increases in these areas, opportunities for solitude should be high.

Light commercial pack stock use would continue in Cassidy, Cargyle, and Junction units, with less than 50 clients and 100-200 stock in each unit per season. This use pattern would continue and is not expected to effect a change in wilderness character, or opportunity for solitude.

Cumulative Impacts

Past actions of camping closures at Rainbow, Lillian, Cora, and Sadler Lakes, trailhead quotas on commercial operators (2001) combined with the additional limitations on where camping can occur, group size reduction, trailhead quota reduction, and use and system trail closures have a negative effect on the wilderness value of providing unconfined recreation opportunities.

See discussion in Alternative 1 regarding the cumulative effects of the small dams at Rutherford, Lillian, Chiquito, and McClure Lakes. The cumulative effects will be the same in this alternative.

Cattle grazing in the Lower Mono area will continue to affect the natural and untrammelled characteristics of wilderness in this area, even though an increase in commercial stock use or private use is not expected.

If other wilderness visitor use does not increase and/or wilderness ethics behaviors do not decline, this alternative would likely have a minor to moderate beneficial long-term effect on wilderness character (solitude, natural conditions). Uses will continue and one disturbance source is reduced in extent and intensity of use, but other uses will continue and actually may increase, limiting the beneficial effects of actions to one user group.

Ansel Adams West – Alternative 5

Analysis and Cumulative Impacts

This geographic unit (GU) currently receives about 10 percent of the overall commercial stock use in the two wildernesses. Most of the use occurs in the northwest portion of this GU, with very light use elsewhere. The biggest effect of eliminating commercial pack stock use would be in the northwest analysis units. Overall use by hikers and private equestrians would continue and without commercial pack stock operations, the area would see up to 3000 people in the summer months. A high proportion of the use is non-pack stock outfitters, some of which utilize the commercial packers for dunnage services. It is unclear whether some of the current non-stock outfitters would be able to continue their services to mostly young people and families without the dunnage service.

Commercial pack stock use is heaviest in Staniford, Lillian, Triple Divide, Sadler, and Cora Analysis Units. Any measurable change compared to Alternative 1 would occur site-specifically in these areas. Trails in this region are rough and are not highly developed. Trails accessing popular commercial pack-stock use sites may revert to trails that are more primitive and may have the effect of improving the experiential values in wilderness.

Vandeburg Lake will still receive a high amount of use from the public, commercial pack stock operators have reported at most four trips to this lake in recent years. Three commercial pack stock use trails in the area would no longer be used and are likely to re-vegetate in time.

Lillian Lake would likely remain as popular as it is today. Use would be reduced by 50 people and 150 stock. Although the effects to these destinations would not singularly have much affect by the elimination of pack stock, cumulatively there would be nearly 500 less stock on this trail corridor.

Light commercial pack stock use but a moderate amount of public use occurs over Fernandez Pass into Yosemite National Park. Changes to this area would not be noticeable.

In the Triple Divide unit, commercial pack stock operators currently service parties to Anne and Rutherford lakes. By eliminating a couple trips to Rutherford, there may be improved opportunities for solitude as this destination has a small capacity for camping and being open (few trees) is vulnerable to experiential disturbances. Anne Lake receives some use and a large site used by packers at the north end of the lake would likely be reduced in size and impact over time.

The most noticeable changes in this geographic unit would likely occur at Sadler and Cora Lakes. Currently about 14 trips and 140 head of stock utilize this area each summer at Sadler and similar numbers at Cora. Three large stock camps (private stock users frequent these camps as well) at Sadler show signs of impacts from stock holding and large parties. Cora Lake has some highly impacted sites (including some with evidence of stock holding). The sites have been heavily and repeatedly used by all types of wilderness visitors (only a portion of which are

commercial pack stock clients). Without commercial pack stock use, these sites would probably be reduced in size over time, and rehabilitation or naturalization efforts could lead to overall visual and ecological improvement in the area. Cora would still receive a high amount of use; by eliminating a portion of the use, some improvements would likely occur. Since most of the use occurs in August, fewer encounters with commercial pack stock may improve the opportunities for solitude at Cora and Sadler.

Destinations such as Joe Crane, Isberg Lake, and Rockbound Lake and other remote destinations would only be affected slightly by the elimination of the commercial pack stock operations since they use these areas infrequently.

Fish Creek/Convict/McGee – Alternative 1

Analysis

Pack stations will continue to use over 35 destinations in this alternative. Destinations are not controlled in this alternative so new locations could be used or shifts in intensity or frequency of use of any destination could occur over time. With shifts in intensity or frequency of use there could be localized adverse short to long-term effects to wilderness character (natural conditions) if impacts to campsites, expand, or become more severely affected. Short-term adverse effects to solitude could also occur at any destination where use increases.

In the Convict drainage, pack station use will be limited by competing for the single quota. This could however continue to allow for growth in their activities in this drainage. Shifting destinations within the drainage could lead to additional impacts. Commercial pack stock use to Cloverleaf, if it were to increase, would likely see additional erosion of the trail. Opportunities for solitude could become compromised. The existing quota of 10 will probably help maintain moderate to high opportunities for solitude generally throughout the drainage. The annual operating plan specifies that pack stock use cannot go beyond Dorothy Lake so use and stock impacts to Mildred, Bright Dot cannot occur in this alternative. Short-term minor adverse effects to solitude and longer term minor to moderate adverse effects to natural conditions are possible at Cloverleaf Lake if trail deterioration continues. .

McGee Canyon will be an area of high commercial pack stock use and very high stock numbers. Day rides in the lower portion of the canyon will contribute to additional encounters with stock parties. Use to the various destinations will likely continue to be dispersed, with regular use of the Round Lake site. Access to this site could deteriorate without any improvements required at campsites. Use to Baldwin, though occasional now, could increase with no direct controls and trail deterioration would be expected. Use to Meadow Lake (east of Golden) is prohibited and over time with removal of disturbance, the impacts of the trail will possibly re-vegetate. Access to the California Conservation Corps (CCC) camp will likely continue to degrade.

Coldwater will continue to see very high stock passing through to Duck Pass. Use to Woods Lake can occur and could increase if operators choose to either market that location or if visitor demand led to a shift in patterns. Increased use would be appropriate from a Recreation Category 3 view, but the trail and campsite would show impacts of even light stock use. Day rides will continue to contribute to the high encounters between parties and a sense of congestion. Crowding will be present throughout much of the summer season.

Purple-Bench unit will continue to have very high levels of commercial stock use as trailhead quotas (15 per day) allow for a high level of commercial stock use. The Purple Lake area will see a high concentration of use with commercial stock being a dominant presence. Use of multiple trails into camps and between camps will likely continue, and conflicts where the system trail goes through a large stock camp will continue to cause confusion in this area for the public. Grazing, though limited in the past few years from intensive site-specific management, will possibly show some recovery and then receive use again. Intensive management of the packer use will be needed into the future if the levels of use from the past continue. There will continue to be confusion with the elevation fires closure, with some sites above and some below 10,000 feet in the same area. Firewood has been scarce but the surrounding forest is productive and downed wood sources vary year to year.

Upper Fish will get moderate levels of stock use. Horse Heaven, the Lee and Cecil junction, and Tully Lake will receive repeated use, though light to moderate. The trail to Lee and Cecil will get used for spot and dunnage trips only yet this continued use will not allow for much recovery of the substantially damaged trail. Use to Tully Lake will continue with access issues that will likely not get resolved and perpetuate the multiple trails into the area. If commercial stock use levels were to increase as they could in this alternative, Tully Lake could exceed standards for a Recreation Category 1 area. Crowding and diminished opportunities for solitude would be possible with any increase in use to this destination. The stock camp at Horse Heaven will continue to have a high impact but will not likely increase in size from its present total area.

Cascade Valley will be an area of moderate stock use. Management of grazing resources at Third Crossing, Cascade Valley, and Second Crossing will greatly dictate the level of commercial stock use that would overnight in the area as opposed to just pass-through. Stock camps at Third and Second Crossings will continue to be noticeable and, especially at Third, somewhat intrusive to the visitor passing through on the trail. Crowding and encounters between hikers and stock will only be high in the Cascade Valley and Iva Belle areas. Iva Belle hot springs will continue to see degradation with pack stock contributing to the impacts by facilitating access to the area. Trailhead quotas are currently not limiting use, and commercial stock use accounts for up to 30 percent of the use in this area. Commercial pack stock use could, under current management continue to grow.

Silver Divide will continue to see a high level of commercial stock use, concentrated at Grassy Lake and Jackson Meadows. Commercial stock destinations will fluctuate over the years with some years Grassy getting more use, other years Jackson, and this past year Long Canyon. Packers tend to both adjust to the conditions of the year and competition with other packers in the area, all which vary year-to-year. There are few limits on grazing currently and management of grazing will likely respond reactively to impacts. Stock camps will continue to expand and proliferate as Silver Divide continues to be a desirable crossroads of multiple pack stations, used for traveling trips and two-day spot and dunnage trips, both requiring overnight holding of stock.

Margaret and Onion Springs will each have a trailhead quota, which could increase the use at Margaret lakes. Commercial pack stock use will probably continue to be the primary use with up to 50 percent of the use by the commercial pack station, but the overall use is very low. Destinations are not limited and pack station use could disperse to multiple destinations in the basin. Opportunities for solitude will likely be high unless the area does see use pattern changes and becomes more desirable for visitors than it currently is.

Cumulative Impacts

Past grazing of pack stock at Lee and Cecil has possibly contributed to the severe impacts along the trail corridor. Grazing was suspended in 2002 operating plans but travel to Lee and Cecil was allowed to continue. There has been some improvement with the reduction in use but impacts remain severe. The grazing suspension will likely continue under this alternative, thereby removing the potential for cumulative effects.

Past grazing of pack stock at Second Crossing was suspended in 2002 due to concerns and severity of impacts. This led to a shift to other grazing resources west of second crossing up to Cascade Valley. The shift in grazing has minor short-term adverse effects locally to natural conditions.

Cascade Valley has been closed to grazing for nearly twenty years. This closure led to dispersal to other areas for grazing, such as Grassy and Jackson. With no corresponding reduction in grazing use will shift and has possibly contributed to the impacts becoming severe at Grassy and Jackson. Continued grazing contributes to moderate long-term adverse effects to natural conditions at these meadows.

The Mammoth Lakes basin is the source of considerable day use activity that has a cumulative effect on the permitted activities including backpackers and stock users. All these uses contribute to crowding and loss of solitude north of Duck Pass and at Duck and Pika Lakes. Minor to moderate adverse effects to solitude will be a cumulative effect with on going commercial packs tock use as managed in this alternative.

The camping closure that was implemented at Purple Lake in the early 1980s had the effect of moving use from the outlet of Purple to Purple Lake. This improved the area around the outlet but may have had the effect of increased crowding at sites on the north of the lake and conflicts between pack stock and hikers camped in close proximity to each other.

The northeastern portion Fish Creek drainage is identified as the Sierra National Forest but is administered by the Inyo National Forest. This action, which has been in effect for over thirty years, has had the effect of creating discontinuity for administering the wilderness. Funding the administration of this piece of land has been low priority for both Forests and at times has not received attention or management. This has contributed to impacts not being addressed or mitigated in a timely fashion.

Fish Creek/Convict/McGee – Alternative 2 – Modified

Analysis

In Fish Creek, an estimated 1600 commercial stock were used in the past in conjunction with spot, dunnage and all-expense trips. Under this alternative, there will be a net decrease of at least 300 stock and a 46 percent reduction of the number of all-expense trips from Mono Creek to Mammoth and Yosemite. The effect of this will be fewer encounters with commercial pack stock, potential reductions or improvements of campsite impacts with fewer occurrences of use of the sites, and an overall increase in opportunities for solitude. The use that would continue would have minor to moderately intense adverse effects to naturalness (at campsites and on trails) and minor to moderate effects to recreation experiences, both would be short-term. These effects would be limited in their extent, which would be the beneficial effect of destination quotas limiting the frequency of use to destinations.

Designated campsites for overnight holding of stock will have a moderate long-term beneficial effect in areas on the Silver Divide (Grassy Lake, Jackson Meadow, Long Canyon, Olive Lake) by reducing the overall extent of impact that can occur with stock holding camps. With the Silver Divide being at the crossroads of west side and east side packers, as well as multiple packers traveling through on the PCT/JMT, the concentration of these impacts will have some beneficial effects. The concentration of impacts may create intensive effects to vegetation, soils, the potential depletion of firewood resources and human waste concentration.

In the Convict drainage, there will be two operators, both with low use. There will be a very slight reduction in use. Use will be limited to Cloverleaf Lake with a party size limit that responds to concerns on the trail to lake. Use will likely disperse to Edith Lake, which is more suitable for pack stock with many large camps that are well screened, protecting opportunities for solitude while camping. The public use is very low in the upper part of this canyon where commercial pack stock use will be authorized. There are many impacts from periods of higher use in the past. The designation of specific use trails and site-specific system trail designations should afford the area improved character within ten years. The extent of impacts will decrease and natural conditions will see a minor to moderate long-term beneficial effect.

There will be moderate to high commercial stock use concentrated within the McGee Canyon trail corridor. Lower levels of use to Baldwin Lake and moderate levels of use to Steelhead Lake and Grass Lake will contribute minor to moderate adverse effects to the trail system and minor effects to recreational experiences. Collectively this canyon will see the noticeable effects of moderately heavy stock use on trails and very few campsites. Improvements to campsite access at Round Lake, “CCC Camp,” and Big McGee Lake will occur over the first five years. The most noticeable effect will likely be experiential with encounters with stock occurring on a regular basis from mid July through August. There will have an adverse effect on those visitors who do not enjoy encountering stock and stock impacts, but will be short-term and of moderate intensity.

The same level of day rides will occur in McGee Canyon with improved turnarounds that will help reduce some localized impacts. This use will contribute to some crowding and encounters on the first two miles of trail inside wilderness, but not beyond. The effects are limited in extent and short-term, however negative the effects of day rides are to another visitor’s experience.

The Coldwater Analysis Unit is used primarily as a pass-through for commercial pack stock use. Only one destination, Woods Lake will experience overnight commercial stock use. The level of use is consistent, in fact low, for a Recreation Category 3 area. This lake has very high opportunities for solitude despite its location within a very high use area for backpackers, day hikers, and anglers. This condition, the high opportunities for solitude at Woods Lake and the high public use, will probably not change. There is a moderate to high level of day rides conducted in this area. Trails that are not stable, suitable or may further use conflicts are not authorized for day ride activities (Sky Meadow and Emerald to Skeleton). There will still be a high presence of stock throughout the basin. This is consistent with a Recreation Category 3.

The Purple-Bench Analysis Unit will continue to see high stock use. Up to 500 stock currently use this unit, mostly concentrated at Purple Lake. There will probably be up to 100 less stock in this area with the reduction of all-expense trips from Mono Creek to Mammoth, and with this reduction in overlapping operators there may be fewer encounters with stock. Designating three campsites at Purple will not change current patterns, but the sites will be contained and access

improved within five years. The current practice of using any number of use trails to travel between campsites and to grazing areas will be eliminated. Effects will be restored slowly over time. This will however increase the encounters on the main trail around Purple Lake.

The allowance for campfires through a modification of the elevation campfire closure will reduce confusion occurring presently with some sites above the 10,000 feet and others below. The area is on the borderline of the elevation closure and dead and downed wood sources vary year to year. It is possible that campfire rings will proliferate in this area. The campsite at Purple Bench, used primarily for traveling trips may get less use and the access to the site will improve.

The number of trips in Upper Fish Creek has the potential to increase but with a similar number of stock. A slight increase in encounters with stock parties is possible. This area has moderate to high opportunities for solitude and it is not expected that this increase will change the character of the area. Non-commercial use in the area is low and dispersed over a high number of possible destinations. Encounters would likely be limited to the trail.

Use will be limited to Tully Lake through a party size limit that corresponds to the capacity of the destination. This will prevent the site used by packers from increasing and will protect the area from changing character if use patterns were to change.

Packer use to Lee and Cecil Lakes will not be authorized. Impacts to the trail system will likely improve over the next ten years with the removal of pack stock use on the trail. Opportunities for solitude will increase and should be very high. The wilderness character and experience will improve in this area.

Horse Heaven will remain a destination for packer use and the site that is currently impacted and used will probably not improve, but will not degrade. The site is well screened and opportunities for solitude will remain moderate even with occupied sites. Designated sites at Point Camp, Sheep Camp, and Hilton Camp will prevent further proliferation of stock camps. Access will improve and the sites will be contained.

Cascade Valley will have the potential for a slight increase in commercial pack stock use. This increase is identified for Cascade Valley above Iva Belle Hot Springs and for Tully Hole. Both of these areas can sustain more use as the trail access is on a primary trail. Encounters with the public may increase.

Conditions at Iva Belle will be improved by the prohibition of spot and dunnage drops at the hot springs. Spot and dunnage trips can be taken to Sharktooth Creek camp, ¼ mile below the hot springs. This will help prevent the overuse of the hot springs by not providing service directly to the site. It is expected that parties will bring less equipment, supplies, and food if they have to walk the last ¼ mile. A designated stock camp at Sharktooth Creek will formalize the use of a site that has been used for years. Improved access and site containment will lessen impacts. Iva Belle Hot Springs will continue to have high use, a small percentage of which is supported by packers. Opportunities for solitude are low and the experiential values are mixed. The area is unique and heavily impacted. Most visitors do not seek solitude or pristine conditions, but seek the modified environment of hot pools designed for soaking. This condition will not change.

Silver Divide will be an area with a high level of overlapping operations. Up to 300 stock per year currently use the area. This will likely be reduced by at least 150 stock by reducing the traveling trips through the area (mentioned above). With a condition of a one-night stay limit, the area will see only passing use and will probably improve from present conditions. With the

designation of stock camps at Grassy and Jackson, access improvement and site containments, there will be an end to the proliferation of sites in these locations. General trail conditions may improve over time with less stock but this would be minimal unless trail improvements took place. Peter Pande Lake will have limited use until the trail is improved. Opportunities for solitude will probably remain the same. There will be no effects to the high wilderness character at Peter Pande Lake, Olive Lake, Wilber May Lake and Lost Keys Lake since allowable use levels will be one to six trips a season to each of those destinations. Opportunities for solitude will be moderate to high throughout the Silver Divide except along the PCT/JMT corridor.

Margaret Lakes Basin is a very low use area. Packer use accounts for nearly 40 percent of less than 50 parties that visit the area a season. The primary location for packer spot and dunnage trips is Frog Lake, which has a limited capacity. Other visitors can easily travel further to Coyote, Fern, or Margaret lakes and avoid stock or other parties if they choose to enhance their opportunities for solitude. It is not expected that opportunities for solitude will be affected by the level of packer use in this alternative. The poor trail conditions can potentially affect the experience of visitors in the area and is not likely to improve or degrade with the actions in this alternative.

Cumulative Impacts

Non-commercial visitor use levels in these areas are moderate and dispersed throughout the geographic unit. Most of the use is concentrated along the PCT/JMT trail corridor. The commercial pack-stock use actions in this alternative will have a cumulative effect of contributing to crowding and adverse effects to solitude while traveling on the PCT/JMT corridor. The effects of encounters will be short-term and minor in intensity and overall reduced from current levels as a result of limiting all-expense trips through the area.

Cascade Valley has been closed to grazing for nearly twenty years. This current closure combined with the additional restrictions in this alternative will greatly limit the grazing resources in this area. This may lead to more packing in of feed, to support trips and a possible increase in stock numbers as a result. Stock numbers that increase in one area would have to be reduced in other areas to be within overall seasonal stock limits. The cumulative effect will have beneficial impacts to the natural qualities of wilderness by reducing impacts at individual meadows. The effects can be moderate and long-term.

In 2002, grazing at Lee and Cecil Lakes was suspended through operating plan direction. Travel to the lakes was allowed to continue. With this alternative, no use of this trail will help reduce impacts. These impacts will likely remain severe until restorative work is completed. With one substantial source of disturbance removed, the area will have the appearance of recovery and will look noticeably improved within a few years. Physical mitigation to headcuts and trail incision will be required to affect change on the hydrologic function in the riparian areas impacted by the trail.

The Mammoth Lakes basin attracts considerable day use activity that has a cumulative effect on permitted activities, including backpackers and stock users. All these uses contribute to crowding and loss of solitude north of Duck Pass and at Duck and Pika Lakes.

The camping closure that was implemented at Purple Lake in the early 1980s had the effect of moving use from the outlet of Purple to the north side of Purple Lake. This has led to crowding and conflicts between pack stock and hikers camped in close proximity to each other. Actions

proposed in this alternative will concentrate pack stock to identified campsites, and concentrate and contain sites and trails used by the commercial packers.

Fish Creek/Convict/McGee – Alternative 2

Analysis

Overall, there would be a potential increase of 57 trips to 30 destinations with this alternative. As with all other locations, it is not expected that pack station would reach the destination quotas on an annual basis, this does allow for fluctuations of client demands. If the entire quota was used it would be used with the same level of stock that has currently serviced less trips. In Fish Creek, up to 1600 stock were utilized in the past. Under this alternative, there will be a net decrease of at least 300 stock as a result of reducing the number of all-expense trips from Mono Creek to Mammoth and Yosemite by 46 percent.

Designated campsites for overnight holding of stock will be implemented which will concentrate and contain the impacts associated with stock camps and general improvements will be noticeable within 5 years. This will have a moderate long-term beneficial effect locally by reducing the overall extent of impact that can occur with the stock holding camps.

In the Convict drainage, there will be two operators, both with low use. There will be a very slight reduction in use. More importantly, use will be limited to Cloverleaf Lake with a party size limit that responds to concerns on the trail to Cloverleaf Lake. Use will shift to Edith, which is more suitable for pack stock with many large camps that are well screened which helps protect opportunities for solitude while camping. The public use is very low in the upper part of this canyon where the packers will be authorized. There are many impacts from periods of higher use in the past. With the designation of specific trails where now there are multiple and difficult to follow use trails and incomplete system trails, this area should improve in character within 10 years. The extent of impacts will decrease and natural conditions will see a minor to moderate long-term beneficial effect.

McGee Canyon will see a potential increase of 24 trips with a seasonal limit of 700 stock. The same level of day rides will occur with improved turnarounds required that would help reduce some localized impacts occurring. The increase allowance is identified for the McGee Pass Trail corridor to facilitate spot and more likely dunnage trips, which have low stock people ratios along an already highly developed and sustainable trail. With a potential for more trips with fewer stock-per-party, there may be an increase in encounters with the public. Improvements to campsite access at Round Lake, the CCC camp and Big McGee Lake will occur over the first five years. Campfires that will now be allowed will affect visitor equity issues at Big McGee and Steelhead Lakes. It will be very difficult to achieve compliance with the elevation fire closure in these areas and may lead to further depletion of natural wood sources.

The Coldwater unit is used primarily as a pass-through for commercial pack stock. Only one destination, Woods Lake is identified for light use. This lake has very high opportunities for solitude despite its location within a very high use area for backpackers, day hikers, and angling activities. This condition, the high opportunities for solitude at Woods or the high public use, will likely not change. There is a moderate to high level of day rides conducted in this area. Trails that are not stable or suitable or may further use conflicts are being denied for day ride activities (Sky Meadow and Emerald to Skeleton). There will still be a high presence of stock throughout the basin, but it is consistent with a Recreation Category 3.

Purple-Bench Analysis Unit will continue to see high stock use. Up to 500 stock currently use this unit. This will likely be up to 100 less with the reduction of all-expense trips from Mono creek to Mammoth, and with this reduction in overlapping operators there may be fewer encounters with stock. Designating three campsites at Purple will not change current patterns, but the sites will be contained and access improved within five years. The current practice of using a myriad of use trails to get from camp to camp and to grazing areas will be eliminated and will be restored slowly over time. This will however increase the encounters on the main trail around Purple. The allowance for campfires with packed in wood for clients of pack stations will most likely lead to public non-compliance with the elevation fire closure. The area is on the borderline of the elevation closure but, due to very heavy use over a long period, the wood resources are depleted, yet with the forest still productive the conditions change year to year. It is expected that campfires rings will proliferate in this area. The campsite at Purple Bench, used primarily for traveling trips may get less use and the access to the site will improve.

The destinations identified for use in Upper Fish Creek have the potential to increase by ten trips. This area has moderate to high opportunities for solitude and it is not expected that this increase will change the character of the area. Use will be limited to Tully Lake with a party size limit in place that corresponds to the capacity of the destination. This will prevent the site used by packers from increasing and will protect the area from changing character if use patterns were to change. Campfire use here may lead to non-compliance issues with the public. Packer use to Lee and Cecil will be eliminated. Impacts to the trail system will likely improve over the next ten years with the removal of pack stock use on the trail. Opportunities for solitude will increase and should be very high. The wilderness character and experience will improve in this area. Horse Heaven will remain a destination for packer use and the site that is currently impacted and used will likely not improve but will not degrade. The site is well screened and opportunities for solitude will remain moderate even with occupied sites. Designated sites at Point Camp, Sheep Camp, and Hilton Camp will prevent further proliferation of stock camps. Access will improve and the sites will be contained.

Cascade Valley will have the potential for an increase of nine trips. This increase is identified for Cascade Valley above Iva Belle Hot Springs and for Tully Hole. Both of these areas can sustain more use as the trail access is on a primary trail; however, encounters with the public may increase. Use at Iva Belle will be only slightly lowered. The current prohibition that limits pack stock to within ¼ mile of the spring will be maintained. A designated stock camp will formalize the use of a site that has been used for years, and will improve the access and contain impacts with a setback from water sources. Iva Belle Hot Springs will continue to have high use, a small percentage of which is supported by packers. Opportunities for solitude are low and the experiential values are mixed. The area is unique, yet heavily impacted. Most visitors do not seek solitude or pristine conditions, but seek the modified environment of hot pools designed for soaking and camping. This condition will not change. It is expected that over the next 10-15 years management actions will be needed to reduce impacts and/or use.

Silver Divide will see a potential increase of five spot and dunnage trips. These have been identified to occur at Chief Lake, along the PCT and Long Canyon. Four trips would be authorized to Chief Lake: this is an insignificant increase. Long Canyon would see up to four more trips. It is a remote location that is rarely visited by the public. Campsites in this canyon are suitable for pack stock as they are in forested and well-hardened locations. There is evidence of higher use levels here in the past. The opportunities for solitude may decrease but will still be

high. There may be some displacement of use on all-expense trips to Long Canyon and a reasonable foreseeable action may be to identify grazing allocations to individual operators.

Silver Divide will be an area with a high level of overlapping operations. Up to 300 stock currently use the area. This will likely be reduced by at least 150 stock, by reducing the traveling trips through this area (mentioned above). With a condition of a one night stay limit, the area will see only passing use and will improve, from present conditions. There should be at least one less packer utilizing the area because of the primary operator concept. With the designation of stock camps at Grassy and Jackson, access improvement, and containments there will be an end to the proliferation of sites in these locations. General trail conditions may improve over time with less stock but this would be minimal unless trail improvements took place. Peter Pande will have limited use until the trail is improved, and opportunities for solitude will remain the same. The destination has high wilderness character and gets low use from the public.

Margaret Lakes Basin is a very low use area. Packer use accounts for nearly 40 percent of less than 50 parties that visit the area a season. The primary location for the packer for spot and dunnage trips is Frog Lake, which has a limited capacity. Other visitors can easily travel further to Coyote, Fern, or Margaret lakes and avoid stock or other parties if they choose to enhance their opportunities for solitude. It is not expected that opportunities for solitude will be affected by the level of packer use in this alternative. The trail conditions probably have the biggest effect on the experience of visitors. Trails are dusty with sections of multiple trailing on the western slope approaching Arch rock. The poor condition of the trails is in contrast to the remote and generally low use basin. This diminishes the character of the area. This is likely not going to change with this alternative.

Cumulative Impacts

The past actions of limiting use to all users through trailhead quotas combined with limitations on commercial packers in 2001 that are being modified with this action will have an effect on the commercial pack station client's freedom of choice and the ability to attain a completely unconfined wilderness experience. The action greatly reduces the area of operation and prevents certain locations from exceeding desired conditions. The combined actions of grazing restrictions, limitation on trips and areas of use, controls on the number of stock, party size limitations, and limitations on stays in Silver Divide and Purple Lake will improve the natural conditions of the area by reducing use in areas of concern and preventing use from dispersing to new locations.

Grazing at Lee and Cecil was suspended in 2002 operating plans but travel to Lee and Cecil was allowed to continue. With this action, no use along this trail will help reduce impacts but these will remain severe until restorative work is done. With one substantial disturbance removed, the area will have the appearance of recovery and will likely look noticeably improved within a few years. Physical mitigation to headcuts and trail incision will be required to affect change on the hydrologic function in the riparian areas where the trail has had impact.

Cascade Valley has been closed to grazing for nearly twenty years. This closure combined with the restrictions to grazing in this alternative will greatly limit the grazing resources in this area. This may lead to more packing in of feed, to support trips and a possible increase in stock numbers as a result. Stock numbers that increase in one area would have to be reduced in other areas to be within overall seasonal stock limits.

The Mammoth Lakes basin is the source of considerable day use activity that has a cumulative effect on the permitted activities including backpackers and stock users. All these uses contribute to crowding and loss of solitude north of Duck Pass and at Duck and Pika Lakes.

The camping closure that was implemented at Purple Lake in the early 1980s had the effect of moving use from the outlet of Purple to Purple Lake. This has led to crowding and conflicts between pack stock and hikers camped in close proximity to each other. Actions proposed in this alternative will concentrate pack stock to identified campsites, and concentrate and contain the use of sites and trails by packers.

The northeastern portion Fish Creek drainage is identified as the Sierra National Forest administered by the Inyo National Forest. Funding the administration of this piece of land has been low priority for both Forests and at times has not received attention or management. This has probably contributed to impacts not being addressed or mitigated in a timely fashion.

Fish Creek/Convict/McGee – Alternative 3

Analysis

In this alternative, there would be a reduction in overlap from Alternative 1 in regards to spot and dunnage services. This would result from the limitation on trailhead access defined by the primary operating area guidelines that states that each trailhead quota will have identified operators based on pre-wilderness plan special use permit specifications. This will reduce overlap that has occurred since the wilderness plan as operators have trucked stock to trailheads not historically used. This type of overlap will be eliminated. Overlap that occurs because of traveling trips will not likely be reduced and may increase if operators choose to change to full-service type trips. The use pattern had shifted from full service to spot and dunnage over the last ten years. This resulted from among operational choices, from a trend towards maximizing service day limitations. With the replacement of service days to seasonal stock numbers, this could lead operators to shift towards full service trips. If traveling trips gain popularity because of this, there will be more overlap of operators, especially at locations along popular travel routes such as those from Mono Creek to Yosemite, or Mono Creek to Reds Meadow. Competition for campsites and grazing will provide some limitations to this potential trend.

At Coldwater/Duck, there would be no direct limitations on use or services to destinations north of Duck Pass (i.e., Woods Lake, Skeleton Lake). This is an area where very low stock use occurs except as a travel through to locations south of Duck Pass. This is not expected to change due to a higher demand for services beyond a short distance, but the potential is there. Destinations such as Woods Lake could be affected by increases in use. Currently it is relatively remote compared to the very high and intense use in the rest of the wilderness portion of lakes basin. Although the character of Woods Lake could change, it would be well within the standards and desired condition of a Recreation Category 3.

Purple Analysis Unit would be limited to 450 stock a year. This is a 25 percent reduction in stock numbers from past use (in 2001 over 600 commercial stock were recorded). This will respond to concerns documented of intense impacts at the primary destination associated with this trailhead, Purple Lake. At this location, a number of other actions will combine to reduce the impacts of current/historical stock use. Grazing limitations and the removal of the drift fence will reduce the loose grazing and consequently impacts associated with loose grazing. Designated sites will concentrate the impacts of stock holding. A limitation of no more than five nights a year when

not with clients at Purple will reduce grazing pressures. In addition, the prohibitions on use trails that have provided access between camps will further reduce the extensiveness of noticeable stock impacts. Essentially stock use will become concentrated at identifiable locations. The allowances for campfires by packers at designated sites with guides (wranglers) will likely lead to some non-compliance to the prohibition by the public. The area between Ram and Franklin and Virginia will be prohibited for use by packers. This is no change from Alternative 1. Virginia Lake will probably have the same levels of stock use as currently (Alternative 1).

Cascade Valley will continue to be an area with a high level of stock. With a destination quota of eight trips to Iva Bell Hot Springs impacts associated with facilitated use to this destination may be reduced. The probability of this area experiencing more use and use being facilitated into the future by commercial pack stock was high in Alternative 1. With known risk factors, not necessarily the result of pack stock use, but the result of overall high use concentrated at the hot springs, public use will continue to lead to crowding, low opportunities for solitude and noticeable resource impacts. Other destinations in this unit will receive the same levels of use and overlap will continue between operators based at Reds and Lakes Basin and those traveling through. There may be more use occurring in the east end of this unit, at Third Crossing and Cascade Valley itself. This may occur as a result of displacement from Silver Divide with the one night stay limit and competition for grazing resources. However, with grazing limits in place at all locations in this valley, there should be sustainable grazing managed over time. There may be frequent use of campsites and more encounters with stock parties than currently. This may have some minor adverse effects to wilderness character solitude, natural conditions).

Margaret lakes will have low to moderate commercial stock use, with a seasonal limit of 150 stock. Public use in this area is light, and is expected to remain so. Access to commercial pack stock will be limited to the main trail into Frog, Coyote, Bathtub, Margaret, and Rainbow. If pack stock were to frequent Rainbow Lake more than current use, there may be increased impacts along the trail corridor. Impacts on the trail corridor below Coyote to the junction of Baby Lake will continue. This is caused by grazing and by both commercial pack-stock use and the administrative use by the Forest Service. Noticeable impacts here are in contrast to an otherwise low use and low impact area and can have and continue to have experiential impacts to visitors under this alternative.

Silver Divide will continue to be a high overlap area for multiple operators. If traveling trips increase as a result of the elimination of service days this area could see more operators. There could be an increase in packing in feed to accommodate traveling trips in this area if grazing is the only or primary limitation. This may result in more stock on trails, which in turn could lead to increases in trail maintenance and heavy maintenance. Stock impacts to trails (increased dust with fine soils) have some experiential impacts to other visitors, especially hikers. This area will continue to see moderate hiker use outside the JMT trail corridor and very high use along the JMT corridor. Stock camps at Grassy, Jackson Olive, and Long Canyon will concentrate stock impacts at campsites, which may help improve overall conditions at these destinations. There may be an increase in use to Long Canyon to access grazing resources. This may change the character of this destination somewhat from the past number of years; however, use in this canyon has been higher in the past, especially in the days of sheep grazing. Use trails to Pick and Shovel Mine, Brave Lake, grazing access above Grassy, and the Goodale Pass by-pass will all be authorized for commercial pack stock use. This will continue access to most all places pack stock occurs in Alternative 1. Exceptions will be no authorizations to Peter Pande tarn and the Lake of

the Lone Indian Creek use trail. Only with some restorative work will these trails show improvement. Removing one source of impact will prevent further deterioration.

A party size limit will be implemented at one location in this alternative, a 10 person 15 stock limit to Peter Pande Lake. Stock numbers will remain low to moderate to this destination over time, with not more than four trips by commercial packers in a season. These actions will insure that campsites do not expand in size and continued trail deterioration will be minimized.

Upper Fish Creek will continue to receive moderate commercial stock use. Overlap in this area will be minimal, as it is in Alternative 1. Occasional overlap at Horse Heaven will continue but probably less than 10 nights a year will commercial packers be here, and rarely if ever at the same time. Tully Lake will have a party size limit (8 persons and 15 stock) and a limit on number of trips to the destination as well as a designated site for commercial stock use. These actions combined should insure that use does not exceed a Recreation Category 1 standard for use levels, solitude, and maintaining a high wilderness character. One access trail to Tully will also limit the impacts currently occurring with multiple poorly located trails. Access to Lee and Cecil will be prohibited in this alternative. This will help reduce the trailing impacts that have occurred in the recent past from grazing and the prohibition will include no access for spot and dunnage trips, which is a change from the No Action (Alternative 1). Red and White use trail will be available for use but may need to be monitored to insure that conditions in this recreation category do not change with this use.

McGee will maintain similar stock levels than occurring under the No Action alternative. There will be no overlap in operation in this area for spot and dunnage, a change from some occasional overlap that can occur in Alternative 1 (No Action). Some exiting of traveling trips could occur, but it is expected to be infrequent. Day ride use will be a noticeable use on the main trail on the first 4 miles from the trailhead. Some crowding and frequent encounters will be likely with the level of day rides approved in this alternative. Stock access to Steelhead Lake will continue to cause some deterioration of the trail until this trail is improved to support this use. This will continue to have some experiential affects on visitors who may expect more pristine conditions off the main trail. Eliminating commercial stock on the Baldwin Mine trail will help reduce further trail deterioration, and is consistent with the Recreation Category 1 designation.

Convict drainage, accessed via Laurel Lakes will see a reduction in use as a result of implementing this alternative. The trail will remain a single quota trail where commercial operators will need to compete with the public. In addition, there will be a limit of 80 stock per season to this area. Under the No Action, there has been as much as 100 stock per season since 2001 and over 200 stock per year prior to the implementation of the Wilderness Plan. In addition, there will be party size limits at Cloverleaf Lake that will allow the maximum persons but only eight stock. This will help maintain the trail condition and prevent further deterioration until improvements to this trail are made. There will also be a limit of four trips to Cloverleaf Lake a year, insuring that the conditions of a Recreation Category 1 are not exceeded. There will be no more than 18 trips into all other destinations in this drainage. If all 18 trips were taken, they would have to be with very small stock numbers and not exceed the 80 seasonal limits. This will mean that there will be either few trips a year with larger numbers of stock (relative) or more trips with less stock. In both cases (and both will surely happen given the demands of the year), there will be a limit on growth and services provided by pack stock into this drainage. This will help maintain a low Recreation Category 2 status to the area.

In this alternative, Geneveive, Dorothy and Edith lakes will be changed to a Recreation Category 2 from a 1. These areas show signs of heavy use in the past, and except for Cloverleaf, they were incorrectly categorized from the intention of the 2001 Wilderness Plan. However, the use levels established in this alternative will help keep it at a low Recreation Category 2, which is reasonable given past use and the capability (capacity and setting) of this area.

Cumulative Impacts

The past actions of sheep and cattle grazing have had effects on the resource conditions in this area. Current use, both grazing and recreation visitor use (commercial and non-commercial) contribute only slightly more affect than what occurred historically. It is likely that use and impacts, though still noticeable through out this area, have been greatly reduced over the year because of on-going management actions. Past actions include camping closing at Purple and Duck lakes outlets, removal of a boat rental facility and service at Duck Lake, and closing Cascade Valley, Second Crossing and Lee and Cecil to grazing. These actions in addition to those proposed in this alternative greatly limit the extent of commercial activities in this portion of the wilderness.

With a reduction in available grazing from current reported use, a reasonably foreseeable action may be that annual operating plan decisions are made to allocate grazing to individual operators prior to the season to insure that competition for grazing does not exceed standards. The effect of this would be further regulation and administrative monitoring requirements to insure that standards are not exceeded.

If Red and White use trail were to become more defined or resource impacts develop, a reasonably foreseeable action would be to discontinue this approval.

The Mammoth Lakes basin is the source of considerable day use activity that has a cumulative effect on the permitted activities including backpackers and stock users. All these uses contribute to crowding and loss of solitude north of Duck Pass and at Duck and Pika Lakes.

Fish Creek/Convict/McGee – Alternative 4

Analysis

Access via trailheads on the Inyo National Forest will remain similar to the No Action with the exception of reduced trailhead quota on Fish Creek for commercial pack stock. With the 20 percent reduction in service days, overall use will be reduced by 20 percent but not likely across the board at the locations. Without direct controls, some locations could receive more use than is currently occurring if use patterns shift or destinations become more desirable. The portals to this geographic region are few relative to the size of the region. Four trailheads, Fish Creek, Duck, McGee, access the Fish creek drainage from the north and east. Graveyard and Mono can access the area from the South. Use therefore can disperse out much more and the potential for less control at destinations in this region will be higher. The primary control for the extent of the commercial stock use is the trail suitability determinations and campsite designations.

The Margaret Trailhead directly accesses Margaret basin. Similarly, the Convict Trailhead directly accesses Convict basin. In these locations, there will be more direct influence of the trailhead control than in the other locations.

Thirty locations are identified for commercial pack stock services in this region. These locations are dispersed throughout the region and only the more remote locations off well-maintained system trails are unavailable to the commercial stock. High opportunities for solitude and high wilderness character will be protected in areas such as Tully Lake, Lee Cecil, Red and White Lake, Ram Lake, Cloverleaf, Rainbow Lake (Margaret area), and Peter Pande, that are available for commercial use in Alternatives 1, 2 and 3. Trails that access these destinations will likely show less sign of use and impact with the reduction of one major user group. Although use may not have been frequent at these locations, the potential for light, continued use that could lead to experiential and resource effects will be eliminated.

Destinations that are vulnerable to increased use and still available to commercial stock in this alternative include Pika Lake, Virginia Lake, Olive, Long Canyon, Lost Keyes. Increase use is not a given at these locations but without direct controls on the frequency or use by pack stock and only an external control that controls people, not stock there could be some changes in patterns. Lost Keyes, in a Recreation Category 1 would need to be closely monitored to insure that if use increased here that standards and guidelines for experiential and resource factors are maintained.

The thirty locations will probably see moderate to high levels of commercial stock use and opportunities for solitude will be low.

All-expense trips will likely be reduced with fewer grazing resources available and the effect of reducing service days may result in maximizing service day allocations with fewer all expense type trips and a shift to spot and dunnage type trips.

Cumulative Impacts

The past actions of sheep and cattle grazing have had effects on the resource conditions in this area. Current use, both grazing and recreation visitor use (commercial and non-commercial) contribute only slightly more affect than what occurred historically. It is expected that use and impacts, though still noticeable through out this area, have been greatly reduced over the year because of on-going management actions. Past actions include camping closing at Purple and Duck lakes outlets, removal of a boat rental facility and service at Duck Lake, and closing Cascade Valley, Second Crossing and Lee and Cecil to grazing. These actions in addition to those proposed in this alternative greatly limit the extent of commercial activities in this portion of the wilderness more so than any other Alternative other than Alternative 5.

The extent of commercial pack stock operations will be noticeable reduced and combined with past actions will contribute to loss of visitor experiences while at the same time having a beneficial effect on natural conditions by removing a disturbance source in many more areas of the wilderness.

With a reduction in available grazing from current reported use, a reasonably foreseeable action may be that annual operating plan decisions are made to allocate grazing to individual operators prior to the season to insure that competition for grazing does not exceed standards. The effect of this would be further regulation and administrative monitoring requirements to insure that standards are not exceeded. The cumulative effect to the resource would be beneficial and long-term.

The Mammoth Lakes basin is the source of considerable day use activity that has a cumulative effect on the permitted activities including backpackers and stock users. All these uses contribute to crowding and loss of solitude north of Duck Pass and at Duck and Pika Lakes.

The past action of designating a large portion of the Fish Creek drainage as a Recreation Category 1 (2001 Wilderness Plan) combined with the limitations on the geographic extent of commercial operations in this alternative, will both enhance and insure that wilderness character and high opportunities for solitude (two critical wilderness values) are protected. These two actions also greatly limit opportunities in this region for recreation by those who desire or need pack stock support. Clients of packers will have fewer opportunities for solitude and unconfined recreation with this alternative in the Fish Creek area which otherwise offers a vast resource of settings and attributes for the wilderness visitors. With commercial pack stock clients concentrated in areas where there is also heavy hiker use, these locations will require intensive management or else they will quickly show signs of degradation from heavy concentrated use. Locations that will be vulnerable to these cumulative impacts would be Purple Lake, Cascade Valley, and Duck Lake. Some visitors, those not dependent on pack stock, will likely receive disproportionate benefits of this alternative.

Fish Creek/Convict/McGee – Alternative 5

Analysis and Cumulative Impacts

This geographic unit currently has a very high level of commercial stock use. This is compounded by the fact that it is the area with the most overlap of packer operations. Up to 7 packers conduct some of their operation in the Silver Divide unit and 3 to 5 operators have recorded use in Upper Fish, Cascade Valley and Purple units. By eliminating all packer use there would be a noticeable change in the character of this area. Encounters with pack stock by visitors would be reduced to only a few private parties a year. Overall, use would be decreased by approximately 15 percent. Trail conditions would improve and the need to construct highly developed trails would be greatly reduced.

By eliminating the intensive packer use at Purple Lake, with up to 500 head of stock, the character of the area would change. Three very large packer camps with associated stock holding areas would no longer be needed. It is expected that at least one site, and possibly two, would be used as stock camps. The size would be reduced since private stock parties are smaller than commercial stock parties. The disturbance to soils and vegetation at these sites would be reduced over time. It is reasonable to expect that some restoration measures would take place over time by field staff that would help expedite some recovery at these sites. Deer Camp would possibly be removed or at least greatly contained due to its close proximity to water. The proliferation of use trails in this area, (used to access camps and grazing) would no longer be used and would eventually become naturalized. There would be no encounters with packers and stock by the hikers and private stock parties and no competition for campsites at Purple, which at times has been an issue since this is a popular stop over for through PCT/JMT hikers. A closure to camping at the outlet of the lake has had the effect of pushing the camping to around the lake, which has led to competition for sites as well as some crowding and a generally low level of solitude in this area.

Virginia Lake receives less packer use at the destination; however, it is possible to encounter traveling commercial pack stock parties on this trail. Campsites at Virginia would most likely not be restored or managed differently than today.

Cascade Valley has numerous destinations used by packers and has been a location where recreational grazing has occurred. Past actions have closed some meadows to grazing to allow for recovery. These closures would likely remain; however, there would be little need to continue them since commercial grazing would be eliminated and very little private stock use occurs. In lower Cascade Valley, at Fish Creek or Iva Belle Hot Springs, there are significant effects of high recreation use. Packers contribute somewhat by providing spot and dunnage services to the area. By eliminating the packer use, there will be little to no effect or improvements in this area and overall use will continue to high and highly congested. Opportunities for solitude are low at this location but high elsewhere in the unit. The intense camping impacts at the hot spring would continue, with highly compacted soils, vegetation loss, and a greatly modified environment with hot pools having been created to enhance the site for soaking.

Margaret Lakes receive very low use by both the public and packers. Less than 200 people a year visit the area, about 25 percent of which is packer use. By eliminating this use, the areas would have very high opportunities for solitude with the most improved solitude at Frog Lake, which is the popular destination for packers. Most of the rest of the Margaret Lakes basin receives very light packer use and the conditions, experientially and resources would not change with the No Action alternative.

Convict Analysis Unit receives its packer use via the Laurel Lake trailhead at the north end of the basin. The main trail up Convict Canyon has been closed to pack stock due to a bridge that was washed away by a flood, rebuilt once, washed away again, and never rebuilt. There are many day hikers in this area but few get beyond Mildred Lake. Packer use has been concentrated at Geneveive and Edith lakes and a lesser extent Dorothy and Cloverleaf lakes. Eliminating packer use would show improvements at campsites at Geneveive. Most other locations would not be improved unless some management actions were taken. This area not being a high profile area, may not receive future actions and any recovery would probably be slow over time hastened by the lack of continued disturbance. The trail to Cloverleaf Lake may improve over time as it receives light but continued pack stock use and has some unstable sections through riparian that show some degradation. Without pack stock on this trail annually, and with little chance that private pack stock would travel to this destination, the trail may improve. Opportunities for solitude would be improved slightly, but because this area receives light use to begin with, the effects would not be noticeable.

McGee Creek has moderate packer use, with up to 500 head of stock traveling through the canyon a summer. There would be a noticeable change from today with no encounters with stock. Stock travels and down the trail almost daily in August, when visitor use is at its peak. This packer use is over 20 percent of total overnight use in this area so the effect would be noticeable. The trails would not need to be built with as much structure and features to sustain the hiker use. Hiker use would remain the same or possibly increase slightly. Current quotas on the public allow for more hiker use than is currently occurring.

Upper Fish Creek is accessed primarily but not exclusively from McGee Pass. Packer destinations in this unit include Lee Creek, Tully Lake, and Horse Heaven. Both Lee Creek and Horse Heaven have established stock camps where overnight holding of stock and/or grazing

takes place. The impacts on the trail to Lee Lake, which may be substantially due to grazing access from the packer camp to the lake, will be greatly improved when pack stock is removed from the trail. A recent action that suspended the grazing activity showed a reported improvement in the condition of the trail within one year of removing this use. The site used at Horse Heaven would remain as a stock camp for private parties but the extensive drift fence would not be needed and would probably be removed. The site used a Tully Lake is only moderately impacted but is in a good location. The use trail that is used to access the site by packers would no longer be needed and could be restored.

Silver Divide, with the heaviest concentration of commercial pack stock use in the region, would show the most effects of eliminating packer use. The heavily impacted destinations, Grassy and Jackson, mostly impacted by grazing and large packer camps would gradually recover. With substantial restoration work, the sites could be contained. The holding area, which is not as compacted as the main camping area, may recover quicker but efforts would be needed to rehabilitate these sites. It is not expected this would be done for a number of years, if at all, so any recovery would be slow. Trails, especially the Minnow creek trail which by mid season can be extraordinarily dusty and with loose churned soils from pack-stock use would be more compacted with the absence of commercial stock. Generally, the areas of Silver Divide that receive the most non commercial use—the JMT/PCT—would show no change and the western part of the Silver Divide area would have higher opportunities for solitude and less noticeably impacted sites. Peter Panda trail, which is highly eroded and unstable, would likely be relocated and a less obtrusive trail would be needed than if pack stock use were to continue to access the area.

Mono Creek/Rock Creek – Alternative 1

Analysis

In this alternative, much of this geographic unit will see moderate commercial stock on the primary trails with very high, intensive commercial stock along the Upper Mono Creek Trail and Hilton lakes drainage. Stock numbers would be high overall in this region and could increase to over 2000 stock from an average of 1500 stock. This could happen if trailhead quotas filled more regularly and service day allocations were to be at Wilderness Plan levels. With the ratio that has occurred the past two years the stock numbers could swell to over 2000 a year in Hilton and the upper portion of Mono Creek. This could lead to moderate adverse effects and to opportunities for solitude in some locations such as Fourth Recess, Pioneer Basin, and Hilton lakes. Depending on timing of use, behavior of user groups there could be minor to moderate adverse effects to natural conditions if sites expand or impacts become more intensive.

Tamarack Basin, managed with a commercial quota of eight persons a day could see increased use if client demands or marketing shifts use. Various use trails are used by the commercial packers, which contribute to confusion with some trail impacts quite noticeable. Campsites could proliferate if use was to increase and, if stock holding were to become more common, stock camps could increase the overall impacts in the area. The commercial packer has indicated a desire to increase use in this area, including for overnight holding of stock to meet desires of clients to experience stock. An otherwise low use area could change in character from current use patterns if this shift were to occur.

Little Lakes Valley allows for a commercial quota of 10 persons a day. The current packer use is very low, with up to 10 trips a year and 60 people. This could shift to a much higher number; up to 600 people (commercial) could easily be allowed through the quota. This would take place with a shift away from another area such as Hilton or Mono Pass, or a shift away from traveling trips by the operator at Rock Creek that currently does a substantial number of traveling and all-expense trips, which utilized more service days. A shift away from traveling trips to spot and dunnage could allow the operator to utilize areas such as Tamarack and Little Lakes Valley, which currently does not get the commercial stock use. Crowding and congestion would become even more severe in Little Lakes Valley if this was to occur.

Morgan Lakes utilizes the Little Lakes Valley trailhead quota but currently gets no more than one to 2 trips a year. There are a number of stock camps that look as if they have not been used in years, and many impacts remain from the mining era (stumps, debris, and wide trails). Use could shift here with only controls at the trailhead, but increased use could probably occur without additional impacts to the area.

Hilton Lakes will continue to receive very high stock use. Trailing of stock in and out of the drainage for daily trail rides by guests at base camps will probably continue and will accelerate deterioration of the trail resources and make the impacts of stock use quite noticeable. This will continue if stock camps are not defined. Use between stock camps occurs as the result of large parties that are broken into smaller parties to comply with the party size regulation yet still group together during these periods. This practice is expected to continue. The traffic and at times intensive activity caused by the type of commercial stock activity that occurs here (multiple large parties, day riding from the base camps with riding stock coming in and out daily) can contribute to a diminished wilderness experience for those seeking solitude. Access to the upper basin would continue and conditions at Third and Fourth lakes would remain moderately impacted at campsites and noticeably deteriorated trail conditions. Multiple operators would continue in this area, with the dominant use by one operator.

The Mono Creek corridor, west of Mono Pass will be a high commercial stock use area. Multiple large stock camps will continue to get frequent use and impacts will continue to be moderate to severe at the stock camps; the sites will expand over time. There will probably continue to be confusion to the public traveling in this vicinity. A cause of this confusion is access to the stock camps, which often look like the primary trail and when followed takes a visitor into a stock camp, and considerable multiple trails and short cuts. Without any improvements to the primary trail, short cutting will continue and the trails will continue to deteriorate and cause experiential impacts to all visitors. The loose grazing that occurs throughout the Mono Creek corridor will have experiential effects on other visitors that may not enjoy the stock through camps and the noise from bells around their necks that often occur near the camps.

Golden Lake is available for packers to access. The trail shows severe impacts that will persist with continued use of any type. Golden has not been a recorded destination of packers. Identified as a trail class two, it currently does not meet standards of that trail class and would take considerable development to bring it up to standard, which could facilitate more use than currently is occurring. The destination has limited opportunities for camping out of sight, sound of others camped, and increased use could lead to diminished opportunities for solitude.

Pioneer Basin will have similar effects as Mono Creek. As an interior destination, the Mono Pass trailhead does not directly control the use. Use also comes into this area from the west, primarily

the lower Mono trailhead. Severe multiple trailing and severe use trail impacts may not be contained by allowing the use to continue. Large stock camps will likely continue to expand in total area over time. The use trails to the upper basin and lakes (10,900 are currently approved for use) will likely continue to cause impacts. All identified packer-use trails are available. If these trails were to get more use, widespread impacts could be evident throughout the basin. With no direction to contain the use trail or campsite impacts these impacts will continue and proliferate.

Hopkins is an interior destination used for both overnight stay on traveling trips as well as destination trips. Use could increase here in this alternative with no direct controls. The stock camp at Lower Hopkins Lake will likely expand and other sites could receive commercial use in the future if the primary site becomes too impacted.

Commercial stock use into both Laurel and Second Recess has been non-existent the past few years from lack of trail maintenance and the difficulty that created for stock users to travel on these trails. If these trails were to receive the maintenance that is prescribed, commercial stock use could easily be re-established in these drainages. Use could disperse from other concentrated areas such as Pioneer Basin and Hopkins and be distributed more evenly. This would reduce some of the potential experiential impacts of concentrated stock use. It may also require increased maintenance and management of more sites and trails. By dispersing impacts over a wider area, there would be a wider extent of less severe impacts.

Commercial pack stock use in the Silver Peak unit will be pass-through use for traveling trips and spot and dunnage use to Mott Lake. Stock could camp at multiple locations, Pocket Meadow, Silver Pass Meadow, or Silver Pass Lake Meadow. Loose grazing of stock in this area will continue with effects to visitor experiences. Use to Mott Lake from commercial pack support would be regulated by the Mono Creek trailhead single quota, which accesses multiple destinations and is not a direct control; the effect would be at least the possibility of increased use to Mott Lake if the trail were to be maintained at the prescribed level. Opportunities for solitude will be low throughout the summer along the trail and low to moderate at Mott Lake with limited camping opportunities out of sight and sound of each other.

There will be a high concentration of use at Lower Graveyard Lake with low opportunities for solitude and a high level of commercial stock use and stock support. Use could be authorized into the upper basin and with that, the trail could deteriorate even further. Few good sites exist and those that do would likely increase in size and impact with continued use. Use to Arrowhead and Feather lakes is controlled by the same trailhead as to Graveyard lakes. This allows for continued use and potential increased use to these destinations in the future. Arrowhead can sustain more use but even a light increase to Feather Lake would change the character of the area with the lake having few durable sites for camping, particular with pack stock or pack stock supported.

Bear Ridge would remain a pass-through area with very little chance of any harmful effects even if use were to increase.

Volcanic Knob could receive considerable more use with only the indirect control of the trailhead quotas. Traveling trips could frequent the destination more as grazing resources are available and it is convenient location for an overnight stop. This could have short-term adverse effects to opportunities for solitude and be in conflict with the status as a Recreation Category 1 area.

Cumulative Impacts

Past actions in Pioneer Basin to close to pack stock grazing has allowed for some recovery of the meadows and with actions of this alternative, continued recreation by hikers and stock (private and commercial) there will be only inadvertent impacts to these same meadows by other use (fishing, camping, hiking). Recovery will continue and these actions will not cause any additional adverse effects to natural conditions as they are recovering.

There is a high density of use trails in Pioneer Basin from years of recreational use. This is probably the result of both the lack of past action to maintain the system trail as well as a continued popularity of the basin by the public and commercial pack stock. The high density of use trails, and some associated damage including multiple incised trails, will continue under current allowances.

Mono Creek, Hopkins, Second Recess, and Third Recess all show signs of lack of trail maintenance in the past ten to twenty years. Commercial pack stock use contributes to the condition in these areas, but public use and lack of management has played a big contribution as well. The cumulative effect of this is some severe trail erosion, very rough and dusty trails all of which combine to have an affect on visitor's experience. It is expected that this will continue under current management until adequate trail work is undertaken. There is short-term minor to moderate adverse effects to a visitor's experience with the noticeable impacts to trails throughout the area.

Little Lakes Valley receives a high volume of day use. With developed campgrounds adjacent to the wilderness boundary and resort facilities along the access road to this wilderness boundary, the area draws hundreds of visitors a day into Little Lakes Valley during the summer months. No regulation of day use is in place, yet the relatively small level of backpacking and pack stock use is regulated. Access to classic mountaineering routes (Bear Creek Spire) also draws a type of user into the area, and many of these routes experience low-level impacts on the climbing and access routes and some crowding.

Hilton Lakes was the location of multiple structures and facilities that were removed after the 1964 Wilderness Act was passed to comply with wilderness standards. Impacts from an earlier period of heavy use are not very evident but some impacts such as highly compacted areas and a log jam at the outlet of Davis Lake from debris from old structures demolished by the U.S. Forest Service remain on the landscape. The area has significantly improved wilderness character from the time it was designated wilderness. Continued use by pack stock will continue under this alternative and although intense, is arguably less affecting than conditions that pre-existed the Wilderness Act.

Mono Creek/Rock Creek – Alternative 2 – Modified

Analysis

Commercial stock use would be concentrated in approximately 22 discrete areas of the potentially hundreds of destinations in this geographic unit. There is a significant reduction in the extent of commercial pack stock operations in this geographic unit. The result of this is to concentrate stock use impacts and prevent the expansion of impacts into new areas in the unit. There would be moderate commercial stock use at these destinations. The use prescribed at each

destination is consistent with the recreation category and the capacity and setting of the destinations.

Of the 22 areas where spot and dunnage trips occur, five of these would have two overlapping spot and dunnage operations and in two areas, there would be three overlapping spot and dunnage operations. The primary area of overlap from all-expense trips would be in Mono Creek, with occasional overlap in other areas. The effect of this would be some potential for higher encounters with stock and diminished experiential qualities for those that do not care to encounter stock. The area is also used intensively for all expense and traveling trips, which will contribute to encounters. These types of trips are reduced from current levels in this alternative so there would likely be a reduction from current levels in encounters with stock parties in the Mono Creek corridor.

The proposed action will allow some growth to the Tamarack area. This area is currently low use with a high percentage of that use by the commercial packer. This is not expected to change with the allowances for growth. There are a number of suitable camp locations for moderate to large groups. The sites are well screened to protect opportunities for solitude. Some day use occurs but it is likely that wilderness character (solitude and natural conditions) will remain high in this basin due to the low levels of use.

Little Lakes Valley is a high use area with a relatively low level of commercial stock use. This alternative will allow for some growth to Ruby, Long, and Chickenfoot Lakes. Use to Gem Lake will not be authorized because it is a destination where camping is limited and impacts from heavy use by day hikers and backpackers are noticeable. Campsites for spot and dunnage drop sites would be established at these locations to mitigate the impacts of trailing to camps and to prevent a proliferation of campsites and trails used by the packers. There would be long-term beneficial effects of eliminating commercial stock use to Gem Lakes; however public use, including high levels of day use, will continue.

Morgan Lakes would remain low use and little effects of pack stock use would be noticeable. Day rides are authorized on the Morgan Lakes Trail but do not occur very often. This additional use would not cause any change in character to this area.

Commercial pack stock use in the Hilton Lakes area would be reduced slightly, and the Recreation category assignment would change from a Recreation Category 2 to a Recreation Category 3. The effect of this would be that the uses would be managed more intensively and consistent with Recreation Category 3. There may be more signing and concentration of use and impact. There would still be three operators in the area, but most of the use occurs with one operator. Use to the upper basin would be reduced by up to 70 percent. Maintaining lower levels of use in the upper basin will prevent further degradation that might otherwise occur if use (and subsequent impact) is allowed to increase to destinations under a trailhead quota scheme.

The designation of stock camps, and limiting travel to use-trails that access campsites, would likely represent an improvement in the Hilton Lakes area by reducing trailing and campsite impacts. The trailing of stock between campsites on use trails would be prohibited. The lower basin (Davis and Second lakes) would remain low to moderate in wilderness character. Opportunities for solitude and high wilderness character would be insured above Third Lake.

The number of all-expense trips that pass-through from Mono Creek north from Mono Pass is reduced to 16 trips a year. This will greatly reduce conflicts between hiking and stock parties and

improve the experiential conditions for backpackers. It will limit opportunities for recreational experiences with commercial pack trips. This effect will be long-term and adverse to the commercial client.

The Mono Corridor in the Fourth Recess Analysis Unit will have designated camp sites for all-expense trips in established, existing sites. With the design of these sites, including the establishment of appropriate access, there will be a reduction in confusion that currently exists between system trails and trails accessing stock camps. Identifying one route will greatly reduce trail impacts and improve the experiential conditions in the canyon. These sites will also be contained to prevent further expansion. Establishing and designing the site will improve the overall condition of these sites. There will be long-term beneficial effects to natural conditions from containing the impacts. The extent of impacts will be reduced in these areas in the long-term.

Also in the Fourth Recess Analysis Unit, there will be an improvement in Third Recess Canyon through the elimination of pack stock into this basin. The trail condition will not improve without some level of trail maintenance, reconstruction, and restoration. However, by eliminating the commercial pack stock, further deterioration of the trail may be limited. Clients of pack station will still be able to travel by foot to Third Recess. Opportunities for solitude may be improved in this area. Over time, and with mitigation, natural conditions will improve along the trail corridor.

The general conditions in Pioneer Basin will be improved through containment of pack stock operations to a limited number of trails and campsites. Many miles of use trails were identified by the operators in this basin. In this action, there will be only one trail maintained to the upper basin and one trail to the second lake. All use trails and short cuts will be prohibited from use. The overall reduction in the number of use trails will have a positive effect on the character (natural conditions and solitude opportunities) of the area. Two established stock camps at Mudd Lake will improve the overall condition by containing stock related impacts in the suitable areas near Mudd Lake. Non-pack stock visitors will likely have more opportunities to select sites that are not used or impacted by pack stock.

Use into Hopkins drainage will be limited to eight trips a year. This allows for a slight increase from a high of six trips in 2001. Use will be limited to lower Hopkins Lake with prohibited access on the use trail that loops to the upper basin. With this prohibition, the trail may improve but private stock will continue to use this trail. Opportunities for solitude will remain the same in this area and are generally considered moderate to high. Camping is concentrated at the lake, which has limited capacity. One stock camp will be identified to help mitigate a conflict at this location. Opportunities for solitude will be low when stock parties are present here. The overall reduction in traveling trips between Mono Pass and Mammoth will likely translate to a reduction in the number of trips to this location, thereby maintaining and or slightly improving the opportunities for solitude at lower Hopkins Lake.

Very light and limited use will occur in the Laurel and Second Recess Analysis Units. Most of the use in Second Recess unit will occur in the Mono Corridor on a primary trail. Slight increases (from 7 to 10 trips) are being proposed which will not greatly change the character of this area. Laurel will remain lightly used only if all-expense trips are managed to avoid significant increases in use. Stock is prohibited above the stock camp below Laurel Lake. This will insure that opportunities for solitude remain high at Laurel and Grinnell Lakes. With the absence of stock impacts in these locations, the character of this area will also be high.

Use in the Silver Peak Analysis Unit will be reduced by the overall reduction in traveling trips from Mono Pass north. The use in the analysis unit is on the PCT/JMT trail with associated grazing. In addition, trips to Mott Lake will be limited to the existing number allowing no growth in use to Mott Lake. Mott Lake is a popular destination with limited camping and in August can have low opportunities for solitude. This proposal will maintain these conditions. By establishing a stock camp at Mott Lake it may encourage overnight holding of stock in an area that currently only receives spot and dunnage use. This may change the character of the destination slightly. It is not expected that it would receive much of this type of use.

Use into Graveyard Analysis Unit would be limited to 50 spot and dunnage trips a year. The current high is 55 trips in the past three years. The trail to Arrowhead and Feather Lake is hard to follow and shows no signs of current use. Use at both lakes is low and opportunities for solitude are high. A recreation category change at Feather Lake (from a Recreation Category 2 to a Recreation Category 1) along with specific limitations of trips to Feather Lake will insure that the pristine qualities of this low capacity destination are not impacted by commercial pack stock use over time.

Use at Graveyard Lake would remain near current levels. Conditions would not change and would be maintained with this action. Use would however be limited to the lower lakes and opportunities for solitude at the upper lakes would be improved by the limits on packer use.

Services in the Devils Analysis Unit would be allowed to increase to up to eight trips a year from the four that are currently occurring. The primary destination here is Devils Bathtub Lake. This is also an easily accessible and popular day use area for both hikers and stock.

Bear Ridge would remain primarily a pass-through area to access the JMT/PCT from Lake Edison. Use will not likely increase and stock numbers on this trail will stay the same as the past few years. Public use on this trail is very light with less than 30 parties a year. Pack station use will stay at similar levels, up to 35 parties taken in a year via Bear Ridge. Total use in this area will remain light and effects from commercial pack stock use will be minimal.

Volcanic Analysis Unit will remain very low use for packers, and most of the use will be to support the State of California Department of Water Resources to supply the snow survey cabin and site in Volcanic meadow.

Cumulative Impacts

In the Hilton Creek drainage, past actions including the removal of structures, reduced maintenance of the trail to the upper basin, limitations on the packers such as prohibiting camping on the peninsula, agreements between the Forest Service and the packer to not hold stock overnight in the drainage, have all led to fewer opportunities for commercial pack stock. Overall impacts have been reduced by many of these past actions. When the additional actions of this alternative are in place, there will be a cumulative effect of greatly reducing the extent of human influences in the drainage. This will have beneficial effects to some visitors experience and natural conditions by reducing the overall extent of impact. It will also have adverse effects to those visitors that are prohibited or limited in their use and enjoyment (unconfined recreation) of the area via the commercial pack stock services.

A similar effect occurs in Pioneer Basin. Actions in the past have closed the area to grazing. Lack of maintenance of the system trail has led to the creation of multiple user trails to access various portions of the basin. This action alternative will greatly reduce to the areas where

commercial pack stock services can occur and the extent of commercial stock impacts. By prohibiting the use of most of the use trails, and all of the use trails where noted resource concerns existed, many of these trails will show signs of recovery. Identifying two system trails should facilitate a reduction in use trails. There is substantial work needed to bring the trails to standard, when that work is completed, there should be a noticeable improvement to the character of the basin.

Deferred trail maintenance in Mono Creek, Hopkins Creek, and Second Recess Canyon has similar cumulative impacts as described in Alternative 1. Continued commercial pack stock use contributes to the condition in these areas, but public use and lack of management has proved to be a big contribution as well. The cumulative effect of this is some severe trail erosion and very rough and dusty trails, all of which combine to have an affect on visitor's experience. It is likely that this will continue under Alternative 2 - Modified until adequate trail work is undertaken. With the noticeable impacts to trails throughout the area, there is short-term minor to moderate adverse effects to a visitor's experience. There will be localized moderate to sever effects to natural conditions along these trail corridors until trail work improves the conditions.

It is expected that over time trails in the Mono Geographic Area, specifically on the Sierra National Forest, will be improved. Improvements to the trail system will greatly reduce the visual and experiential impairment noticeable throughout the Mono Creek corridor. In particular, trail conditions to Mott Lake, Mono Creek trail, Pioneer Basin, Second Recess Canyon, and Third Recess Canyon all would be improved with future trail projects. These projects could change the character of places like Third and Second Recess if they are built to facilitate visitor use.

Little Lakes Valley receives a high volume of day use. Hikers, anglers, climbers, and sightseers combine to create crowding and adverse effects to solitude. With developed campgrounds adjacent to the wilderness boundary and resort facilities along the access road to this wilderness boundary, the area draws hundreds of visitors a day into Little Lakes Valley during the summer months. No regulation of day use is in place, yet the relatively small level of backpacking and pack stock use is regulated. Activities outside the wilderness boundary have a cumulative effect on solitude and natural conditions as the intensive use causes trailing and multiple trailing impacts and impacted sites along the trail corridor. Gem Lake receives a high volume of use and the trail along the lakeshore shows signs of disturbance to natural conditions. Pack stock use added to this will have cumulative effects to natural and experiential conditions in this area.

It is not expected that private stock use would increase or that this use would have any effect on the areas where commercial use is being prohibited in this alternative. Private stock use is very light and stock numbers are low in comparison to the commercial stock numbers.

Overlapping operators will still exist in Lower Mono, Graveyard, Bear Ridge, and Hilton Analysis Units. Limits to overlap will be made in this alternative with the reduction in traveling trips over Mono Pass to the north. The cumulative effect of this would be campsites receiving less frequent use, reduced need for grazing and a reduction in grazing, and overall less stock use on the Mono corridor trail.

Over time, the combination of actions in this alternative should lead to some noticeable improvements in the Mono Creek area. Reductions in use at locations where risks and concerns have been recorded, containment and design appropriate stock camps, prohibiting use of some impacted use trails, and limits on expansion of packing operations into new areas should be

substantially improve wilderness character through out the Mono region. Limiting commercial pack stock out of many of the higher reaches of drainages (Laurel, Second Recess, Pioneer Basin, and Graveyard) will protect wilderness qualities.

Mono Creek/Rock Creek – Alternative 2

Analysis

Overall, there would be a potential increase of about 26 spot and dunnage trips to 27 destinations with this alternative. As with all other locations, it is not likely that pack station would reach the destination quotas on an annual basis but the quota allows for fluctuations of client demands. If the entire quota was used it would likely be used with the same level of stock that has currently serviced less trips.

Of the 27 areas where spot and dunnage trips occur, five of these would have two overlapping spot and dunnage operations and in two areas, there would be three overlapping spot and dunnage operations. The primary area of overlap from all-expense trips would be in Mono Creek, with occasional overlap in other areas.

The proposed action will allow some growth to the Tamarack area. This area is currently low use with a high percentage of use by the commercial packer. This is not expected to change with the allowances for growth. There a number of suitable camp locations for moderate-to-large groups. The sites are well screened to protect opportunities for solitude. Some day use occurs but it is likely that wilderness character (solitude and natural conditions) will remain high in this basin due to the low levels of use.

Little Lakes Valley is a high use area with a relatively low level of commercial stock use. This proposal will allow for some growth to Ruby, Long and Chickenfoot lakes but limit use to Gem Lakes, a destination where camping is limited and impacts from heavy use by day hikers and backpackers are noticeable. Campsites for spot and dunnage drop sites would be established at these locations to mitigate the impacts of trailing to camps and prevent a proliferation of campsites and trails used by the packers. A party size limit at Gem would insure that large parties would not be dropped here which could expand the size of campsites.

Morgan Lakes would remain low use and little effects of pack stock use would be noticeable. Day rides are authorized on the Morgan Lake trail, which currently does not occur. This additional use would not cause any change in character to this area.

Commercial pack stock use in the Hilton Lakes area would be reduced measurably. There would still be three operators in the area, but most of the use occurs with one operator. The limit on the number of trips reduces the packer use by about 15 percent to Davis and Second Lake. Use to the upper basin would be reduced by up to 70 percent. If the trail to the upper lakes is improved, use could increase up to 12 trips, which would be 30 percent reduction from current use. With the designation of stock camps and limiting travel to use trails that access campsites there would be an improvement in the area and a reduction in trailing and reduction in campsite impacts. The trailing of stock between campsites on use trails would be prohibited. Overall reduction of numbers of stock used in conjunction with the packer operation would be measured to insure an overall reduction. The lower basin (Davis and Second lakes) would remain low to moderate in wilderness character but opportunities for solitude and high wilderness character would be insured above Third Lake.

The number of all-expense trips that pass-through from Mono creek north from Mono Pass is reduced from 35 trips to 16 trips a year. With fewer all-expense trips there will be less loose grazing throughout the Mono corridor, which currently is the source of complaints by backpackers. This will greatly reduce conflicts between hiking and stock parties and improve the experiential conditions for backpackers.

The Mono Corridor in Fourth Recess analysis unit will have designated sites for the all-expense trips in established campsites. With the design of these sites that will establish access in an appropriate location there will be a reduction in confusion that currently exists between system trails and trails accessing stock camps. Identifying one route will greatly reduce trail impacts and improve the experiential conditions in the canyon. These sites will also be contained to prevent further expansion. Establishing and designing the site will improve the overall condition of these sites.

Also in the Fourth Recess Analysis Unit, there will be an improvement in Third Recess through the elimination of pack stock into this basin. The trail condition will not improve without some level of trail maintenance, reconstruction, and restoration. However, by eliminating the commercial pack stock, further deterioration of the trail may be limited. Clients of pack station will still be able to travel by foot to Third Recess. Opportunities for solitude may be improved into this area and over time and with mitigation, natural conditions will improve along the trail corridor.

The general conditions in Pioneer Basin will be improved through containment of pack stock operations to a limited number of trails and campsites. Many miles of use trails were identified by the operators in this basin. In this action, there will be only one trail maintained to the upper basin and one trail to the second lake and all use trails and short cuts will be prohibited from use. The overall reduction in the number of use trails will have a positive effect on the character (natural conditions and solitude opportunities) of the area. Two established stock camps at Mudd Lake would improve the overall condition by containing stock related impacts in the camp-able areas of Mudd Lake. Non-pack stock visitors will have more opportunities to select sites that are not used or impacted by pack stock.

Use into Hopkins drainage will be limited to eight trips a year. This allows for a slight increase from a high of six trips in 2001. Use will be limited to lower Hopkins Lake with prohibited access on the use trail that loops to the upper basin. With this prohibition, the trail may improve but private stock will continue to use this trail. Opportunities for solitude will likely remain the same in this area and are generally considered moderate to high. Camping is concentrated at the lake, which has limited capacity, but one stock camp will be identified to help mitigate a conflict at this location. Opportunities for solitude will be low when stock parties are present here, but overall reduction in traveling trips between Mono Pass and Mammoth will translate to a reduction in the number of trips to this location, thereby maintaining and or slightly improving the opportunities for solitude at lower Hopkins.

Very light and limited use will occur in Laurel and Second Recess Analysis Units. Most of the use in Second Recess unit will occur in the Mono Corridor on a primary trail. Slight increases (from 7 to 10 trips) are being proposed which will not greatly change the character of this area. Laurel will remain lightly used only if all-expense trips are managed to avoid significant increases in use. Stock is prohibited above the stock camp below Laurel Lake and this will insure

that opportunities for solitude remain high at Laurel and Grinnell lakes. With the absence of stock impacts in these locations, the character of this area will also be high.

Use in the Silver Peak Analysis Unit will be reduced by the overall reduction in traveling trips from Mono Pass north. The use in the analysis unit is on the PCT/JMT trail with associated grazing. In addition, trips to Mott Lake will be limited to the existing number allowing no growth in business to Mott. Mott Lake is a popular destination with limited camping and in August can have low opportunities for solitude. This proposal will maintain these conditions. By establishing a stock camp at Mott Lake it may encourage overnight holding of stock in an area that currently only receives spot and dunnage use. This may change the character of the destination slightly. It is not expected that it would receive much of this type of use.

Use into Graveyard Analysis Unit would be limited to 56 spot and dunnage trips a year. The current high is 55 trips in the past three years. The trail to Feather is hard to follow and shows no signs of current use. Use at both lakes is low and opportunities for solitude are high. Use into Feather Lake may increase and this could change the character of the destination that receives only occasional use. There is a potential for new impacts and loss of solitude if use were to increase and this would have some minor to moderate adverse effects to wilderness character. With an allowance for up to ten trips to Feather/Arrowhead Lake, it is possible that all ten trips could go to Feather Lake.

Use at Graveyard would remain at current levels. This is a very popular destination and opportunities for solitude are low as the capacity for camping is limited. Conditions would not change and would be maintained with this action. Use would however be limited to the lower lakes and opportunities for solitude at the upper lakes would be improved by the limits on packer use.

Devils Analysis Unit would be allowed to increase to up to eight trips a year from four that are currently occurring. The primary destination here is Devil Bathtub Lake. This is also an easily accessible and popular day use area for both hikers and stock. Opportunities for solitude are low in this area.

Bear Ridge would remain primarily a pass-through area to access the JMT/PCT from Lake Edison. Use will not increase and stock numbers on this trail will stay the same as the past few years. Public use on this trail is very light with less than 30 parties a year. Pack station use will stay at similar levels, up to 35 parties taken in a year via Bear Ridge. Total use in this area will remain light.

Volcanic Analysis Unit will remain very low use for packers, and most of the use will be to support the State of California Department of Water Resources to supply the snow survey cabin and site in Volcanic meadow.

It is expected that over time, trails in the Mono Creek/Rock Creek Geographic Area, specifically on the Sierra National Forest will be improved. Improvements to the trail system will greatly reduce the visual and experiential impairment noticeable throughout the Mono Corridor. In particular, Mott Lake, Mono Creek trail, Pioneer Basin, Second Recess, and Third Recess all would be improved with trail improvement projects. These projects could change the character of places like Third and Second Recess if they are built to facilitate use and access.

Overlapping operators will still exist in lower Mono, Graveyard, Bear Ridge, and Hilton. Limits to overlap will be made in this alternative with the reduction in traveling trips over Mono Pass to

the north. The cumulative effect of this would be campsites receiving less frequent use, reduced need for grazing and a reduction in grazing, and overall less stock on the Mono corridor trail.

Over time, the combination of actions in this alternative should lead to some noticeable improvements in the Mono Creek area. With reduction in use at locations where risks and concerns have been recorded, containing and designing appropriate stock camps, prohibiting use of some impacted use trails, and limits on expansion of the packing operations into new areas, there should be substantial improvements to wilderness character through out the Mono region. Limiting commercial pack stock out of many of the high reaches of drainages (Laurel, Second Recess, Pioneer Basin, and Graveyard) will protect wilderness qualities and insure that pack stock impacts are minimal and would only occur with private stock use.

Cumulative Impacts

In Hilton drainage, past actions including the removal of structures, reduced maintenance of trail to the upper basin, limitations on the packers such as prohibiting camping on the peninsula, agreements between the Forest Service and the packer to not hold stock overnight in the drainage, have all led to fewer opportunities for commercial pack stock. Overall impacts have been reduced by many of these past actions. When the additional actions of this alternative are in place, there will be a cumulative effect of greatly reducing the extent of influence of commercial pack stock in the drainage. This will have beneficial effects to some visitors experience and natural conditions by reducing the overall extent of impact. It will also have adverse effects to those visitors that are prohibited or limited in their use and enjoyment (unconfined recreation) of the area via the commercial pack stock operator.

A similar effect occurs in Pioneer Basin. Actions in the past have closed the area to grazing. Lack of maintenance of the system trail has led to the creation of multiple user trails to access various portions of the basin. This action will greatly reduce to the areas where commercial pack stock can occur and the extent of commercial stock impacts. By prohibiting the use of most of the use trails, and all of the use trails where noted resource concerns existed, many of these trails will show signs of recovery. Identifying two system trails should accomplish a reduction in use trails. There is substantial work needed to bring the trails to standard, when that is work is completed there should be a noticeable improvement to the character of the basin.

Deferred trail maintenance in Mono Creek, Hopkins, Second Recess, has similar cumulative impacts as described in Alternative 1. Continued commercial pack stock use contributes to the condition in these areas, but public use and lack of management has played a big contribution as well. The cumulative effect of this is some severe trail erosion, very rough and dusty trails all of which combine to have an affect on visitor's experience. It is expected that this will continue under alternative until adequate trail work is undertaken. With the noticeable impacts to trails throughout the area, there are short-term minor to moderate adverse effects to a visitor's experience. There will be localized moderate to sever effects to natural conditions along these trail corridors until trail work improves the conditions.

Little Lakes Valley receives a high volume of day use, hikers, anglers, climbers and sightseeing combine to create crowding and the adverse effects to solitude. With developed campgrounds adjacent to the wilderness boundary and resort facilities along the access road to this wilderness boundary, the area draws hundreds of visitors a day into Little Lakes Valley during the summer months. No regulation of day use is in place, yet the relatively small level of backpacking and

pack stock use is regulated. These activities outside the wilderness boundary have a cumulative effect on solitude and natural conditions as the intensive use causes trailing and multiple trailing impacts and impacted sites along the trail corridor. Gem Lake receives a high volume of use and the trail corridor lakeshore shows signs of disturbance to natural conditions. Pack stock use on top of this will have cumulative effects to natural and experiential conditions in this area.

It is not likely that private stock use would increase or that this use would have any effect on the areas where commercial use is being prohibited in this alternative, as this use is very light and stock numbers are low in comparison to the commercial stock numbers.

Mono Creek/Rock Creek – Alternative 3

Analysis

Devils Analysis Unit will continue to see moderate levels of stock use, light spot, and dunnage served by the Devils/Graveyard quota and day rides. Two operators will continue to provide spot and dunnage services to this basin. One operator will provide day rides, amounting to less than 200-day rides a year.

Graveyard unit will also see the continuation of two operators providing primarily spot and dunnage services at higher levels than the past few years. A recreation category change would be implemented from a Recreation Category 1 to a Recreation Category 2 at Lower Graveyard Lake. This area has been a popular destination for many years and was an error in mapping with the 2001 Wilderness Plan. This is a popular destination for commercial stock and the public. Opportunities for solitude will remain low to moderate at the lower lake. Commercial use will be prohibited above the third lake where the system trail will end in this alternative. The upper basin would have opportunities for higher levels of solitude with this alternative than currently exists in the No Action (Alternative 1), as restrictions on use are not in place.

Also in this analysis unit, access to Feather and Arrowhead lakes will be authorized. With no direct controls at these destinations, there is the potential for there to be some change to the pristine qualities at Feather and wilderness character that currently offers high levels of solitude and mostly pristine conditions, which could be compromised if use patterns shift. If use were to increase the trail, condition may also deteriorate. It will be incumbent upon the packers operating here to insure that these conditions at Feather do not exceed the standards for a Recreation Category 1. With limitations discussed above in the Silver Divide section, there could also be an increase in traveling trips to Silver Divide country over Goodale Pass.

Bear Ridge Analysis Unit will continue to be a travel thru area for two operators. Multiple trails access through this unit to the JMT/PCT corridor. Collectively these trails will allow 230 stock numbers, which is the seasonal stock threshold to the JMT/PCT. This is slight increase over Alternative 1 (No Action). The change from single quota to multiple quotas for Bear Creek and Bear Ridge Trailheads could potentially increase the overall use.

Volcanic Analysis Unit is subject to a recreation category change from a RC1 to a RC2. Currently there is a cabin and a snow survey site with structures in place to relay snow sensor data for Department of Water Resources. These have been in place for over 15 years and make it difficult to manage under the definition of a RC1. It is likely there was a mapping error or lack of information on this condition at the time of the 2001 Wilderness Plan. It is possible that use will shift to Volcanic Lake without any direct controls, but it will remain visited by commercial

operators during the late season (September) to allow hunting access and to support the DWR site.

Silver Peak will remain an area of moderate commercial stock use along the JMT/PCT corridor for traveling trips along the JMT/PCT and to Mott Lake. Due to the low capacity for campsites that are not within sight and sound of each other, Mott Lake will continue to have low to moderate opportunities for solitude. Opportunities for solitude will also continue to be low along the trail corridor and encounters between hikers and stock will be similar to Alternative 1 (No Action), and probably expected. Loose grazing of stock may remain in conflict with campers seeking no quite and solitude.

Second Recess, being an internal destination, does not have any direct controls on use levels. It is expected it will remain the same as current or if the trail is maintained. The trail has not been cleared for a number of years and therefore is difficult for stock to travel, which has discouraged stock use the past years. It could sustain use and be a location where a light dispersion of use may or could relieve conflicts in Mono Creek, Silver Divide, and Silver Peak.

Laurel Analysis Unit is similar to Second Recess in that it has no direct controls regulating the use. Access here would occur from traveling trips or spot and dunnage from the west side (Edison). It has had light use in the past and virtually no use in the recent years and some issues with trail maintenance. Some light use dispersed here would have the same effect as is described in Second Recess. Anything more than occasional stock use beyond the bench at Laurel (approximately 1 mile below Laurel Lake), may cause resource degradation to trails which are not likely to receive much maintenance due to the remoteness of the area. Commercial stock use to Grinnell would not occur in this alternative thereby protecting the area for high opportunities for solitude.

Hopkins, again similar to Laurel and Second Recess, will have no direct controls on use.

Available grazing resources will draw use to this location as a means to make up for a reduction in grazing resources in Silver Divide. Hopkins will very possibly receive more use and this use will be concentrated at lower Hopkins Lake where a designated stock camp will probably get more occurrences of use than in the No Action (Alternative 1). The standards for stock camps will insure that the size and impact is contained. There will be fewer opportunities for solitude and possibly more encounters between stock and hikers groups in this area than in the No Action. Travel to Hopkins Pass is allowed in this alternative, and will be in the form of day rides from the stock camp. With this trail available for use, it will make the Hopkins camp more suitable for longer stays for pack trips.

Pioneer Basin will have a number of direct controls in place with this alternative. Access to use trails will be substantially reduced from the No Action (Alternative 1). This will concentrate commercial stock presence at Mudd Lake stock camps and once the trail is improved to Lake, 10,820 (check) it will be extended to the upper basin via this trail. This greatly limits what has currently been approved and what has occurred in the past. The excessive amount of use trails that exist may have resulted from lack of maintenance on the original system trail, and/or the lack of an adequate trail system to reach locations in the basin desired by hikers and pack stock. It is expected that some of these trails, such as the one on the east end of the basin accessing the upper lakes and the use trail to Lake 10,900 will only be improved with substantial rehabilitation work. But by removing a commercial stock use with its associated potential for further impacts to soft soils and meadow of this basin that are susceptible to hooved trampling, the damage will

at least be arrested. This will improve the experiential values of the setting. Stock camps at Mudd Lake will still receive a high level of use, perhaps more if use in the upper basin is displaced to Mudd Lake. However, there will also be a seasonal destination quota in the area to insure that use does not increase through displacement.

Fourth Recess Analysis Unit will continue to have a high level of stock use. There will be four stock camps that will be designated at and above Third recess junction along the trail corridor. This alternative reduces the number of stock camps that exist in the No Action and will concentrate stock related impacts into fewer locations that can sustain and will contain the impacts through the standards for stock camps. Many of these camps are very large in total area and heavily affected with vegetation loss, pulverized soils in the holding areas and compacted soils in the non-stockholding areas. This alternative will reduce the sites to an appropriate size, location and improve access. Use trails to campsites currently provide for a very confusing trail system in the Mono Creek corridor and this will be improved by establishing one trail into the site and better signing.

Fourth Recess Lake will continue to be a location for concentrated use. A large campsite at the outlet will be used for concentrating large parties supported by commercial packers.

The Mono trail will continue to have some negative experiential affects to the hiking public until repairs and improvements are made. Continued stock use will contribute to the deterioration of this trail.

Little Lakes Valley will have low levels of commercial stock use. Packers have limited their use over the years as the public use increased, particularly day use. By continuing a limited use for commercial services, primarily spot and dunnage and some day rides, there will be a reduction in use conflicts over time between hikers and stock.

Identified camp locations for larger groups at Chickenfoot Lake will insure that larger groups occur at appropriate locations. Limits on party size at Gem Lake insure that the limited camping opportunities and a setting that is not conducive to much solitude are not negatively affected by large stock supported parties.

Tamarack Analysis Unit will have an increase in stock use from recent past use. Use in this area fluctuates year to year in the No Action Alternative. This will likely continue to be the case. Tamarack does not have a draw or demand like other destinations in the region and is not expected to start drawing more use. It is probably capable of supporting 125 stock a season with established stock camps and limitations on use trails and short cuts that are currently identified by packers and had been used until the 2001 Wilderness Plan limited travel to existing system trails unless authorized.

Hilton Analysis Unit will continue to have a high level of commercial stock use but with more constraints than Alternative 1. There will still be three operators in the drainage but two operators will be infrequent, with light use per season and access in the drainage from the north via Hilton creek. This separates the use somewhat and it would be less than a few nights a season when more than one operator would be in the drainage at the same time. Use trails in the area are excessive and in this alternative, like the proposed action, will be greatly reduced, concentrating stock use on primary trails. Use trails that appear to be in place to travel between camps used by packers will be prohibited and over time, these areas may re-vegetate with the disturbance removed. Hilton will remain an area that is dominated by packer use. Use will be prohibited

above Third Lake thereby insuring that stock impacts do not extend into more areas of the drainage over time and that use patterns will not change.

Cumulative Impacts

There will be continued cumulative effects of high day use combined with pack stock use in Little Lakes Valley. The actions in the alternative insure that pack stock use does not increase and remains at a very low level. With developed campgrounds adjacent to the wilderness boundary and resort facilities along the access road to this wilderness boundary, the area draws hundreds of visitors a day into Little Lakes Valley during the summer months. No regulation of day use is in place, yet the relatively small level of backpacking and pack stock use is. Access to classic mountaineering routes (Bear Creek Spire) also draws a type of user into the area, and many of these routes experience low-level impacts to the climbing routes and some crowding. Lack of actions in these developed areas has had an effect on the wilderness experiential values in this area.

Hilton Lakes was the location of multiple structures and facilities that were removed after the 1964 Wilderness Act was passed to comply with wilderness standards. Impacts from an earlier period of heavy use remain on the landscape. The area has improved wilderness character significantly from the time it was designated wilderness. Actions in this alternative continue use at high levels yet the overall impacted area has been reduced between past actions since the 1964 (removing facilities) and in this alternative by limiting the extent and locations of commercial pack stock services.

Mono Creek/Rock Creek – Alternative 4

Analysis

Locations within the Upper Mono corridor (east of Second Recess) are primarily influenced by use levels over Mono Pass from the Mono trailhead. West of Second Recess, the Lower Mono trailhead accesses the Lower Mono corridor and Graveyard trailhead accesses the Graveyard/Goodale Pass area. Mono Pass trailhead, even though it is being reduced from 15 to 10 people per day, will have little direct effect on some key locations such as Hopkins, Pioneer Basin, and Fourth Recess.

Use could become concentrated at any of three locations with no guarantee that it will disperse between these destinations. Destinations vulnerable to increases in use would be Pioneer Basin, Lower Hopkins Lake, Second Recess, and Fourth Recess. Crowding already occurs at Fourth Recess, and with limited camping, any increases to Fourth Recess could degrade the already low opportunities for solitude. Hopkins Lake also has limited camping potential and may become a primary destination for overnight stock use other than camps in Mono Creek.

Traveling trips may be fewer with the reduction of service days. This area currently receives a high level of all expense traveling trips. With reduced service days, there may be a shift to more spot and dunnage type of services and fewer traveling trips, which utilize service days. The effect of this would be reduced impacts because of fewer occurrences of use at the already existing stock camps and possibly more people in the upper Mono Creek, Fourth Recess, and Pioneer Basin. Opportunities for solitude would likely be diminished in Pioneer Basin.

As described above in the wilderness scale, with controls on people and not stock, there will be an increase in the numbers of stock in this area to compensate for the reduced service days and daily quota. Increased stock on the Mono Trail will continue to degrade the trail, which is not currently built to standard, with a consequence of degrading the experiential qualities for the visitor.

With a trailhead quota of 10 people a day, the number of commercial parties would be greatly reduced in the month of August. This use may be spread out to July or September but that will be dependent on demand. It is possible that the service days cannot be utilized due to quota availability in the month of August, which is peak season. An overall reduction in use would not equate to reduction in impacts if stock numbers do not correspondingly go down, or frequency of use at certain locations increases.

In the Hilton area, use will be limited to 10 persons a day. This is typically an area used in the early season with less frequent use in August. Pack operations generally shift their business to trips over Mono Pass and traveling trips from Mono to Mammoth and/or Yosemite National Park. With quota space being constricted on the Mono Pass trailhead, it is possible that more use would occur throughout the season in Hilton to make up for the loss of opportunity over Mono Pass. If more use were to occur in Hilton, commercial pack stock use would be even more dominant than it is currently, which is over 40 percent of the use. If designated campsites concentrated the camping impacts and trail limitations concentrated the stock use to the lower basin as this alternative proposes, then the primary impact would be to a visitor's wilderness experience with increased crowding at Second and Davis Lake and encounters with pack stock on the trail. Again, without direct controls on stock numbers, if stock were to increase in the very small area authorized for the commercial stock use in Hilton with this alternative, there would be very intense and concentrated stock impacts, including odors and/or urine and manure along the primary corridor and destinations of the drainage.

Tamarack may have similar effects as those described for Hilton Lakes. Use may disperse to Tamarack if quota availability allows. In this alternative, the quota is reduced at Tamarack from eight to six. However, this would still allow for considerably more use than occurs in Alternative 1, 2 or 3. Since Tamarack is relatively remote and has lighter impacts, it is vulnerable to the increased impacts that increased stock use could bring. Dorothy Lake would receive all the use, as it would be the only designated campsite for packer operations. Dorothy is suitable for pack stock use but may receive intense impacts if use were to increase. Encounters with pack stock in this area would likely increase and opportunities for solitude would likely decrease.

Little Lakes Valley may also provide some potential for dispersal for packer operations that would be limited by reduced quota on Mono Pass. Again, the quota is eight people a day. This still allows for considerable growth in commercial packer operations from the Alternative 1 – No Action, and Alternatives 2 and 3. Chickenfoot Lake and Long Lake are the two identified camp locations for all commercial packer use (including spot and dunnage). The use would probably remain primarily spot and dunnage and would be easy for the packer to accomplish being so accessible from the pack station. Chickenfoot Lake is conducive for parties, including large parties, and very little increased impact would occur here or at Long Lake. The amount of use would be consistent with a Recreation Category 3 area, where use is managed intensively. The increased encounters with stock would likely create the most impact to wilderness experience, and could create more crowding and loss of opportunities for solitude.

At the west end of this geographic region, the primary control point would be Mono Creek trailhead for lower Mono Creek, Graveyard for Graveyard lakes, and Devil's Bathtub, Bear Ridge, and Bear Creek trailheads for Bear Ridge and Volcanic. This later trailhead also becomes the primary regulator of use along the PCT/JMT from Volcanic to Seldon Pass. Trailhead quotas would not change from current use, but overall use levels determined by service day would be reduced by 20 percent. Possible increases in stock numbers would result with corresponding effects to the Mono trail, Goodale Pass trail, and JMT/PCT. Use patterns would likely stay the same, with intense use continuing to lower Graveyard Lakes and no improvement to the opportunities for solitude. With fewer options for dispersing use in this alternative, the crowding may become exacerbated. Arrowhead Lake may get more use because of this action as it becomes one of the few locations where use can disperse.

More remote locations such as Feather and Upper Graveyard lakes will, over time, become more remote and have high opportunities for solitude and high wilderness character.

The Silver Peak area would probably receive less commercial pack stock use if the 20 percent service day reduction were to result in fewer all-expense trips (as it likely will). Most of the commercial pack-stock use would then go to Mott Lake, with fewer stock encounters along the trail to Silver Pass. Mott Lake may see increased use as one of the few destinations where commercial stock use will continue. Opportunities for solitude will be reduced and crowding and a sense of remoteness will be very hard to come by in August.

Bear Ridge will likely remain a pass-through area for accessing the PCT and JMT. Use patterns will not change, nor will the small reduction in overall use have any noticeable effect on resource or experiential conditions in this area.

Cumulative Impacts

These actions, when combined with present activities will have a cumulative effect in some locations of increasing use and potentially impacts or at least decreasing opportunities for solitude and wilderness experiences. Little Lakes Valley will experience the cumulative effect of displacing pack stock use into an area where there is a very high day hiking visitation. With developed recreation sites in close proximity to the wilderness boundary, and Little Lakes Valley providing easy hiking into extraordinarily scenic settings, this area may experience some intense crowding and diminished experiential wilderness qualities.

Hilton Lakes will also have multiple use types occurring with this action possibly displacing even more commercial pack stock use into the lower basin. Cumulatively, the actions effectively concentrate a lot of use into a smaller area, with limits on trails to the upper basin. Though this protects the upper basin and achieves high opportunities for solitude, there may be an effect of displacing the non-packer use into the upper basin to find solitude from the intense packer use concentrated in the lower basin.

Mono Creek/Rock Creek – Alternative 5

Analysis and Cumulative Impacts

This area currently receives a high level of commercial pack stock use. This region includes that area accessed from the east over Mono Pass, and from the west from Lake Edison. It also

includes Hilton Lakes and Tamarack north and south of Rock Creek respectively. 25 percent of the use over Mono Pass is by packers, 45 percent of the use in Hilton Lakes is by packers.

Hilton Lakes has been used intensely by packers. The primary access is from Rock creek with a small amount of use accessing from Hilton Creek to the east. Up to 750 head of commercial stock have been recorded in a season in Hilton, with the primary destinations being Davis Lake and Second Lake. A very rough and deteriorated trail exists to the upper basin and with the removal of packer use, this trail could be maintained at very minimal level and sustain the use. The entire area will take years to recover from the intense packer use, as many trails and camps are heavily compacted. Light use will continue by hikers and day hikers and it is not likely that this will be high priority for management actions for restoration. With no action, the character of the area will change dramatically. There will be no encounters with stock where currently there is 20-70 stock a day traveling on the trails. Opportunities for solitude would be increase significantly, although most of the use in here by packers is concentrated in early season.

The Mono Creek corridor, including the side canyons (recesses) and basins, attracts moderate to high use area for all types of use. By eliminating packer use there would be noticeable changes in the Mono corridor, to trails, campsites, and in the number of encounters. Specific locations that would be most affected would be Fourth Recess, Pioneer Basin and lower Hopkins Lake.

Up to 600 commercial stock travel to, or through, Fourth Recess (which includes the Mono trail to just below Hopkins junction). Fourth Recess itself has recorded up to 200 stock a season. With the elimination of packer, use there would be a noticeable change. There would be higher opportunities for solitude, as the capacity for camping is limited at Fourth Recess Lake. Fewer parties would be camping without the assistance of spot and dunnage support. Campsites would likely remain impacted at the lake; there is no stock camp here.

The trail corridor from Mono Pass to just below Hopkins would be affected by eliminating stock, including fewer encounters, higher opportunities for solitude, reduction in the number of stock camps and in the impacts of these stock camps. Many of the stock camps along the trail corridor have substantial use trails to them that provide confusion of the trail system. The trail itself is highly eroded, rough and in need of repairs. The repairs needed without pack stock would be greatly reduced, and the trail could be maintained and reconstructed at a lower development level than with current packer use levels. This would enhance the wilderness character of the area by providing more a primitive trail.

Lower Hopkins Lake would show some improvements with the absence of packer use. There is one large stock camp, with an associated holding area, that would be contained or eliminated over time. The area receives less than 10 trips a year so opportunities for solitude would be increased somewhat. Private stock use would still occur but trails could be maintained at lower standards, use trails eliminated (specifically lower Hopkins to upper basin).

Up to 200 commercial stock access Pioneer Basin in a season. With the elimination of this use, the system and use trails that have been identified for use by packers will not be needed. Some of these trails are noticeably degraded and by removing one source of the disturbance, the trails may not improve but will not degrade further. Without significant mitigation, these trails will not naturally recover and in some cases may continue to degrade. Multiple stock camps at Mudd Lake will no longer be needed and it is expected that one site will be identified as a suitable location for private stock parties and over time, the other sites will be contained and/or rehabilitated. The trail system can be greatly reduced to a few primitive trails and allow for

cross-country travel by the foot travelers. The basin is open and as such is vulnerable to perceptions of crowding, even with a relatively small amount of visitors. Removing up to 70 visitors a season, mostly in August, will only moderately improve the opportunities for solitude.

Currently up to 350 stock travel in the Graveyard area per season. The primary destination is lower Graveyard Lakes. With no commercial stock, the biggest effects would be noticed at lower Graveyard and along the trail corridor to Goodale Pass. Opportunities for solitude would increase at lower Graveyard with the absence of commercial pack stock services, but would probably be only moderate since this is a popular destination for backpackers. Camping opportunities are moderate at the lake and the presence of other parties camped is noticeable. One large site frequented by packers at the outlet would remain similarly impacted, with a large impacted area. This may over time decrease in size due to fewer large parties and no temporary holding for stock or disturbance by bringing stock in and out and unloading them at the site.

Very little use occurs at Feather and Arrowhead lakes, and therefore, little change would occur at these locations.

Second Recess, Volcanic, Tamarack, and Bear Ridge Analysis Units receive low commercial use. Volcanic sees less than 10 stock a year. This use is primarily associated with hunters or to assist crews at the snow-survey site. The need to continue to provide stock support for the snow survey would probably be conducted by the Forest Service with their stock. Private hunting parties would possibly replace commercial stock support and the same level of stock would occur in Volcanic. Bear Ridge is used primarily as a pass-through to access the JMT/PCT from Lake Edison. The greatest effect of eliminating packer use would be on the trail system and may lead to decrease need for maintenance and reconstruction over time. Second Recess use is along the Mono trail and similar decrease in maintenance may be an effect. Tamarack receives less than 50 stock a year and the effect of eliminating this use would be in increasing already high opportunities for solitude.

Little Lakes Valley also receive very low packer use, similar levels to Tamarack. This area however receives very high public use, primarily day hikers. It is one of the highest day use areas in the two wildernesses on the Inyo National Forest. The effect of eliminating packer use would be barely noticeable. Trails are built substantially in this valley to accommodate high use. These trails have gradually been narrowed from when the main trail was a mining road. These actions have improved the wilderness character of the area but the high use and lack of opportunities for solitude due to proximity and easy access from developed recreation sites will continue.

Bishop/Humphreys – Alternative 1

Analysis

This region will have a high level of commercial stock along primary trails and popular destinations. Numbers of stock used could increase over time. Some secondary trails and use trails to remote locations are prohibited for stock use in this alternative, but some areas without trails areas remain available for commercial pack stock to use. Frequency of use to these destinations is not controlled therefore changes in patterns and increases in frequency of use at destinations could occur. This leaves a potential for increases in impacts.

Gable Lakes are managed as a case-by-case trail. Commercial use has occurred in the past but the condition of the trail has limited the opportunities for pack stock and in some years,

prohibitions have been identified in the annual operating plan. If use were to be approved on a case-by-case basis, it would receive only occasional and infrequent commercial stock use. However, the trail is managed as a trail class 3 in this alternative, which would allow for a highly developed trail into the Gable Lakes drainage. Managing the trail to this level would be in conflict with the needs implied by the case-by-case designation for pack stock, and in conflict with the Recreation Category 1 designation.

Pine Creek would have a high concentration of pack stock use on the main trail to Honeymoon Lake. Moderate use at lower and upper Pine Lakes would continue and Honeymoon Lake and dunnage trips to the Pass would constitute the bulk of commercial pack stock use in east of the pass. Honeymoon Lake would be a location where opportunities for solitude would be compromised and crowding can affect visitor's experience. Campsite impacts, with large total area of vegetation loss and soil compaction would persist and possibly expand in this alternative.

In French Canyon, there will be opportunities for pack station services to access more remote locations. Use trails to Royce Lake, French Lake, Steelhead Lake, Shepherder Lake, and Alsace Lake are all authorized to commercial pack stock. Since a level of use is not prescribed to these locations, there is a danger that if use levels were to increase at any one of these locations, it would lead to more trailing impacts, campsite impacts, and a general loss of existing solitude at these more remote locations. If commercial packers, however, use the destinations at the level they currently are, these locations may not experience much change over time.

The campsite at Royce Falls in French Canyon will continue to see a high level of stock use. The camp is used for two-day spot trips over Pine Creek Pass. The frequency of this type of use is not directly controlled. The camp has experienced significant expansion, extends across the system trail, and is a noticeable impact for travelers on the trail. It is likely that impact will continue. Loose grazing in French Canyon will also have effects on a visitor's experience with noticeable impacts to meadows, and the possibility of loose stock roaming the canyon.

No system trail to Merriam Lake would result in commercial stock use to Merriam having the potential to cause further erosion with a lack of the means to maintain or reconstruct the trail. The current use trail authorization does not specify which trail should be used (there is one on both sides of the creek). Use would continue on both trails with an effect on a wider area. Lack of an identified system trail would cause a conflict between the allowable use and the trail resources. Use trail to LaSalle would be authorized in this alternative and could lead to diminished solitude and deteriorated trail conditions over time.

Hutchinson Meadow would receive use from multiple operators. Use typically does not converge here often but has the potential to in this alternative. Multiple stock camps would persist and new ones could be created and developed over time. The area shows signs of extensive impacts due to many years of campsite development and expansion from hikers and stock travelers. The area will continue to be subject to crowding and noticeable impacts from use. The drift fence will be allowed to remain and its size could have an effect on visitor's wilderness experience.

In Glacier Divide unit, Golden Trout Lake will have a high concentration of commercial stock use. The current packer will probably utilize the same sites and multiple trails to access the various sites causing resource concerns and confusion to the visitors. The proliferation of use trails could be curtailed with active management that defines appropriate trail and campsites for packer use, but to date that has not occurred. Without active management, the area could continue to degrade, particularly the trail accessing the lake, which will not be on the system in

this alternative. This will cause a conflict between trail management direction and allowable uses which will likely result in noticeable impacts.

Lower Honeymoon Lake and Packsaddle Lake would be approved as use trails. While the trail to Honeymoon could easily withstand some increase in pack stock use, Packsaddle is vulnerable to increased use both from potential impacts to the fragile meadows surrounding the lake to the experiential qualities and opportunities for solitude that could be compromised with increased or facilitated use to this area. Both areas have limited camping opportunities where other camped at the same time could affect the wilderness experience.

The Muriel Lake trail will also not be managed as a system trail. A short section through the riparian area will persist and possibly degrade further with continued commercial pack stock use. No limits on the frequency of commercial stock use may exacerbate this situation over time. Further impacts or reduction of impacts will be dependent on the timing of use, the snow pack and the wetness of the area and then number of stock that use the area.

Humphreys Basin will have moderate commercial stock use. Use will be allowed on most cross-country routes in the basin. It is expected that most use will continue to go to Desolation Creek/Lake and Humphreys Lake. Light use would occur to Mesa and Tomahawk and if this pattern were to continue, little change would be evident in this area.

The North Fork of Bishop Creek will remain a high use area and commercial pack stock will be heavy. The area is used mostly as a travel through to destinations west of the pass. Upper Piute Lake receives occasional use throughout the summer by commercial stock. Day rides to Loch Leven will occur and will add to the congestion at that popular day use destination but is consistent with Recreation Category 3 area if managed intensively.

Lamarck Trail will be managed as a Trail Class 3. If managed to this level it could facilitate more commercial stock use than currently occurs. With an improved trail, the trailhead quota may get used more frequently by commercial pack stock. This would have the potential for moderate adverse effects to solitude and natural conditions effect on the south side of Lamarck Col.

Horton will receive low and infrequent commercial pack stock use. It will probably be early season use and have no effect to this area.

Sabrina will have high commercial stock use. Multiple destinations disperse the pack stock use. Dingleberry and Emerald Lake will receive the highest concentration of use. Without a system trail to Emerald there may be conflicts between use and trail resources in the future. Use will remain primarily spot and dunnage. Impacts will be to trails, campsites and in frequent (daily) encounters with pack stock on the trail. Baboon Lakes will be managed to a high level (Trail Class 3) and this could facilitate additional use, which could affect some qualities of the destinations. Limited camping exists at Baboon Lake and opportunities for solitude have the potential to be diminished if use were to increase.

Tyee would remain a case-by-case trail for only occasional use. The trail would be managed as a highly developed Trail Class 4. This would cause some conflict between trail assignment and the commercial use assignment, which in the future may lead to some reconsideration of the commercial use.

Bishop Pass would be a high use commercial stock use primarily as a travel through to Sequoia-Kings Canyon National Park. The Chocolate-Ruwau trail would be managed as a Trail Class 3,

which would greatly change the character of this loop. By improving the trail, pack stock use could be facilitated and lead to commercial stock use expanding to sites at Chocolate and Upper Chocolate. Currently, pack stock use has been limited to Bull Lake and not beyond to Chocolate or onto Ruwau Lake. Ruwau can be accessed from Long Lake. Marie Louise Lake would not be managed as a system trail and commercial pack stock would not be approved.

Treasure Lake will be open to commercial stock use and up to eight persons a day could be allowed. This could lead to increase in use if the quota were to be utilized more days a season. Opportunities for solitude will be low to moderate.

Cumulative Impacts

Effects of past use and management actions are particularly evident in Pine Creek, Piute, Sabrina, and Bishop Creek. All these areas show evidence of high commercial and public use, including commercial and private backpacking, mountaineering, pack stock, and day use. Actions in the 1970s established quotas on these high use trails for private users. Commercial use, although it did not increase was not controlled on a daily basis. One effect of trailhead quotas on only high use trails may have been to disperse use to other less crowded areas. The addition of trailhead quotas on all trailheads (2001) may help prevent further impacts in light to moderately used areas. Site-specific campfire closures that were put into place in Piute, Sabrina, and Bishop Creek helped reverse the depletion of wood and prevent further scarring and mutilation of trees that was occurring.

The cumulative effect of past actions and on-going commercial pack stock activities in this No Action Alternative are that there will be the potential for minor to moderate local adverse effects to natural conditions if use patterns change and new impacts are created as a result of the change in use. There is also a moderate adverse cumulative effect to visitor freedom for all users, with past and present restrictions and limitations on visitor use. These limitations have had moderate beneficial effects on natural conditions and some experiential components of wilderness character, particularly at high use destinations such as Blue Lake, Long Lake, Piute Lake, and Golden Trout Lakes.

Past high use including commercial pack stock and commercial and private backpackers in the Golden Trout Lakes are (Humphreys Basin) led to some severe trail and campsite impacts and a proliferation of use trails. A closure to camping was put into effect in the 1980s, which was only partially effective at reducing site and trail impacts. In 2003 there was a rehabilitation project in Humphreys Basin, focused at Golden Trout Lakes. The project removed fire-rings and set back campsites at Golden Trout Lakes, responding to the 2001 elevation campfire closure. When removing campsites, consideration was given to the packers needs and to minimize the need for use trails. Actions in this alternative may lead to continued needs for this type of project work as the multiple use trails continue to be available for pack stock use.

Currently there is a capital investment project on the Pine Creek Trail. This work will improve the condition of the trail and may facilitate pack stock use by making travel easier and safer. Use levels however would be more dependent on market demands than trail conditions. Substantial investment and development of this trail contributes to the development of the area. Scenic qualities in the lower portion of this trail are greatly diminished by a large Tungsten mine just outside the wilderness boundary. The mine, now closed, is in the midst of rehabilitating the landscape yet the scars are visible from within the wilderness. Future uses of this land could

further diminish the scenic and experiential qualities for visitors. Pack stock uses that will continue in this alternative at moderate to high levels, combined with the diminished experiential qualities and a highly developed trail all contribute to some effect on the wilderness character of the area.

There will be a potential cumulative effect of continued allowances for commercial pack stock trips up to Lamarck Col. Use will be facilitated into Sequoia-Kings canyon national Park into a more remote and pristine area. Increased use can have adverse effects on the natural conditions of this pristine area, and loss of opportunities for solitude.

Day use, facilitated by developed recreation sites in the Bishop Creek drainage, in addition to the commercial pack-stock use activities in this alternative, will have cumulative effects on crowding and wilderness experience in Piute, Sabrina, and Bishop Creek in this alternative. There will be short-term moderate adverse effects to some people's experience as a result of high recreation use and various recreational activities in the first 6 miles of the trail into the wilderness.

Bishop/Humphreys – Alternative 2 – Modified

Analysis

In this region 35 destinations will be used by commercial pack stock. This is a very small proportion of this very extensive geographic unit. A heavy concentration of packer use will occur in Sabrina, Bishop Creek, French Canyon, and the Glacier Divide areas. Generally, locations that were suitable and sustainable were identified for potential growth while areas where impacts were high (or current use was of a concern) use was reduced. These will be discussed below.

Only two analysis unit areas, French Canyon and Hutchinson, would have overlapping spot and dunnage operations: French Canyon with two operators and Hutchinson with three. A very small number of all-expense trips (approximately 20) would travel through the area. There are two operators doing versions of the North and South lakes loop through Sequoia Kings Canyon National Park. These operators run occasional trips from Mono Creek to the south going out either Pine Creek or Bishop Pass and trips from Pine Creek to Sequoia Kings Canyon via Hutchinson Meadow.

In the Gable Analysis Unit, the trail is being identified as Not Recommended for Stock. No packer operations would occur. Currently packers do not go there but have expressed their desire for trail improvements so they can access the lakes. Opportunities for solitude would remain high.

Pine Creek Analysis Unit would allow for some increases in spot and dunnage along the Pine Creek trail. This increase, if it were to be realized would occur along the primary trail corridor and have very little additional effects on encounters while camping or traveling since it would be a minor increase over the course of the season. The trail has a high level of development and suitable for stock travel at moderate to high levels.

A slight increase is allowed for Honeymoon Lake. The designation of campsites for all commercial pack stock clients (including spot and dunnage drops) and limits to only two commercially occupied sites at one time would reduce conflicts with other visitors, limit the area of impact, and contain the stock related impacts at Honeymoon Lake. This lake has limited

capacity for camping and more than two parties at a time would reduce opportunities for solitude.

Commercial pack stock would not be allowed beyond Honeymoon Lake to access either Chalfant Lakes or Granite Park. This would insure that the area remains more primitive and that trail development is kept to a minimum, as it is not needed to support commercial pack stock. Opportunities for solitude at Chalfant Lakes will be high. Granite Park receives a lot of public use and will remain moderate for solitude and high for wilderness character.

Horton Creek will have occasional early season packer use. It is used in conjunction with spring horse drives and six trips with two different operators. These trips will not have much effect on the area. It will remain a low-use area.

In French Canyon, the use will be reduced to Elba and Moon lakes until the trail is improved. This is not expected to occur in the next few years. Substantial work will be necessary to make it suitable for increased use. Maintaining low stock use levels to these lakes will ensure that natural conditions do not degrade further. The low use levels would have very little adverse effects to solitude while camping in this location as visitors can disperse to various lakes.

Use will also be reduced from the high use year to Merriam Lake. One trail will be eliminated to remedy a duplicate trail system. This will concentrate use onto the one trail but that use is relatively light (four trips a year). There is not expected to be any adverse effects to naturalness or solitude with this low level of use.

Access to Royce Lakes will be authorized for light use (two trips a year) and this will not likely change the use trail access or the character of the area. French Lake use will be capped at the current high of two trips a year. Limits on the number of stock will ensure that the trail does not become defined over time. This will allow for these destinations, French Lake, Royce Lakes, and Merriam Meadow to remain low use and limit stock related impacts. No stock camps are identified at French or Royce so stock impacts will be minimal. Merriam has one camp identified on the bench below the lake and no travel by pack stock beyond the camp is allowed. This will protect the lakes identified by the packer for use from additional stock impacts. The bench above Elba and Moon lakes will be off limits to commercial pack stock, thereby preventing any further deterioration of the use trail from Elba Lake to Alsace Lake.

The Glacier Divide unit will see an overall reduction from high use years. This reduction would take place at Golden Trout Lakes, to help reduce any adverse effects to the trail accessing Golden Trout Lakes. It is expected that this level of use will continue to cause visual and experiential impacts for visitors. However with the reduction in use trails the proliferation of trails between camps and shortcuts between trails may be curbed and this will help improve the experiential values of this destination.

Trail impacts are by far the most noticeable at this destination and effect on the wilderness character of the area with trail impacts, crowding and campsite impacts, will continue at moderate intensity. With the potential action of removing the commercial stock use from the current trail alignment, which passed through a series of riparian areas where incision and multiple trailing is severe, to more durable location west of the lakes, there is a chance that even high levels of use can be sustained with fewer impact to naturalness. Active restoration of the system trails and use trails is needed if any improvements or beneficial effects to naturalness are to be realized.

Muriel and Packsaddle Lakes should maintain their current qualities of moderate and high wilderness character, with Packsaddle Lake receiving only occasional use and Muriel Lake receiving moderate use. The trail to Muriel Lake should not deteriorate further with this level of use and when improved can probably sustain a light increase.

Humphreys Analysis Unit would allow the same level of use; however, this use would shift from Humphreys Lake to Desolation creek/lake and Mesa/Tomahawk Lakes. No stock use would be allowed beyond Tomahawk to Knob Lake. Limited use around Tomahawk and Mesa Lakes will be authorized as long as trailing does not become evident. This area has sparse vegetation and decomposed granite soils where trailing is currently not an issue. Light use should maintain this condition. The area will continue to have high opportunities for solitude. Limited use to Humphreys will protect the primitive trail from becoming more established and thereby requiring development.

Piute Analysis Unit, east of Piute Pass will remain a corridor of high stock use. The campsites used at Piute Lake will be improved to allow for stock access and to insure that no further deterioration occurs. This area receives a high level of day and overnight backpacking use.

Day rides will likely continue at existing levels. Day rides will be occasional (less than 50 a season) to Loch Leven Lake and rarely beyond. There will be effects to crowding because of this, but limited to no noticeable or measurable effects to the trails. The level of use is consistent, in fact low, for a Recreation Category 3 area.

Trips into the Lamarck Lakes area will be limited to five trips a year and the commercial pack and riding stock will not be allowed past Upper Lamarck Lake. This will reduce but not solve the concerns raised by Sequoia-Kings Canyon National Park that packer use is facilitating access into upper Evolution Basin. It is not expected, however, that five trips spot and dunnage to Upper Lamarck Lake will reduce the use noticeably.

The Sabrina Analysis Unit will see a potential for more trips with the same level of stock. The biggest change in use could occur at Emerald Lakes. This area is slightly off the main trail and currently receives mostly moderate packer use. This is a location suitable for family type trips because of the closer proximity to the trailhead and camping opportunities that maintain opportunities for solitude due to the vegetative screening. There will be an overall increase in parties supported by pack stock but not likely to be an increase in stock numbers. More visitors will be serviced with less stock if the growth potential is realized in Sabrina. The prohibition on a number of use trails will concentrate use to the main trail and maintain solitude and character off trail in the basin.

Tyee Lakes will see the same level of use that is currently occurring, very light use with no more than two trips a year. This will not change the character of the area or effect solitude for visitors as it receives moderate day use mainly by anglers and day hikers from the Bishop Creek developed sites.

Bishop Creek will continue to have a moderate level of stock use primarily passing though to Sequoia-Kings Canyon National Park. The limit on trips is the only control currently for the packers into the Park. The trail on the Inyo National Forest side is highly developed and can withstand high levels of use, including stock use. The potential growth for the packer will be along this main trail and over into the park, with limitations on use of trails off the main corridor. No use is permitted beyond Bull Lake. Use will be capped to Marie Louise Lake with a party

size limitation to insure that continued use the area does not expand trail and campsite impacts. Hurd Lake will be an area for potential growth and with its location off the main trail, located in lodgepole pine and with suitable campsites for large parties. It will become more developed but not effect either the character or the solitude component for the area. Ledge, Ruwau, and Chocolate lakes will all be off limits to pack use. By concentrating the pack use on the highly developed main trail and greatly limiting use off this corridor the majority of the basin will not be subject to stock related impacts. Opportunities for solitude off the main trail will be moderate to high and because of the trail prohibitions (i.e., Ruwau, Chocolate, Ledge, and Margaret lakes) the effects of commercial pack stock use in areas off the main trail will be minimal.

Treasure Lakes will have the potential for an increase in use, but will remain light use, up to eight trips a year. Limiting use to the main trail corridor and not beyond the lower lakes will insure that stock related impacts are contained. Trail conditions along the last $\frac{3}{4}$ mile to the lower lakes will not likely improve but will not deteriorate with this level of use.

Cumulative Impacts

High visitor use, both commercial and non-commercial, outfitter guide and packers, has occurred for over thirty years in many parts of this region. Impacts are noticeable in Piute, Sabrina, Bishop Creek, Golden Trout Lakes, and French Canyon. Trailhead quotas reduced spikes in use, which probably helped reduce campsite impacts at many locations in Humphreys Basin and Sabrina Basin. Closures to campfires in the 1980s at Sabrina and Piute and the camping closure at Golden Trout Lake, along with active management to restore campsites and fix trails, have all reduced the extent of the impacts. All these areas show evidence of high commercial and public use, including commercial and private backpacking, mountaineering, pack stock, and day use. Additional action in this alternative of limiting trips to locations where risks are evident or resource impacts have been identified, and prohibiting commercial pack stock on a number of use trails will have a moderate long-term beneficial effect to natural conditions. Removing a source of disturbance and/or reducing the frequency of the disturbance will allow for recovery of some trails and impacts at destinations such as Muriel and Golden Trout Lakes. It will also limit opportunities for unconfined recreation for those visitors who rely upon commercial pack stock to access these areas. The areas will still be available to the clients by foot travel.

Work on the Pine Creek trail (trail construction project currently in progress) should improve the condition of the trail and may facilitate pack stock use by making travel easier and safer. Use levels however would be more dependent on market demands than trail conditions. Scenic qualities in the lower portion of this trail are greatly diminished by a large tungsten mine just outside the wilderness boundary. The mine, now closed, is in the midst of reclamation, yet the scars are visible from within the wilderness. Future uses of this land could further diminish the scenic and experiential qualities for visitors. Pack stock uses that will continue in this alternative at moderate to high levels, will add to the effect on experiential qualities on the lower section of this trail. Having the use and trail standard compatible will improve some of the experiential qualities by fixing the impacts of commercial stock, private hiking use and past mining use.

Past high use of commercial pack stock and commercial and private backpackers in the Golden Trout Lakes area (Humphreys Basin) led to some severe trail and campsite impacts and a proliferation of use trails. A closure to camping was put into effect in the 1980s, which was only partially effective at reducing site and trail impacts. In 2003, there was a rehabilitation project in Humphreys Basin, focused at Golden Trout Lakes. The results of this project work and past

action combined with the actions in this alternative will further reduce the extensiveness of impacts in this area by containing the commercial use to a limited number of trails and campsites. The chance of the project work being successful (that is, impacts do not return) are higher with this alternative than Alternative 1, 2, 3 or 4 as a definitive limit and reduction on trips to this area is prescribed until trail conditions are improved. This will have long-term beneficial effects that will reduce the cumulative effects of continued commercial pack stock in the area.

Day use, facilitated by developed recreation sites in the Bishop Creek drainage will continue to have some minor to moderate effects on crowding and wilderness experience in Piute, Sabrina, and Bishop Creek in this alternative. This, combined with increasing day rides out of North Lake may increase conflicts between hikers and stock users and contribute to more crowding and experiential impacts on the trail to Piute Pass.

Bishop/Humphreys – Alternative 2

Analysis

In this region 48 discrete destinations will be used by commercial pack stock. A heavy concentration of packer use will still occur in Sabrina, Bishop Creek, French Canyon, and Glacier Divide areas. Collectively at these 48 destinations there are allowances for 69 additional spot and dunnage trips. Generally locations that were suitable and sustainable were identified for potential growth while areas where impacts were high or current use was of a concern were identified for reductions. These will be discussed below. Only two areas, French Canyon and Hutchinson, would have overlapping spot and dunnage operations: French Canyon with two operators and Hutchinson with three. A very small number of all-expense trips would travel through the area, two operators doing versions of the North Lake/South Lakes loop through Sequoia Kings Canyon National Park—an occasional trip from Mono Creek to the south, going out either Pine Creek or Bishop, and trips from Pine Creek to Sequoia Kings Canyon via Hutchinson meadow.

In Gable Analysis Unit no packer operations would occur with the trail being identified as Not Recommended for Stock. Currently packers do not go there but have desired for the trail to be improved so they can access the lakes. Opportunities for solitude would remain high. Wilderness character would continue to be diminished by the remnants of the mining operation.

Pine Creek Analysis Unit would allow for some increases in spot and dunnage along the Pine Creek trail. Only a slight increase is allowed for Honeymoon Lake and this, combined with designated campsites for all commercial pack stock clients and limits to only two commercially occupied sites at one time would reduce conflicts with other visitors, limit the area of impact, and contain the stock related impacts at Honeymoon. This lake has limited capacity for camping and more than two parties at a time would reduce opportunities for solitude. Commercial pack stock would not be allowed beyond Honeymoon Lake to access either Chalfant Valley or Granite Park. This would insure that the area remains more primitive and that trail development is kept to a minimum, as it is not needed to support commercial pack stock. Opportunities for solitude in Chalfant will be high, but Granite Park receives a lot of public use and will remain moderate for solitude and high for wilderness character.

Horton Creek will have occasional early season packer use. It is used in conjunction with spring horse drives and six trips with two different operators will little effect on the area, and it will remain a low use area.

In French Canyon the use will be reduced to Elba/L and Moon Lakes until the trail is improved. This is not expected to occur in the next few years and substantial work will be needed to make it suitable for more use. Use will also be reduced from the high use year to Merriam and one trail will be eliminated to reduce a duplicate trail system. This will concentrate use onto the one trail but that use is relatively light (four trips a year). Royce Lake will be allowed for light increase (two to four trips a year) and this will not change the use trail access or the character of the area. French Lake use will be capped at the current high of two trips a year. This will allow for these destinations, French, Royce, and Merriam to remain low use and limit stock related impacts. No stock camps are identified at French or Royce so stock impacts will be minimal. Merriam has one camp identified on the bench below the lake and no travel by pack stock beyond the camp is allowed. This will protect the lakes that had been identified for packer use from further stock impacts. The bench above Elba and Moon will be off limits to commercial pack stock, thereby preventing any further deterioration of the use trail from Elba to Alsace Lake.

The Glacier Divide unit will see an overall reduction from high use years. This reduction would take place at Wahoo Creek (vicinity of Golden Trout Lakes), Muriel, and Packsaddle. Increases would be allowed at Hutchison meadow. Muriel and Packsaddle should maintain their current qualities, with Packsaddle receiving only occasional use and Muriel receiving moderate use. The trail to Muriel should not deteriorate further with this level of use and when improved can probably sustain a light increase.

The overall level of use at Golden Trout Lakes would remain the same. It is expected that this continued level of use at Golden Trout Lakes will continue to cause visual and experiential impacts for visitors. However, with the reduction in use trails, the proliferation of trails between camps and between trails may be curbed. This will help improve the experiential values of this destination. Active restoration of the trails and use trails is needed if any improvements in the area are to take place in the next 10-20 years. Trail impacts are by far the most noticeable and affect the wilderness character of the area more than the crowding or campsite impacts, both of which are high in the month of August. This area being opened to campfires from clients of commercial pack stations would probably suffer from the issues of non-compliance discussed in the Wilderness section. A proliferation of fire-rings would likely occur and confusion over a fire closure would be inevitable when some visitors can have fires while others cannot. With the amount of both public and commercial use at this location it could become very problematic to manage effectively.

Humphreys Analysis Unit would allow the same level of use; however, this use would shift from Humphreys Lake to Desolation Creek/Lake and Mesa/Tomahawk. No use would be allowed beyond Tomahawk to Knob Lake and only limited use around Tomahawk, Square, and Mesa lakes as long as trailing does not become evident. This area is mostly sparse vegetation and decomposed granite soils where trailing is currently not an issue. Light use should maintain this condition. The area will continue to have high opportunities for solitude. Limited use to Humphreys will protect the primitive trail from becoming more established and thereby requiring development.

Piute Analysis Unit, east of Piute Pass will remain a corridor of high stock use. The campsites used at Piute Lake will be improved to allow for stock access to insure that no further deterioration occurs. This area receives a high level of day and overnight backpacking use. Sanding at the pass will be allowed to continue and may facilitate early stock use into Golden Trout Lakes which may contribute to the deterioration of trail conditions on the trail to Golden Trout. This will continue to be an issue until the trail is either relocated or developed to sustain this level of use. The day ride allocation will increase to 600-day rides a season. This will increase encounters between hikers and stock and contribute to crowding, but is consistent with a Recreation Category 3 designation if managed closely to insure additional damage does not occur. It is assumed that with a substantial trail there would be no additional environmental change as result of increased day use.

North Piute Analysis Unit will receive light use by two operators overlapping spot and dunnage to Piute canyon. Trail concerns will not change and this level of use will probably not have any effect on the current poor trail conditions in Piute Canyon below Hutchinson meadow.

Trips into the Lamarck area will be reduced from the high use year by nearly 50 percent. This will reduce but not solve the concerns raised by Sequoia Kings Canyon that packer use is facilitating access into upper Evolution Basin. It is not expected, however, that five trips (spot and dunnage) to upper Lamarck Lake or the Col will reduce the use noticeably. Wilderness permit use has not increased on Lamarck trail for over ten years, and in fact has decreased.

Sabrina Analysis Unit will see a potential for more trips with the same level of stock. Up to 30 more trips will be allowed but limited to areas in the basin that can sustain that use. The biggest change will occur with Emerald Lakes. This area is slightly off the main trail and currently receives mostly moderate packer use. This is a location suitable for family type trips with the closer proximity to the trailhead and camping opportunities. This location maintains opportunities for solitude due to the great screening and campsite locations that separate parties in the same area. There will be an overall increase in parties supported by pack stock but not likely to be an increase in stock numbers, so more visitors will be serviced with less stock if the growth potential is realized in Sabrina. The prohibition on a number of use trails will concentrate use to the main trail and maintain solitude and character off trail in the basin.

Tyee will see the same level of use that is currently occurring, very light use no more than two trips a year. This will not change the character of the area or effect solitude for visitors as it receives moderate day use mainly anglers and day hikers from the Bishop Creek developed sites.

Bishop Creek will continue to have a moderate level of stock use primarily passing through to Sequoia Kings Canyon. The limit on trips is the only control currently for the packers into the Park. The trail on the Inyo National Forest side is highly developed and can withstand high levels of use, including stock use. The potential growth for the packer will be along this main trail and over into the park, with limitations on use of trails off the main corridor. No use is permitted beyond Bull Lake, yet Bull Lake is suitable for an increase in trips without changing the character or creating additional stock related impacts to the area. Use will be capped to Marie Louise Lake with a party size limitation to insure that by allowing this continued use the area of impact does not expand and trail impacts do not increase. Hurd Lake will be an area for potential growth and with its location off the main trail but in lodgepole and with suitable campsites for large parties it will become more developed but not effect either the character or solitude component for the area. Ledge Lake, Ruwau, and Chocolate Lakes will all be off limits to pack

use. By concentrating the pack use on the highly developed main trail and greatly limiting use off this corridor the majority of the basin will not be subject to stock related impacts. Opportunities for solitude off the main trail will be moderate to high and in some location such as Chocolate, Ruwau, and Ledge may increase.

Treasure Lakes will have the potential for an increase in use but will remain light use, up to eight trips a year. Limiting use to the main trail corridor and not beyond the lower lakes will insure that stock related impacts are contained. Trail conditions along the last ¾ mile to the lower lakes will not improve but will not deteriorate with this level of use.

Cumulative Impacts

High visitor use has occurred for over thirty years in many parts of this region. Impacts have been noticeable in Piute, Sabrina, Bishop Creek, Golden Trout Lakes, and French Canyon. Trailhead quotas reduced spikes in use, which probably helped reduce campsite impacts at many locations in Humphreys Basin and Sabrina Basin. Closures to campfires in the 1980s at Sabrina and Piute and the camping closure at Golden Trout Lake along with active management to remove campsites, and fix trails, have all reduced the extent of the impacts. All these areas show evidence of high commercial and public use, including commercial and private backpacking, mountaineering, pack stock, and day use. Additional action in this alternative of limiting trips to locations where risks are evident or resource impacts have been identified, and prohibiting commercial pack stock on a number of use trails will have a moderate long-term beneficial effect to natural conditions. Removing a source of disturbance and /or reducing the frequency of the disturbance will allow for recovery of some trails and impacts at destinations such as Muriel and Golden Trout Lakes. It will also limit opportunities for unconfined recreation for those visitors that rely upon commercial pack stock to access these areas. The areas will still be available to the clients by foot travel.

Work on the Pine Creek trail will improve the condition of the trail and may facilitate pack stock use by making travel easier and safer. Use levels however would be more dependent on market demands than trail conditions. Scenic qualities in the lower portion of this trail are greatly diminished by a large Tungsten mine just outside the wilderness boundary. The mine, now closed, is in the midst of rehabilitating the landscape yet the scars are visible from within the wilderness. Future uses of this land could further diminish the scenic and experiential qualities for visitors. Pack stock uses that will continue in this alternative at moderate to high levels, will add to the effect on experiential qualities on the lower section of this trail. Having the use and trail standard compatible will improve some of the experiential qualities by fixing the impacts of commercial stock, private hiking use and past mining use.

Past high use of commercial pack stock and commercial and private backpackers in the Golden Trout Lakes area (Humphreys Basin) led to some severe trail and campsite impacts and a proliferation of use trails. A closure to camping was put into effect in the 1980s, which was only partially effective at reducing site and trail impacts. In 2003, there was a rehabilitation project in Humphreys Basin, focused at Golden Trout Lakes. The results of this project work and past action combined with the actions in this alternative will further reduce the extensiveness of impacts in this area by containing the commercial use to a limited number of trails and campsites. The chance of the project work being successful (that is, impacts do not return) are higher with this alternative than Alternative 1. The exception is with campfire use. There is a risk

with opening the area to campfires by clients of commercial pack stock that many of the fire-rings will return.

Day use, facilitated by developed recreation sites in the Bishop Creek drainage will continue to have effects on crowding and wilderness experience in Piute, Sabrina, and Bishop Creek in this alternative. This combined with increasing day rides out of North Lake may increase conflicts between hikers and stock users and contribute to more crowding and experiential impacts on the trail to Piute Pass.

Bishop/Humphreys – Alternative 3

Analysis

Gable Lakes will officially be closed to commercial pack stock through the designation of the entire trail as Not Suitable for Commercial Stock (NSCS). Under the No Action alternative there is no official restriction but no use is recorded. The effect therefore will be minimal.

Pine Creek will remain an area with moderate to high stock numbers. This use would be concentrated along the trail corridor to Honeymoon Lake and Pine Creek Pass with some use at lower and upper Pine Lakes. Similar to the Proposed Action (Alternative 2) use would be managed more directly at Honeymoon Lake with designated campsites for spot and dunnage parties. With an additional control of commercial packer clients occupying no more than two sites at a time. This will reduce crowding that occurs under the No Action alternative where there are no limits. Camping opportunities are limited at Honeymoon and opportunities for solitude are greatly compromised with more than one party since campsites are within sight and sound of each other. Allowance for campfires at designated stock camps may affect compliance with the campfires closure by the public at upper Pine and Honeymoon Lake.

Granite Park will have no commercial stock in this alternative. This will continue to be a popular destination for hikers but trail conditions will remain primitive and without commercial stock use there will be little need to maintain this trail at more than its existing primitive standard. Use to Chalfant Valley will be by foot travel only and dispersed into various cross-country routes. The recreation category change in Chalfant from a Recreation Category 2 to a 1, as it is in the No Action alternative, will insure that the drainage remains undisturbed and primitive, with high opportunities for solitude.

French Canyon will maintain a moderate to high level of commercial stock use. The only direct controls on use in this unit would be prohibitions on trail use. Use to L, Elba and Moon could occur in this alternative like No Action but not beyond to Alsace or the Puppet Lake bench or Steelhead. Use to Elba, L and Moon would not be limited and with more occurrences further trail deterioration of this deeply incised trail and further multiple trailing could occur which would continue to cause experiential effects. At remote destinations, visitors often expect more pristine conditions. Conditions on the trail to Elba are not likely to improve without heavy maintenance, relocation, and reconstruction. Improvements to the trail could facilitate more use. Allowances for campfires at designated stock camps may shift use back to this area. Under the No Action, use shifted to the camps in French Canyon where fires are allowed. Recent restoration work at Moon and Elba greatly improved the overall condition and reduced impacts associated with campfires. With allowances for one user group here may be non-compliance with the closure and general confusion about the restrictions. The so called Waterfall Camp at Royce Creek and French Canyon will be designated a stock camp to concentrate impacts and with the standards of

stock camps implemented this site will decrease from its current size of nearly four acres. Improved trail access to the site and a drift fence to prohibit stock travel in the fen-like meadow below this camp will all work together to reduce the impacts associated with the stock use at this site. Only one trail to Merriam Lake will be approved, the one west of the creek which is more sustainable. This will reduce unnecessary multiple trailing that was only occurring as a time saving measure of convenience to operators accessing the lake from the east. Commercial pack stock use will be limited to the bench below Merriam Lake and not beyond to the upper reaches of this basin. This will protect opportunities for solitude and disturbance to trails that may occur with continued stock use, even at low and infrequent levels. Trails above the bench are difficult to find, steep in places where they can be found and generally not suitable for stock use without needed improvement and development. Use trails to Royce and French Lakes will be approved but conditioned with a destination quota to each destination that will limit the number of occurrences and frequency of pack stock use to these Recreation Category 1 areas.

North Piute will continue to have only pass-through use by multiple operators. The Piute trail provides east – west access as well as access to Evolution Valley in Sequoia-Kings Canyon National Park. Trail conditions will continue to be deteriorated until improvements are made.

Glacier Divide will continue to be an area of very high stock use. Commercial stock use will be concentrated at Golden Trout Lake and Hutchinson Meadow along the main trails. There will be low to moderate use at Muriel Lake with limits on the number of trips the level of stock use will be lower than in the No Action where up to 14 trips have been recorded in a year. Impacts at Golden Trout Lake will still be noticeable and will continue along the main trail. With use limited to trails accessing approved designated camps, there may be a reduction in overall multiple trailing in the area. This will improve the experiential qualities of the area somewhat. Allowances for campfires at designated stock camps with packers may lead to non-compliance and confusion regarding the fire closure and lead to increased impacts of fire rings by this non-compliance. The approved use trail to Packsaddle will be complemented by a destination quota to insure that the trail, which is currently not visible and only a cairned route, does not become a visible path. Since Packsaddle is a Recreation Category 1 area, this level of use and the character of the trail accessing should not change in this alternative. Encounters with commercial pack stock use would be infrequent. Commercial pack stock use may not occur every year. Overlap of operators will be minimized by the primary operating area concept but may occur at Hutchinson meadow especially in support of tribal walks. There will also be overlap between operators offering North-South Lake loops from each of the trailhead (North Lake and Bishop Pass). This will continue and perhaps expand if National park regulations do not provide any limits in this type of use.

Humphreys Basin unit will maintain a low to moderate level of commercial stock use.

Use will be controlled by a destination quota to Mesa and Tomahawk Lakes which is virtually cross country and use trail travel in the wide open Humphreys Basin country. Direct controls on the trips to these destinations will help prevent trails from developing over time and will keep the area with a setting of remoteness and undisturbed. Trips to Humphreys Lake will not be controlled and there may be an effect of more use to these lakes. More use could have impacts on the trail condition, which is at very low level, currently undeveloped, and at times hard to follow. No use would be authorized beyond Mesa to Knob Lake.

Piute unit (east of Piute Pass) would remain a very high commercial stock use area. Travel is mostly through travel with some spot and dunnage services to destinations east of the pass such as Piute Lake and Lamarck. Some day rides use would be authorized but this use is relatively light. This is a very popular trail for hikers both day and overnight, providing fishing and hiking opportunities from the campgrounds in Bishop Creek. The trail would remain highly developed trail and help facilitate access to the area. Sanding of the pass helps facilitate early access to the west side of Piute pass and would be allowed to continue as in the No Action alternative.

Horton would remain an area with occasional commercial stock use. Use would be in association with spring horse drives and would be limited to the lower lake. With a seasonal limit of 15 stock, impacts would not be noticeable or change because of this use.

Lamarck unit would maintain a very low level of commercial pack stock use. Less than 10 trips a year occur with the No Action alternative. In this alternative, a seasonal stock limit of 20 head would insure that use does not grow and help respond to concerns expressed by the Park Service that use is increasing into a trail-less area to the south of Lamarck Col. Pack stock support can facilitate more use and will be limited with this alternative. Use would still be authorized to the tarn below the Col and over time the trail impacts will deteriorate but possible at a slow rate with this low level of stock.

Sabrina would continue to be an area with moderately high commercial stock use. This use would be commensurate with use occurring in the No Action alternative (2003 reported use). Few direct controls would be in place. Some prohibitions on use trail use such as that to Fishgut Lakes, the outlet of Donkey, and an alternative to Baboon Lake will all be prohibited thus concentrating commercial stock use to the more sustainable system trails in the basin. Designated stock camps at Emerald, Dingleberry, and Moonlight Falls will concentrate use and stock impacts at these locations. There would be no allowances for campfires at these stock camps since the fire prohibition pre-existed the 2001 Wilderness Plan elevation closure.

Tyee unit would have only occasional day rides and no overnight use with this alternative. The Tyee trail is steep and with continued day use or any increases in day use the trail would become hazardous. No direct controls on day rides exist with this alternative and use could increase over time.

Treasure Lake would remain an area of low stock use in this alternative. A seasonal limit of 25 stock combined with a destination quota of eight trips would insure that occurrences of commercial pack stock would be few though out the season. Camping capacity at this destination is low and the setting is such that opportunities for solitude become compromised with more than one or two parties camped here as sites are easily within sight and sound of each other.

Bishop Pass will be an area of moderate to high stock use. Use would occur primarily on the main trail to Bishop Pass. Commercial stock use would be limited to Bull Lake and not beyond to Chocolate Lake, or to Ruwau from Chocolate. Use to Ruwau would be allowed from Long Lake, possibly having an affect on the area around Ruwau where stock loading and unloading would occur. Camping impacts and opportunities for solitude may be at risk with this allowance. The use trail to Margaret Lakes would also be prohibited, maintaining this destination as a high opportunity for solitude. Limitations on stock use over the pas into Sequoia-Kings Canyon National Park will need to be determined by the Park Service in future planning efforts if the effects of this level of stock become or are determined to be unacceptable in the Park.

Cumulative Impacts

Cumulative impacts are essentially the same as those described in Alternative 2.

Bishop/Humphreys – Alternative 4

Analysis

Gable Lakes will be an area not available to commercial stock with the trail designated as Not Suitable for Stock. This is no different from Alternatives 2 and 3. Although there is no formal designation in Alternative 1, commercial pack stock have not used the area in years. The formal designation insures that stock impacts do not occur in the future, whereas in Alternative 1, the use pattern could change.

Pine Creek trailhead day quota does not change from the No Action with 15 persons a day allowed to access Pine Creek, Pine Creek Pass, and French Canyon. It is not expected that use or impact patterns will change much in this alternative from the No Action. Stock numbers will not be limited and up to 350 stock a year could travel through the Pine Creek drainage, about half of which would access French Canyon. These numbers could increase in the future with no direct controls on stock numbers. Use will continue to be concentrated spatially at Honeymoon Lake and Upper Pine Creek Lake and temporally in the first few weeks of August. Travel beyond Honeymoon to Italy Pass will be prohibited as it is in Alternatives 2 and 3. Honeymoon Lake will continue to have low opportunities for solitude with crowding at the few campsites that are all within sight and sound of each other.

Access to the more remote locations in French Canyon will have more limitations than in the other alternatives. Access to Merriam, Royce, French, and Steelhead Lakes will be prohibited in this alternative, all of which were limited in some fashion in Alternatives 1, 2, and 3. This further concentrates commercial stock use to Elba, L and Moon Lakes and French Canyon. These destinations are currently in a Recreation Category 2 and use could exceed standards if not regulated further. Royce, Merriam, French, and Steelhead will be protected from future impacts; however, current light use show very little disturbance or evidence of use. Opportunities for solitude will be improved for those seeking remote locations without the possibility of stock intrusions.

French Canyon and Royce Falls Camp, in particular, will receive the bulk of use for commercial pack stock in French Canyon. Available grazing resources may attract use since few other locations are available. Further concentration of use at Royce Falls Camp will not affect the already impacted site and with additional management prescribed for these sites there will be an improvement and, even with increased use this site, will not likely degrade further.

Hutchinson meadow will continue to be a location where multiple operators could converge. If use patterns that emerged under the court injunction continue, where operators attempted to maximize their use by traveling into Sequoia Kings Canyon National Park (via Evolution Valley) it is expected that intensive use of this area would continue. The area, which is already heavily impacted, would not degrade further with continued or increased use. With management actions that designate appropriate locations for campsites, the further concentrations would improve the general area, which receives more widespread impacts from stock camps.

Glacier Divide would see continued high use concentrated at Golden Trout Lakes. The use trail proliferation would be contained by maintaining defined routes for commercial pack stock to

access the identified campsites in the area. No new impacts would occur with this strategy and existing impacts would be reduced, as they would be in Alternatives 2 and 3. One difference in this alternative is in the prohibited access to the more remote location of Packsaddle Lake. This destination would see slight improvements with the removal of very low and infrequent commercial pack stock use. Improved opportunities for solitude would occur, though the improvement would be barely noticeable since over the course of the season only a few occurrences of commercial pack stock use had previously occurred. However in Alternative 1, use patterns could change and more use could occur at Packsaddle. The numbers of occurrences of pack stock use are limited in Alternative 2 and 3. Lower Honeymoon Lake could become a more frequented destination for commercial pack stock as it remains one of the few remote locations available. The trail is suitable for light stock use as it is, but if pack stock use were to increase further degradation could result.

Commercial pack stock to Humphreys Basin would have no direct controls to either Humphreys or Desolation Lake, but no other cross country travel or use trail travel in the wide open basin would be permitted. Use could shift to locations where trails would be maintained at the lowest level, TC1. This may result in some conflict between increasing use to these destinations and the trail maintenance level as use is displaced from other locations previously available to the commercial operator. Opportunities for solitude at these two available destinations could degrade if use patterns shift.

Use in the Piute Analysis Unit from North Lake to Piute Pass will continue to have a high level of commercial pack stock use. It is possible that over 700 stock a year would travel over Piute Pass and with controls on people and not stock and a daily quota remaining 15 person a day, there could be a shift towards fewer people being serviced by more stock. This would be quite noticeable in this canyon, which in the No Action alternative, has received this level of use the past couple of years. Opportunities for solitude would be low but not likely to be in conflict with the Recreation Category 3 designation for this area.

Commercial pack stock use to lower Lamarck Lake and beyond would be prohibited in this alternative. This would reduce expressed conflicts in Sequoia-Kings Canyon National Park that commercial services were considered to be facilitating. It is expected that public use will continue to increase into the Park as the public continues to seek more remote and challenging trips in the backcountry, with or without pack stock support. The area would reduce the use from about 4 parties a year and 24 stock. It is not expected that the impacts on the trails would be improved without rehabilitation efforts.

Horton will continue to be used as an early season destination primarily associated with spring horse drives. It may, however, be used at any time of year but is not likely that use patterns would shift to this location as it is far enough away to deter the casual use of this trailhead.

Commercial pack stock would continue at high levels in the Sabrina Basin. Up to 300 stock a year could be expected in this alternative. The only difference in trail use for pack stock is the prohibition in this alternative to Topsy Turvy and Baboon Lakes. Presently, use is infrequent to these destinations and this action would not likely cause a shift in use to other locations in the basin. Trail maintenance would be lower to Emerald Lakes. This could cause some conflict if commercial stock continues at existing levels to Emerald and with no direct controls use could increase to Emerald and, if so, trail deterioration could occur with the lower trail class level.

Tyee would be designated as Not Suitable for Commercial Stock in this alternative. Limited use that has been allowed the past few years would be eliminated. This may reduce the few conflicts that occur with stock and day hikers in particular on this steep and narrow trail.

Bishop Creek would continue to be an area with a high level of commercial stock use.

Marie Louise Lake would be prohibited for commercial stock use in this alternative. This would result in fewer trail concerns over time and increased opportunities for solitude. The lake has few good locations for camping and by removing stock to this destination, it would insure that camps do not enlarge and, although impacts may persist, they will not increase. The trail to Marie Louise has never been on the system and by including it on system in this action (as well as in Alternatives 2 and 3) some level of maintenance would prevent degradation of the trail. The level of development implied by a TC2 trail may not be needed with the elimination of commercial stock; however, it is consistent with the RC2 designation of this destination. Use will continue to be primarily concentrated on the main trail with the primary purpose of commercial services to access Sequoia- Kings Canyon National Park.

Treasure Lakes will be maintained at a lower level in this alternative yet stock numbers could increase with only a trailhead quota in place on people. With six persons a day, this area may see increased use. Opportunities for solitude will continue to be low to moderate and crowding may be increased if stock numbers increase.

Cumulative Impacts

The effects of past, present and reasonably foreseeable projects are similar to Alternative 1, 2 and 3. Visitors on the Pine Creek trail will be affected by activities at the Tungsten mine site, which may contribute to some diminished wilderness character on the first section of trail. Reducing pack stock use in this alternative will not show any changed affects on the section of trail. Reduced pack stock use may lead to increased use of other types such as hiking, backpacking or private stock use in these areas. This may result from perceived fewer conflicts with pack stock in this alternative.

Developed recreation use in Bishop Creek will contribute to increases in public use of adjacent wilderness lands. This will probably be in the form of day hiking. Similar to Pine creek, there may be an increase in use because of perceived fewer stock in the backcountry.

There would be no other adverse cumulative effects.

Bishop/Humphreys – Alternative 5

Analysis and Cumulative Impacts

This area is characterized by a high level of packer use currently. With the absence of packer use there would be a noticeable change in social, resource, and wilderness character conditions in most but not all of the units in this region.

Two units, Granite Park and Gable currently have no reported stock use. This is due primarily to the condition of the trail as not passable or suitable for pack stock. Elimination of commercial stock use would not affect these areas. Horton receives very low use, and only in early season, late June with horse drives to the pack stations. The elimination of packer use would have very little effect or noticeable change in the resource or social conditions in Horton. Two recreational

cabins in Horton and the presence of structures and a mining past have more effect on the area than the light use. Gable also has evidence of past mining activity with significant mining debris that has an impact on the character of the area.

Pine Creek also has a mining history evident in the landscape. This effect to wilderness character takes place in visual intrusions of a large tungsten mine at the base of the canyon, which is currently closed but contributes to diminishing visual qualities. The trail that is a road for the first section also diminishes wilderness qualities and with the elimination of the packer use these effects would continue. The trail is substantially constructed with the capital investment project currently in progress. The highly developed trail needed to ascend the steep canyon may be overbuilt for hiker only traffic if stock is eliminated. Destinations in the canyon that would see improvement would be Upper Pine Lake and Honeymoon Lake. Honeymoon Lake receives the majority of packer use in the canyon and would likely see improvements to camping opportunities with less occupied sites and gradual improvement of the highly compacted camping area from the continual use of pack stock for loading and unloading.

French Canyon would see improvements with the absence of pack stock. The degraded trail conditions in French Canyon and to Elba Lake would not likely improve quickly without substantial investment. However, with the removal of pack stock use, the trail to L and Elba may stabilize although in a degraded condition. The condition of the trail has an effect on a visitor's sense of remoteness and the obvious imprint of man almost 15 miles from the trailhead has an experiential effect. The conditions may not improve quickly but a sense of remoteness may improve if stock support ceases. The camp at the junction of Royce Creek ("Waterfall Camp") in French Canyon would not be needed from holding the number of stock often needed with packer operations. Given that is already highly impacted; it would probably remain a stock camp for private stock use but over time could be contained to a quarter of its current size with very little investment. Removing the disturbance, much of which is related to the churned up soils from stock holding is easier than restoring the compacted soils at the core of a site where most camping activities take place.

Hutchinson meadow is an area where camping is concentrated. Packer use contributes to this on a frequent basis in the month of August. Use will continue to concentrate and campsites that are well established will not be affected by the absence of packer use. The sites that are used for holding stock may be used infrequently and see some minor recovery to vegetation loss and expansion of compacted soils and core area. These sites have been used annually by Native American tribal walks and this activity will continue with large stock and people numbers for a short duration in August or September.

Moderate use by packers occurs in the Humphreys Basin area. Desolation Creek and Humphreys Lakes receive the most use by packer spot and dunnage services and a few cross-country trips to Mesa Lake each season. Opportunities for solitude will increase slightly in Humphreys, with up to 15 less parties a year. This may improve the social conditions of the area since it is a very open destination with low camping capacity and even two parties camped would affect the experiential qualities if they are seeking solitude. Humphreys tends to be a destination that is a base camp for those ascending Humphreys peak. These types of parties (climbers) often tend not to be seeking solitude at base camp locations. Camping conditions will most likely not change and with the trend toward an increase in the peak climbing activities use will probably continue to increase at this location with or without packer use.

In Glacier Divide, the primary packer destination is Golden Trout Lakes and secondary destination is Muriel. The trail to Muriel Lake has a section through the meadow that is wet and with early and even mid season access with pack stock there is considerable impact. With the absence of packer use, the trail will only be used by hikers. Very little private stock goes there now. The condition of the trail will improve due to the absence of stock disturbance to the wet soils. The campsites at Muriel are for spot and dunnage parties, not stock holding, and will remain the same.

Golden Trout Lake has substantial use trails and high impacts to the trail itself. The impacts to the main trail to the lower lake will not improve without substantial investment. Given its popularity, it may be high on the list of trails to reconstruct, but may not see any work for 10 to 15 years. When this work is conducted the trail needed to access the lakes will be less developed than what would be needed for the level of commercial pack stock use today. Use trails that are used to access camps by packers will diminish over time due to the lack of use and there will probably be an overall improvement to the area with the absence of what is currently over 600 head of stock per year in July and August.

Other more remote locations in the region receive very low packer use. These include Honeymoon Lake, Tomahawk, and Knoblock and conditions in these places will most likely remain the same.

Piute Creek (the east side of the pass) is high use for backpackers and day hikers as well as the commercial packer use presently. There are often high encounters between hikers and between hikers and stock on this trail in July and August. Hiker-stock encounters will be nearly zero while hiker-hiker encounters will remain high. Opportunities for solitude while camping would not change as most packer services go over the pass. The area would probably maintain the same character of a high use corridor. There would no longer be the sanding of the pass and this would have little effect on hiker access. There may be more braiding of the trail in this section as the trail melts out and hikers avoid the snow.

Currently, Lamarck receives low packer use. With the elimination of packers, the area would still receive a moderate amount of backpacker and day use. Encounters with other hiking and camping would not change. The trail to the pass would still receive moderate use, as this is a popular access to Sequoia-Kings Canyon National Park. The opportunities for solitude will likely not change, as the packer use is less than ten stock a year. Some trail improvement and therefore improvement to wilderness character may take place with the absence of stock but improvements would not be noticeable for a number of years.

Sabrina currently receives a high level of packer use, with just under 300 stock a year used in conjunction with primarily spot and dunnage services. The majority of the use goes to Dingleberry, Moonlight Falls, and Emerald Lake. With the absence of use to Emerald (140 stock a year) the trail will have less noticeable impacts with less use trails to sites. Encounters will be fewer, especially camper encounters. Emerald Lake serves as a great site for family camping and packer services to this destination cater to the family. There may be fewer families as a result of the no action. The large stock site at Moonlight Falls will see some improvement especially in the use trail access and the visual effects of a highly compacted site once the stock use is absent. This is a moderate to high use area for backpackers and day hikers and this use would continue with impacts on trails and at campsites. Packer use is dispersed and low amongst the other destinations, including Hungry Packer, Hell Dive, Blue Lake, Baboon, and Midnight Lake.

Bishop Pass is a very high use area for backpackers, day hikers, and packer use. Visitors are primarily accessing Sequoia-Kings Canyon National Park (SEKI). This trailhead acts as the main control for use into the Dusy Basin area. Packer use is also primarily into SEKI, with light use dispersed to destinations in the lower canyon. Most of the use is spot and dunnage to Saddlerock Lake and above. Visitors will have few to no encounters with stock parties with Alternative 5, only the occasional and infrequent private stock party. Most campsites will stay the same, as impacts are contained and concentrated at the existing sites, and will likely not change with the No Action alternative.

Treasure Lakes receives low commercial use, less than 50 stock per year. Only a few parties are transported to Treasure Lakes and the effect of no packer use will be minimal to encounters, overall use levels, and resource impacts.

Florence/Bear – Alternative 1

Analysis

Commercial pack stock use in this region will continue to be concentrated in few areas with multiple operators overlapping services. Traveling trips will pass through this area, primarily along the JMT/PCT corridor and predictably stop at locations with available grazing resources. Destinations including Hilgard Branch, Bear Creek, Kip Camp, Rosemarie Meadow, and Sallie Keyes will receive this type of use. In these locations stock camps, most likely the ones that have existed for many years will continue to receive impact. Increased impacts would come in the form of expanded stock holding areas, expanded tent sites, more bare soil, and vegetation loss. It is possible that as stock camps become too impacted or if multiple operators converge in one location at the same time, new stock camps could be created.

Spot and dunnage service will occur in these same locations. Bear Creek, Bear Ridge, Hooper, and Florence trailheads control daily use into this area. For destinations north of Seldon Pass, single quotas for Bear Ridge and Bear Creek of 10 are the external controls. Various and numerous destinations can be reached from these trailheads, including Apollo, Cirque, and Marcella Lakes all with various use trails approved to allow for multiple access points to these lakes. If use were to increase at these locations, which currently receive very low use, it could change the character of these destinations.

Rose Lake is another destination off the primary trail where use could increase over time. Lou Beverley, Sandpiper, Three Island, and Medley Lakes are also subject to use pattern changes with no direct controls. Use trail approvals allow for on-going and potential increases in use if the trails were to be maintained to the prescribed levels. These more remote locations would remain remote and opportunities for solitude will likely remain.

Italy Lake is open for pack stock use in this alternative. Although it is rarely used, due to impassable trail conditions, and not likely to be used by commercial pack stock, this alternative allows for the use of Italy Lake, which allows potential for the area to change, or for more use to be facilitated into the upper area. If access is improved by major trail reconstruction opportunities for solitude will continue to be diminished.

South of Seldon Pass, between Seldon Pass and Florence Lake there will be multiple commercial pack stock offering a variety of services. There will be continued and possible increasing use up to Sequoia-Kings Canyon from the Florence Lake trailhead that allows for 15 commercial

persons a day. Sallie Keyes will have multiple stock camps and impacts will persist with concentrated pack stock use occurring by virtue of the scenic qualities and the location of the destination.

Destinations within the Hooper unit are controlled by the Hooper trailhead. Gordon Lake, Bear Dome, and Hooper Lake will continue to receive light to moderate use.

South of Florence, the Dutch unit will have moderate commercial stock use. Two commercial operators will disperse use to Dutch Lake, Crater Lake, Hidden Lake, Rodeo Meadow, and Thompson Lake but use to each destination will be light.

Cumulative Impacts

Muir Trail Ranch and Lost Valley are private inholdings within the interior of the wilderness boundaries. Muir Trail Ranch operates a guest ranch on the property that opened in 1940. There is four-wheel drive access to the private property, which has been under a Special Use Permit since 1948. The presence of the road has both experiential and environmental effects. Multiple trailing has occurred due to confusion, desire for direct access to eastbound destinations, and historical grazing by the pack stock associated with the permits issued in the area. This causes some confusion and a high density of trails in a small corridor. Both the presence of the road and the confusion and resource impacts of multiple trailing can diminish the wilderness experience for users. Both the private inholdings and their associated four-wheel drive access trail impact wilderness character.

Florence/Bear – Alternative 2 – Modified

Analysis

In this region 15 discrete destinations or zones will be used by commercial pack stock. Generally, locations that were suitable and sustainable were identified for potential growth while areas where impacts were high or current use was of a concern were identified for reductions. These are identified below. The PCT/JMT corridor is the primary area of packer use in this geographic unit, with most of the commercial stock use will be concentrated along the PCT/JMT.

Areas of overlap in this region will generally remain the same with a high concentration of overlap along the JMT/PCT between spot and dunnage operators out of Edison and Florence Lakes as well as the overlap with traveling trips. Hilgard Branch (Italy Analysis Unit) Seldon Pass and Sallie Keyes will continue to see up to five operators because of two operators providing spot and dunnage services to the same areas in addition to these traveling trips. Dutch, Ward, and Apollo Analysis Units will have two overlapping operators in a few destinations. This alternative does not change the overlap of operations, and with the potential growth, may bring about more occurrences of overlap.

Sallie Keyes unit will see up to 300 stock a season. It is expected that less than 200 stock will be the norm unless patterns shift and more traveling trips occur. This is not likely since all-expense traveling trips are limited to current levels. Trends the past two years show increases in use to Sequoia–Kings Canyon National Park, access via the JMT in this region may draw packer use in the future until or unless the National Park limits their use. Designated sites at Sallie Keyes will insure that a proliferation of sites does not occur. There may need to be a management of concurrent itineraries for traveling trips to insure that overuse of stock campsites does not occur.

Opportunities for solitude in this area will be moderate while camping and low while traveling on the trail system. This is a very high use area for backpackers and through hikers along the PCT/JMT. Stock use is low relative to backpacker use and these actions will not change this ratio.

Hilgard Branch in the Italy Analysis Unit will have low to moderate stock use (up to 14 trips). Commercial stock are prohibited beyond Hilgard Branch. This limitation will have minor effects since although commercial pack stock are currently not limited they do not utilize this area. To facilitate stock travel beyond the designated stock camps, trails will remain primitive.

The Seldon Pass Analysis Unit will have growth opportunities for spot and dunnage services. It is expected that more clients will be serviced with less stock to realize this growth. Opportunities for solitude will stay the same with possibly more encounters with stock parties along the JMT. Some growth in services will probably take the form of re-supplies to through hikers of the JMT/PCT.

Bear Lakes will not be accessible to stock use. Clients of commercial packers will only be able to be serviced 1.5 miles from the PCT/JMT junction. Opportunities for solitude will remain moderate to high.

The Hooper Analysis Unit will receive low commercial stock use, primarily at Gordon Lake. Opportunities for solitude in this analysis unit will remain high due to low commercial stock use and little trail development into the area. Commercial stock use that does occur in this area is limited to spot and dunnage trips. Due to the proximity of destinations in this analysis unit to the pack stations, overnight holding of stock rarely occurs in the Hooper Basin, and there are no opportunities for grazing of stock in the Basin.

Cumulative Impacts

Muir Trail Ranch and Lost Valley are private inholdings within the interior of the wilderness boundaries. Muir Trail Ranch operates a guest ranch on the property that opened in 1940. There is four-wheel drive access to the private property, which has been under a Special Use Permit since 1948. The presence of the road has both experiential and environmental effects. Multiple trailing has occurred due to confusion, desire for direct access to eastbound destinations, and historical grazing by the pack stock associated with the permits allowed in the area. This causes some route confusion and a high density of trails in a small corridor. Both the presence of the road, including encounters with motorized uses and the confusion and resource impacts of multiple trailing can diminish the wilderness experience for users. Both of the private inholdings and their associated four-wheel drive access trail affect the wilderness character.

An increase in stock numbers in the Sallie Keyes Analysis Unit is possible due to the change from trailhead quotas to destination quotas. This could increase interaction between the public and commercial stock operators in the heavily used San Joaquin River corridor and the Sallie Keyes/Senger Creek area.

Florence/Bear – Alternative 2

Analysis

In this region 17 discrete destinations or zones will be used by commercial pack stock. Collectively at these 17 destinations there are allowances for 49 additional spot and dunnage

trips. As with all areas of potential growth, this growth is in number of trips with an overall limit on number of stock based on the past few years of use. Growth in trips will need to take place with the same number of stock, so it is expected that more people will be served with less stock per party if growth is realized. Generally locations that were suitable and sustainable were identified for potential growth while areas where impacts were high or current use was of a concern were identified for reductions. The PCT/JMT corridor is the primary area of packer use and for potential growth in this region.

Areas of overlap in this region will generally remain the same with a high concentration of overlap along the JMT/PCT between spot and dunnage operators out of Edison and Florence Lakes as well as the overlap with traveling trips. Hilgard Branch (Italy Analysis Unit) Seldon Pass and Sallie Keyes will continue to see up to five operators because of the duplicate spot and dunnage services by two operators and these traveling trips. Dutch, Ward, and Apollo units will have two operators in a few destinations. This alternative does not change the overlap of operations, and with the potential growth, may bring about more occurrences of overlap.

Sallie Keyes unit will see up to 300 stock a season and it is likely that less than 200 stock will be the norm unless patterns shift and more traveling trips occur. With trends the past two years towards increases in use to Sequoia –Kings Canyon, access via the JMT in this region may draw packer use in the future. Designated sites at Sallie Keyes Lake will insure that a proliferation of sites does not occur. There may need to be a management of itineraries for traveling trips to insure that overuse of stock campsites does not occur. Opportunities for solitude in this area will be moderate and along the trail low. This is a very high use area for backpackers and through hikers along the PCT/JMT. Stock use is low relative to backpacker use and these actions will not change this ratio.

Hilgard Branch in the Italy Analysis Unit receives a high level of use, mostly hikers and moderate stock use. Up to 14 spot and dunnage trips a year will be the limit. Most clients that are dropped here will continue over Italy Pass or other cross-country routes that are popular in the area. Stock will not be allowed beyond Hilgard meadow. Two designated stock camps will be managed in this area for the occasional traveling or all-expense trips. With limited grazing there will be fewer trips staying here and staying for shorter stays.

The Seldon Pass Analysis Unit will have growth opportunities for spot and dunnage services. It is expected that more clients will be serviced with less stock to realize this growth. Opportunities for solitude will stay the same with possibly more encounters with stock parties along the JMT. Some growth in services will probably take the form of re-supplies to hikers of the JMT/PCT.

Bear Lakes will be limited to stock use. Clients of commercial packers will only be able to be serviced 1.5 miles from the PCT/JMT junction. Opportunities for solitude will remain moderate to high.

The Hooper Analysis Unit will receive low commercial stock use, primarily at Gordon Lake. Opportunities for solitude in this analysis unit will remain high due to low commercial stock use and little trail development into the area. Commercial stock use that does occur in this area is limited to spot and dunnage trips. Due to the proximity of destinations in this analysis unit to the pack stations, overnight holding of stock rarely occurs in the Hooper Basin, and there are no opportunities for grazing of stock in the Basin.

Cumulative Impacts

Muir Trail Ranch and Lost Valley are private inholdings within the interior of the wilderness boundaries. Muir Trail Ranch operates a guest ranch on the property that opened in 1940. There is four-wheel drive access to the private property, which has been under a Special Use Permit since 1948. The presence of the road has both experiential and environmental effects. Multiple trailing has occurred due to confusion, desire for direct access to eastbound destinations, and historical grazing by the pack stock associated with the permits issued for the area. This causes some confusion and a high density of trails in a small corridor. Both the presence of the road, including encounters with motorized uses and the confusion and resource impacts of multiple trailing can diminish the wilderness experience for users. Both the private inholdings, and their associated four-wheel drive access trail, affect the wilderness character.

An increase in stock numbers in the Sallie Keyes Analysis Unit is possible due to the change from trailhead quotas to destination quotas. This could increase interaction between the public and commercial stock operators in the heavily used San Joaquin River corridor and the Sallie Keyes/Senger Creek area

Florence/Bear –Alternative 3

Analysis

Commercial packer use in the Bolsillo, Ershim, and Dutch Boulder units will continue to be pass-through use for destinations in the Dutch unit. Commercial stock numbers will continue to be low and there will be potential overlap between three operators in the southeast corner of Dutch at Thompson Lake. The three operators would access this overlap area from three different trailheads.

East Florence is also a pass-through unit, with most of the use going to the JMT/PCT and Evolution Valley in Sequoia/Kings Canyon National Park. Four operators will continue to overlap in this unit as in the No Action alternative. Stock numbers will be high, over 600 a season in this area primarily concentrated on the main trail from Florence reservoir to the JMT. Activities and structures associated with two in-holding facilities, as well as the influences of the human made reservoir, will continue to reduce the wilderness character in this area, including opportunities for solitude, naturalness, untrammled and undisturbed qualities.
